RE46C141

CMOS Photoelectric Smoke Detector ASIC with Interconnect
Product Specification

General Description

The RE46C141 is low power CMOS photoelectric type smoke detector IC. With minimal external components this circuit will provide all the required features for a photoelectric type smoke detector.

The design incorporates a gain selectable photo amplifier for use with an infrared emitter/detector pair. An internal oscillator strobes power to the smoke detection circuitry for 100us every 8.1 seconds to keep standby current to a minimum. If smoke is sensed the detection rate is increased to verify an alarm condition. A high gain mode is available for push button chamber testing.

A check for a low battery condition and chamber integrity is performed every 32 seconds when in standby. The temporal horn pattern supports the NFPA 72 emergency evacuation signal.

An interconnect pin allows multiple detectors to be connected such that when one units alarms, all units will sound.

The RE46C141 is recognized by Underwriters Laboratories for use in smoke detectors that comply with specification UL217 and UL268.

Features

- Internal Power On Reset
- Low Quiescent Current Consumption
- Available in 16L PDIP, 16L N SOIC or 16L W SOIC
- ESD Protection on all Pins
- Interconnect up to 40 Detectors
- Temporal Horn Pattern
- Low Battery and Chamber Test
- Compatible with Motorola MC145012
- UL Recognized per File S24036
- Available in Standard Packaging or RoHS Compliant Pb Free Packaging.

T_{STG}	-55 to 125	°C
T_J	150	°C

Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. These are stress ratings only and operation at these conditions for extended periods may affect device reliability.

This product utilizes CMOS technology with static protection; however proper ESD prevention procedures should be used when handling this product. Damage can occur when exposed to extremely high static electrical charge.

PIN DESCRIPTIONS

<u>PIN#</u>	<u>PIN NAME</u>	<u>DESCRIPTION</u>
1	C1	The capacitor connected to this pin sets the photo amplifier gain (high) for the push-to-test and chamber sensitivity test. The size of this capacitor will depend on the chamber background reflections. $A=1+ (C1/10)$ where C1 is in pF. The gain should be <10000 .
2	C2	The capacitor connected to this pin sets the photo amplifier gain (normal) during standby. The value of this capacitor will depend on the smoke sensitivity required. $A=1+ (C2/10)$ where C2 is in pF.
3	DETECT	Positive input to the photo amplifier. This input is normally connected to the cathode of an external photo diode operated at zero bias.
4	STROBE	Regulated output voltage of VDD-5 which is active during a test for smoke. This output is the negative side of the photo amplifier circuitry.
5	VDD	Connect to the positive supply voltage
6	IREDD	Provides a regulated pulsed output voltage pre-driver for the infrared emitter. This output usually drives the base of an NPN transistor.
7	IO	This bidirectional pin provides the capability to interconnect many detectors in a single system. This pin has an internal pull-down device.
8	HB	This pin is connected to the metal electrode of a piezoelectric transducer.
9	HS	HS is a complementary output to HB and connects to the ceramic electrode of the piezoelectric transducer.
10	FEED	Usually connected to the feedback electrode through a current limiting resistor. If not used this pin must be connected to VDD or VSS.
11	LED	Open drain NMOS output used to drive a visible LED.
12	COSC	A capacitor connected to this pin with parallel resistor sets the internal clock low time which is approximately the clock period.
13	ROSC	A resistor between this pin and pin 12 (COSC) sets the internal clock high time. This also sets the IREDD pulse width (100-200uS).
14	VSS	Connect to the negative supply voltage.
15	LBSET	This input is connected to a VDD reference voltage to set the low battery warning voltage.
16	TEST	This input is used to invoke two test modes. This input has an internal pull-down.

Typical Application

Figure 2

Notes:

1. C3 should be located as close as possible to the device power pins.
2. C3 is typical for an alkaline battery. This capacitance should be increased to 4.7uF or greater for a carbon battery.
3. R10, R11 and C6 are typical values and may be adjusted to maximize sound pressure.

CIRCUIT DESCRIPTION AND APPLICATION NOTES

Note: All timing references are nominal. See electrical characteristics for limits.

Standby Internal Timing – With the external components specified in the typical application figure for ROOSC and COOSC the internal oscillator has a nominal period of 7.9mS. Normally the analog circuitry is powered down to minimize standby current (typically 4uA at 9V). Once every 8.1 seconds the detection circuitry (normal gain) is powered up for 7.9mS. Prior to completion of the 7.9mS period the IRED pulse is active for 100uS. At the conclusion of this 7.9mS period the photo amplifier is compared to an internal reference to determine the chamber status and latched. If a smoke condition is present the period to the next detection decreases and additional checks are made. Three consecutive smoke detections will cause the device to go into alarm and the horn circuit and interconnect will be active.

