Chapter 1
About This Manual

1.1 Audience

This reference manual is intended for system software and hardware developers and applications programmers who want to develop products with this device. It assumes that the reader understands operating systems, microprocessor system design, and basic principles of software and hardware.

1.2 Organization

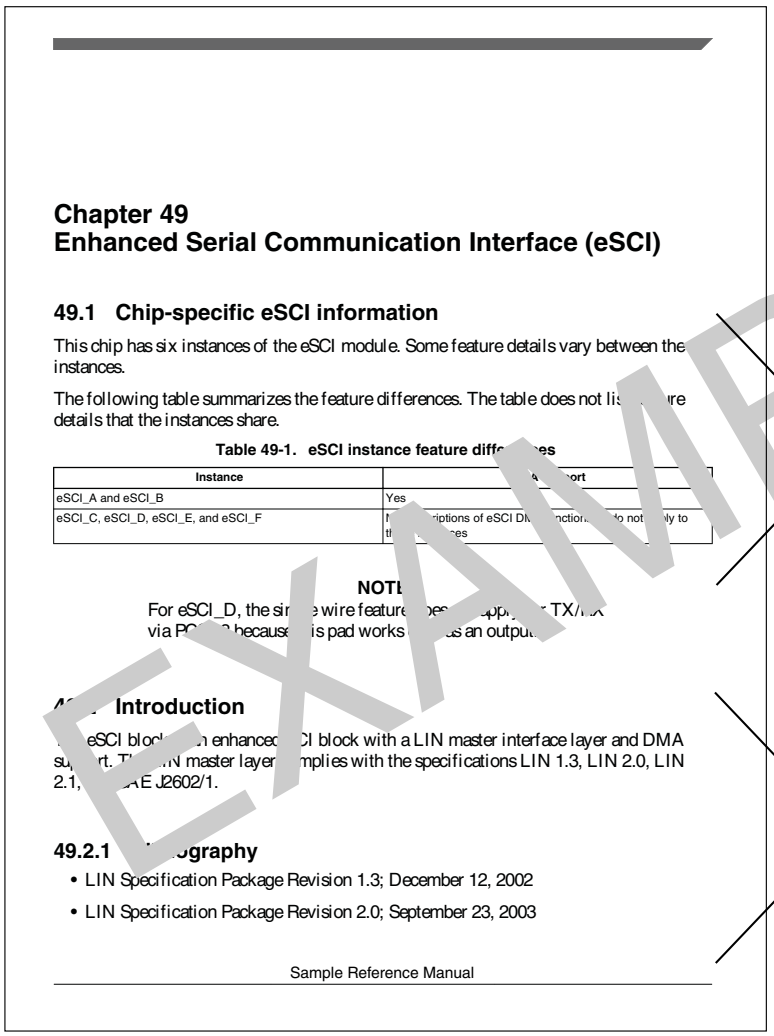
This manual has two main sets of chapters.

1. Chapters in the first set contain information that applies to all components on the chip.
2. Chapters in the second set are organized into functional groupings that detail particular areas of functionality.
   - Examples of these groupings are clocking, timers, and communication interfaces.
   - Each grouping includes chapters that provide a technical description of individual modules.

1.3 Module descriptions

Each module chapter has two main parts:

- The first section, *Chip-specific [module name] information*, provides details such as the number of module instances on the chip and connections between the module and other modules. Read this section *first* because its content is crucial to understanding the information in other sections of the chapter.
- The subsequent sections provide general information about the module, including its signals, registers, and functional description.



Chapter 49
Enhanced Serial Communication Interface (eSCI)

49.1 Chip-specific eSCI information

This chip has six instances of the eSCI module. Some feature details vary between the instances.

The following table summarizes the feature differences. The table does not list feature details that the instances share.

Table 49-1. eSCI instance feature differences

Instance	
eSCI_A and eSCI_B	Yes
eSCI_C, eSCI_D, eSCI_E, and eSCI_F	

NOTE

For eSCI_D, the single wire feature does not support TX/RX via PC because this pad works as an output

Introduction

The eSCI block is an enhanced SCI block with a LIN master interface layer and DMA support. The LIN master layer complies with the specifications LIN 1.3, LIN 2.0, LIN 2.1, and SAE J2602/1.

49.2.1 Bibliography

- LIN Specification Package Revision 1.3; December 12, 2002
- LIN Specification Package Revision 2.0; September 23, 2003

Sample Reference Manual

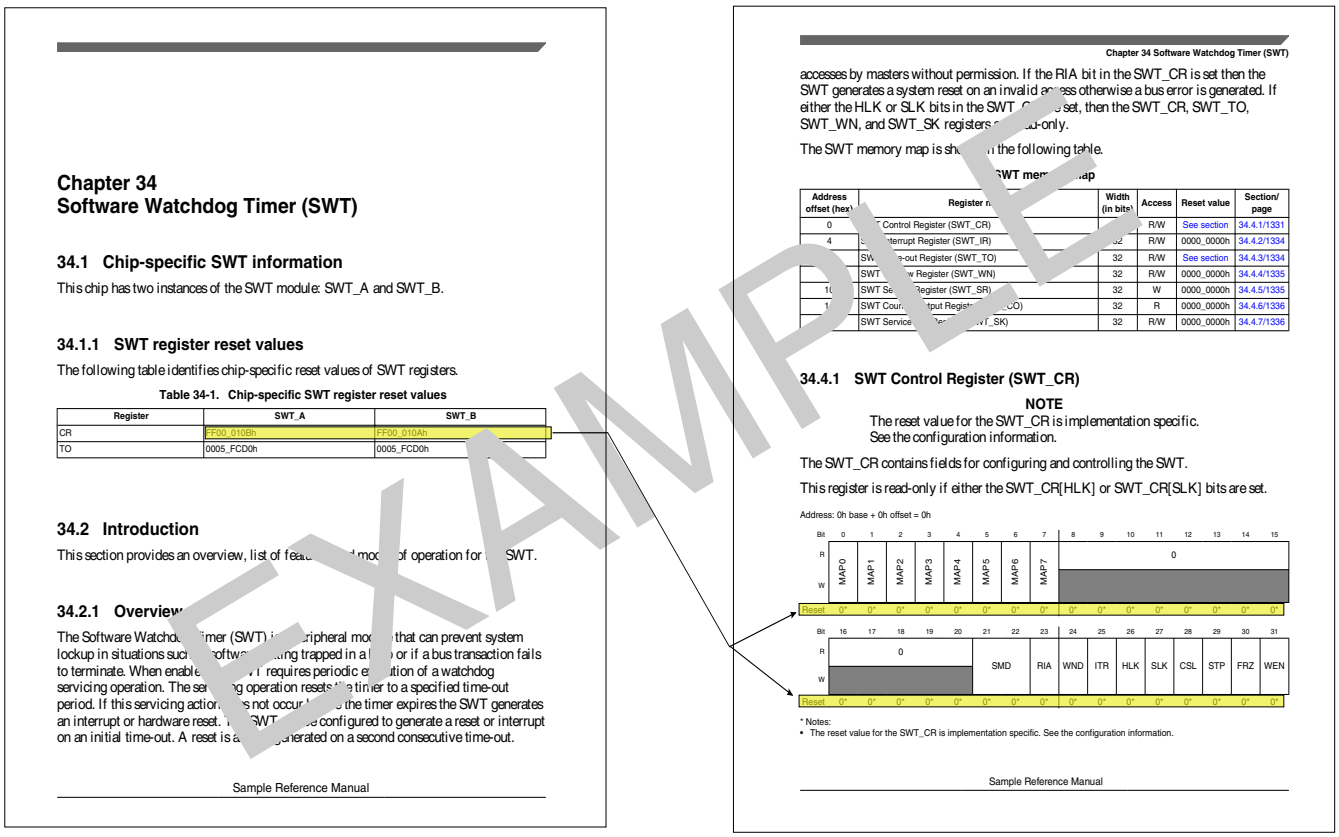
Chip-specific information that should be read first

Beginning of general module information

Figure 1-1. Example: chapter chip-specific information and general module information

1.3.1 Example: chip-specific information that clarifies content in the same chapter

The example below shows chip-specific information that clarifies general module information presented later in the chapter. In this case, the chip-specific register reset values supercede the reset values that appear in the register diagram.



Chapter 34
Software Watchdog Timer (SWT)

34.1 Chip-specific SWT information

This chip has two instances of the SWT module: SWT_A and SWT_B.

34.1.1 SWT register reset values

The following table identifies chip-specific reset values of SWT registers.

Table 34-1. Chip-specific SWT register reset values

Register	SWT_A	SWT_B
CR	FF00_010Bh	FF00_010Ah
TO	0005_FCD0h	0005_FCD0h

34.2 Introduction

This section provides an overview, list of feat... mod... of operation for ... SWT.

34.2.1 Overview

The Software Watchdo... imer (SWT) i... ripheral mo... that can prevent system lockup in situations suc... softw... ting trapped in a l... or if a bus transaction fails to terminate. When enable... T requires periodic e... ution of a watchdog servicing operation. The se... g operation resets ... timer to a specified time-out period. If this servicing actio... s not occur ... the timer expires the SWT generates an interrupt or hardware reset. ... SWT ... e configured to generate a reset or interrupt on an initial time-out. A reset is a... generated on a second consecutive time-out.

Sample Reference Manual

Chapter 34 Software Watchdog Timer (SWT)

accesses by masters without permission. If the RIA bit in the SWT_CR is set then the SWT generates a system reset on an invalid a... ss otherwise a bus error is generated. If either the HLK or SLK bits in the SWT_C... set, then the SWT_CR, SWT_TO, SWT_WN, and SWT_SK registers ... -only.

The SWT memory map is sh... n the following table.

SWT mem... ap

Address offset (hex)	Register n...	Width (in bits)	Access	Reset value	Section/ page
0	... Control Register (SWT_CR)		R/W	See section	34.4.1/1331
4	... terrupt Register (SWT_IR)	32	R/W	0000_0000h	34.4.2/1334
	SW... e-out Register (SWT_TO)	32	R/W	See section	34.4.3/1334
	SWT ... w Register (SWT_WN)	32	R/W	0000_0000h	34.4.4/1335
10	SWT Se... Register (SWT_SR)	32	W	0000_0000h	34.4.5/1335
1	SWT Cour... tput Regist... CO)	32	R	0000_0000h	34.4.6/1336
	SWT Service ... (SWT_SK)	32	R/W	0000_0000h	34.4.7/1336

34.4.1 SWT Control Register (SWT_CR)

NOTE
The reset value for the SWT_CR is implementation specific.
See the configuration information.

The SWT_CR contains fields for configuring and controlling the SWT.

This register is read-only if either the SWT_CR[HLK] or SWT_CR[SLK] bits are set.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	MAP0	MAP1	MAP2	MAP3	MAP4	MAP5	MAP6	MAP7	0							
W																
Reset	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0					SMD	RIA	WND	ITR	HLK	SLK	CSL	STP	FRZ	WEN	
W																
Reset	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*

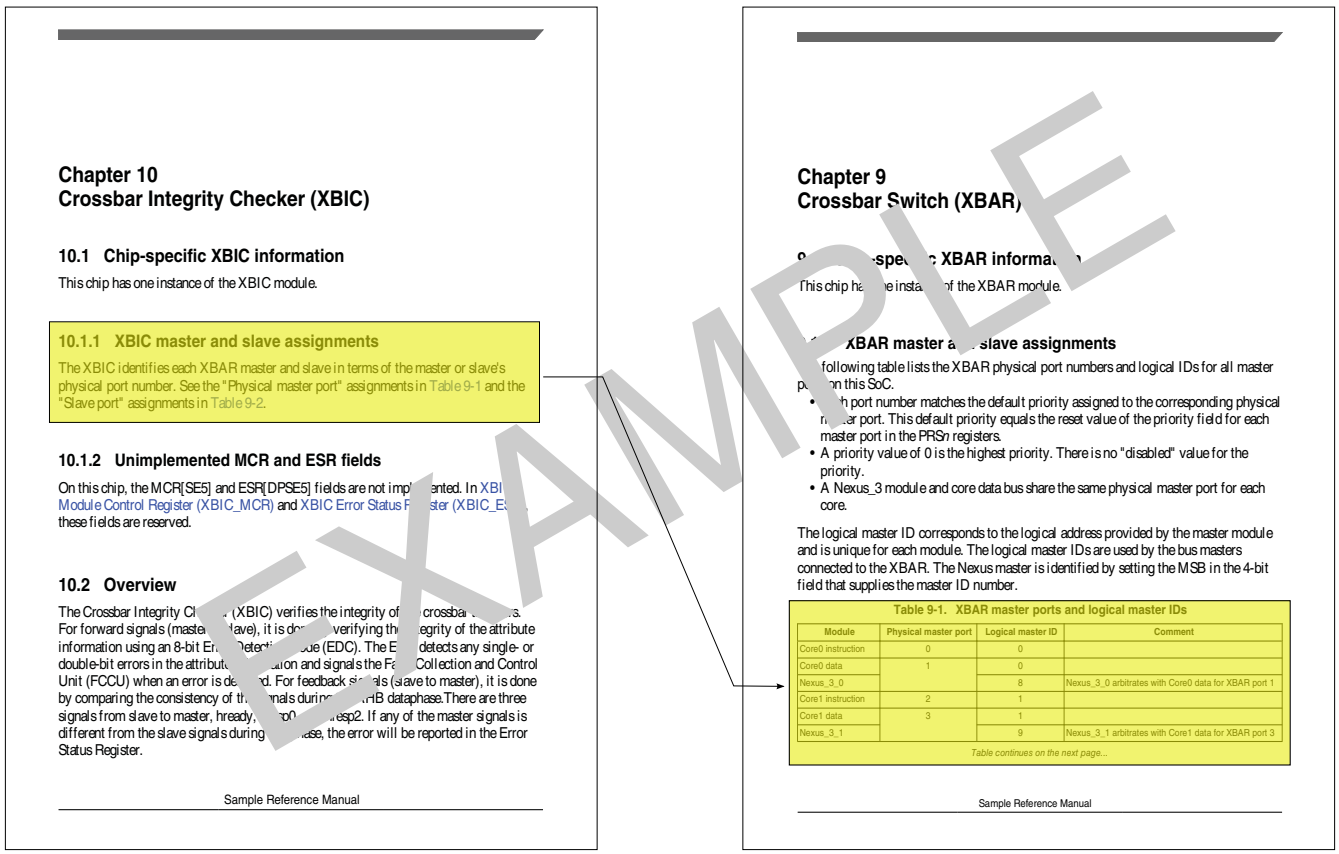
* Notes:
- The reset value for the SWT_CR is implementation specific. See the configuration information.

Sample Reference Manual

Figure 1-2. Example: chip-specific information that clarifies content in the same chapter

1.3.2 Example: chip-specific information that refers to a different chapter

The chip-specific information below refers to another chapter's chip-specific information. In this case, read both sets of chip-specific information before reading further in the chapter.



Chapter 10
Crossbar Integrity Checker (XBIC)

10.1 Chip-specific XBIC information

This chip has one instance of the XBIC module.

10.1.1 XBIC master and slave assignments

The XBIC identifies each XBAR master and slave in terms of the master or slave's physical port number. See the "Physical master port" assignments in Table 9-1 and the "Slave port" assignments in Table 9-2.

10.1.2 Unimplemented MCR and ESR fields

On this chip, the MCR[SE5] and ESR[DPSE5] fields are not implemented. In XBIC Module Control Register (XBIC_MCR) and XBIC Error Status Register (XBIC_ES... these fields are reserved.

10.2 Overview

The Crossbar Integrity Ch... (XBIC) verifies the integrity of ... crossbar ... For forward signals (maste... lave), it is do... verifying th... egrity of the attribute information using an 8-bit Er... Detecti... ue (EDC). The E... detects any single- or double-bit errors in the attribut... tion and signals the Fa... Collection and Control Unit (FCCU) when an error is de... d. For feedback si...ls (slave to master), it is done by comparing the consistency of th...nals during ...hB dataphase.There are three signals from slave to master, hready, ...sp0, ...esp2. If any of the master signals is different from the slave signals during ...ase, the error will be reported in the Error Status Register.

Sample Reference Manual

Chapter 9
Crossbar Switch (XBAR)

9 ...-spe... : XBAR informa...

This chip ha... e insta... of the XBAR module.

... XBAR master a... slave assignments

The following table lists the XBAR physical port numbers and logical IDs for all master p... on this SoC.

- ...h port number matches the default priority assigned to the corresponding physical ...er port. This default priority equals the reset value of the priority field for each master port in the PRSn registers.
- A priority value of 0 is the highest priority. There is no "disabled" value for the priority.
- A Nexus_3 module and core data bus share the same physical master port for each core.

The logical master ID corresponds to the logical address provided by the master module and is unique for each module. The logical master IDs are used by the bus masters connected to the XBAR. The Nexus master is identified by setting the MSB in the 4-bit field that supplies the master ID number.

Table 9-1. XBAR master ports and logical master IDs

Module	Physical master port	Logical master ID	Comment
Core0 instruction	0	0	
Core0 data	1	0	
Nexus_3_0		8	Nexus_3_0 arbitrates with Core0 data for XBAR port 1
Core1 instruction	2	1	
Core1 data	3	1	
Nexus_3_1		9	Nexus_3_1 arbitrates with Core1 data for XBAR port 3

Table continues on the next page...

Sample Reference Manual

Figure 1-3. Example: chip-specific information that refers to a different chapter

1.4 Register descriptions

Module chapters present register information in:

- Memory maps containing:
  - An offset from the module's base address
  - The name and acronym/abbreviation of each register
  - The width of each register (in bits)
  - Each register's reset value
  - The page number on which each register is described
- Register figures
- Field-description tables
- Associated text

The register figures show the field structure using the conventions in the following figure.

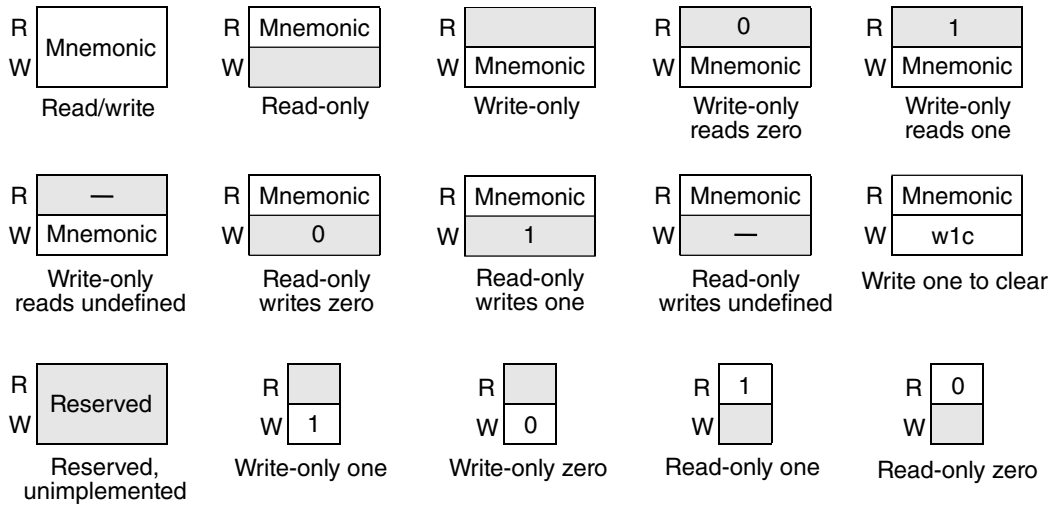


Figure 1-4. Register figure conventions

1.5 Conventions

1.5.1 Notes, Cautions, and Warnings

Note, Caution, and Warning notices appear throughout this manual. Each notice type alerts readers to a specific kind of information.

NOTE

Notes convey information that may be tangential to a topic or that may not apply to all readers.

CAUTION

Caution notices call out information that readers should know before taking further action. Cautions frequently point to trouble spots that may damage the chip or board.

WARNING

Warning notices inform readers about actions that could result in unwanted consequences, especially those that may cause bodily injury.

1.5.2 Numbering systems

The following suffixes identify different numbering systems:

This suffix	Identifies a
b	Binary number. For example, the binary equivalent of the number 5 is written 101b. In some cases, binary numbers are shown with the prefix *0b*.
d	Decimal number. Decimal numbers are followed by this suffix only when the possibility of confusion exists. In general, decimal numbers are shown without a suffix.
h	Hexadecimal number. For example, the hexadecimal equivalent of the number 60 is written 3Ch. In some cases, hexadecimal numbers are shown with the prefix *0x*.

1.5.3 Typographic notation

The following typographic notation is used throughout this document:

Example	Description
placeholder, x	Items in italics are placeholders for information that you provide. Italicized text is also used for the titles of publications and for emphasis. Plain lowercase letters are also used as placeholders for single letters and numbers.
`code`	Fixed-width type indicates text that must be typed exactly as shown. It is used for instruction mnemonics, directives, symbols, subcommands, parameters, and operators. Fixed-width type is also used for example code. Instruction mnemonics and directives in text and tables are shown in all caps; for example, BSR.
SR[SCM]	A mnemonic in brackets represents a named field in a register. This example refers to the Scaling Mode (SCM) field in the Status Register (SR).
REVNO[6:4], XAD[7:0]	Numbers in brackets and separated by a colon represent either: • A subset of a register's named field For example, REVNO[6:4] refers to bits 6–4 that are part of the COREREV field that occupies bits 6–0 of the REVNO register. • A continuous range of individual signals of a bus For example, XAD[7:0] refers to signals 7–0 of the XAD bus.

1.5.4 Special terms

The following terms have special meanings:

Term	Meaning
asserted	Refers to the state of a signal as follows: • An active-high signal is asserted when high (1). • An active-low signal is asserted when low (0).
deasserted	Refers to the state of a signal as follows: • An active-high signal is deasserted when low (0). • An active-low signal is deasserted when high (1). In some cases, deasserted signals are described as *negated*.

Table continues on the next page...

Term	Meaning
reserved	Refers to a memory space, register, field, or programming setting. Writes to a reserved location can result in unpredictable functionality or behavior. • Do not modify the default value of a reserved programming setting, such as the reset value of a reserved register field. • Consider undefined locations in memory to be reserved.
w1c	Write 1 to clear: Refers to a register bitfield that must be written as 1 to be "cleared."

Chapter 2
Introduction

2.1 Introduction

The S32R274 is a 32-bit Power Architecture based Microcontroller (MCU) unit for automotive applications. It extends the MPC5775K family by a value device optimized for surround RADAR sensors and midrange front RADAR sensors. The family members are designed to address advanced RADAR signal processing capabilities and merge it with microcontroller capabilities for generic software tasks and car bus interfacing.

S32R274 meets the high performance computation demands required by modern beam-forming fast chirp modulation RADAR systems by offering unique signal processing acceleration together with powerful multi-core architecture. The S32R274 supports automotive safety applications that require a high Safety Integrity Level (ASIL) and adds SHE compliant security features to prevent unauthorized manipulations. The high integration level of S32R274 enables the customer to built compact, safe and secure, low cost RADAR sensors with leading edge performance. The family members have a high level of software compatible for shared hardware modules.

2.1.1 Target applications

S32R274 is a high end automotive MCU designed to support computation intensive application, like ADAS RADAR.

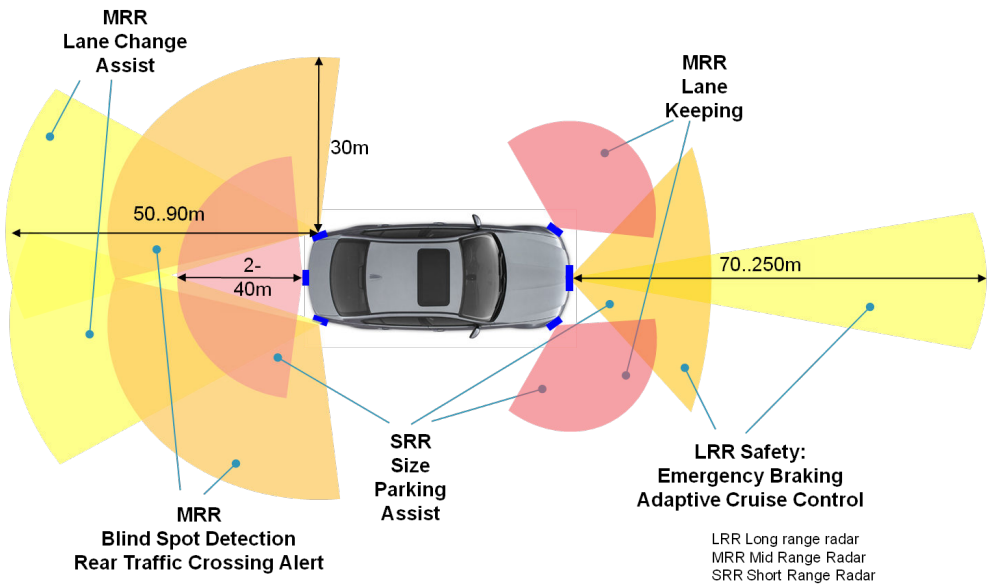

Figure 2-1. RADAR application overview

- Low to mid range RADAR
  - side-looking and surround sensors
  - lane change assist (LCA), blind-spot detection (BSD), rear-traffic-crossing alert (RTCA)
  - sampling rate <= 10MSps, 4 receive antennas
  - fast chirp modulation (FCM)
  - including clustering and tracking
- Long range value RADAR
  - forward looking sensor
  - adaptive cruise control (ACC), emergency breaking assist (EBA), pedestrian protection
  - sampling rate <= 20MSps, 4 receive antennas
  - advanced beamforming and synthetic aperture
  - fast chirp modulation (FCM)
  - including clustering and tracking and basic RADAR FUSION
- Safety application
  - using one lockstep core (z4)
  - optionally using two cores for non-safety functions (2x z7)
  - using various communication interface including Ethernet, FlexRay, FlexCAN, SPI, LINFlexD, I2C
  - optionally keeping one or both z7 cores clocked off

- Generic data processing using two cores in decoupled mode (2x z7)
  - booting from one of the z7 cores
  - keeping the safety core (z4 lockstep system) clocked off
  - optionally keeping the second z7 core clocked off
- Signal processing using SPT and Z7 SIMD units
  - Accelerated hardware FFT, vector math, peak search, statistics
  - Generic DSP functionality with SPE and VFPU unit of Z7 cores
- Security application
  - CSE hardware security engine
  - Boot and software image verfication: secure boot
  - Encryption/ decryption/ signing/ verification of messages sent or received via various communication interfaces including ENET, FlexRay, FlexCAN, SPI, LINFlexD, I2C

2.1.2 Feature list

On-chip modules available within the device include the following features:

- Safety core: Power Architecture® e200Z4 32-bit CPU with checker core
  - 2 cycle delayed lockstep
  - Harvard architecture with 64-bit bus for data and instructions
  - Dual issue: up to two instructions per clock cycle
  - 8 KB instruction cache and 4 KB data cache
  - 64 KB data local memory
    - with background load/store: backdoor access
    - 0-wait state for all read and 32/64-bit write accesses
    - Low number of wait states for backdoor accesses
  - Support for decorated storage
  - Variable Length Encoding (VLE) compliant for higher code density
  - Single precision floating point operations
- Computation cores: Power Architecture® e200Z7 32-bit CPU
  - Dual issue: up to two instructions per clock cycle
  - Harvard architecture with 64-bit bus for data instructions
  - 16 KB instruction cache and 16 KB data cache
  - 64 KB data local memory
    - with background load/store: backdoor access
    - 0-wait state for all read and 32/64-bit write accesses
    - Low number of wait states for backdoor accesses
  - Support for decorated storage
  - Using variable length encoding (VLE) for higher code density

    - 4-way integer processing unit (SPE2)
    - 2-way single-precision Floating Point Unit (EFPU2)
- 2 MB on-chip code flash (FMC flash) with ECC
    - Three ports (one per CPU) shared between code and data flash with 4 × 256 bit buffer for code and data flash including prefetch functions
    - Data flash is part of the code flash module
    - Including 64 KB EEPROM emulation
- 1.5 MB on-chip SRAM with ECC
    - Decorated memory controller to support atomic read-modify-write operations
    - Single- and double-bit error visibility is supported
    - Up to four ports (one per CPU and SPT) and up to 8 banks allow simultaneous accesses from different masters to different banks
- RADAR processing
    - Signal Processing Toolbox (SPT) for RADAR signal processing acceleration
    - Cross Timing Engine (CTE) for precise timing generation and triggering
    - Waveform generation module (WGM) for chirp ramp generation
    - 4x 12-bit ΣΔ-ADC with 10 MSps
    - One DAC with 10 MSps
    - MIPICSI2 interface to connect external ADCs
        - Four data lanes, with up to 1 Gbps per lane and in total
        - One clock lane
- Memory Protection
    - Each core memory protection unit provides 24 entries
    - Data and instruction bus system memory protection Unit (SMPU) with 16 region descriptors each
    - Register protection
- Clock Generation
    - 40 MHz external crystal (XOSC)
    - 16 MHz Internal oscillator (IRCOSC)
    - Dual system PLL with one frequency modulated phase-locked loop (FMPLL)
    - Low-jitter PLL to ΣΔ-ADC and DAC clock generation
- Functional Safety
    - Enables up to ASIL-D applications
    - End to end ECC ensuring full protection of all data accesses throughout the system, from each of the systems masters through the crossbar and into the memories and peripherals
    - FCCU for fault collection and fault handling
    - MEMU for memory error management
    - Safe eDMA controller
    - User selectable Memory BIST (MBIST) can be enabled to run out of various reset conditions or during runtime

    - Self-Test Control Unit (STCU2)
    - Error Injection Module (EIM)
    - On-chip voltage monitoring
    - Clock Monitor Unit (CMU) to support monitoring of critical clocks
- Security
    - Cryptographic Security Engine (CSE2) enabling advanced security management
    - Supports censorship and life-cycle management via Password and Device Security (PASS) module
    - Diary control for tamper detection (TDM)
- Support Modules
    - Global Interrupt controller (INTC) capable of routing interrupts to any CPU
    - Semaphore unit to manage access to shared resources
    - Two CRC computation units with four polynomials
    - 32-channel eDMA controller with multiple transfer request sources using DMAMUX
    - Boot Assist Module (BAM) supports internal flash programming via a serial link (LIN / CAN)
- Timers
    - Two Periodic Interval Timers (PIT) with 32-bit counter resolution
    - Three System Timer Module (STM)
    - Three Software Watchdog Timers (SWT)
    - Two eTimer modules with 6 channels each
    - One FlexPWM module for 12 PWM signals
- Communication Interfaces
    - Two Serial Peripheral interface (SPI) module
    - Two inter-IC communication interface (I2C) modules
    - One LINFlexD module
    - One dual-channel FlexRay module with 128 message buffers
    - Three FlexCAN modules with configurable buffers
        - CAN FD optionally supported on 2 FlexCAN modules
    - One ENET MAC supporting MII/RMII/RGMII interface
        - Supports 10/100 Mbps (MII/RMII/RGMII) and >100 Mbps (RGMII)
        - Supports IEEE1588 timestamps and PTP
    - Zipwire high-speed serial communication
        - Supports LFAST and SIPI protocol
        - Fast interprocessor communication with 320 Mbps gross data rate
        - DMA based access to memory resources
- Debug Functionality
    - 4-pin JTAG interface and Nexus/Aurora interface for serial high-speed tracing
    - e200Z7 core and e200Z4 core: Nexus development interface (NDI) per IEEE-ISTO 5001-2012 Class 3+

    - All platform bus masters except CSE can be monitored via Nexus/Aurora
    - Device/board boundary Scan testing supported with per Joint Test Action Group (JTAG) (IEEE 1149.1) and 1149.7 (cJTAG)
    - On-chip control for Nexus development interface by JTAGM module
- Two analog-to-digital converters (SAR ADC)
    - Each ADC supports up to 16 input channels
    - Cross Trigger Unit to enable synchronization of ADC conversions with eTimer
- On-chip voltage DC/DC regulator for core clock (VREG)
- Two Temperature Sensors (TSENS)

2.2 Family comparison

The following table provides a comparison of two devices S32R274 and MPC5775K . This information is intended to provide an understanding of the range of functionality offered by this family. For full details of all of the family derivatives please contact your marketing representative.

Table 2-1. S32R274 Family Comparison

Feature	S32R274	MPC5775K
CPUs	e200z420 lock-step 2x e200z7260	
SIMD	SPE2 + EFP2 (z7)	
Maximum Operating Frequency	240 MHz (z7 cores) / 180 MHz (z4)	266 MHz (z7 cores) / 133 MHz (z4)
Flash	2 MB with ECC	4 MB with ECC
EEPROM support	64 KB (emulation)	96 KB (emulation)
RAM	1.5 MB with ECC	
ECC	end-to-end	
MPU	Core MPU: 24 entries per core, System MPU: 2x16 entries	
eDMA	safe eDMA with 32 channels, 64 triggers	
Control ADC	2x 12-bit SAR ADC, 1 MSps input mux for 16 external channels	4x 12-bit SAR ADC, 1 MSps, input mux for 37 external channels
SD-ADC	4 channels, 10 MSps	8 channels, 10 MSps
SPT	1x	
CTE	1x	
WGM	1x	
CTU	1x	2x
SWT	3x	
STM	3x	
PIT	2x	
CRC	2x

MC_CGM	1x	
MC_RGM	1x	
TSENS	2x	
Debug	JTAGC, JTAGM, CJTAG, with class3+ Nexus, Aurora only	
Safety level	ISO26262 SEooC ASIL-B to ASIL-D	
Temp. range (Tj)	-40 to 150˚C	

2.3 Block diagram

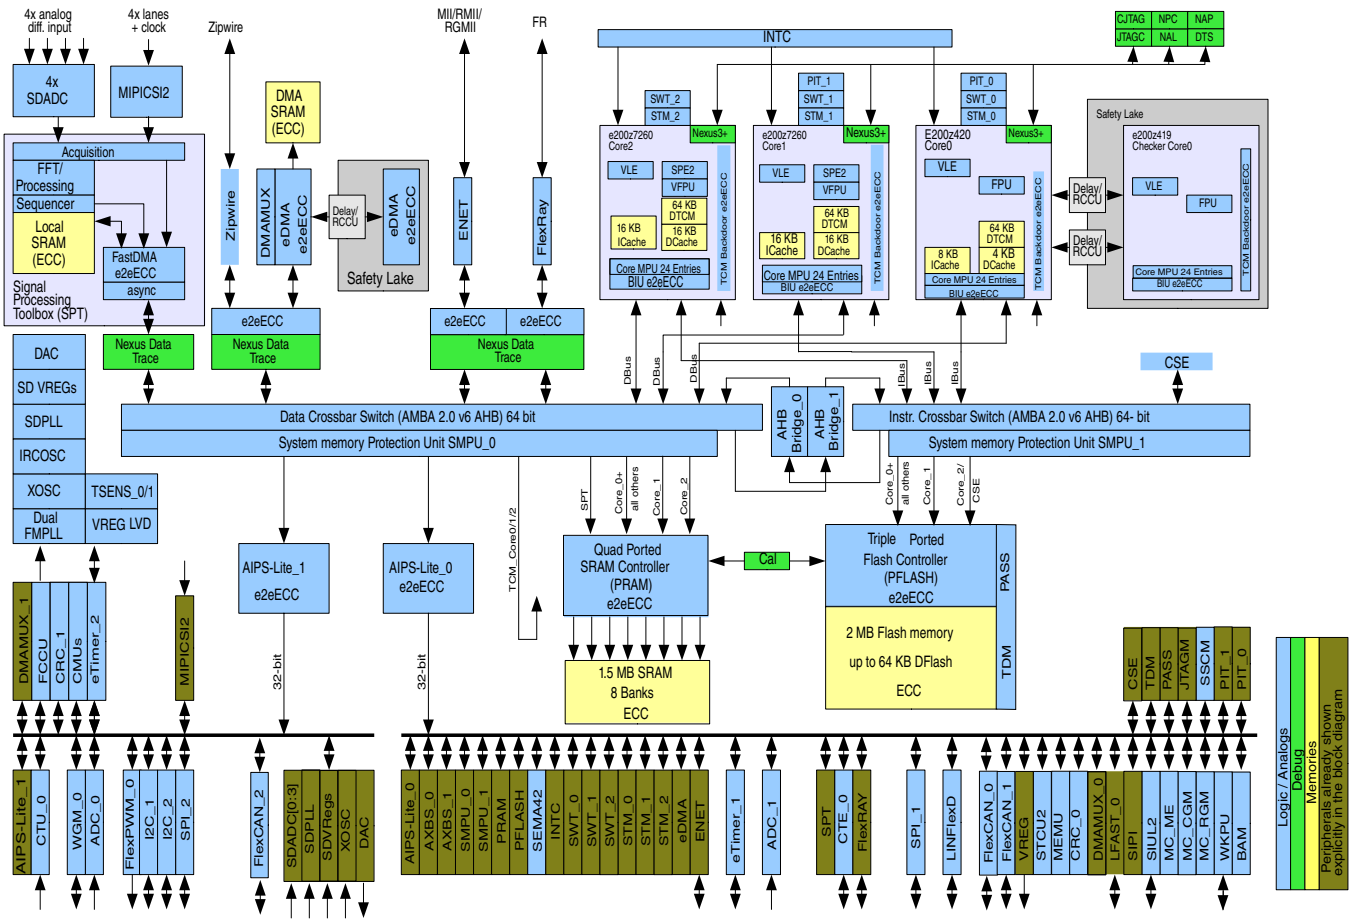

Figure 2-2. S32R274 block diagram

NOTE

DTCM corresponds to DMEM. For details, see Core chapters in this document.

2.4 Package

The chip family member is offered in the following package type:

- 257-ball MAPBGA, 0.8 mm ball pitch, 14 mm x 14 mm outline

Chapter 3
Memory Map

3.1 Introduction

See the device Memory map tables attached to this document as an Excel file. Locate the paperclip symbol on the left side of the PDF window, and click on it.

Chapter 4
Signal Multiplexing and Signal Description

4.1 Generic pins/balls

The I/O Signal Description Table contains information on pins/balls of this device. See the device I/O Signal Description and Input Multiplexing Tables (Excel file) attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the Excel file to open it and select the I/O Signal Table tab.

4.2 Pad states

The following table shows the pad types and states.

Table 4-1. Pad states

PADs	Type	POR[1]	RESET	SELF TEST	RUN
PAD_0	GPIO	high impedance	high impedance	high impedance	high impedance
PAD_1	GPIO	high impedance	high impedance	high impedance	high impedance
PAD_2	GPIO	high impedance	high impedance	high impedance	high impedance
PAD_3	GPIO	high impedance	high impedance	high impedance	high impedance
PAD_4	GPIO	high impedance	high impedance	high impedance	high impedance
PAD_5	GPIO	high impedance	high impedance	high impedance	high impedance
PAD_6	GPIO	high impedance	high impedance	high impedance	high impedance
PAD_7	GPIO	high impedance	high impedance	high impedance	high impedance
PAD_8	GPIO	high impedance	weak pull down	high impedance	weak pull down
PAD_9	GPIO	high impedance	high impedance	high impedance	high impedance
PAD_10	GPIO	high impedance	high impedance	high impedance	high impedance
PAD_11	GPIO	high impedance	high impedance	high impedance	high impedance
PAD_12	GPIO	high impedance	high impedance	high impedance	high impedance
PAD_13	GPIO	high impedance	high impedance	high impedance	high impedance
PAD_14	GPIO	high impedance	high impedance	high impedance	high impedance
PAD_15	GPIO	high impedance	weak pull down	high impedance	weak pull down

Table continues on the next page...

TCK	GPIO	high impedance	weak pull-up	weak pull-up	weak pull-up
TMS	GPIO	high impedance	weak pull-up	weak pull-up	weak pull-up
JCOMP	GPIO	high impedance	weak pull-down	weak pull-down	weak pull-down

1. Pads marked as high impedance will be in either high-impedance or weak low drive state when VDD_LV_CORE is off and HV_VDD_IO is below 1.5V.
2. When VDD_HV_PMC/VDD_HV_IO supply is powered, while any other supply holds the part in reset, as well as VREG_POR_B is HIGH, then PAD_19 can become pull up [i.e. the state of pad during self-test] briefly before going to Hi-Z [i.e. the state of the pad in Run/Reset].
3. Could be drive low if running offline STCU or pull-down if running online STCU

NOTE

Define 'Dext_pull_level' as the device PULL UP on a pad in the RUN column. 'Dext_pull_level' is '1' for weak PULL UP, '0' for weak pull down, and 'Hi-Z' for high-impedance.

If the user's implementation requires an external pull up or pull down (Pext_pull_level) on each pad to SAFE state then the following options could be executed:

- First priority is to implement an external pull level ('1' or '0') as per the protocol planned to be used in end application. For example: PAD_119 is used as I2C_1 SCLK then the preferred level of external pull is high as per the usage (Pext_pull_level='1'). See IO Signal Description and Input multiplexing tables attached as an excel file with this document.
- Second priority is to implement an external pull level ('1' or '0') (Pext_pull_level) to same level as the default design pull level (Dext_pull_level) on that pad (Pext_pull_level=Dext_pull_level). Following this guidelines would save on minor leakage on a pad in case if an external pull level (Pext_pull) is opposite to the pull level in RUN mode (Dext_pull).

4.3 GPIO safe state configuration

The following table shows the GPIOs behavior when chip is in SAFE mode. It is dependent on the SIUL2_MSCR[SMC], FCCU in fault state and MC_ME_SAFE_MC[PDO].

SIUL2_MSCR[SMC]	FCCU Fault State	MC_ME_SAFE_MC[PDO]	GPIO (SIUL)	Dedicated FCCU EOUT pads[1]
1	0	0	Not Hiz	Not Hiz
1	0	1	Not Hiz	Not Hiz
1	1	0	Not Hiz	Not Hiz
1	1	1	Not Hiz	Not Hiz
0	0	0	Not Hiz	Not Hiz
0	0	1	Hiz	Not Hiz
0	1	0	Hiz	Not Hiz
0	1	1	Hiz	Not Hiz

1. Fault output (EOUT) signalling should be enabled. See FCCU

4.4 Special cases of IBE and OBE control

The following table lists the input buffer enable[IBE] and output buffer enable[OBE] configurations of all pads in the device.

Table 4-2. Special cases of IBE and OBE control

Module	Function[1]	Direction	OBE Control via	IBE Control via	Notes

4.5 PCB routing guidelines

Following are the PCB routing guidelines applicable for this chip.

4.5.1 Decoupling Capacitors

- For detailed decoupling capacitor values and placement recommendations please see AN5251 - Hardware Design Guide.

4.5.2 MIPICSI2

- Route all signals on top and bottom layer only.
- Route all the signals of single instance in same PCB layer.

- Use low loss dielectric constant material in PCB stack up for MIPICSI2 signal adjacent layers e.g. megtron.
- Route the MIPICSI2 signals 'P' and 'N' channel as differential pair with control impedance of 100 ohm.
- The differential pairs should be matched in less than a mil.
- All the signals should be matched with tight tolerance preferably 1 mil.

4.5.3 LVDS (AURORA and LFAST)

- The LVDS pairs should be routed as differential pair with control impedance of 100 ohm and tolerance of 10 mil.
- All the signals of an interface should be tightly matched to less than 1% of the total length.

4.5.4 SAR-ADC

- Use single ground strategy for board
- The VrefP and VrefN nets should have at least one decap soldered direct on the chip pin.
- The VrefP and VrefN should be short and clean trace and not cross digital section or splits.
- The analog section should be at least 200 mil away from any digital component.
- Route ADC channels on inner layer with ground layer on both sides.
- Use thick trace or shape to provide supply to SARADC.

4.5.5 Power supply

- Use large shape to feed power for all interfaces. The thickness of shape should be at least greater than 200 mil.
- Place the smallest value decap directly on the chip pin between the VDD (supply) and VSS (ground) for each interface.

Chapter 5
Clocking Overview

5.1 Introduction

This chapter describes the architecture for the system level clocks and includes the following information:

- System clock specifics
- Clock architecture
- Clock sources
- Clock monitoring
- Programmable clock dividers
- Clock control registers
- Progressive Clock Switching

NOTE

This chapter covers only clocks that are generated on the device. Protocol clocks that are provided by external devices are covered in the respective chapters where they are used.

The clock (system clock) for the computational shell (which includes the three CPUs as well as all modules that run in the high speed domain), memories, and debug logic is independent from the peripheral clocks. This allows the system clock to be a frequency modulated clock to reduce electromagnetic emissions, while having a precise clock for the peripheral timer and communication functions. It also allows the system clock to be reduced during low computational activity periods to help reduce power consumption, while providing a fixed frequency to the communication interfaces and timers.

The device boots from the internal 16 MHz RC oscillator (IRCOSC), and uses this as a backup clock in the event of a PLL or oscillator failure (if backup clock is enabled). The backup clock is enabled in the Mode Entry Module (MC_ME).

There are three possible ways to provide the source clock:

- External oscillator

- External crystal
- IRCOSC

From one of these input sources, the internal clocks are generated from one of the two PLLs, PLL0 and PLL1, PLL0_PHI_CLK and PLL1_PHI_CLK, respectively. These two clocks, along with the XOSC_CLK, IRC_CLK, and SDPLL_CLK, can be selected to drive system peripherals depending on the configuration of the Auxiliary Clock Selectors in the Clock Generation Module (MC_CGM). The PHI1 output of PLL0 (PLL0_PHI1_CLK) can also be used as the clock source for PLL1. There are a total of 15 clock selectors which allows developers to drive each of system peripherals with an independent clock source. There is also one additional clock selector which is used exclusively for the system clock.

Each of the outputs of the module clock selectors have their own divider which allows for even more clock frequency granularity being able to divide the outputs by up to 512 for a given peripheral. On selected outputs of the clock dividers are Clock Monitor Units (CMU) that are used to test the integrity of the clocks making sure that their frequencies stay within necessary operating limits. If any of the CMUs detect an issue with the clock signal that is being monitored, an interrupt or system reset could be generated, depending on how the CMUs are configured.

5.2 Clock generation

The top-level clock generation architecture is given in the following figure. All clock selectors and dividers in the figure are located and programmed in the Clock Generation Module (MC_CGM). All dividers are integer dividers (1, 2, 3, …, n) with the ranges given in the diagram. All dividers connected to the System Clock Selector in the figure have 50% duty cycle outputs.

NOTE

All references to SDPLL_CLK would refer to SDPLL_CLK160 unless explicitly mentioned otherwise.

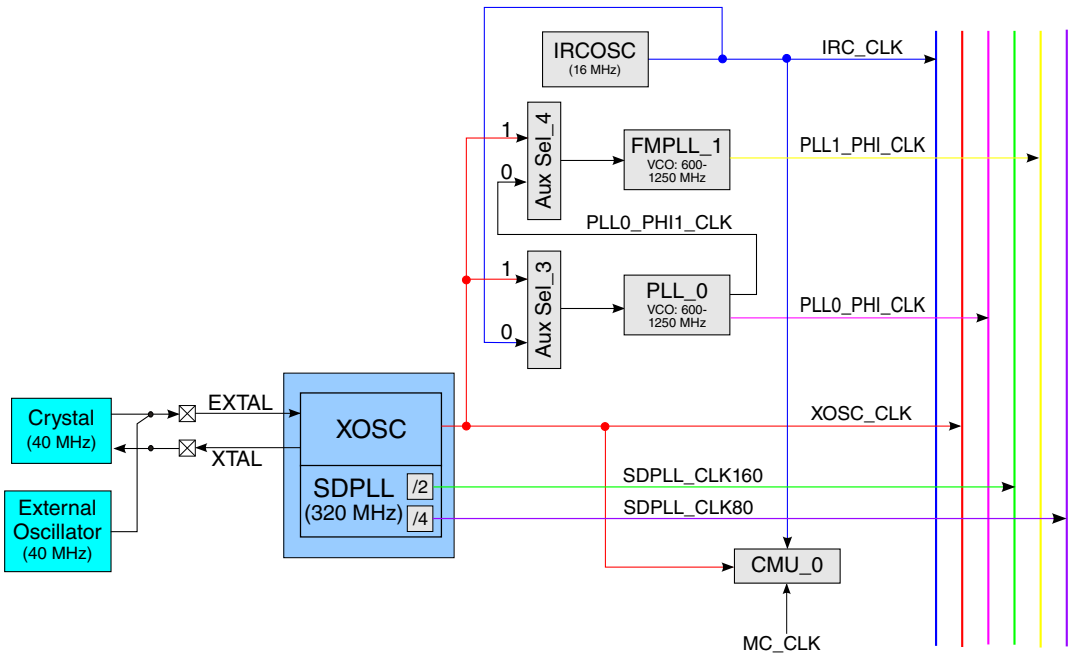

Figure 5-1. Clock sources

Figure 5-1 shows the potential clock sources. The IRC_CLK is a reliable clock source, that runs independently from any other component. It is the main clock source during boot or in case of lock loss in the PLL.

During Run mode, the clock generation is typically based on the XOSC. The XOSC module requires an external oscillator source, either a crystal or an external clock generator. For use with the Sigma Delta ADCs, this external crystal needs to be 40 MHz. If a 40 MHz crystal is used, PLL0 and SDPLL are driven by the XOSC. SDPLL_CLK is primarily used for the 320 MHz Sigma Delta ADCs and the analog RADAR system.

PLL0_PHI_CLK is used to drive the clock for the digital system. PLL1 is driven by the either the XOSC_CLK or PLL0:PHI1. PLL1 also supports Frequency Modulation to distribute the emitted electromagnetic radiation (EMR) over a frequency spectrum.

The following clocks are available from the clock source structure for individual clock domains (see Figure 5-1):

- IRC_CLK
- XOSC_CLK
- PLL0_PHI_CLK
- PLL1_PHI_CLK
- SDPLL_CLK

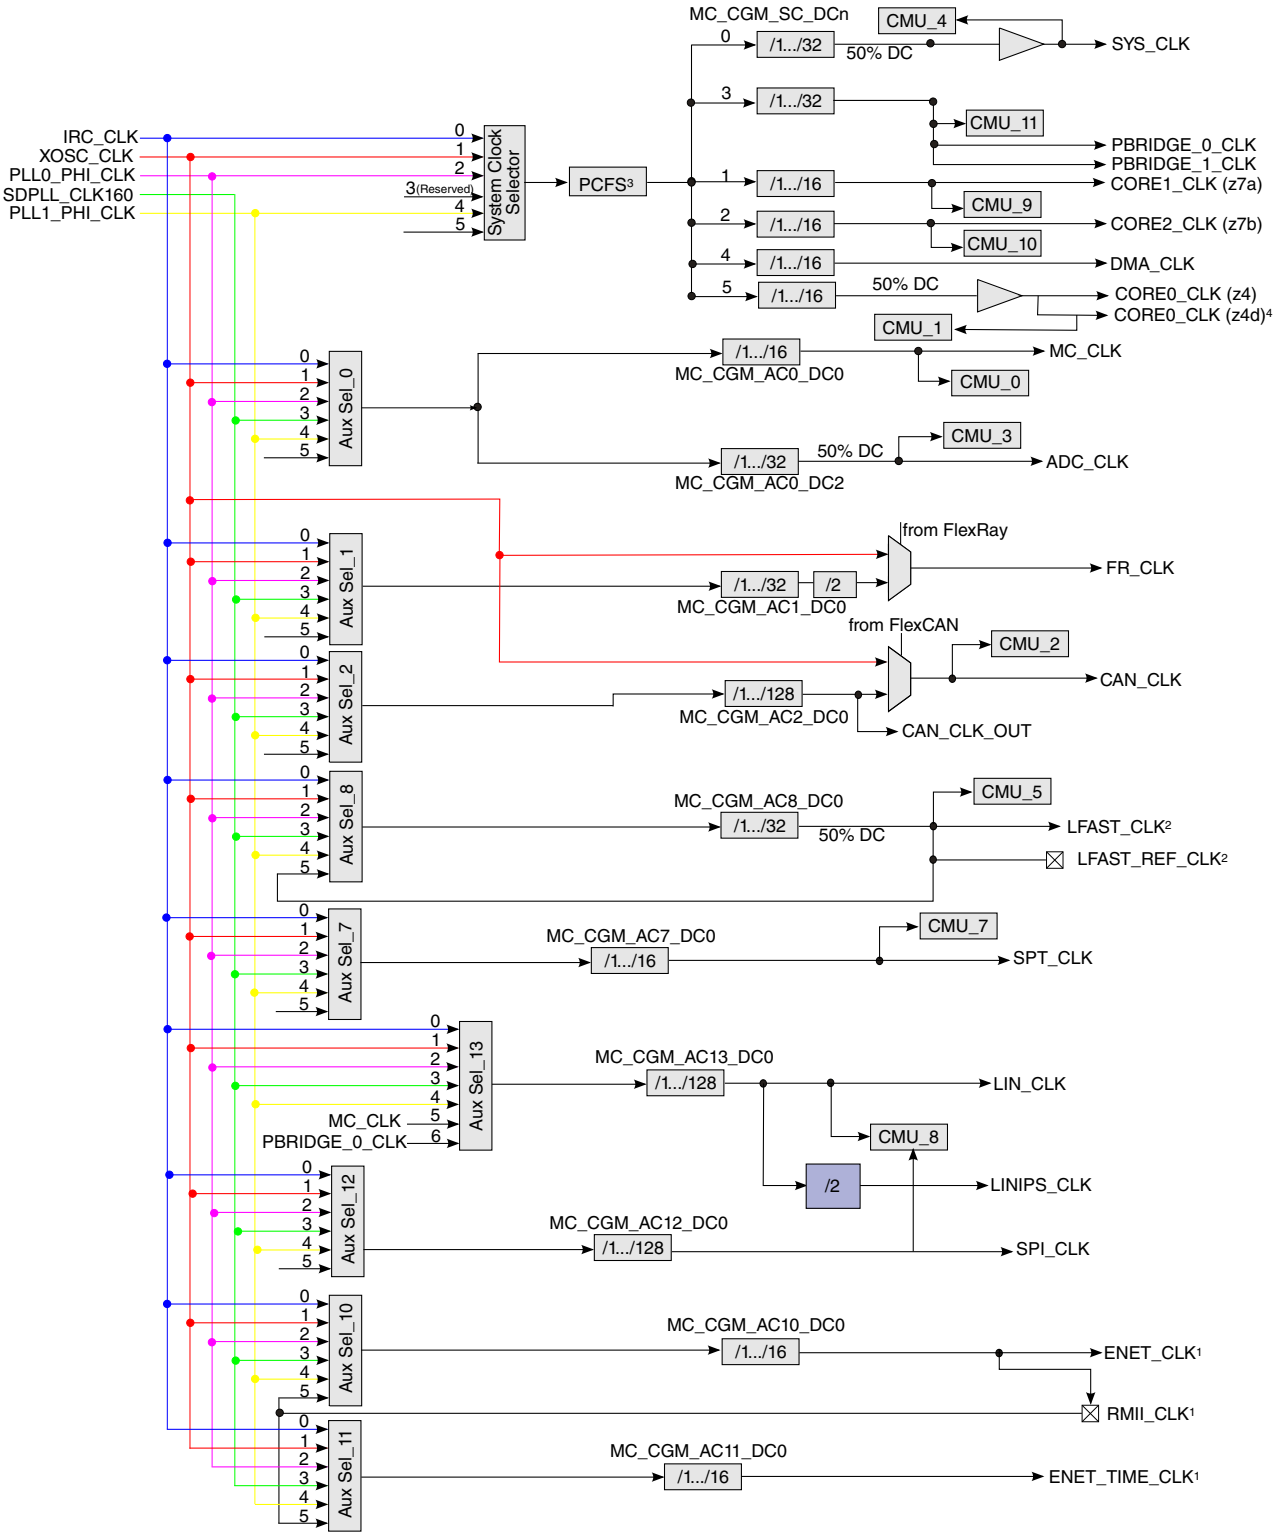

Figure 5-2. Clock selection

NOTE

1. See ENET clocking for details.
2. See LFAST clocking for details.

3. Progressive Clock Frequency Switching (see Progressive System Clock Switching for details).
4. This is the lock step core clock which is gated when lock step is disabled.

Figure 5-3 shows how the CLKOUT signals are selected using the MCB_CLKOUT_SEL register.

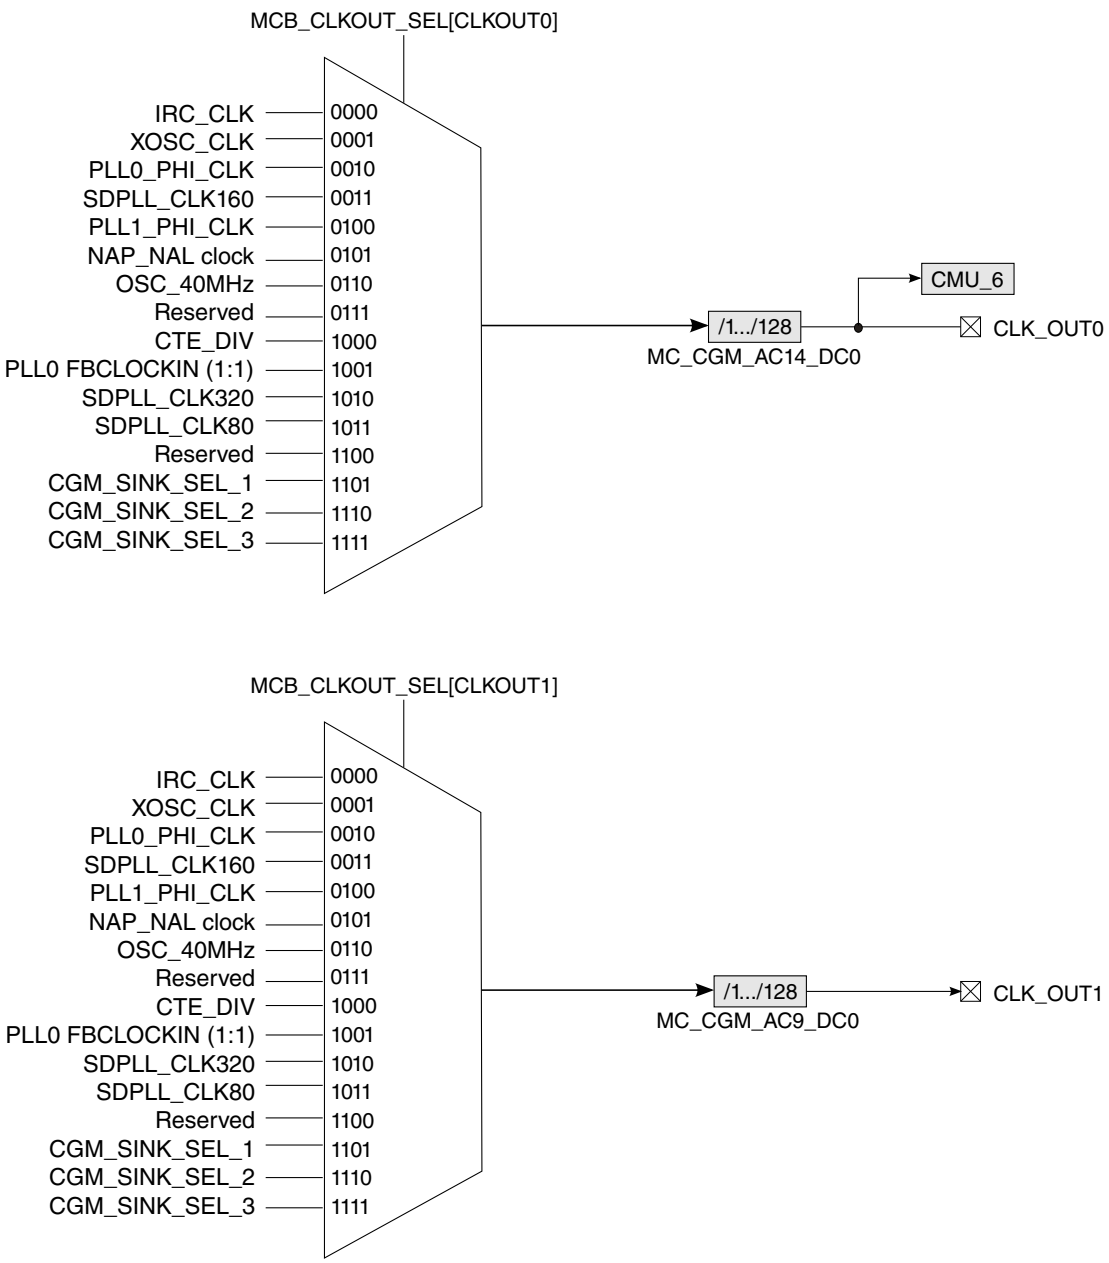

Figure 5-3. CLKOUT selection

The main clock is the system clock (SYS_CLK). It drives the Safety core and the crossbar. It is a divided version of the progressive clock switching (PCFS) clock output. Besides the System clock there are two more CPU clocks, the CORE1_CLK and CORE2_CLK for the two decoupled cores. They can be selected to be the same as the SYS_CLK or full speed clock coming from the PCFS output directly without division. For reliability reasons the CORE0_CLK has an independent clock tree and independent buffering, thus, reducing common cause faults (CCF). The CORE0_CLK is monitored by CMU_1. SYS_CLK is divided by 2, and this reduced clock is used for other XBAR masters (eDMA, LFAST, ENET, and FlexRay including the required port splitters) and for the two PBRIDGE peripheral bus bridges (PBRIDGE_0, PBRIDGE_1). The frequencies of the system clock structure, including the peripheral clocks (DMA_CLK, CORE2_CLK, CORE1_CLK, PBRIDGE_0_CLK, and PBRIDGE_1_CLK), can be gradually reduced using the fine granularity offered by the progressive clock frequency switching module (see the PCFS block in Figure 5-2). This is based on a fractional clock divider allowing smooth ramping of the current of the CPU and peripherals used for basic operation.