Once every 32 seconds the status of the battery voltage is checked. This status is checked and latched at the conclusion of the LED pulse. In addition, once every 32 seconds the chamber is activated and using the high gain mode (capacitor C1) a check of the chamber is made by amplifying background reflections. If either the low battery or the photo chamber test fails the horn will chirp for 7.9mS every 32 seconds.

The oscillator period is determined by the values of R9, R12 and C5 (see typical application FIG 2). The oscillator period $T = T_R + T_F$ where $T_R = .6931 * R12 * C5$ and $T_F = .6931 * R9 * C5$

Smoke Detection Circuitry – A comparator compares the photo amp output to an internal reference voltage. If the required number of consecutive smoke conditions is met the device will go into local alarm and the horn will be active. In local alarm the C2 gain is internally increased by ~10% to provide alarm hysteresis.

Push to Test Operation – If the TEST input pin is activated (V_{ih}) then, after one internal clock cycle, the smoke detection rate increases to once every 250mS. In this mode the high gain capacitor C1 is selected and background reflections are used to simulate a smoke condition. After the required consecutive detections the device will go into a local alarm condition. When the TEST input is deactivated (V_{il}) and after one clock cycle the normal gain capacitor C1 is selected. The detection rate continues at once every 250mS until 3 consecutive no smoke conditions are detected. At this point the device returns to standby timing.

LED Operation – In standby the LED is pulsed on for 7.9mS every 32 Seconds. In a local alarm condition or the push to test alarm the LED pulse frequency is increased to once every 0.5 seconds. In the case of a remote alarm the LED not active.

Interconnect Operation – The bidirectional IO pin allows for interconnection of multiple detectors. In a local alarm condition this pin is driven high immediately through a constant current source. Shorting this output to ground will not cause excessive current. The IO is ignored as an input during a local alarm.

The IO pin also has an NMOS discharge device that is active for 1 second after the conclusion of any type of local alarm. This device helps to quickly discharge any capacitance associated with the interconnect line.

If a remote active high signal is detected the device goes into remote alarm and the horn will be active. Internal protection circuitry allows for the signaling unit to have a higher supply voltage than the signaled unit without excessive current draw.

The interconnect input has a 500mS nominal digital filter. This allows for interconnection to other types of alarms (carbon monoxide for example) that may have a pulsed interconnect signal.

Low Battery and Chamber Test – In standby an internal reference is compared to the voltage divided VDD supply. Low battery status is latched at the conclusion of the LED pulse. The horn will chirp for 7.9ms every 32 seconds until the low battery condition no longer exists. In standby a chamber test is also performed every 32 seconds by switching to the high gain capacitor C1 and sensing the photo chamber background reflections. Two consecutive chamber tests failures will also cause the horn to chirp for 7.9mS every 32 seconds. The low battery chirp occurs next to the LED pulse and the failed chamber test chirp 16.2 seconds later. The low battery and chamber tests are not performed in a local or remote alarm condition. The low battery alarm threshold is approximately equal to $((5 \cdot R15) / R14) + 5$ where R15 and R16 are in the same units.

Diagnostic Mode – In addition to the normal function of the TEST input a special diagnostic mode is available for calibration and test of the smoke detector. Taking the TEST pin below VSS and sourcing ~300uA out of the pin for 1 clock cycle will enable the diagnostic mode. In the diagnostic mode some of the pin functions are redefined. Refer to the table below for redefined pin functions in the diagnostic mode. In addition in this mode STROBE is always enabled and the IRED is pulsed at the clock rate of 10.5mS nominal.

Pin Name	Pin Number	Description
IO	7	Disabled as an output. A high on this pin directs the photo amplifier output to pin C1 (1) or C2 (2), determined by the level on LBSET (15). Amplification occurs during the IRED active time.
LBSET	15	If IO is high then this pin controls the gain capacitor that is used. If LBSET is low then normal gain is selected and the photo amp output appears on C1 (1). If LBSET is high then high gain is selected and the photo amp output is on C2 (2).
FEED	10	If LBSET (15) is low then taking this input high will enable hysteresis, which is a nominal 10% gain increase in normal gain mode.
COSC	12	If desired this pin can be driven by an external clock.
HORNB	8	This pin becomes the smoke integrator output. A high level indicates that an alarm condition has been detected.
LED	11	The LED pin is used as a low battery indicator. For VDD above the low battery threshold the open drain NMOS is off. If VDD falls below the threshold the NMOS turns on.

Timing Diagrams

Standby Timing, No Alarm (not to scale)

Low Supply or Chamber Test Failure

Chamber Test and Warning is Offset from Low Battery Test and Warning by 21.5 Seconds

Timing Diagrams (continued)

Local Alarm Timing (not to scale)

Horn Temporal Pattern

Interconnect Timing

Notes:

1. Smoke is not sampled when the horn is active. Horn cycle is self completing in local alarm but not in remote alarm.
2. Low battery warning chirp is suppressed in local or remote alarm.
3. IO Dump active only in local alarm, inactive if external alarm.