Besides the system clock domain, there are several other clock domains that do not allow progressive clock switching or frequency modulation. They are used for communication interfaces (FR_CLK, CAN_CLK, LFAST_CLK), for the motor control system (MC_CLK and ADC_CLK), and RADAR processing (SD_CLK, DAC_CLK, CTE_CLK, SPT_CLK). MC_CLK drives Motor Control system modules CTU_0, ETIMER_1, ETIMER_2, flexPWM_0.

CLK_OUT*n* drive the clk_out*n* pin, which can be used to monitor internal clocks (divided down so that the clk_out*n* is < 60 MHz) or to share the clock driving other chips.

Most of the clocks are clock monitored using CMU modules detecting missing or faulty clocks. The reference for the CMUs is the IRCOSC. The IRC_CLK itself is supervised by the external clock (XOSC_CLK).

Figure 5-4 shows how the clocks from the clock selectors are connected to the system components. All BIUs (bus interface units to the PBRIDGE bus) are running on PBRIDGE_0_CLK or PBRIDGE_1_CLK. These clocks are only active at the peripherals on active bus cycles to this particular module.

Thus, all modules also have a module clock that is typically a gated (per module) version of the PBRIDGE_*n*_CLK. Besides this, the software watchdog timer SWT uses the more reliable internal RC oscillator clock IRC_CLK. This clock is always on, and thus, well apt for safety functions.

The IRC_CLK may be used for safety relevant functions in the Fault Collection and Control Unit (FCCU). Furthermore, this clock is used for the digital filters to detect external interrupt events. Thus, the system can resume from STOP mode, while the system clock is gated off and only the IRC_CLK is running.

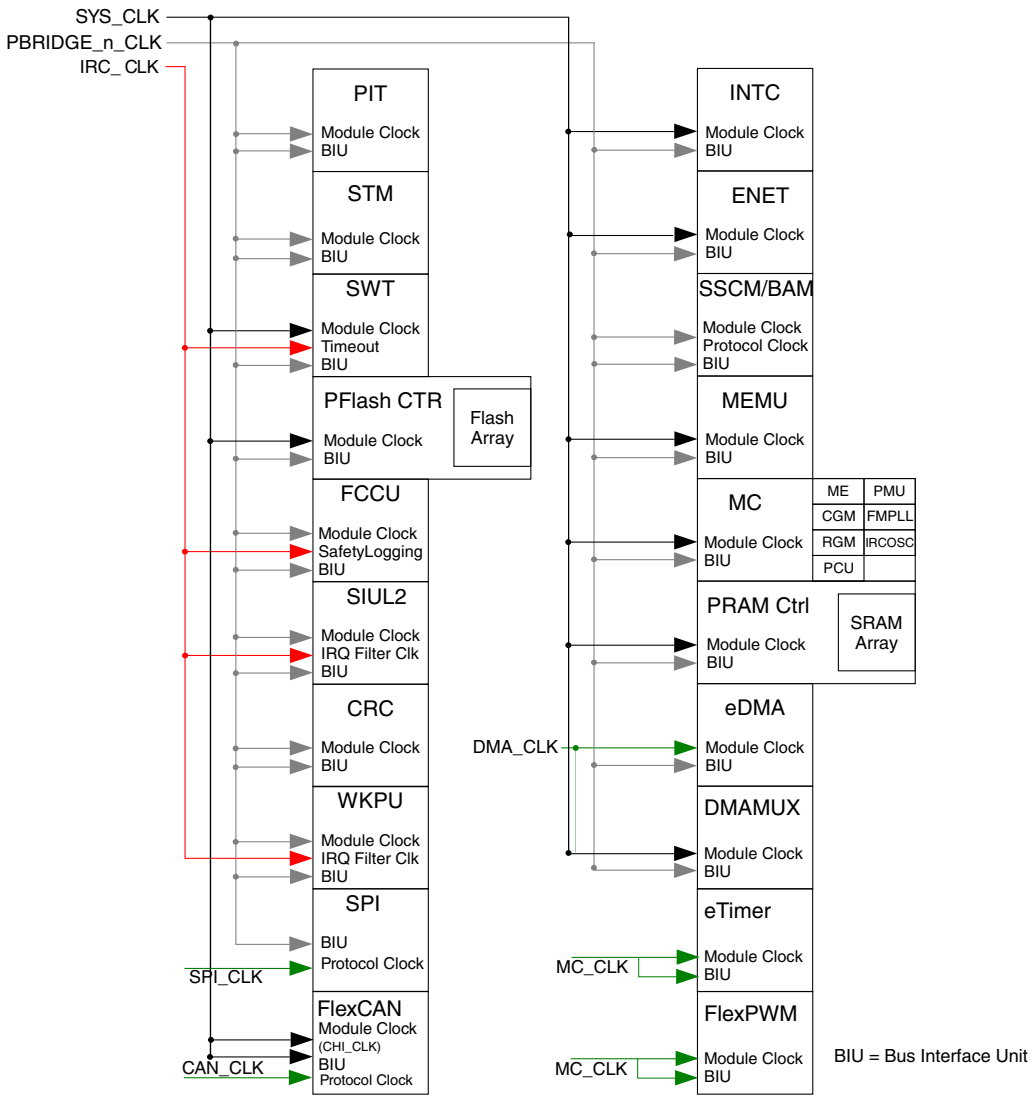

Figure 5-4. Clock distribution

The functional clocks MC_CLK, ADC_CLK, FR_CLK, CAN_CLK, LFAST_CLK, SD_CLK, DAC_CLK, CTE_CLK, and SPT_CLK are routed to the corresponding IP modules.

Special care needs to be taken to the clock distribution in the high fidelity RADAR analog subsystem (see Figure 5-5).

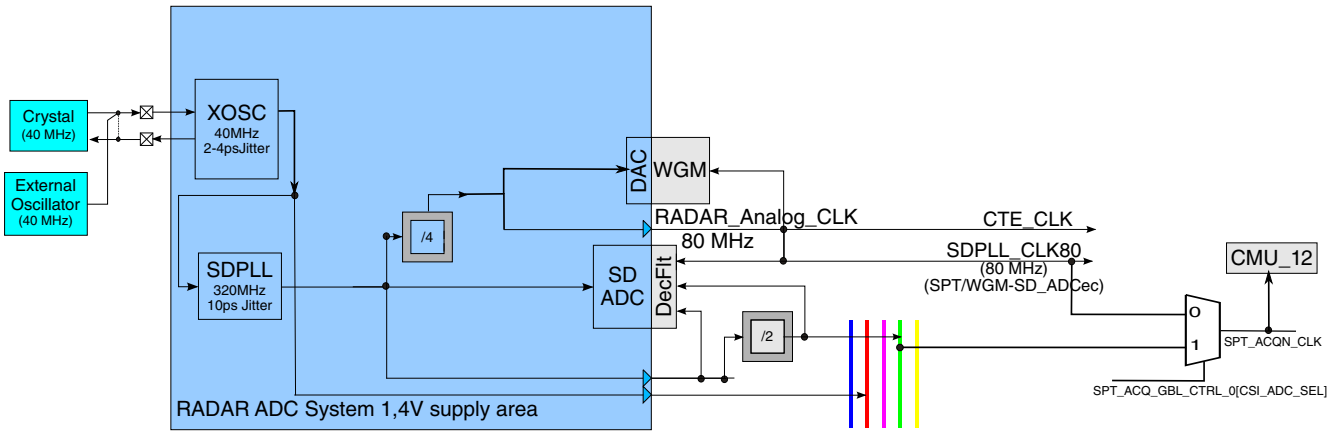

Figure 5-5. Clocks in the analog RADAR block

5.2.1 MC_CGM registers

The following table shows the relationship between the output clocks and the MC_CGM registers.

NOTE

See Clock Generation Module (MC_CGM) for specifics on register implementation.

Configure the Auxillary Clock Selectors and Dividers before enabling the corresponding module. After every reset, first clear the Auxiliary Clock Mux selected source (MC_CGM_ACm_SC)and the division values (MC_CGM_ACm_DCp). And only then, select the required clock source and division values. Here m refers to (0..15) and p refers to (0..2). After each reset the Auxillary Clock Selectors should be switched twice.

Table 5-1. MC_CGM relationship to clocks

5.3 System clock frequency limitations

The maximum frequency of operation for the device system level clocks is given in the following table. In addition, the system clocks are subject to the following limitations:

- TCK frequency should be less than half of SYS_CLK frequency. For example, if SYS_CLK is running on IRC, TCK frequency should be less than 8 MHz
- Core_1/Core_2 clock can always run in 2:1 or 1:1 with respect to SYS_CLK (Core_1/Core_2: SYS_CLK)
- DMA_CLK cannot be slower than AIPS clock
- DMA_CLK: SYS_CLK = 1:1
- SYS_CLK: PBRIDGE_n_CLK can only be 2:1
- SPT_CLK > SYS_CLK

The device has three frequency modes; Z7 cores will work on 240, 180 and 120 Mhz respectively in these modes. It is expected there may be performance scale-down in the frequency scaled-down mode (120 MHz). Accesses from Z7 cores and accesses from other masters to Z7 TCM will be impacted accordingly.

Table 5-2. Platform Clock Modes

	Z7 Cores	Z4 Core		
Mode	Core_1/Core_2	Core_0	AHB/SRAM/FLASH (SYS_CLK)	IPS (PBRIDGE_x_CLK)
4:2:2:1	240	120	120	60
4:4:2:1	180	180	90	45
2:2:2:1	120	120	120	60

NOTE

The user is responsible to verify that these values are not exceeded.

Each PBRIDGE (PBRIDGE_0, PBRIDGE_1) is capable of clocking the PBRIDGE interface of each peripheral slot individually at the XBAR frequency, or at the XBAR frequency divided by two.

In **2:2:2:1** mode, the user must program the source clock to be 120 MHz and not 240 MHz or higher for the traces to work. The divider values should be programmed accordingly.

Table 5-3. Maximum system level clock frequencies

System clock	Maximum frequency
CORE0_CLK	180 MHz plus modulation (+/-2%)
SYS_CLK	120 MHz plus modulation (+/-2%)
PBRIDGE_x_CLK	60 MHz plus modulation (maximum modulation expected is +/-2%)
CORE2_CLK	240 MHz plus modulation (+/-2%)
CORE1_CLK	240 MHz plus modulation (+/-2%)
DMA_CLK	120 MHz plus modulation (maximum modulation expected is +/-2%)
MC_CLK	160 MHz
ADC_CLK	80 MHz
SD_CLK	320 MHz
DAC_CLK	10 MHz
CTE_CLK	80 MHz
WGM_CLK	80 MHz
SPT_CLK	200 MHz

Table continues on the next page...

Table 5-3. Maximum system level clock frequencies (continued)

System clock	Maximum frequency
FR_CLK	40 MHz
CAN_CLK (FlexCAN)	40 MHz
LFAST_CLK	20 MHz
CLK_OUT0	60 MHz
LIN_CLK	80 MHz
LINIPS_CLK	40 MHz
CLK_OUT1	60 MHz
ENET_CLK	50 MHz
ENET_TIME_CLK	100 MHz
SDPLL80_CLK	80 MHz
SDPLL160_CLK	160 MHz
SDPLL320_CLK	320 MHz
XOSC_CLK	40 MHz
IRC_CLK	16 MHz
SPI_CLK	80 Mhz

In order to maintain synchronization between the different system clock branches (for example, SYS_CLK output from the System Clock Selector), there are limitations on the frequencies of those clocks. The system clocks must be binary multiples of each other with the frequency relationships described in the electrical specifications.

5.3.1 Supported clocking configuration for magic carpet modes

The support clocking scenarios are listed below per MC_ME modes

Table 5-4. DRUN/RUNx/HALT0

SDPLL ON/OFF	PLL1 ON/OFF	PLL0 ON/OFF	XOSC ON/OFF	IRC ON/OFF	SYS_CLK SOURCE	Source to PLL0	Source to PLL1	_MC(CONFIG) values[1]
OFF	ON	ON	ON	ON	PLL1	XOSC	PLL0	0x001300F4
OFF	ON	ON	ON	ON	PLL1	XOSC	XOSC	0x001300F4
ON	ON	ON	ON	ON	PLL1	XOSC	PLL0	0x001301F4
ON	ON	ON	ON	ON	PLL1	XOSC	XOSC	0x001301F4
OFF	ON	OFF	ON	ON	PLL1	NA as PLL0 is OFF	XOSC	0x001300B4
ON	ON	OFF	ON	ON	PLL1	NA as PLL0 is OFF	XOSC	0x001301B4

1. _MC (CONFIG) value is actually the MC_ME_*_MC for the respective modes. Example MC_ME_DRUN_MC for DRUN mode.

Table 5-5. STOP0

SDPLL ON/OFF	PLL1 ON/OFF	PLL0 ON/OFF	XOSC ON/OFF	IRC ON/OFF	SYS_CLK SOURCE	Source to PLL0	Source to PLL1	_MC(CONFIG) values[1]
OFF	OFF	OFF	OFF	ON	IRC	NA as PLL0 is OFF	NA as PLL1 is OFF	0x00130010
OFF	OFF	OFF	ON	ON	IRC	NA as PLL0 is OFF	NA as PLL1 is OFF	0x00130010

1. MC_ME_STOP0_MC

NOTE

This does not reflect the configurations for self test modes

5.3.2 Aurora clock

The supported clock frequency of the Aurora clock input has a valid range of 625 MHz to 1.25 GHz. The NAL/NPC works at CORE0_CLK or SYS_CLK frequencies. The frequency of this clock must be > Aurora clock ÷ 10. For 1.25 GHz Aurora clock frequency, the SYS_CLK frequency must be ≥ 125 MHz.

Since the SYS_CLK is limited to 120 MHz, therefore, the Aurora clock is limited to 1.15GHz. When SYS_CLK is 90Mhz, the Aurora clock will be limited to 870 MHz (considering worst case setup and hold time).

NOTE

In case a mode transition is made into a mode such that the resultant SYS_CLK frequency is lower than the limit mentioned above, then the Aurora trace will get stalled. The connection with the debugger will need to be restarted after the SYS_CLK goes above the limit again.

During reset the SYS_CLK source is always IRC so this limitation also holds true, and the user will need to reconnect to the debugger after reset. If the reset is a software generated functional reset, then the user can avoid the process of reconnection by flushing out all traces from the chip before starting the reset event.

5.3.3 CSE clock

To meet SHE1.1 performance targets, configure Concurrent Secure Boot Mode through DCF Records (Refer to attached DCF Sheet) so that the CPU can configure the PLL to run the CSE at 120 MHz, instead of 16MHz/2 IRCOSC clock which is default clocking source.

5.4 Default clock configuration

At power up, the IRCOSC is the default clock for the entire system. All system clock dividers are set to one at power on reset.

NOTE

Do not access unimplemented address space for XOSC and IRCOSC register areas OR write software that is not dependent on receiving an error when access to unimplemented XOSC and IRCOSC space occurs.

5.5 Clock sources

The following clock sources are described in this section:

- PLL0
- PLL1 (FMPLL)
- SDPLL
- External Oscillator (XOSC)
- External Clock (EXTAL Bypass)
- 16 MHz Internal RC Oscillator (IRCOSC)

5.5.1 PLL

The PLL in the device is a Dual PLL which provides separate system and peripheral clocks as shown in the following figure. The PLLs are disabled after power on and must be enabled by software. The block diagram for the Dual PLL is shown in the following figure.

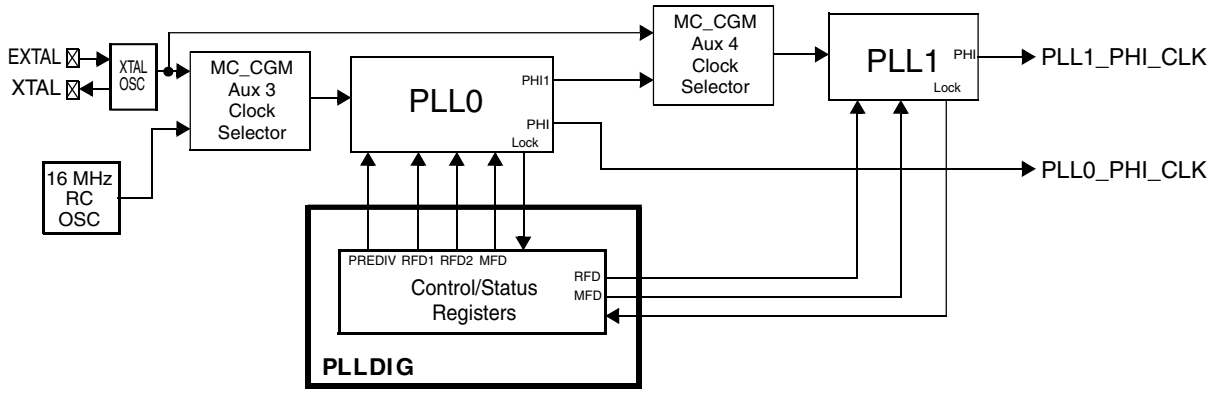

Figure 5-6. Dual PLL digital interface block diagram

5.5.1.1 PLL0 - base PLL (non-FM)

PLL0 is the primary PLL. This PLL is used to source a non-Frequency Modulated clock to the device modules and also the reference clock to PLL1.

5.5.1.1.1 PLL0 input clocks

The possible input clock sources for PLL0 are the XOSC_CLK and external reference clock. The external reference clock input is the EXTAL pin. AUX Clock Selector 3 selects which input clock will be used as the source for PLL0.

NOTE

IRC_CLK should not be used as reference clock of PLL in normal application. The Jitter and clock variation on PLL while running IRC will be too high for any useful application purposes.

5.5.1.1.2 PLL0 output clocks

The output clocks from PLL0 are PHI and PHI1. The PHI output clock (PLL0_PHI_CLK) drives the peripheral clock and the system clock when PLL1 is not locked or active. The PHI1 output provides one of the input references for PLL1.

5.5.1.2 PLL1 - FMPLL

PLL1 is a Frequency Modulated PLL (FMPLL) which is used to drive the system clock. PHI is the output of PLL1 which drives the System Clock and AUX Clock Selectors of the MC_CGM.

5.5.1.2.1 PLL1 input clocks

Either the XOSC output or the PHI1 signal from PLL0 may be selected (AUX Clock Selector 4 in the MC_CGM) as the source for PLL1.

5.5.1.2.2 PLL1 output clocks

The output clock from PLL1 is the PHI clock, which drives the system clock. The PHI output clock contains a fractional divider that can be applied to the loop divide of the PLL to achieve good granularity in the PLL1_PHI_CLK frequency.

5.5.1.2.3 PLL register interface

This device has a single digital interface for the dual PLLs. The digital interface provides register control of all features of the PLLs. Details are provided in the Dual PLL Digital Interface (PLLDIG) chapter.

5.5.1.3 SDPLL

SDPLL drives the System Clock and AUX Clock Selectors of the MC_CGM. SDPLL also drives SDADC and DAC. It is the primary source for MC_CLK. It is the primary source for MC_CLK. SDPLL should be enabled only after the configuring SPT_ACQ_GBL_CTRL_0[CSI_ADC_SEL] field. This is necessary to avoid glitches in the clock of SPT and MIPI modules.

5.5.1.4 PLL register reset values

All reset values for the PLLDIG registers that are device specific are shown in the following table. All other register reset values are shown in the Dual PLL Digital Interface (PLLDIG) chapter.

Table 5-6. Dual PLLDIG register reset values

Offset (hex)	Register	Reset value (hex)
0000h	PLL0CR - PLL0 Control Register	0000_0000h
0008h	PLL0DV - PLL0 Divider Register	0000_0000h
0020h	PLL1CR - PLL1 Control Register	0000_0000h
0028h	PLL1DV - PLL1 Divider Register	0000_0000h

5.5.1.5 PLL initialization information

Coming out of reset PLL0 and PLL1 are disabled per the DRUN mode configuration register, MC_ME_DRUN_MC.

1. Configure PLL0 and related modules.
   a. With PLL0 disabled, program the PLL0 clock source in MC_CGM_AC3_SC[SELCTL]. Default source is the 16 MHz IRCOSC. Write MC_CGM_AC3_SC[SELCTL] = 1 to select the XOSC as source.
   b. Program PLL0DV[PREDIV], PLL0DV[RFDPHI1], PLL0DV[MFD], and PLL0DV[RFDPHI].
   c. If desired, modify the AFE_OSCDLY[EOCV] to adjust the external oscillator stabilization count, used when the external oscillator is turned on (by the MC_ME).
   d. The XOSC frequency is compared to the IRCOSC source when the XOSC is turned on.
2. Turn on the XOSC and PLL0.
   a. Configure a mode configuration for turning on PLL0 and the XOSC. In a mode configuration register (for example, MC_ME_DRUN_MC) set MC_ME_<*mode*>_MC[XOSCON] = 1 and MC_ME_<*mode*>_MC[PLL0ON] = 1. If desired, also set MC_ME_<*mode*>_MC[SYSCLK] = 2 for this new mode configuration to use PLL0 (PLL0 PHI output) as the sysclk.
   b. Enter that mode by two writes to MC_ME_CTRL register to enter that mode. This is required even if entering the same mode.
3. Wait for the mode transition to complete.
   a. Wait for the mode transition to complete by polling MC_ME_GS[S_MTRANS] or enabling an interrupt for flag MC_ME_IS[I_MTC]. A timer, even if it is the watchdog, should be used to make sure the mode transition completes. Mode transition will NOT complete until:
      - The XOSC counter expires (if the new mode configuration changes MC_ME_<*mode*>_MC[XOSCON] = 1), and
      - PLL is locked (if the new mode configuration changes MC_ME_<*mode*>_MC[PLL0ON] = 1)
   b. Confirm the desired target mode was entered by checking the status of MC_ME_GS[S_CURRENT_MODE].
4. Configure PLL1 and related modules.
   a. With PLL1 disabled, program PLL1 clock source in MC_CGM_AC4_SC[SELCTL]. Default is MC_CGM_AC4_SC[SELCTL] = 0 which selects PLL0_PHI1.
   b. Program PLL1DV[MFD] and PLL1DV[RFDPHI].

c. If required, program the PLL1FM register with the desired frequency modulation parameters and enable FM modulation, PLL1FM[MODEN] = 1. The PLL1FM register must not be written after PLL1 is enabled and operating in normal mode.

5. Turn on PLL1.
   a. Configure a mode configuration for turning on PLL1, and keeping the XOSC and PLL0 on. In a mode configuration register (for example, MC_ME_DRUN_MC), initialize MC_ME_<*mode*>_MC[XOSCON] = 1, MC_ME_<*mode*>_MC[PLL0ON] = 1 and MC_ME_<*mode*>_MC[PLL1ON] = 1. If desired, also set MC_ME_<*mode*>_MC[SYSCLK] = 4 for this new mode configuration to use PLL1 as the sysclk.
   b. Enter that mode by two writes to ME_CTRL register to enter that mode. This is required even if re-entering the same mode.
6. Wait for the mode transition to complete.
   a. Wait for the mode transition to complete by polling MC_ME_GS[S_TRANS] or enabling an interrupt for flag MC_ME_IS[I_MTC]. A timer, even if it is the watchdog, should be used to make sure the mode transition completes. Mode transition will NOT complete until:
      - XOSC counter expires (if the new mode configuration changes XOSCON to 1), and
      - PLL1 is locked (if the new mode configuration changes MC_ME_<*mode*>_MC[PLL1ON] = 1).
   b. Confirm the desired target mode was entered by checking the status of MC_ME_GS[S_CURRENT_MODE].

NOTE

See the Mode Entry Module (MC_ME) chapter for details.

5.5.2 External oscillator (XOSC)

The external oscillator (XOSC) is provided as a reference for the on-chip PLLs. It can also can be used as a clock source to the ADCs, timer, serial interfaces, LFAST, and as a system clock source. It is available for observation on either of the CLK_OUT*n* pins, and is used as a reference to calibrate the IRCOSC frequency.

The external oscillator of 40 MHz input frequency allows a crystal or external clock to be used as the reference clock for the microcontroller.

5.5.2.1 XOSC register write protection

The XOSC registers have write protection as shown in the Register Protection table.[1]

5.5.2.2 XOSC reset value

The following table shows the default reset value for the XOSC registers.

Table 5-7. XOSC register reset values

Offset	Register	Reset value
00h	Oscillator Control Register (AFE_OSCCTRL)	0000_0001h
04h	Oscillator Status Register (AFE_OSCSTS)	0000_0001h
08h	Oscillator Delay Register (AFE_OSCDLY)	0000_0080h

5.5.3 16 MHz internal RC oscillator (IRCOSC)

The microcontroller has a 16 MHz internal RC oscillator which is always enabled and can be used as the clock source for the PLLs. The IRCOSC is the default clock after reset.

5.6 Peripheral Clocks

Figure 5-4 shows the clock distribution to peripherals.

5.6.1 Enabling of peripherals and clock sources

Software should take care that the clock sources (system clocks and protocol clocks) selected for a peripheral are already enabled in the current mode before initiating the target mode transition to enable the peripheral. For example, in FlexCAN when XOSC is selected for the CAN engine clock source (CAN_CTRL1[CLKSRC]), before enabling FlexCAN peripheral clock the user must ensure XOSC is enabled in the current mode prior to the target mode transition that will enable the FlexCAN.

1. See Register Protection section in Device Configuration chapter for bit field details.

5.6.2 Disabling of peripherals and clock sources

Software should take care that the clock sources (system clocks and protocol clocks) selected for a peripheral are not disabled during any mode transition preceding a mode transition to disable the peripheral. For example, in FlexCAN when XOSC is selected for the CAN engine clock source (CAN_CTRL1[CLKSRC]), before disabling FlexCAN peripheral clock the user must ensure XOSC is enabled in the current mode prior to the target mode transition that will disable the FlexCAN. If need be, XOSC should be disabled only after that.

5.6.3 LFAST clocking

The device includes an LFAST module to support inter-processor communication. A single LFAST PLL, which requires a 20 MHz reference, supports high speed operation of the LFAST module. For low speed LFAST operation, the reference clock is used directly by the LFAST module.

The following figure shows the clock routing for the various LFAST modules on the device, including connections to the DRCLK_IO and DRCLK pins.

The LFAST PLL requires a 20 MHz reference. The source may be the PLL0_PHI_CLK,PLL1_PHI_CLK, IRC_CLK, SDPLL_CLK, the external oscillator (XOSC_CLK) or input from the external LFAST device via PAD_135 package pin. When this reference clock is generated internally, it can also be output on the PAD_135 pin. The PAD_135 connection is shown in Figure 5-7. Input/Output direction of PAD_135 pin is controlled by MSCR135 in the SIUL2.

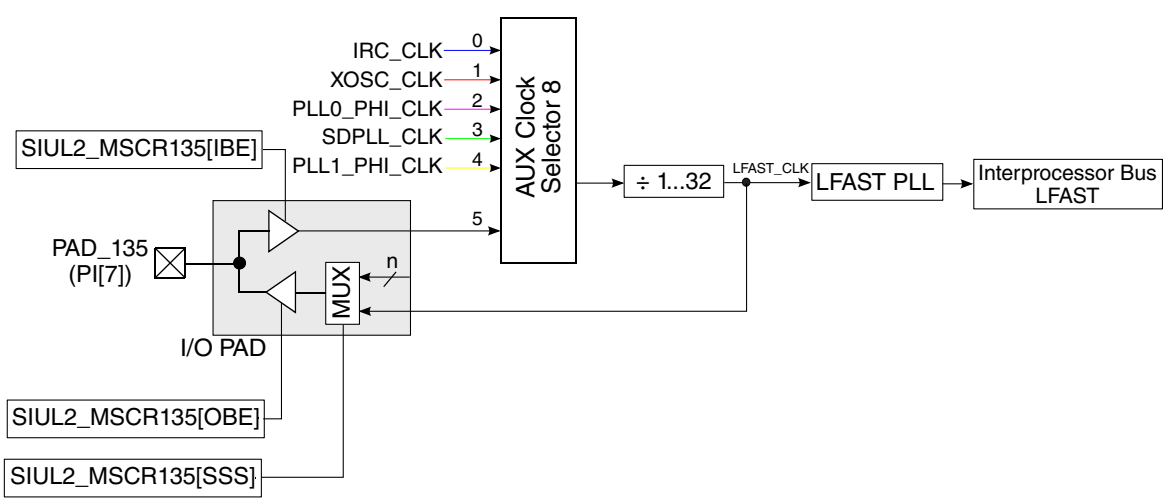

Figure 5-7. LFAST clocking

5.6.4 FlexRay clocking

The FlexRay protocol clock is sourced from either the non-FM PLL0_PHI_CLK, PLL1_PHI_CLK, XOSC_CLK, IRC_CLK, or SDPLL_CLK. When using the external oscillator clock, a 40 MHz crystal is required for proper operation. Clock selection is controlled by configuring the FR_MCR register, and the selection is output from the FlexRay block.

The clock mux is a glitchless mux and requires both the inputs to be on during clock switching.

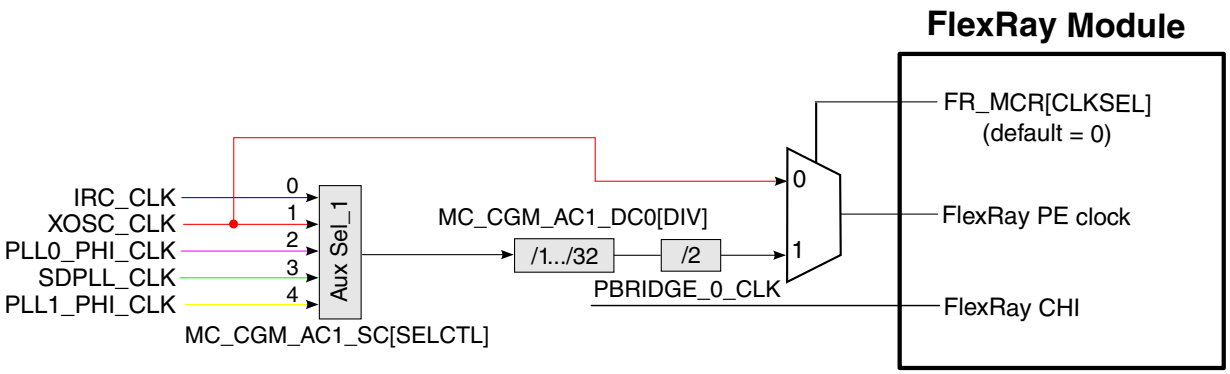

Figure 5-8. FlexRay clocking

5.6.5 FlexCAN clocking

As seen in Figure 5-9, the CAN_CLK is generated from either the XOSC, PLL0_PHI_CLK, IRC_CLK, SDPLL_CLK, or PLL1_PHI_CLK. The selected clock source can be divided by a value written to the MC_CGM_AC2_DC register in the MC_CGM. The output of this divider (CAN_CLK_OUT) drives one of two inputs of a multiplexer on the FlexCAN. The other input is driven by XOSC_CLK. The FlexCAN_CTRL1[CLK_SRC] bit selects whether the CAN_CLK_OUT or XOSC_CLK will drive the output of the multiplexer for the CAN_CLK(PE Clock/Protocol Clock).

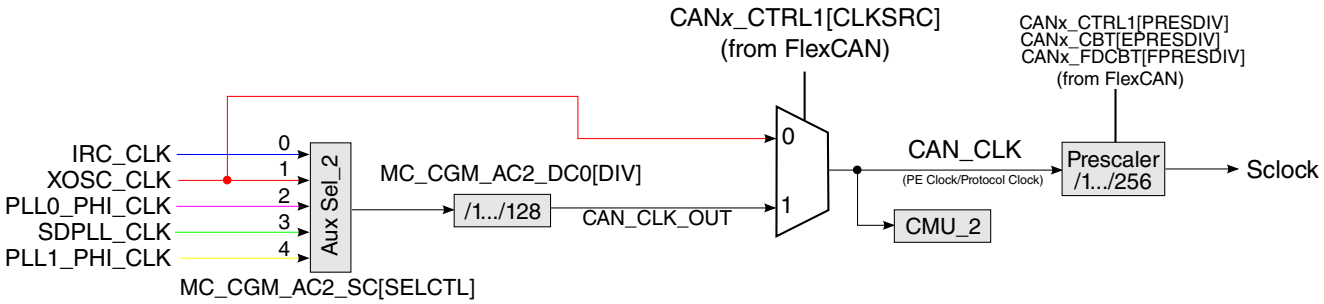

Figure 5-9. FlexCAN clocking

NOTE

FlexCAN modules should never be kept on in STOP mode. They must be disabled by configuring a Mode Entry Module Low-Power Peripheral Configuration Register (MC_ME_LP_PCn) for peripheral clock frozen in STOP mode and selecting this low-power configuration in the appropriate MC_ME Peripheral Control Register.

5.6.6 MIPICSI2 clocking

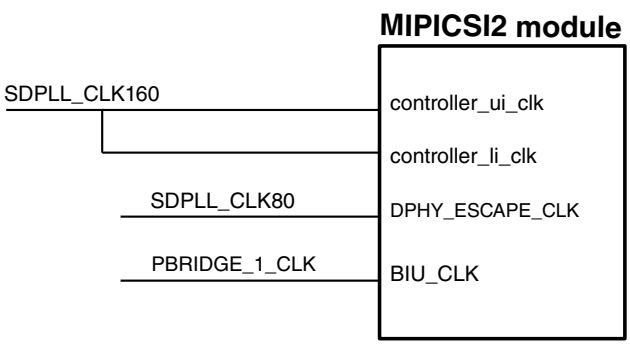

Figure 5-10. MIPICSI2 clocking

5.6.7 ENET clocking

The ENET's AHB interface clock is SYS_CLK. Its BIU clock is PBRIDGE_0_CLK.

The ENET protocol clock is sourced from either the PLL0_PHI_CLK, PLL1_PHI_CLK, XOSC_CLK, IRC_CLK, SDPLL_CLK, or from an external clock source as selected by the MC_CGM_AC10_SC register. These sources can be divided by a value written to the MC_CGM_AC10_DC register in the MC_CGM. The output of this divider is ENET_CLK.

The ENET time is sourced from either the PLL0_PHI_CLK, PLL1_PHI_CLK, XOSC_CLK, IRC_CLK, SDPLL_CLK, or from an external clock source as selected by the MC_CGM_AC11_SC register. These sources can be divided by a value written to the MC_CGM_AC11_DC register. The output of this divider is ENET_TIME_CLK.

NOTE

A ENET clock requirement is that the SYS_CLK frequency must be at least 2X the ENET_CLK. Eg for MII at 100 Mbps, the ENET_ClK is 25 MHz and therefore the SYS_CLK must be at least 50 MHz.

NOTE

RGMII mode operation is limited to **4:2:2:1** system clocking mode and needs 120 MHz SYS_CLK.

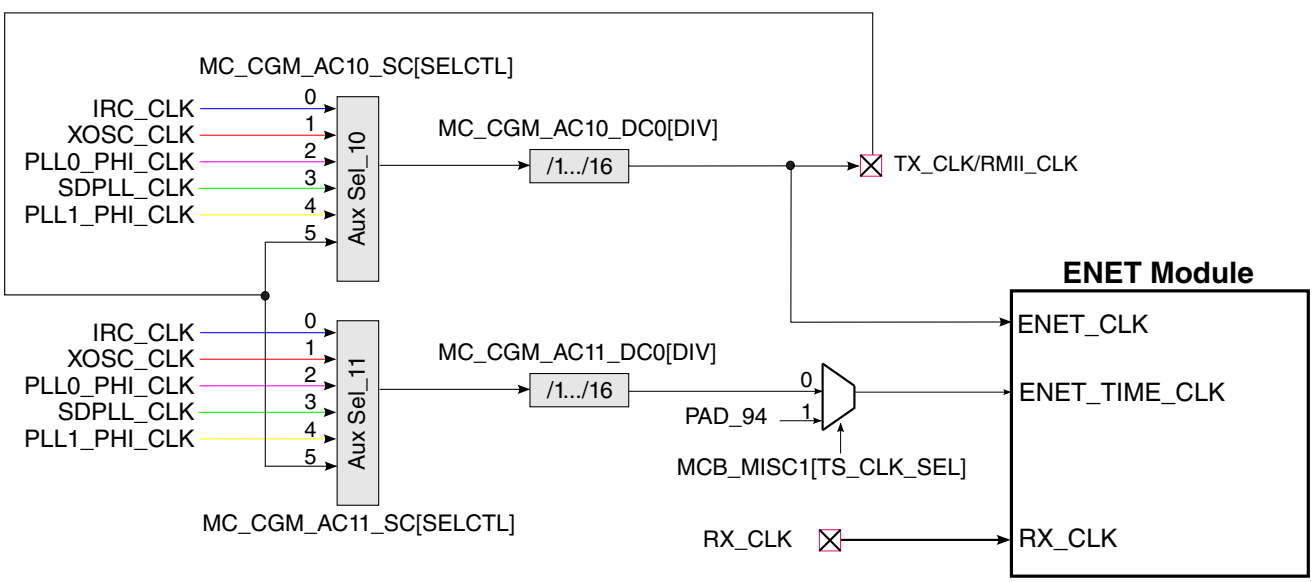

Figure 5-11. ENET clocking

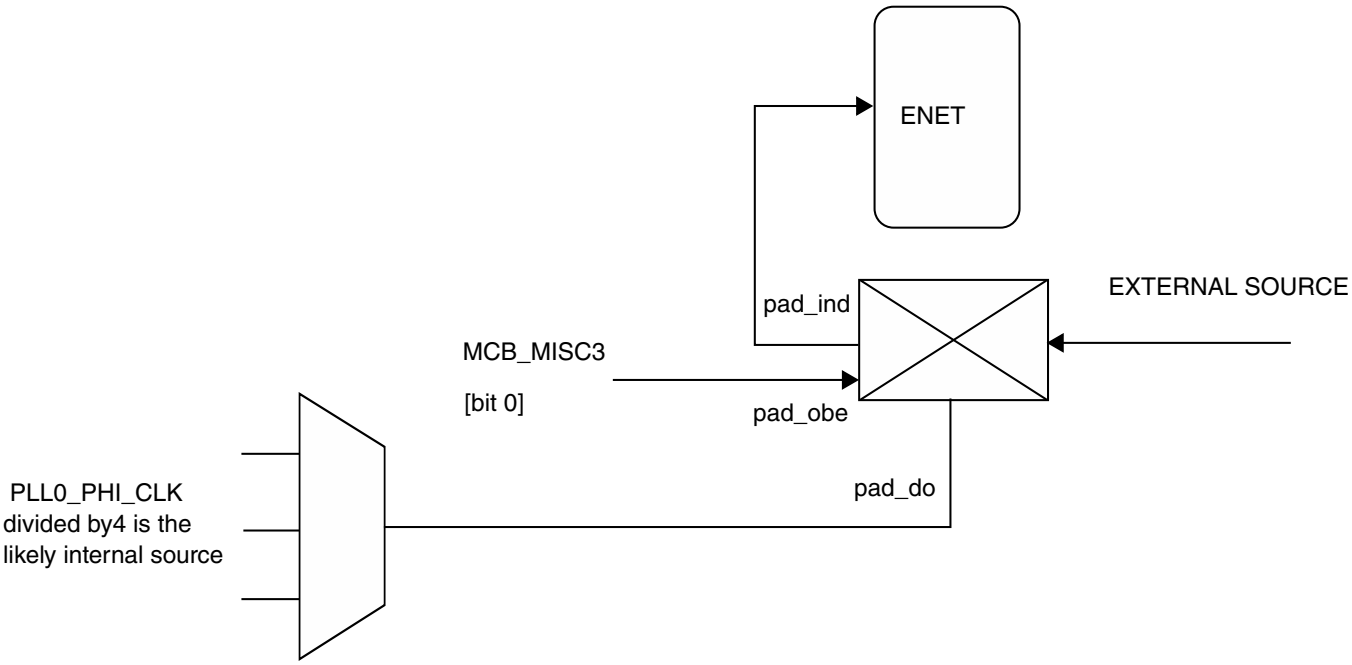

Figure 5-12. ENET RMII clocking

MCB_MISC3[RMII_MODE] is used to control the ENET clocking mode:

- 0: External clock is used as the source of RMII
- 1: This chip will provide RMII clock outside

A proper clock selection must be made on AUX10. The preferred clock is PLL0_PHI_CLK (200 MHz) divided by 4.

In RGMII Mode, reference clock for RGMII_TXC is driven from PAD_130.

5.6.8 SPT clocking

The SPT clock is sourced from either the PLL0_PHI_CLK, PLL1_PHI_CLK, XOSC_CLK, IRC_CLK, or SDPLL_CLK. The PLL0_PHI_CLK can be divided by a value written to the CGM_AC7_DC register in the MC_CGM. The output of this divider is SPT_CLK.

5.6.9 LINFlexD clocking

LINFlexD can select (using MC_CGM_AC13_SC) from one of seven possible clock sources for its LIN_CLK. LIN_CLK is then used to create the baud clock.

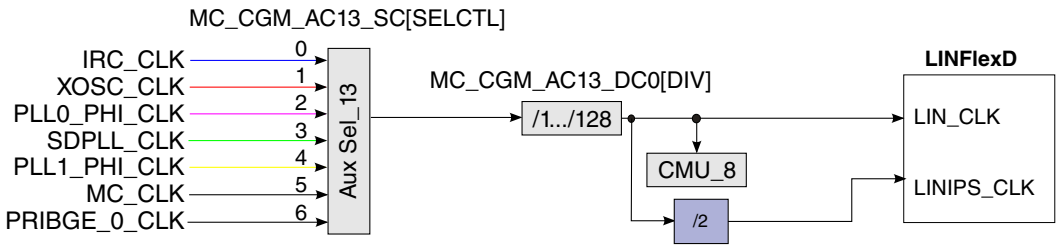

Figure 5-13. LINFLexD clocking

5.6.10 I²C clocking

On this chip, the PBRIDGE clock sources the I²C module clock, which in turn sources the I²C protocol clock. The IBCR[MDIS] field controls only whether the I²C core/protocol clock is enabled/disabled. It cannot disable the I²C module clock. Therefore, when the IBCR[MDIS] field's setting disables the I²C core/protocol clock:

- The I²C module itself is not entirely disabled.
- The field for the I²C module in the applicable MC_ME Peripheral Status register does not indicate that the module is "frozen."

5.7 Clock monitoring

For all safety critical clocks the microcontroller detects a missing clock or incorrect frequency. To achieve this clock monitoring units (CMUs) are used. Each CMU is programmed independently. The IRC_CLK and XOSC_CLK are used as the clock monitor references. Detailed information on the CMUs can be found in the Clock Monitor Unit chapter.

5.7.1 CMU configuration

This section explains the CMU configuration.

Figure 5-14 shows the block diagram for CMU_0 used for MC_CLK, XOSC and IRCOSC monitoring.

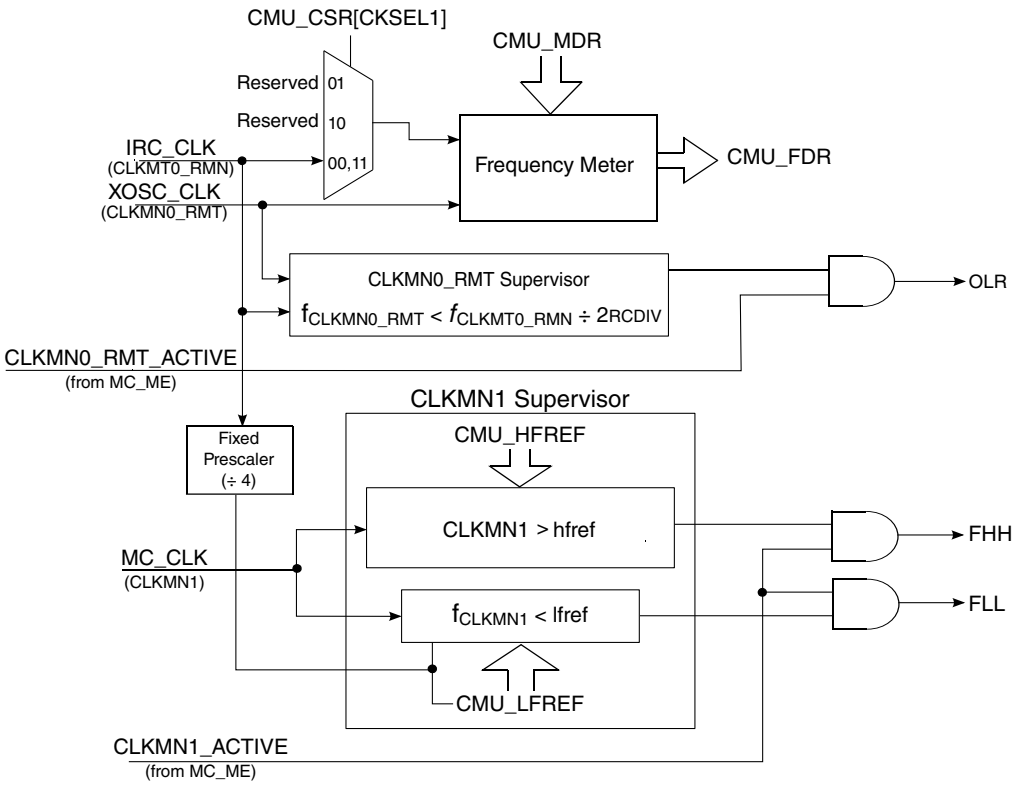

Figure 5-14. CMU_0 Block Diagram

NOTE

CLKMN0_RMT_ACTIVE refers to status (whether it is active or not) of XOSC_CLK. This can also be checked from the status in MC_ME_GS[S_XOSC].

CLKMN1_ACTIVE refers to the status (whether it is active or not) of MC_CLK. This can also be checked from the status in MC_ME_GS of the clock selected in CGM_AC0_SS for MC_CLK .

Figure 5-15 shows the block diagram for CMU_8 used for LINFlexD clock monitoring.

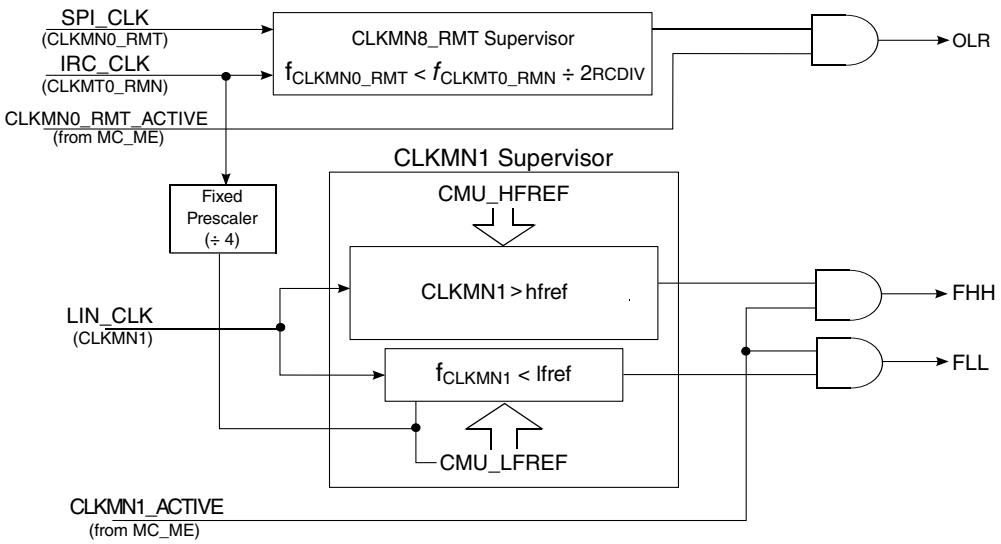

Figure 5-15. CMU_8 Block Diagram

NOTE

CLKMN0_RMT_ACTIVE refers to status (whether it is active or not) of SPI_CLK. This can also be checked from the status in MC_ME_GS of the clock selected in CGM_AC12_SS for SPI_CLK.

CLKMN1_ACTIVE refers to the status (whether it is active or not) of LIN_CLK. This can also be checked from the status in MC_ME_GS of the clock selected in CGM_AC13_SS for LIN_CLK.

Figure 5-16 shows the block diagram for CMU_[1:7,9:12].

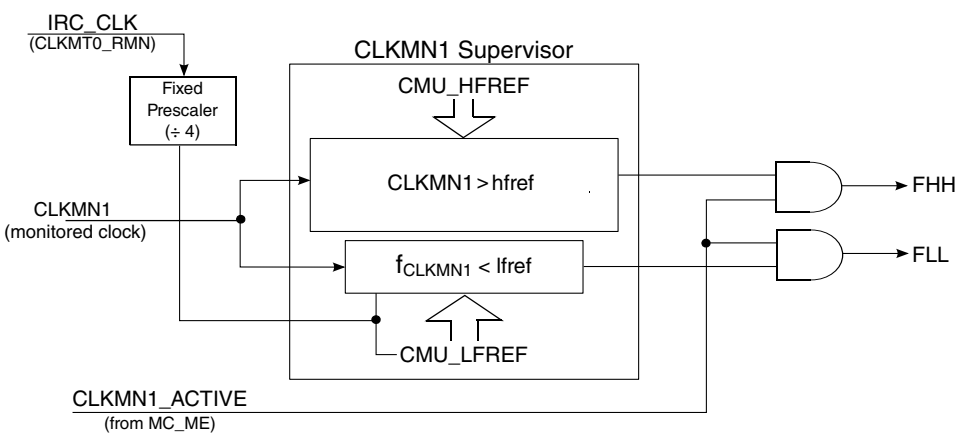

Figure 5-16. CMU_[1:7,9:12] Block Diagram

NOTE

CLKMN1_ACTIVE shows the status (whether it is active or not) of CLKMN1, the source of which comes from the MC_CGM and varies depending on the CMU. Table 5-1 shows the relevant source for CLKMN1 for each CMU

5.7.1.1 Clock input sources

Table 5-8 shows the clocks that are monitored by each CMU. These signals are connected internally on the chip, but are not accessible via pins on the boundary of the device. IRC_CLK is the reference clock for all clock monitors. Only CMU_0 implements the XOSC monitor. CMU_0 uses the IRC_CLK clock to measure if the XOSC_CLK is too low. CMU_0 can also be used to calibrate the IRC_CLK frequency using the XOSC_CLK. All other CMUs are configured identically.

Table 5-8. Clock input sources

Clock module	Monitored clock
CMU_0	XOSC_CLK, IRC_CLK, MC_CLK
CMU_1	CORE0_CLK
CMU_2	CAN_CLK
CMU_3	ADC_CLK
CMU_4	SYS_CLK
CMU_5	LFAST_CLK
CMU_6	CLK_OUT0
CMU_7	SPT_CLK
CMU_8	LIN_CLK, SPI_CLK
CMU_9	CORE1_CLK
CMU_10	CORE2_CLK
CMU_11	PBRIDGE_0_CLK, PBRIDGE_1_CLK
CMU_12[1]	SPT_ACQN_CLK

1. CMU12 monitored clock is dependent on SPT acquisition unit clock source. In SDADC-SPT use-case, input clock to CMU12 will be SDPLL_CLK80 and in MIPI-SPT use case, input clock to CMU12 will be SDPLL_CLK 160.

5.7.1.2 CMU registers and field availability

This table specifies which registers and fields are available on a given CMU for this device

Table 5-9. CMU registers availability

Address Offset	Register	CMU	Note
0000h	CMU_CSR	All	Only CMU_0 has the fields CMU_CSR[SFM] and CMU_CSR[CLSEL1]. Only CMU_0 and CMU_8 have the field CMU_CSR[RCDIV].
0004h	CMU_FDR	CMU_0	-
0008h	CMU_HFREFR	All	-
000Ch	CMU_LFREFR	All	-
0010h	CMU_ISR	All	CMU_ISR[OLRI] is in CMU_0 and CMU_8 only.
0014h	Reserved	-	-
0018h	CMU_MDR	CMU_0	-

5.7.2 External oscillator (XOSC) monitor

The XOSC frequency is compared to a minimum value limit. If the measured XOSC frequency is below the limit, a flag is set, and an interrupt is generated, if enabled. Frequency limits are given in the device Data Sheet.

5.7.3 Internal RC oscillator (IRCOSC) monitor

The period of the IRCOSC can be measured in CMU_0, using the XOSC_CLK as a reference. This allows for application trimming of the IRC_CLK frequency.

5.7.4 System clock monitors

A CMU is assigned to monitor the frequency of the checker core, both Peripheral bridges, motor control, and ADC clocks.

5.7.4.1 PLL0 Monitor

Software can program an upper and lower limit on the expected PLL0_PHI_CLK frequency. If the monitor is enabled, and the measured frequency is above or below the limits, a flag bit is set, and an interrupt is generated, if enabled. The default condition of the clock monitor is disabled.

5.8 Loss of system clock behavior

This device has built-in mechanisms for detecting loss of the oscillator or PLL clocks, and provides several options for reaction to a loss of clock in the application.

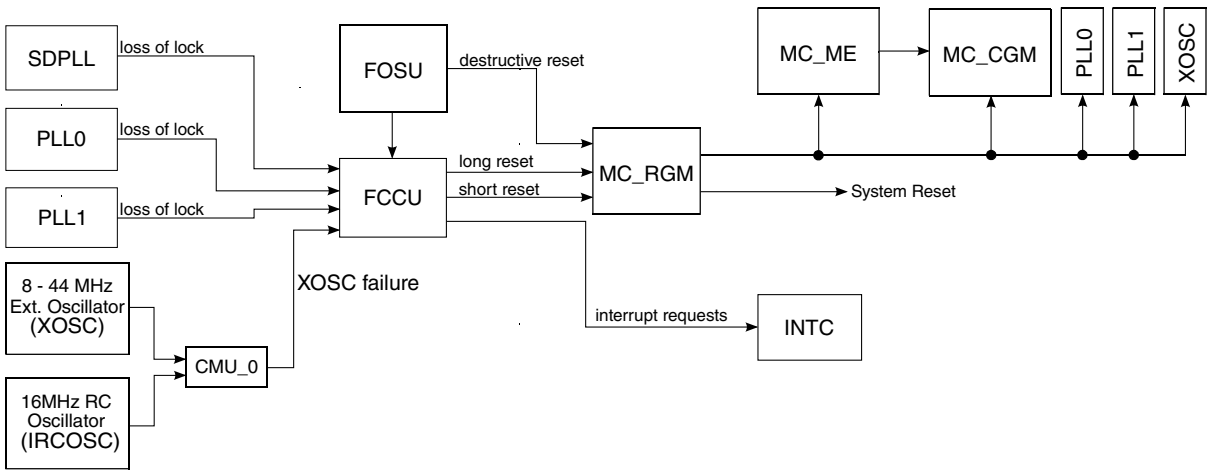

Figure 5-17. Loss of clock logic

5.8.1 Loss of PLL/XOSC_CLK

As shown in Figure 5-17, each loss of lock signal from each PLL and the XOSC_CLK failure signals are monitored by the FCCU. The FCCU can be programmed to generate a short or long reset sequence when a clock failure occurs, or simply to generate an interrupt. In the case of the interrupt, only the backup clock in the PLL can provide clocks to the system in order to perform a system clock switch. There is no automatic system clock switch, and the user is required to program the switch through the Mode Entry module (MC_ME).

If a long reset is selected the PLL, XOSC_CLK, MC_ME, and MC_CGM are reset to their default states, and the system clock is switched to the IRC_CLK. If a short reset is selected, the clock configuration is maintained, but again, the PLL backup clock is the only available clock to clock the system through an MC_ME mode switch.

NOTE

There is no direct interrupt corresponding to PLL Loss of Lock, if an interrupt is desired then it must be configured as the relevant NCF (for PLL loss of lock) reaction via the FCCU after enabling the LOLIE bit.

5.8.2 Loss of IRC_CLK

The frequency of the IRC_CLK is monitored by the frequency meter in CMU_0. There is no automated trigger of an FCCU error condition if the IRC_CLK fails. Since the IRC_CLK is the boot and backup clock, a failure is a catastrophic failure.

5.9 Progressive clock switching

The Progressive Clock Frequency Switching (PCFS) blocks are shown in the system-level clock diagram in Figure 34-3. They are used for ramping the system and peripheral clocks. See the clock Generation Module (MC_CGM) chapter for more information on the PCFS.

Chapter 6
Reset Overview

6.1 Introduction

The chapter describes the global and local reset behavior of the device.

6.1.1 Global Reset

The global reset behavior refers to device reset behavior controlled by the MC_RGM which affects several modules of the device at the same time. The global reset is linked to the reset process described in Global Reset Process.

6.2 Global Reset Process

This section describes the global reset process. Throughout this section the term *global* is omitted.

6.2.1 Overview

The global reset process is a sequence of several reset phases. Each reset phase has a specific entry condition, a specific exit condition, and a specific device reset behavior, which is different among the reset phases. The reset phases are executed in a specific order, thus building the actual global reset process. There are several modules contributing to the global reset process. All modules of the device can be affected by the global reset process.

6.2.2 Reset Process Modules

All modules which can enter, gate, or control the reset process are listed in Table 6-1 together with their type of contribution. The types of contribution are described in Table 6-2.

Table 6-1. Reset Process Modules

Module	Contribution Type		
	event	gating	control
Reset Generation Module (MC_RGM)	v	v	v
Power Management Controller (PMC)	v	v	v
Mode Entry Module (MC_ME)	v		
System Status and Configuration Module (SSCM)		v	
Self-Test Control Unit (STCU2)	v		
Fault Collection and Control Unit (FCCU)	v	v	
JTAG Controller (JTAGC)	v

Table 6-2. Module Contribution Type

Contribution Type	Description
event	The module may generate events which may trigger the entry into a reset state, if the event configuration in the MC_RGM allows this.
gating	The module can prevent the exit of a reset state if it has not reached a certain internal state.
control	The module controls the sequence of the reset process.

6.2.2.1 Reset Generation Module (MC_RGM)

The MC_RGM is one of the two controlling module for the reset process. The MC_RGM can receive events from other modules and starts the reset process based on the configuration for these events. The event configuration defines the reset phase at which start the reset process starts. The MC_RGM controls the reset process sequence based on the gating information it receives from the gating modules.

6.2.2.2 Power Management Controller (PMC)

The PMC provides two types of signals for the reset process control.

As long as the supply voltages are not reliable, the PMC provides signals to put the whole device into a power on reset state.

As long as the supply voltages are reliable but above or below certain operational limits, the PMC provides signals to allow the device to enter the reset process.

6.2.2.3 Mode Entry Module (MC_ME)

The MC_ME can generate events to enter the reset process. These events can be triggered only by application software.

6.2.2.4 System Status and Configuration Module (SSCM)

The SSCM is started automatically during a specific phase of the reset process. The SSCM fetches DCF records from the flash memory and distributes the read values via an internal DCF bus to the related modules. As long as the SSCM is still fetching DCF records, this specific reset phases can not be exited.

6.2.2.5 Self-Test Control Unit (STCU2)

The STCU2 controls the execution of the start-up and shut-down selftest. Depending on its configuration the STCU2 is started when PHASE3[DEST] is left or when software triggers the selftest. The STCU2 generates a functional event when the self testing has been completed.

In case, SSCM security reset gets generated while STCU2 self test (offline or online) is running, the SSCM security reset shall get masked. After STCU2 self-test run is over, long functional reset is issued to all LBIST partitions. The SSCM security reset (which is a source of destructive reset) is generated again during UTEST scanning. Hence, the system gets the destructive reset which would trigger offline STCU2 self-test (if not bypassed through DCF record) and this cycle repeats.

6.2.2.6 Fault Collection and Control Unit (FCCU)

The FCCU generates reset events and gates the reset process while it is configuring itself based on the DCF record content.

6.2.3 Reset Process Sequences

This section specifies the reset processes sequences. An overview of the reset process sequences is given in the following figure. When the reset process has reached the IDLE state, the device is operational.

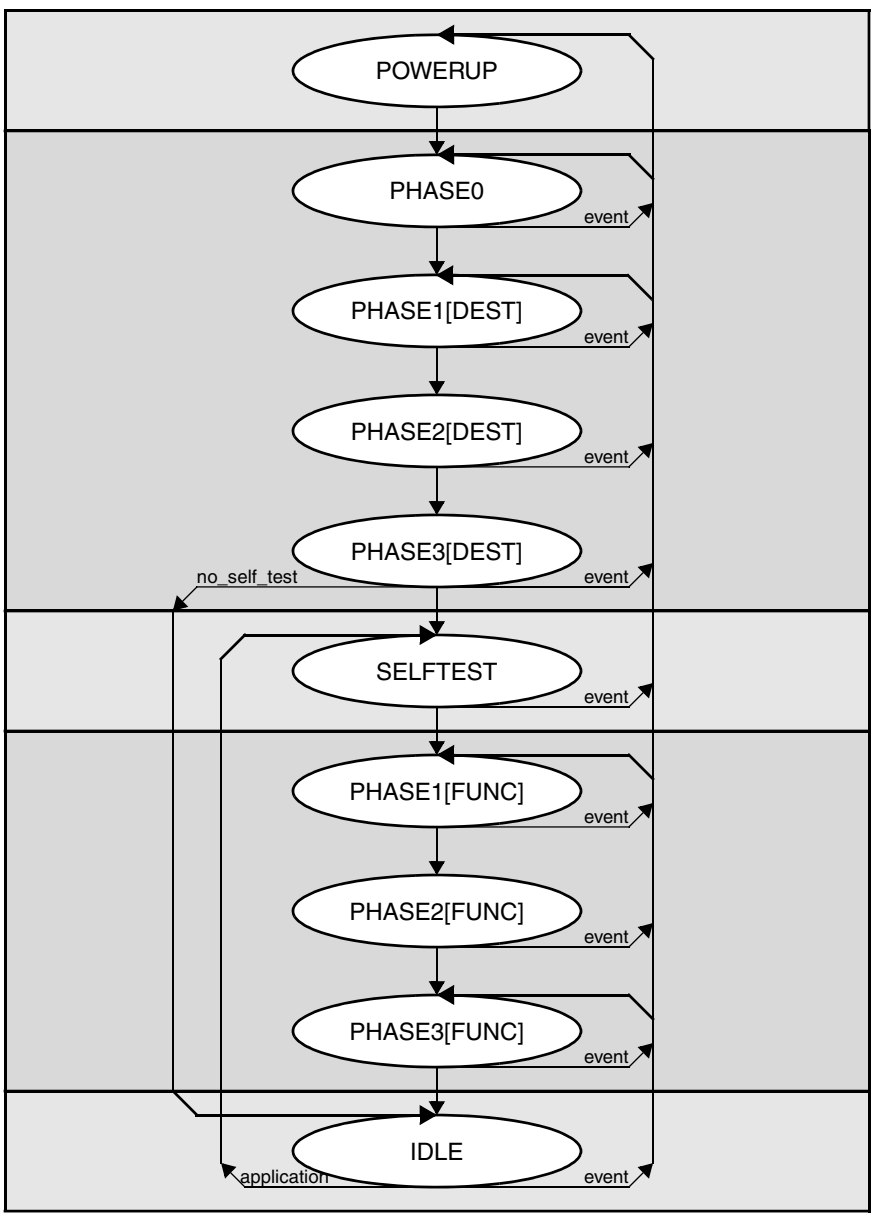

Figure 6-1. Reset Process Sequences

6.2.4 Reset Process State Transitions

This sections specifies the transitions between the reset states in the reset process. For each state, the state entry, the state execution, and the state exit is described.

6.2.4.1 POWERUP

6.2.4.1.1 POWERUP State Entry

This state is entered from any state if at least one of the following events appear

- Power is applied to the unpowered device.
- PMC has detected a POR condition.
- VREG_POR_B pin is driven low

6.2.4.1.2 POWERUP State Execution

During this state, the PMC is waiting for stable power supply.

6.2.4.1.3 POWERUP State Duration

There are no bounds on the duration of this state.

6.2.4.1.4 POWERUP State Exit

Table 6-3. POWERUP Next State Table

Next State	Condition	Process/Module Started at Exit
PHASE0	(1) The VREG_POR_B pin is high	IRCOSC MC_RGM

6.2.4.2 PHASE0

6.2.4.2.1 PHASE0 State Entry

This state can be entered from

- all other reset states when the state exit condition is present.

6.2.4.2.2 PHASE0 State Execution

All trimming bits are reset to their default values.

6.2.4.2.3 PHASE0 State Duration

The maximum duration of this state is dependent on all voltages achieving the right voltage range.

6.2.4.2.4 PHASE0 State Exit

Table 6-4. PHASE0 Next State Table

Next State	Condition	Process/Module Started at Exit
PHASE1[DEST]	(1) The MC_RGM indicates that all sources of enabled destructive reset events are deasserted, and (2) the IRCOSC module indicates the generation of a stable clock, and (3) the PMC module indicates that all supplies are in the operational range, that is, the PMC module has deasserted the following LVD-HVD signals (AFE regulator LVDs are by default masked. They can be unmasked using Multipurpose registers.)	

6.2.4.3 PHASE1[DEST]

6.2.4.3.1 PHASE1[DEST] State Entry

This state can be entered from state

- PHASE0,
- PHASE1[FUNC],
- PHASE2[FUNC],
- PHASE3[FUNC],
- IDLE.

6.2.4.3.2 PHASE1[DEST] State Execution

There are no state changes in any module, only a counter in the MC_RGM is running.

6.2.4.3.3 PHASE1[DEST] State Duration

The duration of this state is 512 IRCOSC clock cycles.

6.2.4.3.4 PHASE1[DEST] State Exit

Table 6-5. PHASE1[DEST] Next State Table

Next State	Condition	Process/Module Started at Exit
PHASE0	The MC_RGM has detected that the source of an enabled destructive reset event is asserted.	
PHASE2[DEST]	512 IRCOSC clocks passed by after state entry.	FLASH - starts initialization sequence FCCU - enters configuration state in preparation for receiving DCF record content STCU - waits for configuration via DCF records

6.2.4.4 PHASE2[DEST]

6.2.4.4.1 PHASE2[DEST] State Entry

This state can be entered from state

- PHASE1[DEST].

6.2.4.4.2 PHASE2[DEST] State Execution

FLASH executes initialization sequence and is ready for array accesses.

6.2.4.4.3 PHASE2[DEST] State Exit

Table 6-6. PHASE2[DEST] Next State Table

ON	Module is functional.

Chapter 7
System Boot

7.1 Overview

The device supports two types of boot schemes:

- Normal Boot
- Secure Boot

7.2 Normal boot

7.2.1 Entering boot modes

The device detects the boot mode based on SSCM_STATUS[BMODE]. BMODE is decided by LifeCycle and status of FAB (Force Alternate Boot Mode) and ABS (Alternate Boot Selector) pins (see the following table).

1. To boot either from FlexCAN or LINFlex, the device must be forced into an Alternate Boot Loader Mode via the FAB pin which must be asserted before initiating the reset sequence. The type of alternate boot mode is selected according to the ABS (Alternate Boot Selector) pin. Boot from FlexCAN and LinFLEX is only available when LifeCycle is MCU_PROD or CUST_DEL.
2. If FAB is not asserted and LifeCycle is MCU_PROD or CUST_DEL, the device boots from the first flash-memory sector which contains a valid boot signature.
3. If LifeCycle is OEM_PROD or IN_FIELD, then FAB and ABS pins are ignored and device always boots from Flash.
4. If no flash memory sector contains a valid boot signature, the device will go into static mode.
5. If Life cycle (LC) = Failure Analysis (FA), then device will go into static mode.

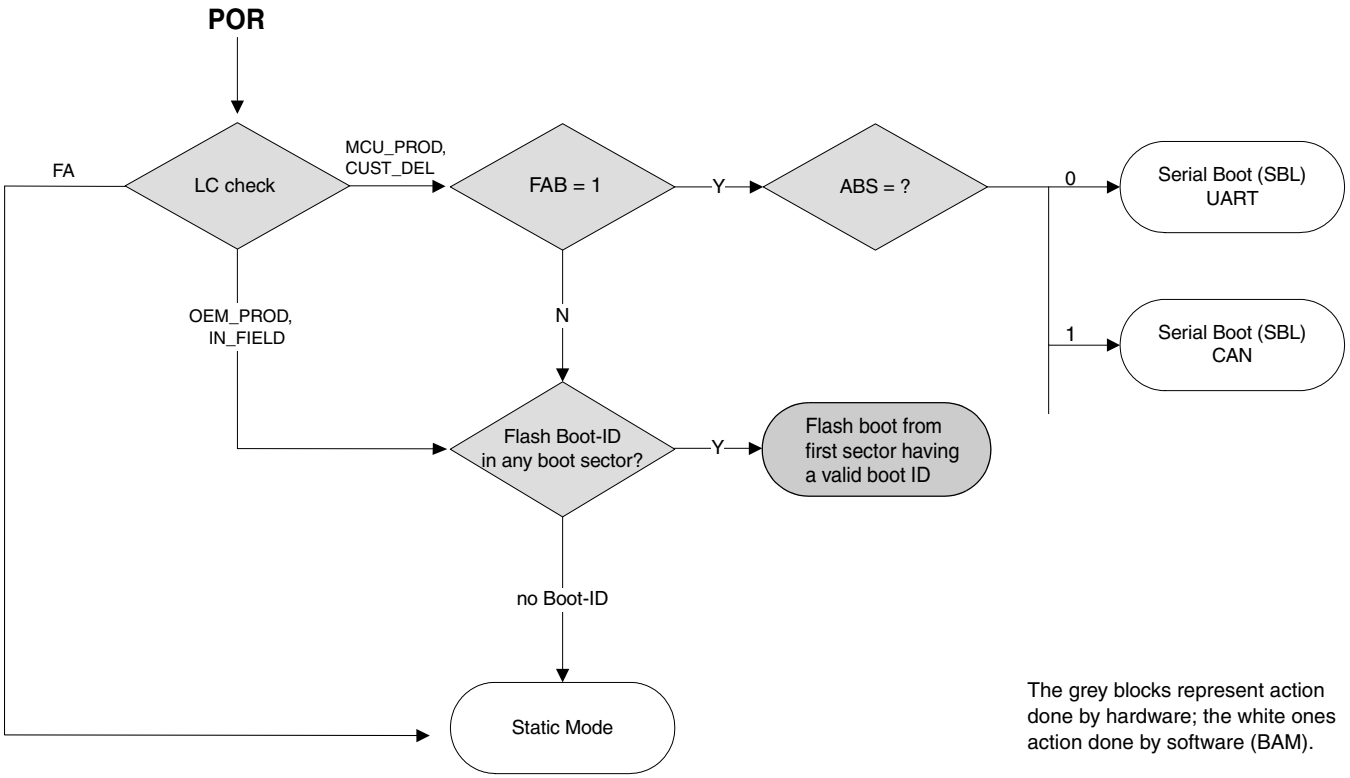

Figure 7-1. Boot mode selection

Table 7-1. Hardware configuration to select boot mode

LC	FAB pin	ABS pin	SSCM_STATUS[BMODE]	Functionality
MCU_PROD, CUST_DEL	0	x	Single Chip/Flash Boot	Flash Boot
MCU_PROD, CUST_DEL	1	0	SCI Serial Boot loader	UART Boot (BAM)
MCU_PROD, CUST_DEL	1	1	CAN Serial Boot Loader	CAN Boot (BAM)
OEM_PROD, IN_FIELD	x	x	Single Chip/Flash Boot	Flash Boot
FA	x	x	-	Static Mode

7.2.2 Boot Assist Module (BAM)

The Boot Assist Module (BAM) is a block of read-only memory containing VLE code which is executed according to the boot mode of the device. The code stored in the BAM is not executed when booting in Single Chip mode, except when entering the "Static mode" in case no valid boot-able section has been found, in case lifecycle is Failure Analysis, if invalid address or password is downloaded through serial boot or in case of any communication error over serial interface.

The BAM downloads code into internal SRAM through the following serial protocols and executes it afterwards:

- FlexCAN (CAN_0)
- LINFlex-UART (LINFlex_1)

Depending on the selected boot mode (see Entering boot modes), any download is performed with a fixed baud rate.

NOTE

'Differential XOSC' is not supported when booting from BAM in serial mode.

7.2.3 Features

The BAM provides the following features:

- 64-bit public password protection for serial boot mode
- Serial boot loads the application boot code from a FlexCAN or LINFlex bus into internal SRAM
- Configurable erroneous BAM accesses inhibit

7.2.4 Memory map

The BAM code resides in 8 KB of ROM mapped from address 0xFFFF_C000. The address space and memory used by the BAM is shown in the following table.

Table 7-2. BAM memory organization

Entity	Address
BAM entry point	0xFFFF_C000
RAM area used by the BAM code (do not use)	0x4000_0000–0x4000_00FF
Downloaded code base address	0x4000_0100
BAM exit address	0xFFFF_COCE

The RAM location where to download the code can be any 8 byte-aligned location in the SRAM starting from the address 0x4000_0100.

Caution

Do not use the RAM area used by the BAM code as indicated in the preceding table.

7.2.5 Reset value after BAM execution

BAM uses various modules for its operation and this causes change in reset values of few registers. Impacted registers are listed in below table.

Table 7-3. Reset value after BAM execution

Module	Offset	Register name	Value	Comments
CAN	0x44	CRC Register	undefined	CRC of last packet after CAN download
CGM	0x7E4	CGM_SC_SS	0x0002_0000	Clock switch after request from MC_ME completed
MC_ME	0xC	MC_ME_IS	0x0000_0001	Mode transtion completion Status in BAM
	0x18	MC_ME_DMTS	0x3000_0000	Changed due to DRUN to DRUN mode Transtion in BAM
LINFlex	0x8	LINFlexD_SR	0x0000_0040	Last Recive Data on LIN/UART Download

7.2.6 Functional description

7.2.6.1 Boot through BAM

7.2.6.1.1 Executing BAM

Single chip boot mode (selecting the first bootable Flash sector) is managed by hardware and BAM doesn't participate in it.

BAM is executed in any of the following cases:

- Serial boot mode has been selected by FAB pin;
- Hardware hasn't found a valid Boot ID in any flash memory boot locations;
- If lifecycle is Failure Analysis.

If one of these conditions is true, the device fetches code at location 0xFFFF_C000 and the BAM application starts.

7.2.6.1.2 BAM software flow

The following figure describes the BAM logic flow.

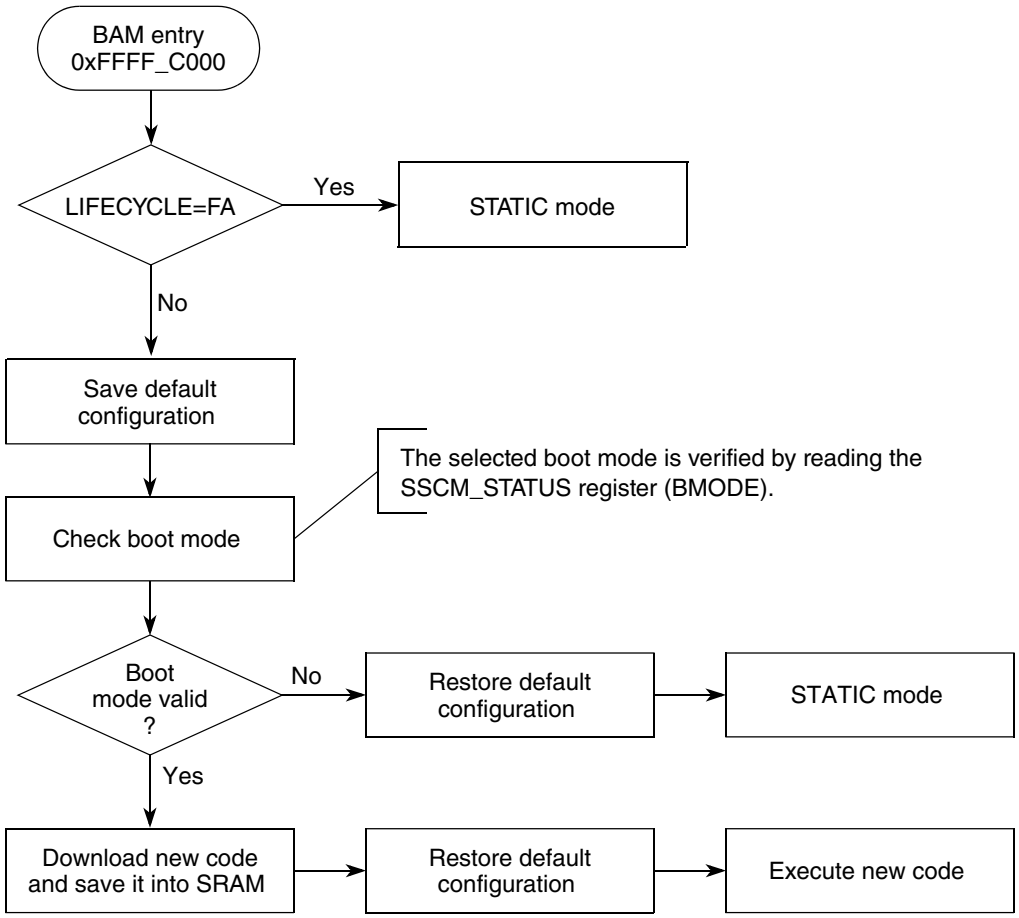

Figure 7-2. BAM logic flow

The first action is to save the initial device configuration. In this way it is possible to restore the initial configuration after downloading the new code but before executing it. This allows the new code to be executed as the device was just coming out of reset.

The SSCM_STATUS[BMODE] field indicates which boot has to be executed (see the following table).

If BMODE field shows the reserved values, the boot mode is not considered valid and the BAM pushes the device into static mode.

In all other cases data is downloaded in serial boot mode and saved into the correct SRAM location.

Table 7-4. Fields of SSCM STATUS register read by BAM to detect the chosen boot mode

Field	Description
BMODE	BMODE Device Boot Mode. 001 FlexCAN (FlexCAN_0) Serial Boot Loader 010 LINFlex-UART (LINFlex_1) Serial Boot Loader other values are reserved

Then, the initial device configuration is restored and the code jumps to the address provided for the downloaded code. At this point BAM has just finished its task.

If there is any error (that is, communication error, wrong boot mode selected, etc.), BAM restores the default configuration and puts the device into static mode. Static mode means the device enters the low power mode SAFE and the processor executes a wait instruction. It is needed if the device can not boot in the mode which was selected. During BAM execution and after, the mode reported by the field S_CURRENT_MODE of the register ME_GS in the module MC_ME Module is "DRUN".

7.2.6.1.3 BAM resources

BAM uses/initializes the following MCU resources:

- MC_ME and MC_CGM modules to initialize mode and clock sources
- CAN_0, LINFlex_1 and corresponding pins when performing serial boot mode
- SWT is disabled in case of a serial boot mode or when entering static mode
- SSCM to check the boot mode and lifecycle (see Figure 7-2)
- External oscillator (XOSC)
- AFE for enabling external oscillator (XOSC)

The majority of the initial configuration is restored before executing the downloaded code.

The frequency of the external oscillator defines the baud rate for serial interfaces used to download the user application. For a LINFlexD transmission, the selected baud rate is f_{XOSC} / 833. For a FlexCAN transmission, the selected baud rate is f_{XOSC} / 40.

7.2.6.1.4 Download and execute the new code

From high level perspective, the download protocol follows these steps:

1. Transmit 64-bit password.
2. Transmit start address, size of downloded code in bytes, and VLE bit.
3. Transmit download data.
4. Execute code from start address.

Each step must be completed before the next step starts.

The communication is done in half duplex manner, any transmission from host is followed by the MCU transmission:

- Host sends data to MCU and starts waiting

- MCU echoes to host the data received
- Host verifies if echoes are correct
  - if data is correct, the host can continue to send data
  - if data is not correct, the host stops to transmit and MCU must be reset.

All multi-byte data structures are sent with MSB first.

A more detailed description of these steps follows.

NOTE

There must be no stringent timeout condition while the host waits for the echoed data from the MCU; especially after step 2. After receiving the actual size of the data to be transmitted, the BAM must initialize the memory receiving the transmitted data with 64 bit writes to avoid ECC errors due to uninitialized memory.

7.2.6.1.5 Download 64-bit password and password check

The first 64-bits received represent the password. This password is compared with PUBLIC password 0xFEEDFACECAFEBEEF. If password matches, then download continues otherwise BAM puts device is SAFE mode.

7.2.6.1.6 Download start address, VLE bit and code size

The next 8 bytes received by the MCU contain a 32-bit Start Address, the VLE mode bit and a 31-bit code length as shown in the following figure.

The Variable Length Instruction (VLE) bit is used to indicate the instruction set for which the code has been compiled. The BAM supports the download of VLE code.

The Start Address defines the location at which the received data will be stored and location at which the MCU will branch after the download is complete. The two LSB bits of the Start Address are ignored by the BAM program, such that the loaded code should be 32-bit word aligned.

The Code Length defines the number of data bytes to be loaded.

NOTE

BAM code allows code length upto 150KB. Start address should not be beyond 0x40100000.

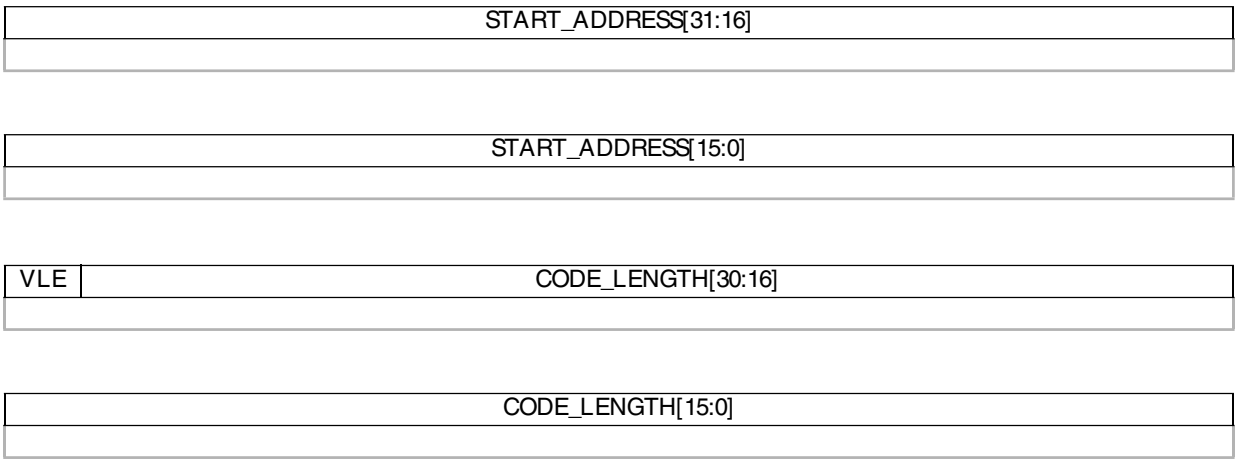

Figure 7-3. Start address, VLE bit, and download size in bytes

7.2.6.1.7 Download data

Each byte of data received is stored into device's SRAM, starting from the address specified in the previous protocol step. It is not verified whether the provided address is a valid address in SRAM or is writable.

The address increments until the number of bytes of data received matches the number of bytes specified in the previous protocol step.

Since the SRAM is protected by a 64-bit wide Error Correction Code (ECC), the BAM performs a series of 64 bit writes to initialize the SRAM are required for the downloaded data. The actual writes are performed in chunks of 32-bit writes. If the last byte received does not fall onto a 32-bit boundary, the BAM fills it with 0 bytes.

Finally a "dummy" word (0x0000_0000) is written to avoid a possible ECC error during core prefetch.

7.2.6.1.8 Execute code

The BAM program waits for the last echo message transmission being completed.

Then it restores the initial MCU configuration and jumps to the code loaded at Start Address which was received in step 2 of the protocol.

At this point BAM has finished its tasks and MCU is controlled by new code executing from SRAM.

7.2.6.2 UART Boot

7.2.6.2.1 Configuration

Boot using the UART protocol is implemented by LINFlex_1 module. Pins used are:

- LINFlex_TX corresponds to pin PF[14]
- LINFlex_RX corresponds to pin PF[15]

The LINFlexD controller is configured to operate at a baud rate of f_{XOSC} / 833, using 8 bit data frame without parity bit and 1 stop bit.

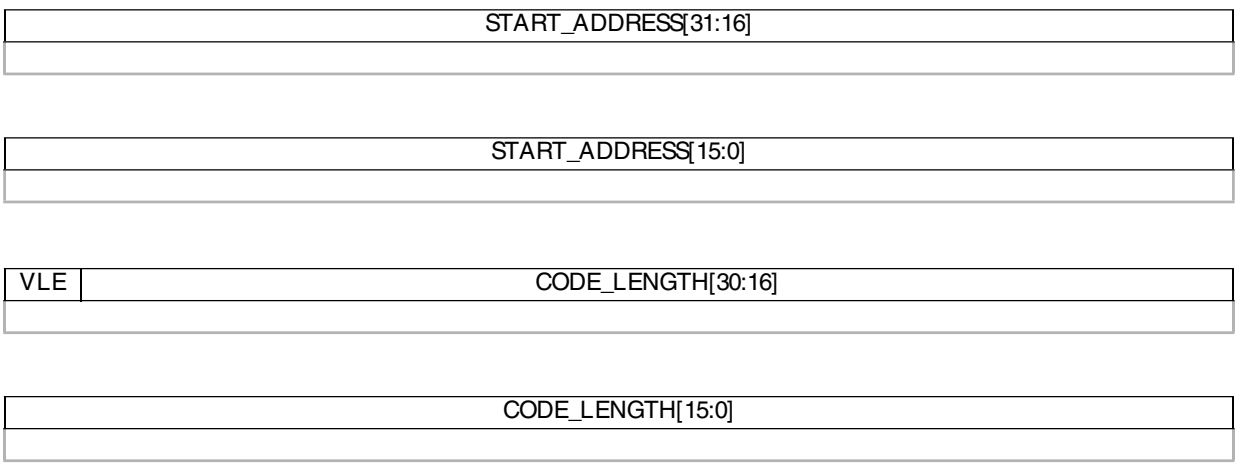

Figure 7-4. BAM LINFlex data frame

7.2.6.2.2 Protocol

The following table summarizes the protocol and BAM action during this boot mode.

Table 7-5. UART boot mode download protocol

Protocol step	Host sent message	BAM response message	Action
1	64-bit password (MSB first)	64-bit password	Password checked for validity and compared against stored password.
2	32-bit store address	32-bit store address	Load address is stored for future use.
3	VLE bit + 31-bit number of bytes (MSB first)	VLE bit + 31-bit number of bytes (MSB first)	Size of download is stored for future use. Verify VLE bit.
4	8 bits of raw binary data	8 bits of raw binary data	4 x 8 bits of data are packed into 32-bit words. These words are saved into SRAM starting from the "Load address". "Load address" increments until the number of data received and stored matches the size as specified in the previous step.
5	none	none	Branch to downloaded code

7.2.6.3 CAN Boot

7.2.6.3.1 Configuration

Boot using the CAN protocol is implemented by FlexCAN_0 module. Pins used are:

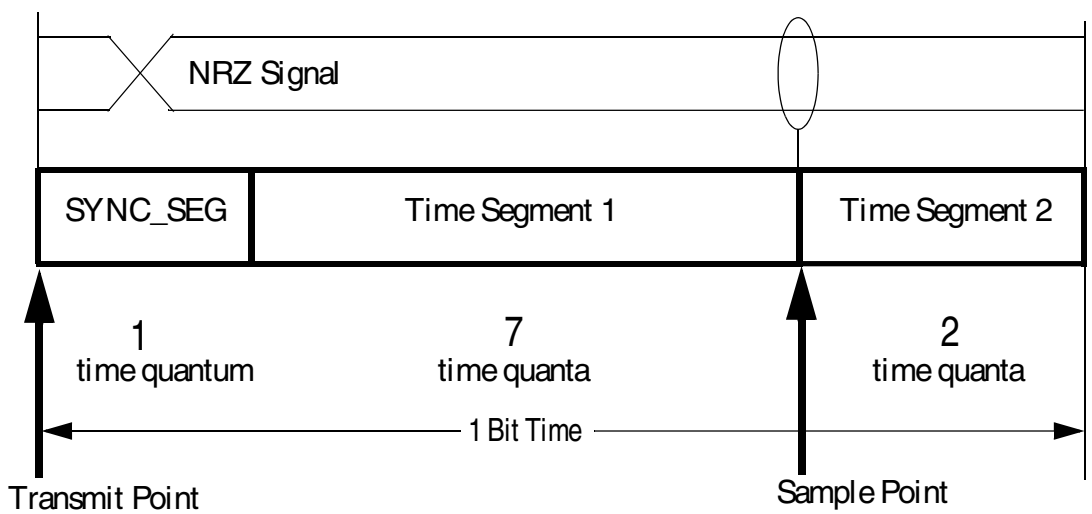
- CAN_TX corresponds to pin B[0]
- CAN_RX corresponds to pin B[1].

Boot from FlexCAN uses the system clock driven by the external oscillator.

The FlexCAN controller is configured to operate at a baud rate = system clock frequency/40.

It uses the standard 11 bit identifier format detailed in FlexCAN 2.0A specification.

FlexCAN controller bit timing is programmed with 10 time quanta, and the sample point is 2 time quanta before the end, as shown in the following figure.



1 time Quantum = 4 system clock periods

Figure 7-5. FlexCAN bit timing

7.2.6.3.2 Protocol

The following table summarizes the protocol and BAM action during this boot mode. All data is transmitted byte wise.

Table 7-6. FlexCAN boot mode download protocol

Protocol step	Host sent message	BAM response message	Action
1	FlexCAN ID 0x011+ 64-bit password	FlexCAN ID 0x001+ 64-bit password	Password checked for validity and compared against stored password.
2	FlexCAN ID 0x012+ 32-bit store address+ VLE bit+ 31-bit number of bytes	FlexCAN ID 0x002+ 32-bit store address+ VLE bit+ 31-bit number of bytes	Load address is stored for future use. Size of download are stored for future use. Verify VLE bit.
3	FlexCAN ID 0x013+ 8 to 64 bits of raw binary data	FlexCAN ID 0x003+ 8 to 64 bits of raw binary data	4 x 8 bits of data are packed into 32-bit words. These words are saved into SRAM starting from the "Load address". "Load address" increments until the number of data received and stored matches the size as specified in the previous step.
4	none	none	Branch to downloaded code

7.2.6.4 Inhibiting BAM operation

Under certain circumstances, you may want to inhibit BAM operation. To do this, set the RAE bit in the SSCM_ERROR register. Any attempt to access the memory range occupied by the BAM will then result in an access error.

7.2.6.5 Interrupt

No interrupts are generated or are enabled by the BAM.

7.3 Secure boot

7.3.1 Overview

CSE supports secure boot execution.The secure boot process starts after a power-on-reset, a destructive or a functional reset if it is enabled through the DCF. For details, refer the DCF tables attached to this document as an Excel file. Secure Boot Command is issued through hardware after Phase3 Reset de-assertion.

After leaving the reset phase, either a concurrent or sequential secure boot can be executed, depending on the configuration through the DCF.

Secure boot is blocked in following cases:

1. Lifecycle is Failure Analysis
2. Serial Boot Mode is selected by asserting the FAB Pin.

The start address of secure boot verification is same as the address pointed by RCHW scanning of a valid boot Flash sector. The size of the code is configured by a DCF record in the UTEST flash sector. Size equal to zero shall be invalid.

The device supports two types of secure Boot mode:

1. Concurrent Secure Boot Mode
2. Sequential Secure Boot Mode

7.3.1.1 Concurrent Secure Boot Mode

When configured for concurrent secure boot, the cores execute code from the flash while the hardware triggers the secure boot of the CSE. Using concurrent secure boot enables a significantly faster verification time, due to the fact that the CPU can configure the PLL to run the CSE at up to 120MHz, instead of from the 16MHZ/2 IRCOSC clock. The CPU must be sure to suspend any CSE operations currently in progress, especially when changing the flash configuration, to avoid any errant calculations.

7.3.1.2 Sequential secure boot mode

When configured for sequential secure boot, the hardware triggers the CSE secure boot while the cores are held in reset. The core's reset are released once the secure boot execution is finished, regardless of whether the test passes for fails. The default system clock is (16 MHz)/2 IRCOSC and since CSE does not have the capability to configure the PLL nor the system clock, sequential secure boot is relatively slower.

In sequential secure boot mode, if CSE hangs (due to any reason), system would get out of reset due to internal CSE timeout but the CSE_SR[BSY] would remain set indicating unsuccessful secure boot. Software could take appropriate action to handle such scenario.

7.3.1.2.1 CSE Local RAM

The device supports 8 Kb of local secure RAM. The firmware is loaded from the secure flash into this RAM and it will be executed from there.

7.3.1.2.2 Chain of Trust

The verification can be performed with a single step over the entire software image or in several steps over partial software sections. The verification of the entire software image requires only a single CMAC, however since run time for a large software image can be high, security related functionality may not be available until the verification is completed. Also, this way of verification requires a continuous stored and monolithic software image. For improved device availability, shortened response time, the verification can be executed in several steps. This is also required if the application code is divided into several sections of non-contiguous addresses or is split into parts which are programmed by different parties. Additionally, multi-step verification enables to assign individual keys to certain code sections. If verification uses multiple steps over several code sections, a chain of trust must be established. In such a case, the verification must start with the first executed code and must not have gaps and span the whole application code. If verification is performed in several steps, only the first section, typically the boot loader, is verified with BOOT_MAC and all subsequent sections require their own CMAC. The CSE must be triggered by VERIFY_MAC command for all subsequent sections except the first one.

Chapter 8
Interrupt and DMA Overview

8.1 INTC configurable parameters

The INTC on this chip supports 3 processors, as shown in the following table:

Table 8-1. INTC processor number and corresponding core

INTC processor number	Corresponding CPU core
0	e200z420n3 (Core_0)
1	e200z7260n3 (Core_1)
2	e200z7260n3 (Core_2)

8.2 INTC interrupt sources

NOTE

For "Interrupt sources mapping", refer the device interrupt sources tables attached to this document as an Excel file. Locate the paperclip symbol on the left side of the PDF window, and click on it.

8.3 INTC monitors

There are maximum 3 monitors per core.

8.4 DMAMUX sources

DMAMUX channel mapping: See the device DMAMUX sources tables attached to this document as an Excel file. Locate the paperclip symbol on the left side of the PDF window, and click on it.

Chapter 9
Functional Safety

9.1 Introduction

The chip is developed according to ISO 26262 and has an integrated safety concept targeting safety-related systems requiring high safety integrity levels. In order to support the integration of the chip into safety-related systems, the following documentation is available:

- Reference Manual - Describes the S32R274 functionality
- Data Sheet (S32R274DS) - Describes the S32R274 operating conditions
- Safety Manual (S32R274SM) - Describes the S32R274 safety concept and possible safety mechanisms (integrated in S32R274, system level hardware or system level software), as well as measures to reduce dependent failures
- Dynamic FMEDA - Inductive analysis enabling customization of system level safety mechanisms, including the resulting safety metrics for ISO 26262 (SPFM, LFM and PMHF) and IEC 61508 (SFF and Beta IC Factor)
- FMEDA Report - Describes the FMEDA methodology and safety mechanisms supported in the FMEDA, including source of failure rates, failure modes and assumptions made during the analysis.

The FMEDA and FMEDA report are available upon request. The chip is a SafeAssure solution, for further information regarding functional safety at NXP, visit www.nxp.com/safeassure.

Chapter 10
Embedded memories

10.1 Overview

The embedded memory architecture for this microcontroller includes:

- On-board SRAM, including system SRAM, local data memory for each processor core, and on-board system error correction code (ECC) flash memory
- End-to-end ECC (e2eECC) error detection and correction
- Embedded memories in the peripherals:
  - FlexRay
  - eDMA
  - Signal Processing Toolbox (SPT)
- PRAM_XBAR

10.2 System SRAM

This microcontroller includes up to 1.5 MB general-purpose on-chip ECC SRAM. Each of the 8 banks of SRAM can be independently configured for either 0- or 1-wait state read operation latency.

10.2.1 SRAM Controller (PRAMC)

This microcontroller's 8 banks of system SRAM interface to the Data Crossbar Switch (XBAR) via a quad-ported Platform RAM Controller (PRAMC). Internally, the quad-ported RAM controller consists of 8 independently configurable RAM controllers (one for each bank of system SRAM) connected to an internal Crossbar Switch. This is shown in Figure 10-1. Note that the configuration of the internal Crossbar Switch cannot be changed but it includes a Crossbar Integrity Checker (XBIC) that provides an error

detection and reporting capability and an error injection feature that is useful for system development and debugging. The XBIC appears in the System Memory Map as XBIC_2 (PRAM). See the Crossbar Integrity Checker (XBIC) chapter for details.

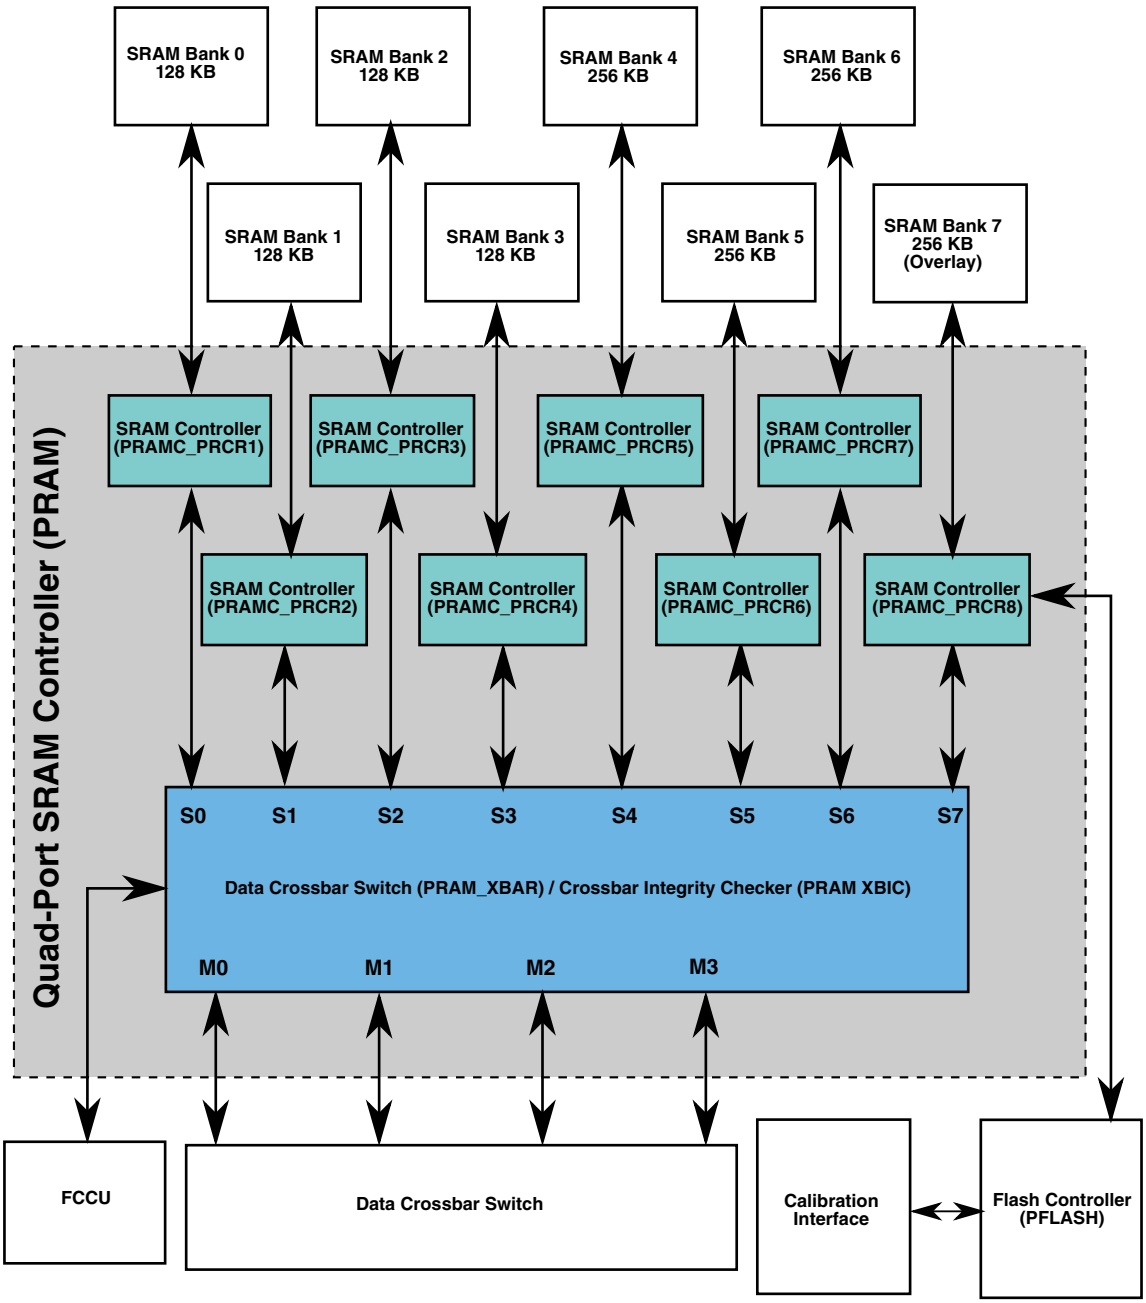


Figure 10-1. System SRAM architecture

10.2.2 Overlay SRAM

As shown in Figure 10-1, SRAM Bank 7 is available for use as *overlay SRAM*. The overlay SRAM feature included in this device is a feature used during calibration and debug activities. Overlay SRAM can be mapped over specific regions of on-chip flash memory so that any access to an overlaid flash address is routed to the overlay SRAM instead. This enables calibration of constant data without requiring additional external RAMs and calibration memory interfaces.

NOTE

1. Overlay SRAM is normally used for system development purposes only.
2. Timing for calibration accesses to a particular overlay SRAM are the same as access to the underlying flash if the overlay SRAM is not being used as a destination for trace streaming at the same time.

The overlay function is implemented as follows using registers in the flash memory controller.

1. Using PFLASH Calibration Region Descriptors (PFCRDn) define one or more (up to 8) overlay regions.
2. Enable individual regions using the appropriate bits in the PFLASH Remap Descriptor Enable Register (PFCRDE).
3. Enable overlay using the PFCRCR[GRMEN] field.

See the PFlash calibration remap support for details on memory overlay (remapping).

10.2.3 Processor core local SRAM

This microcontroller includes 64 KB ECC local data SRAM for each processor core to provide enhanced performance. Each area of core SRAM is accessible by other processor cores and bus mastering peripheral devices. See the System Memory Map for details.

10.2.4 Signal Processing Toolbox (SPT) memory

Signal Processing Toolbox (SPT) has 96 KB parity protected SRAM and Twiddle RAM. Twidlle RAM uses a bit line multiplexing of 4, separating logical neighbor bits by 3 physical bits of other logical words. SPT RAM uses a bit line multiplexing of 4, separating logical neighbor bit by 3 physical bits of other logical words.

10.3 PRAM_XBAR

10.3.1 Overview

Inside SRAM controller is a XBAR similar to the system XBARs with 4 masters (the 4 ports of the SRAM controller) and 8 slaves (the 8 SRAM memory banks). Configuration is similar to the system XBARs.

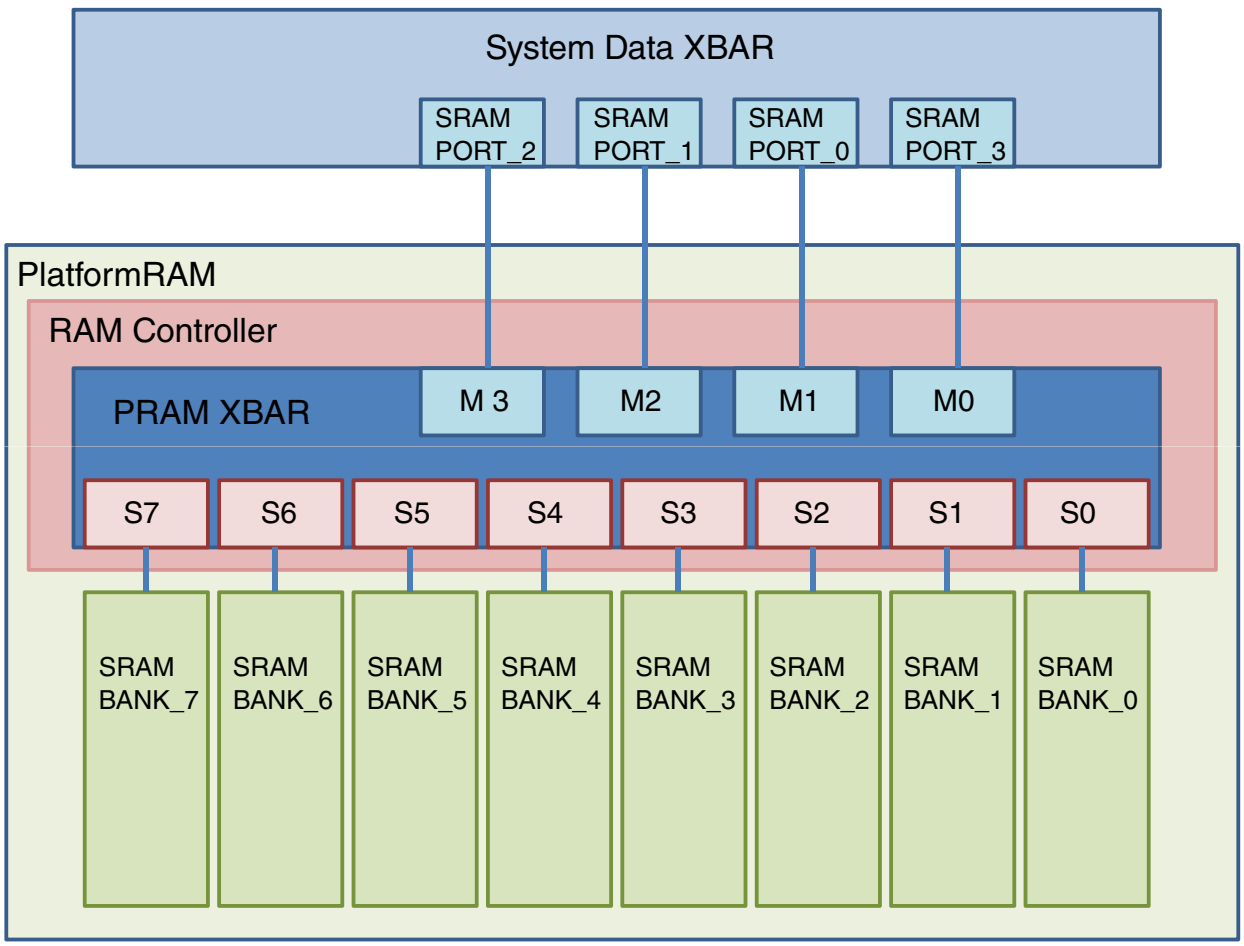

Figure 10-2. PRAM_XBAR block diagram

10.3.2 PRAM_XBAR master assignments

This device contains four masters connected to PRAM_XBAR. The master assignments are shown in the table below:

Table 10-1. PRAM_XBAR master assignments

Master module	Physical master port number
SRAM PORT_3	0
SRAM PORT_0	1
SRAM PORT_1	2
SRAM PORT_2	3

10.3.3 PRAM_XBAR slave assignments

This device contains eight slaves connected to PRAM_XBAR. The slave assignments are shown in the table below:

Table 10-2. PRAM_XBAR slave assignments

Slave Module	Physical slave number
SRAM BANK_0	0
SRAM BANK_1	1
SRAM BANK_2	2
SRAM BANK_3	3
SRAM BANK_4	4
SRAM BANK_5	5
SRAM BANK_6	6
SRAM BANK_7	7

10.3.4 PRAM_XBAR registers

Each slave port of the crossbar switch contains configuration registers. Read- and write-transfers require two bus clock cycles. The registers can be read from and written to only in supervisor mode. Additionally, these registers can be read from or written to only by 32-bit accesses.

A bus error response is returned if a unimplemented location is accessed within the crossbar switch.

The CRS*n* and PSR*n* registers can be programmed to be read-only to prevent changes to their configuration. After being read-only protected, future writes to learn will terminate with an error.

PRAM_XBAR memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Priority Register Slave (PRAM_XBAR_PRS0)	32	R/W	0000_3210h	10.3.4.1/ 213

26–27 PCTL	Parking Control Determines the slave port's parking control. The low-power park feature results in an overall power savings if the slave port is not saturated. However, this forces an extra latency clock when any master tries to access the slave port while not in use because it is not parked on any master. 00 When no master makes a request, the arbiter parks the slave port on the master port defined by the PARK field 01 When no master makes a request, the arbiter parks the slave port on the last master to be in control of the slave port 10 When no master makes a request, the slave port is not parked on a master and the arbiter drives all outputs to a constant safe state 11 Reserved
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 PARK	Park Determines which master port the current slave port parks on when no masters are actively making requests and the PCTL bits are cleared. **NOTE:** Select only master ports that are present on the chip. Otherwise, undefined behavior might occur. 000 Park on master port M0 001 Park on master port M1 010 Park on master port M2 011 Park on master port M3 100 Reserved 101 Reserved 110 Reserved 111 Reserved

10.4 Flash memory

This microcontroller includes up to 2 MB general-purpose on-chip flash memory (includes 64 KB EEPROM emulation) with the following features:

- Three ports (one per CPU) shared between Code and Data Flash with a 4x256 bit buffer for the Code and Data Flash including pre-fetch function
- Single and double bit error visibility are supported
- Support for reading-while-writing (RWW) for accesses to different partitions.
- Test information is stored in a non-volatile One Time Programmable (OTP) UTest block

NOTE

Secure flash blocks associated to CSE are available as data flash blocks only if CSE is disabled.

The included flash memory consists of a flash memory controller and a flash memory array module containing multiple blocks of non-volatile memory. The flash controller provides flash configuration and control functions and manages the interface between the flash memory array and the device's crossbar switch. The following figure shows the memory architecture.

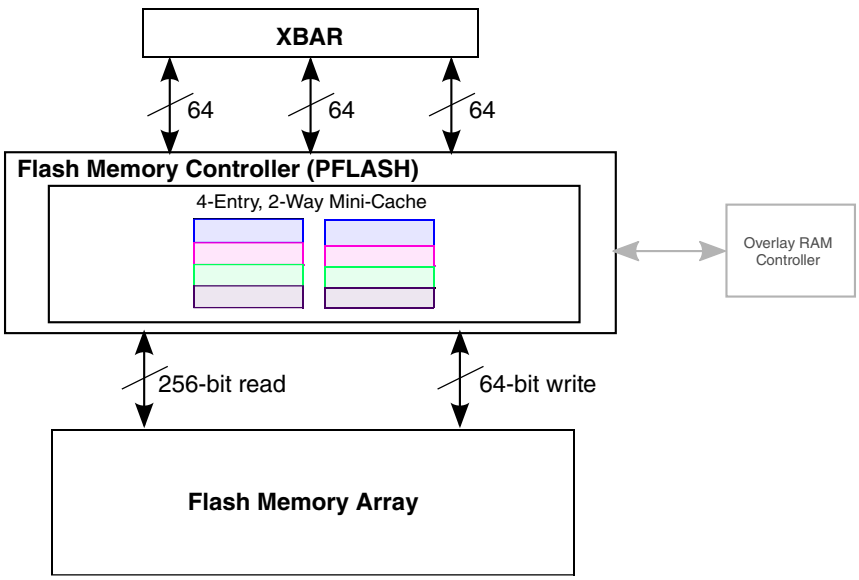

Figure 10-3. Device flash memory block diagram

The flash memory controller (PFLASH) occupies 3 slave ports (one per processor core) on the instruction crossbar switch. Flash memory configuration, performance tuning of flash memory accesses, and overlay RAM configuration are implemented using the flash memory controller's configuration registers. See the Flash Memory Controller chapter for details.

10.4.1 Flash memory controller

The flash controller acts as an interface between the system bus and the flash array and, when flash overlay SRAM is used, serves as the interface to the overlay RAM.

The flash controller contains a 4-entry, 2-way set-associative mini-cache that delivers flash read data with a zero-wait state response on lines that reside in the cache. Each entry contains one flash page, a 256-bit (32-byte) memory value. Read requests that miss the cache generate the needed flash array access.

The flash memory controller contains configuration registers which manage flash functionality such as read buffering in the mini-cache, access control, calibration RAM overlay remapping, and read wait state management of the flash. See the Flash Memory Controller chapter for details.

During Read While Write (RWW) accesses the flash memory controller may report the following non-critical faults to the FCCU (Fault inputs):

- NCF[43], which indicates that during an EDC after ECC check, the flash memory controller detected an error in the address ECC manipulation logic
- NCF[44], which indicates the flash memory controller detected a transaction monitor mismatch when compared to flash safety feedback output

The errors occur when a read operation is attempted on either a block currently being programmed or erased, or any block within the same flash memory partition. The error is also reported by the C55FMC flash memory in the C55FMC_MCR[RWE] bit.

10.4.2 UTest memory space

See 'UTEST Memory Map and DCF Sheet' attached as an Excel file with this document.

10.4.3 Chip-specific flash memory configuration

10.4.3.1 Flash memory controller (PFLASH) register reset values

Table 10-3 lists chip-specific register reset values specific to the this device. Any registers not listed have the reset values shown in their respective sections of this chapter.

Table 10-3. Chip specific flash memory controller (PFLASH) register reset values

Register	Reset Value
Platform Flash Configuration Register 1 (PFCR1)	0x601
Platform Flash Configuration Register 2 (PFCR2)	0x1
Platform Flash Configuration Register 3 (PFCR3)	0x0

NOTE

Although the PFLASH_PFCR1[RWSC] field is 5 bits wide, the MSB of this field has no effect on this chip.

10.4.3.2 Embedded Flash Memory (c55fmc) register reset values

Table 10-4 lists chip-specific register reset values specific to this device. Any registers not listed have the reset values shown in their respective sections of this chapter.

Table 10-4. Chip specific c55fmc flash memory reset values

Register	Reset Value
Module Configuration Register (C55FMC_MCR)	0000_0600h
Extended Module Configuration Register (C55FMC_MCRE)	0301_6102h [1]
Over-Program Protection 0 register (C55FMC_OPP0)	Dependent on customer settings[2]
Over-Program Protection 1 register (C55FMC_OPP1)	Dependent on customer settings[2]
Over-Program Protection 2 register (C55FMC_OPP2)	Dependent on customer settings[2]
Over-Program Protection 3 register (C55FMC_OPP3)	Dependent on customer settings[2]

1. The reset value of the C55FMC_MCRE register is device-specific. The value given applies to devices with 2 MB of flash memory.
2. The reset value of the C55FMC_OPP*n* registers, for each flash memory block mapped to a bit within each register, reflects whether the block has been marked as One Time Programmable (OTP). The C55FMC_OPP*n* registers have the same bit-to-block mapping as the C55FMC_LOCK*n* registers. A 1 indicates a block has been marked as OTP. The reset values of the C55FMC_OPP*n* are similar to the reset values of the TDM_OTPEN*n* registers in the Tamper Detection Module (TDM).

Please refer to attached flash block assignment xls for C55FMC_LOCKx memory map.

10.4.3.3 Flash memory partitioning

Refer to Flash block assignment tables attached as Excel file with the document.

10.5 End-to-end Error Correction Code (e2eECC)

To support market requirements related to improved functional and transient fault detection capabilities, these microcontrollers include *end-to-end ECC support*. End-to-end ECC (aka e2eECC) is structurally different than traditional "ECC at memory" functionality in that it provides for robust error detection capabilities from one endpoint of an information transfer to another with temporary information storage in any intermediate component(s). While memory protected by ECC/EDC traditionally generates and checks additional error parity information local to the memory unit to detect and/or correct errors which have occurred on stored data in the memory, e2eECC

instead performs generation of error protection codes at the source of data generation, sending the encoded data and error protection codes to intermediate storage when a memory write is initiated by a bus master, and performs a check of data integrity using the previously stored error protection codes at a data memory when a read of stored information is requested by a bus master. The intermediate storage may transform the generated error protection codes into another format for storage and then may regenerate the codes for provision when a request is made to read the stored information, or it may simply store the original protection codes unaltered, depending on the particular unit.

Additionally, the error protection codes are generated based on more than just the data associated with a storage location in order to protect additional information associated with an access. In particular, address information corresponding to the access location of the stored information is combined with the store data at the data source to generate error protection codes which cover certain types of addressing errors which may occur in the system interconnect or in the memory unit. Checking of the error protection codes may be done at the memory unit on a store to ensure that no corruption of address or data information has occurred while the request has transitioned through the device from the bus master source, as well as to ensure that within the storage memory, address decoding was performed properly (although not all address decoding errors can be detected this way), or it may simply store the received data and protection codes at the address it receives. On a read request from a bus master, the memory unit retrieves the data information and error protection codes corresponding to the received address from the storage location(s), and supplies the data along with the error protection codes to the requesting device. The requesting device uses a locally stored address value corresponding to the read request to check the returning data and error protection codes to ensure that no errors have occurred in either addressing the memory, or in the retrieved data, thus ensuring that the address sent for the request was not corrupted, that the addressed location was actually accessed (to the extent it is possible to ensure), and that the stored data was error free, to the extend the ECC coding scheme is able to detect. As a result, the fault coverage provided by the end-to-end check is considerably more robust than the previous implementation of locally generated and checked/corrected error protection at each memory unit.

A comparison of the traditional and e2eECC approaches is shown in the following table.

Table 10-5. ECC comparison of data write then read sequence

Traditional ECC	End-to-End ECC (e2eECC)
Bus master initiates data write	Bus master initiates data write and generates ECC checkbits based on 29-bit address and 64-bit data fields
Data write transfer routed from bus master to appropriate bus slave	Data write transfer (including checkbits) routed from bus master to appropriate bus slave
For a bus memory slave, generate the ECC checkbits based on the data value and store data + checkbits into the memory	For a bus memory slave, store data + checkbits into the memory

Table continues on the next page...

Table 10-5. ECC comparison of data write then read sequence (continued)

Traditional ECC	End-to-End ECC (e2eECC)
Bus master initiates data read of previously written memory location	Bus master initiates data read of previously written memory location
Data read transfer routed from bus master to appropriate bus slave	Data read transfer routed from bus master to appropriate bus slave
For a bus memory slave, the memory array is accessed, the controller performs the ECC checkbit decode and syndrome generation, performs any needed single-bit correction and drives the read data onto the system bus interconnect	For a bus memory slave, the memory array is accessed, and the controller passes the read data and associated checkbits onto the system bus interconnection
The bus master captures the read data and continues	The bus master captures the read data and associated checkbits, performs the ECC checkbit decode and syndrome generation, performs any needed single-bit correction and continues

The scope of differences in the operations "covered" by the ECC checks is readily apparent. Thus, the e2eECC concept provides improved fault detection capabilities in two important aspects:

1. The entire data transaction, from the initiating bus master, through the entire platform crossbar steering mechanism to the destination slave target is covered during write accesses. Likewise, a read is checked from the initiating bus master, through the crossbar steering mechanism, through the actual memory read and transmission of the data plus checkbits back to the bus master, where the integrity and correctness of the entire transaction is checked.
2. The selected ECC provides protection of both the address field as well as the data field, again for improved fault coverage.

Additionally, this particular structure also provides a significant implementation improvement. The traditional ECC at the memory approach places the checkbit decode and error syndrome generation with the error/no_error state affecting whether the system bus transfer must be stalled (to correct a single bit error or report a non-correctable event) or is allowed to complete (for error free transfers) in a critical timing arc which often sets the upper limit of operating frequency of the microcontroller. With the e2eECC scheme, the checkbit decode and error syndrome logic is located in the requesting bus master, where there are generally more degrees of implementation freedom and the error/no_error state determination is removed from the system bus cycle termination logic, producing an improved timing arc and generally, higher operating speeds.

Errors which occur within the system interconnect are typically manifested as an incorrect address, incorrect write data, or incorrect read data to be presented to the slave or back to the master. Errors occurring within the storage typically manifest themselves eventually in corrupted read data or checkbits being returned to a requestor. While not all possible errors can be detected this way, this approach provides a substantial

improvement versus traditional methods. Additional on-line diagnostics and/or additional hardware should be able to catch a majority of the errors not covered directly by the e2eECC scheme.

Chapter 11
Device Configuration Format (DCF) Records

11.1 Overview

Device Configuration Format (DCF) records are used by the System Status and Configuration Module (SSCM) to configure certain registers in the device during system boot while the reset signal is asserted.

There are two kinds of DCF records:

- Factory-written DCF records: written to UTEST flash by the factory.
- User-supplied DCF records: written to UTEST flash by the user.

The following figure is a conceptual representation of the functionality of DCF records which is described in this chapter.

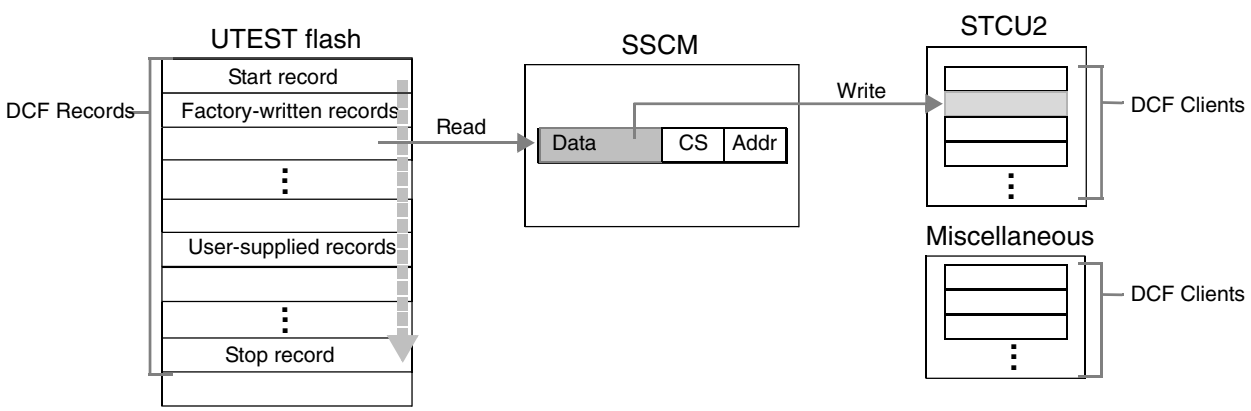

Figure 11-1. Conceptual representation of DCF records functionality

11.2 DCF records in boot sequence

For the device to be used in a user application, the system boot process must properly program the following to the respective flash memories before releasing reset.

- User application code
- Reset vectors for all CPUs
- DCF records
- Life cycle records

The following is a high-level summary of the boot sequence leading to the use of DCF records:

1. When power is applied to a properly programmed device, the Power Management Controller (PMC) takes control of the device.
2. After the system power supplies have reached predefined levels, the Power Management Controller signals the Reset Generation Module (RGM) to begin the boot sequence.
3. During the boot sequence, the RGM enables the System Status and Control Module (SSCM) to read the Device Configuration Format records.
4. SSCM writes the configuration information to the specified registers.
5. After registers are initialized, the SSCM passes the control of the boot sequence back to the RGM, which directs the STCU2 to start the memory and logic built in self tests (MBIST and LBIST).
6. After MBIST and LBIST are complete, RGM releases reset and device starts code execution from reset vector.

11.3 DCF records function

User-supplied DCF records define the following:

- Setup of the initial memory map
- Tests the Self-Test Control Unit (STCU2) runs during the boot sequence
- Flash memory block association with specific password groups
- Flash memory block association with specific tamper detect regions

11.4 DCF records location

Factory-written DCF records start at the first address in the UTEST flash memory area. Refer the 'UTEST Memory Map' tab in the DCF sheet attached with this document as an Excel file

User-supplied UTEST DCF records may be added at the next location in the UTEST memory map immediately following the factory-written UTEST DCF records.

11.5 DCF record structure

A DCF record is a double-word (64-bit) entry consisting of the following:

- Control word: Information to locate the corresponding DCF client internal to the device (pointer to the location of a register internal to the device)
- Data word: Data to be written to that client

DCF Records select the target DCF client by a 30-bit field in the DCF Record consisting of a 15-bit 'Chip Select' field and a 15-bit Address field. Each module that includes DCF clients is assigned a Chip Select during chip definition. The address field is only relevant to the address decoding within that module and may not necessarily relate to the address of a register visible to software.

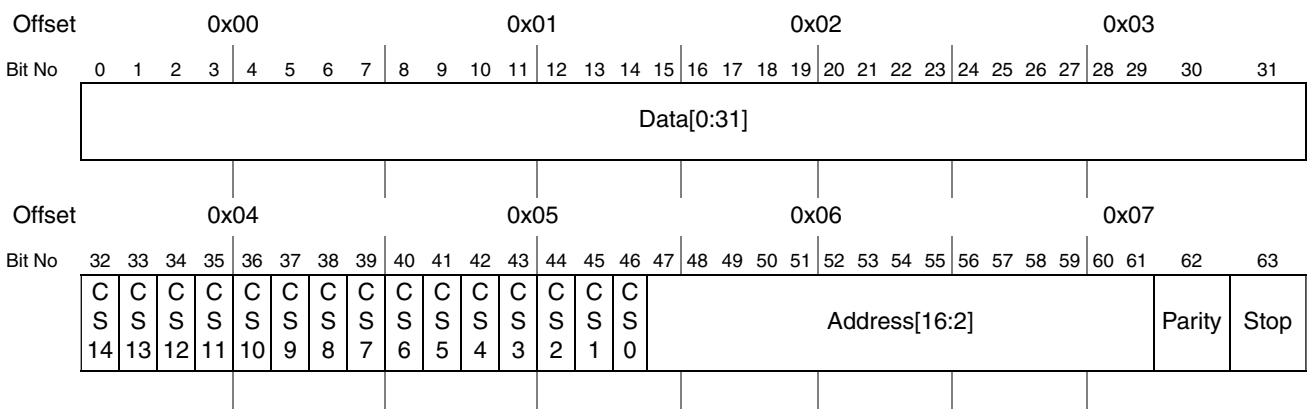

Figure 11-2. DCF Record Structure

NOTE

Attached DCF Sheet is in little endian format. Bit 31 of DCF Client in DCF Sheet is mapped to 0th Bit of Data in DCF Record.

Table 11-1. DCF Record Field Description

Field	Name	Description
0-31	Data[0:31]	32 bits of data that is to be written to the DCF Client
32-46	CS*n*	Chip Select *n* One Chip select is asserted ('1') per DCF record to select the target module for the DCF client. All other Chip Selects should be negated ('0').
47-61	Address[16:2]	Address of the DCF client within the selected module.

Table continues on the next page...

Table 11-1. DCF Record Field Description (continued)

Field	Name	Description
		Note: Address decoding for DCF clients may not match the standard software address map decoding. Details of DCF Client addresses are defined in each module chapter.
62	Parity	Parity Bit for the DCF Record. Note: This bit is NOT implemented for DCF Client written from UTEST.
63	Stop	Stop bit. Indicates the end of the list of DCF Records. Stop = '0' - NOT the end of the list Stop = '1' - End of the list Note: The Erased state of flash is 0xFFFF_FFFF_FFFF_FFFF. Therefore the list ends with the first unprogrammed double word. This location can be programmed with a new record to extend the list.

11.6 DCF records sequence

DCF records must appear as a contiguous series of entries programmed from the beginning of the UTEST flash memory area in the following order.

1. **Start DCF record**: The first DCF record must be a start record. This record must be found at the beginning of a DCF area in flash memory to indicate to the device that the following records must be processed.
2. **DCF records containing configuration data**: DCF records containing configuration data must immediately follow the start record with no blank records in between.
3. **Stop DCF record**: The end of the configuration records is indicated by the stop record. A record with the stop bit set is a stop record. All other bits are ignored. No DCF records following the stop record are processed.

SSCM recognizes the following record as a start record.

Table 11-2. DCF start record

0x00 (0:31)	0x04 (32:63)
0x05AA_55AF	0x0000_0000

The start record is set by the factory at the beginning of the UTEST flash memory area.

SSCM recognizes the following record as a stop record.

Table 11-3. DCF stop record

0:31	32:62	63
Ignored	Ignored	1

The stop bit is never set by the factory, since this would not allow the user to add DCF records. The flash memory location following the last factory-written UTEST DCF record is unprogrammed, with the content of 0xFFFF_FFFF. This is interpreted as the stop record, since the stop bit is set.

User-supplied DCF records may be added in a contiguous manner immediately following the factory-written DCF records. There must never be an unprogrammed record in the series of DCF records as it will be interpreted as a stop record.

The following table shows the series of DCF records when *n* data records are stored in the UTEST flash.

Table 11-4. Series of DCF records in UTEST flash memory

Record type	ADDR offset	DATA			
Start record	0x00	0x05AA_55AF			
	0x04	0x0000_0000			STOP=0
Data records	0x08	WDATA[31:0]			
	0x0C	CS[14:0]	ADDR[16:2]	PRTY	STOP=0
	0x10	WDATA[31:0]			
	0x14	CS[14:0]	ADDR[16:2]	PRTY	STOP=0
	...	...			
Stop record	8*n*-1 + 0x0	Reserved			
	8*n*-1 + 0x4	Reserved			1
	8*n* + 0x0				
	8*n* + 0x4				

It is possible for more than one DCF Record to write to the same DCF client. In this case the later record usually overrides a DCF client value set by a previous record. However, not all DCF clients allow overwrites; this depends on the DCF client implementation.

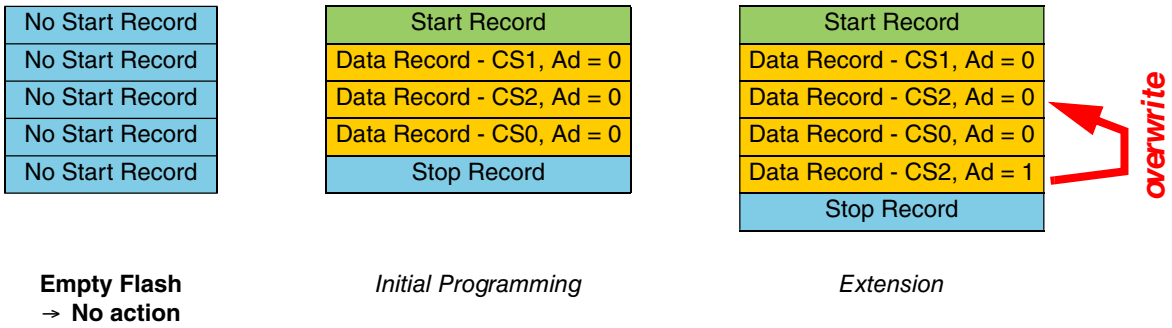

Figure 11-3. Appending DCF records

11.7 DCF clients

DCF clients are 32-bit wide hardware registers inside a module that receive and store the data from a DCF record. This stored data is used to initialize registers and to configure features.

The DCF clients are described in the tables attached to this document as an Excel file. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click the Excel file to open it.

Some DCF clients support a safety feature called Triple Voting. For safe DCF clients, three DCF records (called mirrors) need to be populated in Flash:

- Mirror0: Actual Data, Control Word (CS, Actual Client_Address + 0x4)
- Mirror1: Inverted Data, Control Word (CS, Client_Address + 0x8)
- Mirror2: Right Rotated (by 1 bit) Data, Control Word (CS, Client_Address + 0x10)

The number of bits to rotate depends on the DCF client parameter (Refer "# of Valid Bits" column given in the "UTEST DCF Clients" tab of the DCF heet attached with this document as an Excel file).

If WR_ONCE is one for any DCF client, it will only accept a single write.

The following DCF Bits should not be programmed multiple times

- dcf_ctl_tsens. TS0_AOUT_EN
- dcf_ctl_tsens. TS0_DOUT_EN
- dcf_ctl_tsens. TS1_AOUT_EN
- dcf_ctl_tsens. TS1_DOUT_EN

Below DCF clients are factory programmed and not recommended to be overwritten

- dcl_soc_conf_3. IO_LVD_POR

- dcl_soc_conf_3. LVD_POR
- dcl_soc_conf_3. PMC_SELFTEST_ALL_VD_MASK

Chapter 12
System Integration Unit Lite2 (SIUL2)

12.1 Introduction

12.1.1 Overview

The SIUL2 provides control over all the electrical pin controls and up to 32 ports with 16 bits of bidirectional, general-purpose input and output signals. One of the most important functions of the SIUL2 is that it enables the user to select the functions and electrical characteristics that appear on external device pins. It also controls the multiplexing of internal signals from one module to another and controls device I/O. It supports up to 32 external interrupts with trigger event configuration. The following figure is the block diagram of the SIUL2 and its interfaces to other system components.

The module provides dedicated pad control to general-purpose pads that can be configured as either inputs or outputs. The SIUL2 module provides registers that enable user software to read values from GPIO pads configured as inputs, and write values to GPIO pads configured as outputs

- When configured as output, you can write to an internal register to control the state driven on the associated output pad.
- When configured as input, you can detect the state of the associated pad by reading the value from an internal register.
- When configured as input and output, the pad value can be read back, which can be used as a method of checking if the written value appeared on the pad.

To assist software development, GPIO data registers can be accessed using various mechanisms. These differing mechanisms allow support for port access or for bit manipulation without the need to use read-modify-write operations or access with Power Architecture reservation.

- Access to two 16 bit ports in one access
- Read/write access to a single bit
- A 16-bit Port write with a bit mask, using single 32-bit access.

The external interrupt sources can be configured at the MCU level to be used with any chip pad. From 1 to 32 of the interrupt sources can be configured to have a digital filter to reject short glitches on the inputs. The external interrupt/DMA requests map to the REQ pins in the device packages.

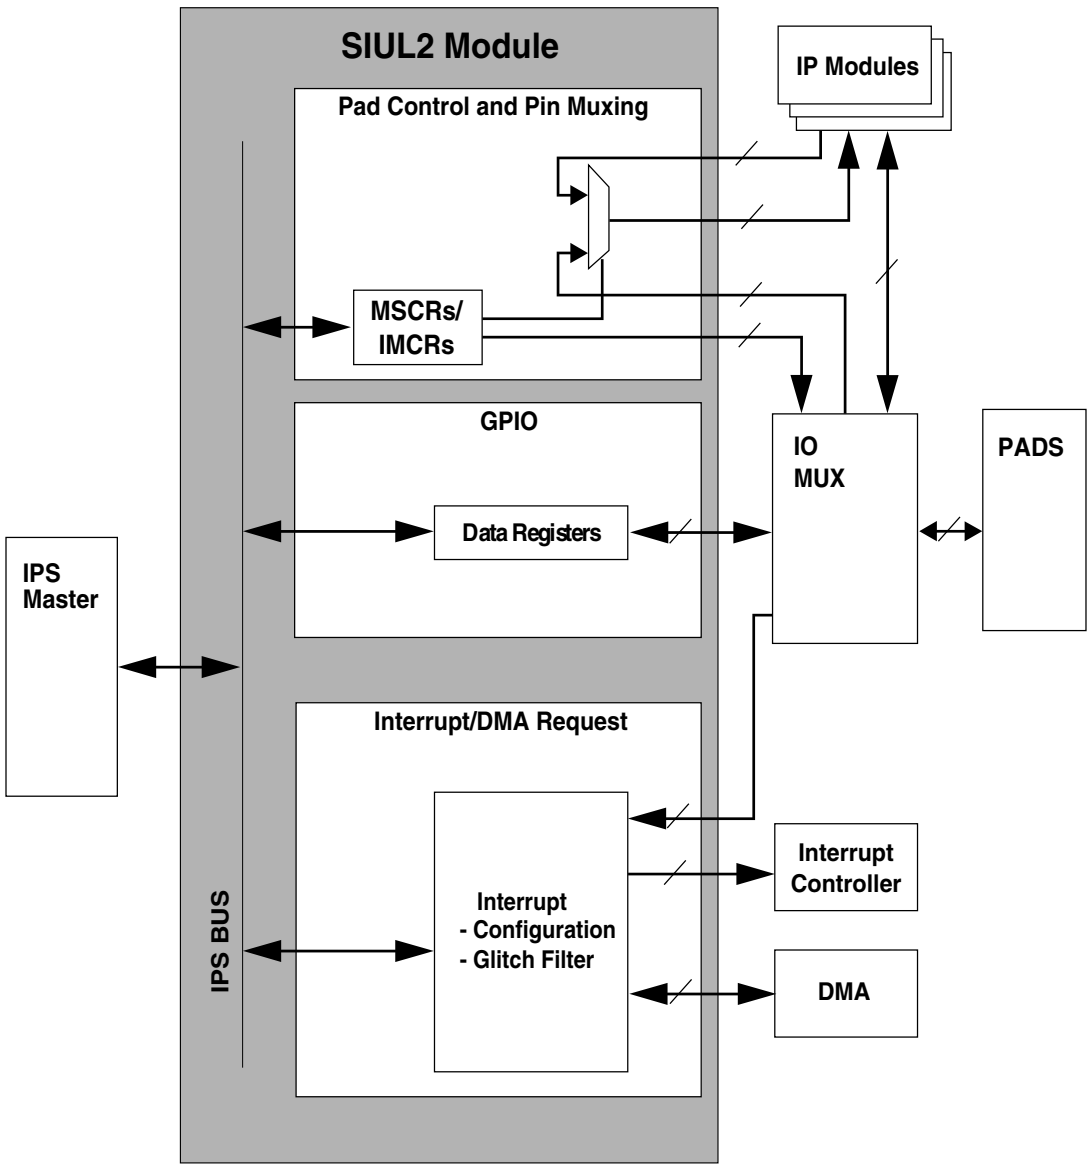

Figure 12-1. SIUL2 block diagram

12.1.2 Features

The System Integration Unit Lite2 supports these distinctive features:

- 1 to 32 GPIO ports with data control
  - Drive data to up to 16 independent I/O channels
  - Sample data from up to 16 independent I/O channels

Two 16-bit registers can be read/written with one access for a 32-bit port, if needed.

External interrupt/DMA request support with:

- 1 to 4 system interrupt vectors for 1 to 32 interrupt sources with independent interrupt masks. For 32 external interrupt sources (REQ pins), four groups have eight interrupt sources each, and each of the four groups is assigned one system interrupt vector.
- 1 to 32 programmable digital glitch filters, one for each REQ pin
- 1 to 4 system DMA request channels for 1 to 32 REQ pins
- Edge detection

Additionally the SIUL2 contains the Multiplexed Signal Configuration Registers that configure the electrical parameters and settings of up to 512 functional pads. The number of these registers that is actually implemented varies by device. These registers configure the following pad features:

- Drive strength
- Output impedance control
- Open drain/source output enable
- Slew rate control
- Hysteresis control
- Inversion control
- Internal pull control and pull selection
- Pin function assignment

- Control of analog path switches
- Safe mode behavior configuration

12.2 Memory map and register description

This section provides a detailed description of all registers accessible in the SIUL2 module in address order. Each description includes a standard register diagram. Details of register bit and field function follow the register diagrams, in bit order.

The following table gives an overview on the SIUL2 registers implemented.

NOTE

Undocumented register spaces in the SIUL2 memory map, including addresses shown as "blank," are reserved. Reserved registers read as 0, and writes to these registers have no effect. If supported and enabled by the MCU, a transfer error is issued for attempts to access a completely reserved register space. A write to reserved register bit has no effect.

NOTE

The implementation of the MSCRn, GPDOn, GPDIn, PGPDOn and PGPDIn and MPGPDOn is not in continuous incremental order in the device. There are GPIO holes. For exact implementation, see the device I/O Signal Description and Input Multiplexing Tables (Excel file) attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the Excel file to open it and select the I/O Signal Table tab.

12.2.1 SIUL2 MCU ID Register #1 (SIUL2_MIDR1)

This register holds identification information about the device.

NOTE

This register is accessible only in 32-bit mode.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	PART_FAMILY												Reserved			
W																
Reset	*	*	*	*	*	*	*	*	*	*	*	*	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	Reserved		PKG		Reserved				MAJOR_MASK				MINOR_MASK			
W																
Reset	0	0	*	*	0	0	0	0	*	*	*	*	*	*	*	*

* Notes:

- MINOR_MASK field: Depends on device version. For reset value, see Table 12-1
- MAJOR_MASK field: Depends on device version. For reset value, see Table 12-1
- PKG field: Depends on device version. For reset value, see Table 12-1
- PART_FAMILY field: Depends on device version. For reset value, see Table 12-1

SIUL2_MIDR1 field descriptions

Field	Description
0–11 PART_FAMILY	MCU Part Number
12–17 Reserved	This field is reserved.

SIUL2_MIDR1 field descriptions (continued)

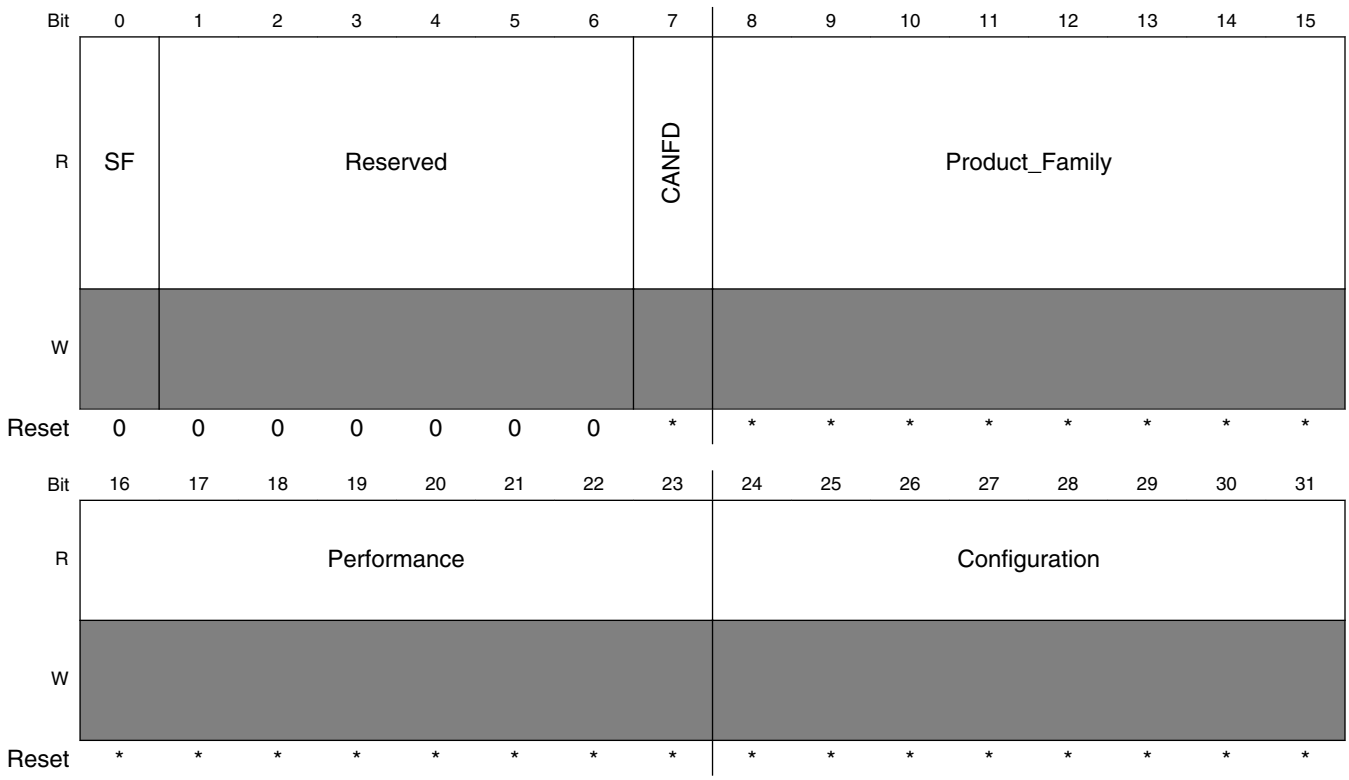
Field	Description
18–19 PKG	Package setting Can by read by software to determine the package type that is used for the particular device: 10: 257-pin BGA
20–23 Reserved	This field is reserved.
24–27 MAJOR_MASK	Major Mask Revision
28–31 MINOR_MASK	Minor Mask Revision

12.2.2 SIUL2 MCU ID Register #2 (SIUL2_MIDR2)

NOTE

This register is accessible only in 32-bit mode.

Address: 0h base + 8h offset = 8h



* Notes:
- Configuration field: Depends on device version. For reset value, see Table 12-1
- Performance field: Depends on device version. For reset value, see Table 12-1
- Product_Family field: Depends on device version. For reset value, see Table 12-1
- CANFD field: Depends on device version. For reset value, see Table 12-1

SIUL2_MIDR2 field descriptions

Field	Description
0 SF	Manufacturer 0 NXP Semiconductor, Inc 1 Reserved
1–6 Reserved	This field is reserved.
7 CANFD	CANFD

Table continues on the next page...

SIUL2_MIDR2 field descriptions (continued)

Field	Description
	0 CANFD is not supported 1 CANFD is supported
8–15 Product_Family	Product Family Number
16–23 Performance	Performance of device, see Table 12-3
24–31 Configuration	Configuration of device, see Table 12-2

12.2.3 SIUL2 DMA/Interrupt Status Flag Register0 (SIUL2_DISR0)

The DMA/Interrupt Status Register contains flag bits that record an event on the external IRQ pins. When an event as defined in IRQ Rising-Edge Event Enable Register (SIUL2_IREER0) and IRQ Falling-Edge Event Enable Register (SIUL2_IFEER0) occurs, the corresponding flag bit is set. The IRQ Flag bit is set regardless of the state of the corresponding DMA/Interrupt Request Enable bit in DMA/Interrupt Request Enable Register (SIUL2_DIRER0) - Standard. The IRQ Flag bit remains set until cleared by software or through the servicing of a DMA request. The IRQ Flag bits are cleared by writing a '1' to the bits. A write of '0' has no effect.

This register hold the interrupt flags.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

12.2.4 SIUL2 DMA/Interrupt Request Enable Register0 (SIUL2_DIRER0)

The DMA/Interrupt Request Enable Register enables the assertion of DMA or interrupt request if the corresponding External IRQ Flag bit is set in SIUL2 DMA/Interrupt Status Flag Register0 (SIUL2_DISR0). The type of request enabled is determined by the corresponding DMA/Interrupt Request Select bit in SIUL2 DMA/Interrupt Request Select Register0 (SIUL2_DIRSR0). This register is used to enable the interrupt messaging to the interrupt controller.

12.2.5 SIUL2 DMA/Interrupt Request Select Register0 (SIUL2_DIRSR0)

The DIRSR selects between the DMA or interrupt request. If the corresponding bits are set in SIUL2 DMA/Interrupt Status Flag Register0 (SIUL2_DISR0) and SIUL2 DMA/Interrupt Request Enable Register0 (SIUL2_DIRER0), then the DMA/Interrupt Request Select bit determines whether DMA or a interrupt request is asserted. The number of bits implemented is specified by the parameter that defines the number of DMA request outputs.

12.2.8 SIUL2 Interrupt Filter Enable Register 0 (SIUL2_IFER0)

This register is used to enable a digital filter counter on the corresponding interrupt pads to filter out glitches on the inputs. The number of interrupts supporting this feature is MCU dependent and can be configured between 1 and 32.

Address: 0h base + 38h offset = 38h

SIUL2_IFMCR*n* field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 MAXCNT	Maximum Interrupt Filter Counter setting MAXCNT can be 0d to 15d. • For a MAXCNT value of 0d, 1d, or 2d, the filter behaves as an ALL PASS filter. • For a MAXCNT value of 3d to 15d, the filter period is TCK*MAXCNT+n*TCK, where n is 0, 1, 2, 3, or 4. TCK is the prescaled filter clock period, which is the IRC clock prescaled to the IFCP value, which is specified in SIUL2_IFCPR. TIRC is the basic filter clock period: 62.5 ns (f = 16 MHz). **NOTE:** The filter delay is 2 TCK clock cycles more than the filter period. In general, TFILTER and TDELAY are not integer multiples of TCK because DIN is asynchronous whereas DOUT is synchronous with respect to the CK clock. The factor n accounts for this uncertainty in filter period calculation.

12.2.10 SIUL2 Interrupt Filter Clock Prescaler Register (SIUL2_IFCPR)

This register is used to configure a clock prescaler which is used to select the clock for all digital filter. Prescaler is applied to the input clock to the SIUL2, which is the system AIPS clock counters in the SIUL2.

Address: 0h base + C0h offset = C0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SIUL2_IFCPR field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 IFCP	Interrupt Filter Clock Prescaler setting Prescaled Filter Clock Period = T(IRC) x (IFCP + 1) T(IRC) is the internal oscillator period. IFCP can be 0 to 15

12.2.11 SIUL2 Multiplexed Signal Configuration Register (SIUL2_MSCR*n*)

NOTE

This register is accessible only in 32-bit mode.

Selects which source signal is connected to the register's associated destination, which is a chip pin that is or can be configured as an output.

For the associated chip-pin destination, the register also specifies the pin's electrical properties.

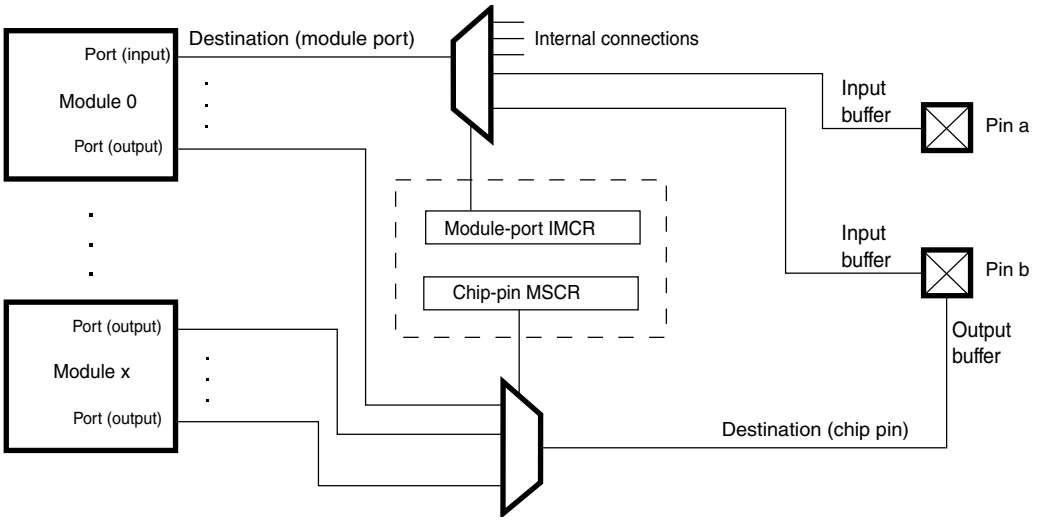

Figure 12-2. MSCR pin connection

The fields in an MSCR vary depending on its associated destination (chip pin).

For chip-pin MSCR assignments, pin types, APC support, and SSS values, see the pin-description table for your chip.

For the implemented register bits of MSCR for each pad, see the device I/O Signal Description and Input Multiplexing Tables. The fields in an MSCR vary depending on its associated destination (chip pin).

For details on the implemented chip-pin MSCR assignments, see the device I/O Signal Description and Input Multiplexing Tables (Excel file) attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the Excel file to open it and select the I/O Signal Table tab.

Address: 0h base + 240h offset + (4d × i), where i=0d to 198d

SIUL2_MSCR*n* field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–3 SRC	Slew Rate Control Used only when the associated destination is a chip pin. 00 Half drive strength with slew rate control 01 Full drive strength with slew rate control 10 Half drive strength without slew rate control 11 Full drive strength without slew rate control
4–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 OBE	GPIO Output Buffer Enable Applies only to digital pins. Otherwise this bit is reserved. 0 Output driver disabled 1 Output driver enabled
7 ODE	Open Drain Enable **NOTE** To enable open drain both OBE and ODE bits need to be set. 0 Open drain function disabled 1 Open drain function enabled
8 SMC	Safe Mode Control Used only when the associated destination is a chip pin. Specifies whether the chip disables the pin's output buffer when the chip enters Safe mode. 0 Disable (the output buffer returns to its previous state when the chip leaves Safe mode) 1 Don't disable
9 APC	Analog Pad Control Used only when the associated destination is a chip pin that supports analog I/O. Enables the pin's analog-input-path switch. 0 Disable (the switch is off) 1 Enable (another module can control the state of the switch)
10–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 IBE	Input Buffer Enable Used only when the associated destination is a chip pin. Enables the associated pin's input buffer. IBE bit shall not be set when APC bit is set. 0 Disabled 1 Enabled
13 HYS	Input Hysteresis Used only when the associated destination is a chip pin. Enables input hysteresis for the associated pin.

Table continues on the next page...

SIUL2_MSCR*n* field descriptions (continued)

Field	Description
	0 Disabled 1 Enabled
14 PUS	Pull Select Determines whether the pull function is a pullup or pulldown when the pull function is enabled by the PUE field. Used only when the associated destination is a chip pin. 0 Pulldown 1 Pullup
15 PUE	Pull Enable Enables the pull function. Used only when the associated destination is a chip pin. 0 Disabled 1 Enabled
16 INV	Invert Inverts the signal selected by SSS before transmitting it to the associated destination (chip pin). 0 Don't invert 1 Invert
17–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 SSS	Source Signal Select Selects which source signal is connected to the associated destination (chip pin). This field has a variable width depending on the number of alternate functions available for that pin/port. For a chip pin, the source signals are outputs from module ports.

12.2.12 SIUL2 Input Multiplexed Signal Configuration Register (SIUL2_IMCR*n*)

NOTE

This register is accessible only in 32-bit mode.

Selects which source signal is connected to the register's associated destination, which is an internal module port that is or can be configured as an input.

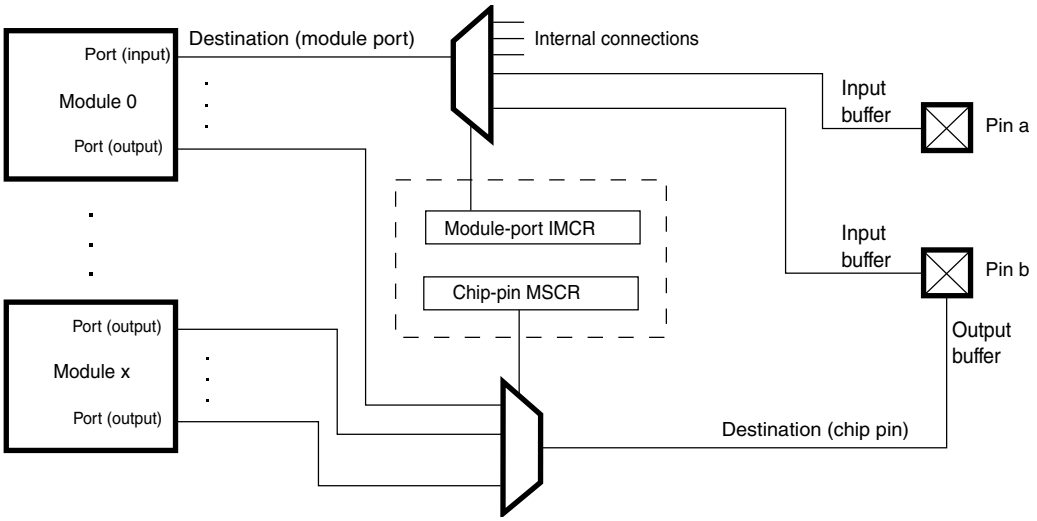

Figure 12-3. IMCR module-port connection

The fields in an IMCR vary depending on its associated destination (module port).

For IMCR assignments and SSS values, see the pin-description table for your chip.

For the implemented register bits of IMCR for each pad, see the device I/O Signal Description and Input Multiplexing Tables. The fields in an MSCR vary depending on its associated destination (chip pin).

For details on the implemented chip-pin MSCR assignments, see the device I/O Signal Description and Input Multiplexing Tables (Excel file) attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the Excel file to open it and select the I/O Signal Table tab.

SIUL2_GPDI*n* field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 PDI_4n	Pad Data In This bit stores the value of the external GPIO pad associated with this register. PDI_4n represents PDI[4n], where n is the instance of the register. For example, for the GPDI3 register, PDI_4n represents PDI12. 0 The value of the data in signal for the corresponding GPIO pad is logic low 1 The value of the data in signal for the corresponding GPIO pad is logic high
8–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 PDI_4n1	Pad Data In This bit stores the value of the external GPIO pad associated with this register. PDI_4n1 represents PDI[4n+1], where n is the instance of the register. For example, for the GPDI3 register, PDI_4n1 represents PDI13. 0 The value of the data in signal for the corresponding GPIO pad is logic low 1 The value of the data in signal for the corresponding GPIO pad is logic high
16–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 PDI_4n2	Pad Data In

Table continues on the next page...

SIUL2_GPDI*n* field descriptions (continued)

Field	Description
	This bit stores the value of the external GPIO pad associated with this register. PDI_4n2 represents PDI[4n+2], where n is the instance of the register. For example, for the GPDI3 register, PDI_4n2 represents PDI14. 0 The value of the data in signal for the corresponding GPIO pad is logic low 1 The value of the data in signal for the corresponding GPIO pad is logic high
24–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 PDI_4n3	Pad Data In This bit stores the value of the external GPIO pad associated with this register. PDI_4n3 represents PDI[4n+3], where n is the instance of the register. For example, for the GPDI3 register, PDI_4n3 represents PDI15. 0 The value of the data in signal for the corresponding GPIO pad is logic low 1 The value of the data in signal for the corresponding GPIO pad is logic high

12.2.15 SIUL2 Parallel GPIO Pad Data Out Register (SIUL2_PGPDO*n*)

These registers are used to set or clear the respective pads of the device. Parallel port registers for input (PGPDI) and output (PGPDO) are provided to allow a complete port to be written or read in one operation, dependent on the individual pad configuration. The difference between PGPDO and GPDO is that PGPDO registers can be used to set the values of all output pins assigned to a device port with a single 16-bit register write vs. the GPDO registers, which are used to set the value on a specific pin with a byte write.

The SIUL2_PGPDO registers access the same physical resource as the SIUL2_PDO and SIUL2_MPGPDO address locations. Some examples of the mapping:

- PPDO[0][0] = PDO[0]
- PPDO[2][0] = PDO[32]
- PPDO[31][15] = PDO[511]

For details on the implemented chip-pin PGPDO assignments, see the device I/O Signal Description and Input Multiplexing Tables (Excel file) attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the Excel file to open it and select the I/O Signal Table tab.

Address: 0h base + 1700h offset + (2d × i), where i=0d to 12d

SIUL2_PGPDO*n* field descriptions

Field	Description
0–15 PPDO	Parallel Pad Data Out Write or read the data register that stores the value to be driven on the pad in output mode. Access to this register location are coherent with access to the bit-wise GPIO Pad Data Output Registers (SIUL2_GPDO).The x and bit index define which PPDO register bit is equivalent to which PDO register bit according to the following equation: PPDO[x][y] = PDO[(x*16)+y]

12.2.16 SIUL2 Parallel GPIO Pad Data In Register (SIUL2_PGPDI*n*)

These registers hold the synchronized input value from the pads. Parallel port registers for input (PGPDI) and output (PGPDO) are provided to allow a complete port to be written or read in one operation, dependent on the individual pad configuration.The difference between PGPDI and GPDI registers is that PGPDI registers can be used to read the values of all input pins assigned to a device port with a single 16-bit register read vs. the GPDI registers, which are used to read the value on a specific pin with a byte read.

For details on the implemented chip-pin PGPDI assignments, see the device I/O Signal Description and Input Multiplexing Tables (Excel file) attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the Excel file to open it and select the I/O Signal Table tab.

Address: 0h base + 1740h offset + (2d × i), where i=0d to 12d

SIUL2_PGPDI*n* field descriptions

Field	Description
0–15 PPDI	Parallel Pad Data In Reads the current pad value. Access to this register location are coherent with access to the bit-wise GPIO Pad Data Input Registers (SIUL2_GPDI). The x and bit index define which PPDI register bit is equivalent to which PDI register bit according to the following equation: PPDI[x][y] = PDI[(x*16)+y]

12.2.17 SIUL2 Masked Parallel GPIO Pad Data Out Register (SIUL2_MPGPDO*n*)

This register can be used to selectively modify the pad values associated to PPDO[x][0:15]. The MPGPDO[x] register may only be accessed with 32 bit writes. 8-bit or 16-bit writes will not modify any bits in the register and cause a transfer error response by the module. Read access will return 0.

Address: 0h base + 1780h offset + (4d × i), where i=0d to 12d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SIUL2_MPGPDO*n* field descriptions

Field	Description
0–15 MASK	Mask Field Each bit corresponds to one data bit in the MPPDO[x] register at the same bit location. 0b The associated bit value in the MPPDO[x] field is ignored 1b The associated bit value in the MPPDO[x] field is written
16–31 MPPDO	Masked Parallel Pad Data Out Write the data register that stores the value to be driven on the pad in output mode. Access to this register location are coherent with access to the bit-wise GPIO Pad Data Output Registers (PDO).The x and bit index define which MPPDO register bit is equivalent to which PDO register bit according to the following equation: MPPDO[x][y] = PDO[(x*16)+y]

12.3 Functional description

12.3.1 General

This section provides a complete functional description of the System Integration Unit Lite2.

12.3.2 Pad Control

The SIUL2 is capable of controlling the electrical characteristic of up to 512 pads. It provides a consistent interface for all pads, both on a by-port and a by-bit basis. The following describes the pad characteristics that can be supported by the SIUL2. Not all of these features will be supported on all devices or on all pads as this is dependent on the specific application needs and the pads implemented on the device.

The required controls are:

- Slew rate control
  - This is needed to offer improved EMC performance.
  - Support for a fast and a slow slew rate.
- Drive strength control
  - This is needed to offer improved EMC performance.
  - Up to 4 different drive strength levels can be supported.
- Pull capability
  - This is needed to offer flexibility in the device configuration and the elimination of external hardware in some cases.
  - The configuration of the pull on any pad should be independently controlled to be either pull-up, pull-down or no-pull enabled.
- Input and Out Buffer control
- Hysteresis
- Inversion
- Open drain
  - Needed to support different pads muxed (e.g. mux I^2C, with non open drain pads)
- Pad Output Assignment
  - This setting defines which chip function has control over the output of the pad.

The setting of each pad out of reset is fixed per MCU, but can be configured individually. In this way it is possible to select special pull settings or peripheral pad ownership per design.

It is possible for the user software to configure each pad independently of all other pads on the device or other pads grouped within a single port. This allows different pad types to be grouped together in ports and allows the necessary flexibility needed for the pads individual operation. This is achieved by grouping all of the above functions into a single register for each pad on the device, and allows each pad to be configured with a single write to one register and allowing simplified duplication of software for each pad with indexed changes for each pad.

12.3.3 General Purpose Input and Output Pads (GPIO)

The SIUL2 allows each pad to be configured as either a General Purpose Input or Output pad (GPIO), and as one or more alternate functions (input or output), the function of which is determined by the peripheral that will use the pad.

GPIO pads can also optionally be implemented without any alternate function.

The SIUL2 is designed to manage up to 512 GPIO pads organized as ports that can be accessed for data reads and writes as 32-bit, 16-bit or 8-bit.

As shown in the following figure, all port access are identical with each read or write being performed only at a different location to access a different port width.

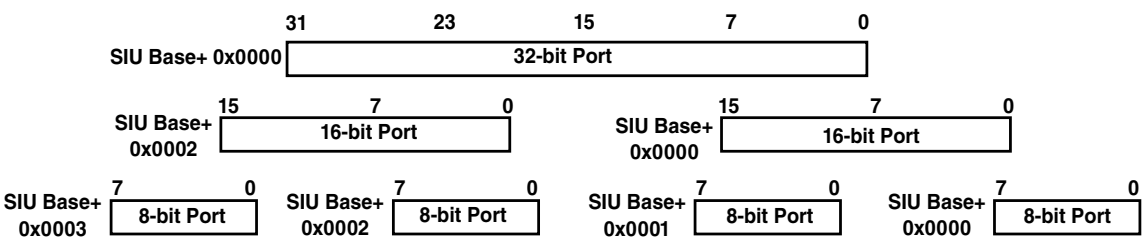

Figure 12-4. Data Port example arrangement showing configuration for different port width accesses

This implementation requires that the registers are arranged in such a way as to support this range of port widths without having to split reads or writes into multiple accesses.

The SIUL2 has separate data input and data output registers for all pads, allowing the possibility of reading back an input or output value of a pad directly. This supports the ability to validate what is present on the pad rather than simply confirming the value that was written to the data register by accessing the data input registers.

The data output registers support both read and write operations to be performed.

The data input registers support read access only.

When the pad is configured to use one of its alternate functions, the data input value reflect the respective value of the pad. If a write operation is performed to the data output register for a pad configured as an alternate function (non-GPIO), this write will not be reflected by the pad value until re-configured to GPIO. All general purpose pads are implemented as bidirectional.

Note

In case the bi-directional operation impacts some performances (e.g. ADC accuracy), or is not required for a specific pad function it is acceptable to limit the functionality of some pads to "Input Only"

12.3.4 Alternative pad functions

Module outputs are controlled by the SIUL2_MSCR[SSS] bit. If an output is required for a specific module (such as DSPI), then SSS should be selected to enable the module to output to the pad. For all modules (except the I2C module - the I2C module requires the IBE bit and ODE bit in the MSCR to also be set, since the protocol connections are bi-directional.) this is all that is required: when SSS is set the module selected correctly configures the pin. See the Pin Muxing spreadsheet attachment for details of the alternate functions and SSS settings for each pad.

Module inputs are controlled by the SIUL2_MSCR[IBE] bit, and associated IMCR register. If the function is for the module to be an input, then IBE and the SIUL2_IMCR[SSS] bit needs to be programmed by the user. See the Pin Muxing spreadsheet attachment for details of the alternate functions and the associated IMCR register and SSS bit settings for each pad.

12.3.5 External Interrupts/DMA Requests (REQ Pins)

The SIUL2 supports 1 to 32 external interrupts, which can be allocated to any pad necessary at the MCU level. This allocation is fixed per MCU.

For the assignments of the external interrupts, see the Signal Description details.

The SIUL2 supports 1 to 4 interrupt vectors to the interrupt controller of the MCU. Each interrupt vector can support up to 8 external interrupt sources from the device pads.

For devices with a number of interrupt sources that is smaller than the maximum number, the MCU can implement either all four interrupt vectors with fewer sources or reduce the number of vectors as the number of sources are reduced. The following figure shows two sample scenarios.

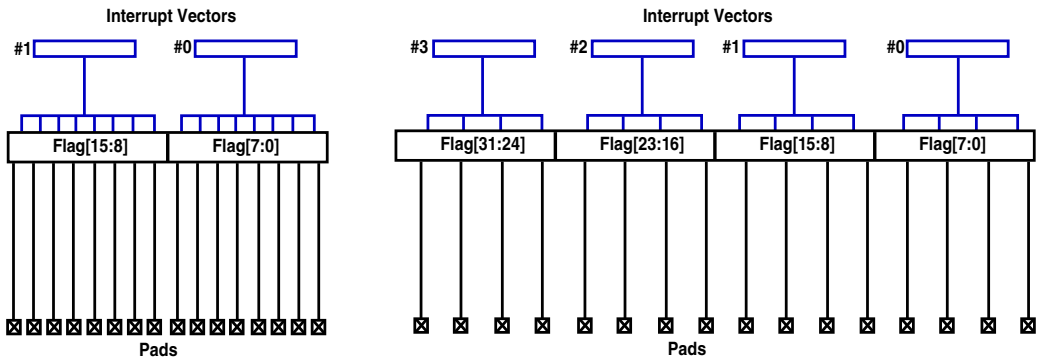

Figure 12-5. Example of different interrupt to vector mapping at MCU level

All the external interrupt pads within a single group (maximum 8 pads) have equal priority. It is the responsibility of the user software to search through the group of sources in the most appropriate way for their application.

The priority of the vectors used by the external interrupt pads is fixed based on the platform and the interrupt controller and its priority levels, but the allocation of pads to each group of interrupts can be independently configured by the MCU.

An MCU-specific number of external interrupt lines can have a digital glitch filters applied to them. The supported range is 1 to 32. The glitch filters need a running internal oscillator clock to work. If no such clock is available, external interrupts will be effectively disabled when the glitch filter is enabled on a interrupt line.

12.3.5.1 External interrupt initialization

When an external interrupt pin is first enabled, it is possible to get a false interrupt flag. To prevent a false interrupt request, during pin interrupt initialization, the user must do the following:

- Mask interrupts by clearing the EIREn bits in DIRER0.
- Select the pin polarity by setting the appropriate IREEn bits in IREER0 and the appropriate IFEEn bits in IFEER0 as desired.
- Configure the appropriate bits in the MSCR[0:199] register for the external interrupt pin(s) desired as follows:
  - Clear the OBE and ODE bits to disable output.
  - Set the IBE bit to enable the pin's input buffer.
  - If using the internal pullup/pulldown, configure the appropriate PUE and PUS fields.

Note

MSCR[SSS] bits do not need to be changed for either MSCR[0:199] or IMCR[0:199] because the external interrupt pin input is directly connected to the SIUL for EIRQ pins.

External interrupt pins should never be configured as outputs (MSCR[ODC] bits are not zeros) when external interrupt inputs are desired because false interrupts could be detected (such as from a GPIO configuration).

- Select the request desired between DMA or Interrupt by writing the appropriate DIRSn bits in DIRSR0.
- Select the desired glitch filter setup for the pins by writing the following:
  - Write the Filter Counter setting to the desired value by writing the MAXCNT[3:0] bits in the IFMCn register for the respective external interrupt that is being used.
  - Set the Filter Clock Prescaler setting from 0 to 15 to the desired value by writing the IFCP[3:0] bits in the IFCPR register.
  - Enable the glitch filter for the desired external interrupt pins by setting the appropriate IFEn bits in IFER0.
- Write to EIFn bits in DISR0 to as desired to clear any flags.
- Enable the interrupt pins by setting the appropriate EIREn bits in DIRER0.

12.3.5.2 External interrupt management

The user can enable or disable each interrupt independently using a single rolled up register, SIUL2_DIRER0.

A pad defined as an external interrupt can be configured by the user to recognize interrupts with an active rising edge, an active falling edge, or both edges being active. A setting of having both edge events disabled is reserved and should not be configured. The user controls the active IRQ edge through the registers SIUL2_IREER and SIUL2_IFEER.

Each external interrupt supports an individual flag which is held in the Flag register (DISR0). This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register.

Refer to the following figure for an overview of the external interrupt implementation.

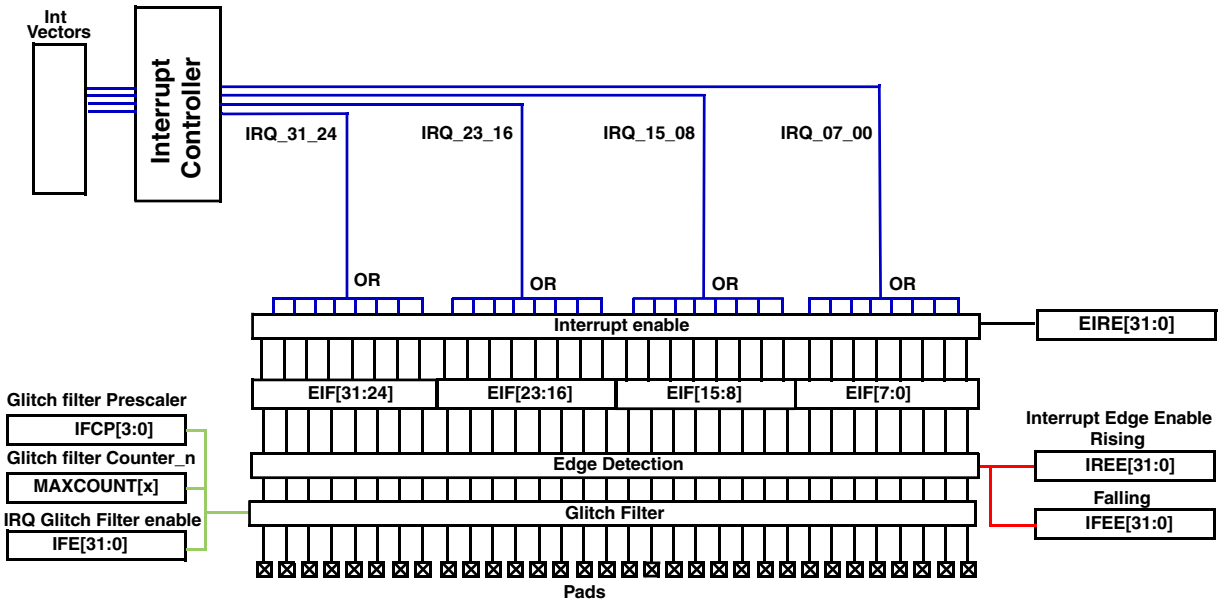

Figure 12-6. External interrupt pad diagram

12.3.5.3 External Interrupt request

The REQ input pins on the device are sources for interrupt or DMA requests. The system has four possible interrupt vectors available for the REQ pins in the SIUL2. The mapping of 32 interrupt request sources to vectors and channels appears in the following table.

Table 12-5. Interrupt source mapping to SIUL2 Interrupt request output for 32 interrupt sources

Vector/Channel #	Interrupt Vector Source
0	REQ[07] | REQ[06] | REQ[05] | REQ[04] | REQ[03] | REQ[02] | REQ[01] | REQ[00]
1	REQ[15] | REQ[14] | REQ[13] | REQ[12] | REQ[11] | REQ[10] | REQ[09] | REQ[08]
2	REQ[23] | REQ[22] | REQ[21] | REQ[20] | REQ[19] | REQ[18] | REQ[17] | REQ[16]
3	REQ[31] | REQ[30] | REQ[29] | REQ[28] | REQ[27] | REQ[26] | REQ[25] | REQ[24]

Chapter 13
Core Complex Overview

13.1 Core Complex Overview

The device has four separate cores that perform various computational and control functions. The main computational shell consists of Main Core_0 that uses e200z4201n3 core, and Main Core_1 and Main Core_2, both of which use an e200z7260n3 core. These three cores are used for general computational functions. A fourth core, referred to as Checker Core_0s, uses an e200z419 core, which is a true subset of the e200z4201n3 core. When enabled, Checker Core_0s operates in Lock Step mode with Main Core_0 executing exactly the same instructions as Main Core_0. Checker Core_0s checks to ensure that Main Core_0 is executing correctly. There is no Lock Step function associated with Main Core_1 and Main Core_2. The e200z419 core, used as Checker Core_0s, differs in hardware from the e200z4201n3 in that it has no Instruction Cache, Data Cache, I-memory, or D-memory.

This chapter provides overviews of the e200z4201n3 core, the e200z419 core, and the e200z7260n3 core.

13.2 Overview of the e200z4201n3, e200z419, and e200z7260n3 cores

The e200z processor family is a set of CPU cores that implement low-cost versions of the Power Architecture.

Each core integrates a pair of integer execution units, a branch control unit, instruction fetch unit, load/store unit, and a multi-ported register file capable of sustaining six read and three write operations per clock. Most integer instructions execute in a single clock cycle. Branch target prefetching is performed by the branch unit to allow single-cycle branches in many cases.

The e200z4201n3, e200z419, and e200z7260n3 are dual-issue, 32-bit Power VLE (variable-length-encoding) compliant designs with 32-bit/64-bit general-purpose registers (GPRs) for improved code density. The VLE ISA is further documented in PowerISA 2.06, a separate document. The base PowerISA 2.06 fixed-length 32-bit instruction set is not directly supported.

An Embedded Floating-point (EFPU2) Arithmetic Processing Unit is provided to support real-time single-precision floating-point embedded numerics operations using the general-purpose registers.

A Signal Processing Extension (SPE2) Arithmetic Processing Unit in e200z7260n3 core is provided to support real-time SIMD fixed point and single-precision, embedded numerics operations using the general-purpose registers. All arithmetic instructions that execute in the core operate on data in the general purpose registers (GPRs). The GPRs have been extended to 64-bits in order to support vector instructions defined by the SPE2 APU. These instructions operate on vectors of 8-bit, 16-bit or 32-bit data types, and deliver vector and scalar results. A limited set of 64-bit scalar operations are also supported.

The e200z4201n3 core differs in hardware from the e200z7260n3 core in several ways. The e200z4201n3 core and e200z7260n3 core have different amounts of Instruction and Data Cache. e200z4201n3 contains an 8 KB Instruction Cache, and a 4 KB Data Cache, and e200z7260n3 contains a 16 KB Instruction Cache, and a 16 KB Data Cache.

Both e200z4201n3 and e200z7260n3 cores contain Nexus Class 3+ real-time debug module with support for program and data trace features as well as extensive trace controls.

A Memory Protection Unit is also included which supports protections of various instruction and data memory areas.

13.3 Features

The following table lists some of the key features of the cores supported in this device.

Table 13-1. e200z4201n3, e200z419, and e200z7260n3 Features

Features	e200z4201n3, e200z419	e200z7260n3
Dual issue 32-bit PowerISA 2.06-VLE compliant CPU	Yes	Yes
In-order execution and retirement	Yes	Yes
Precise exception handling	Yes	Yes
Branch processing unit	— Dedicated branch address calculation adder	— Dedicated branch address calculation adder

Table continues on the next page...

Table 13-1. e200z4201n3, e200z419, and e200z7260n3 Features (continued)

Features	e200z4201n3, e200z419	e200z7260n3
	— Branch target prefetching using BTB	— Branch target prefetching using BTB — Return Address Stack
Load/store unit	— 2 cycle load latency — Fully pipelined — Misaligned access support	— 3 cycle load latency — Fully pipelined — Misaligned access support
General Purpose Register file	32-bit	64-bit
Dual AHB 2.v6 64-bit System buses	Yes	Yes
Local Data Memory (DMEM) with shared AHB 2.v6 64-bit slave interface	— e200z4201n3 core—64 KB DMEM — e200z419 core does not contain either Instruction or Data MEM	64 KB DMEM
Memory Protection Unit (MPU) implementing a 24-entry region descriptor table with support for 6 arbitrary-sized instruction memory regions, 12 arbitrary-sized data memory regions, and 6 additional arbitrary-sized instruction or data memory regions	Yes	Yes
2-Way Set Associative Harvard Instruction and Data Cache	— e200z4201n3 core—8 KB ICache and 4 KB DCache — e200z419 core does not contain either Instruction or Data Cache	16 KB ICache and 16 KB DCache
Embedded Floating-point APU (EFPU2) supporting scalar and vector single-precision floating-point operations	Yes	Yes
Signal Processing Extension (SPE2) APU supporting SIMD fixed-point operations, using the 64-bit General Purpose Register file.	No	Yes
Performance Monitor APU supporting execution profiling	Yes	Yes
Nexus Class 3+ Real-time Development Unit	— e200z4201n3 core—Yes — e200z419—No	Yes
Power management — Low power design - extensive clock gating — Power saving modes: DOZE, NAP, SLEEP, WAIT — Dynamic power management of execution units, Caches and Local memory	Yes	Yes
Testability — Synthesizeable, MuxD scan design — ABIST/MBIST for arrays — Built-in LBIST Unit	Yes	Yes
Book E support	No	No

13.4 Microarchitecture summary

The e200z4201n3 and e200z419 processor cores utilize a five stage instruction pipeline with two stages for execution and e200z7260n3 processor utilizes a ten stage instruction pipeline, with four stages for execution. The Instruction Fetch, Instruction Decode/ Register File Read/ EA Calc, Execute 0/ Memory Access0, Execute1/Memory Access1, and Register Writeback stages operate in an overlapped fashion allowing single clock instruction execution for most instructions. The following figure shows a block diagram of the e200z architecture.

The integer execution units each consists of a 32-bit Arithmetic Unit (AU), a Logic Unit (LU), a 32-bit Barrel shifter (Shifter), a Mask-Insertion Unit (MIU), a Condition Register manipulation Unit (CRU), a Count-Leading-Zeros unit (CLZ), and result feed-forward hardware. Integer EU1 also supports hardware division and a 32x32 Hardware Multiplier array.

Most arithmetic and logical operations are executed in a single cycle with the exception of multiply, which is implemented with a pipelined hardware array, and the divide instructions. A Count-Leading-Zeros unit operates in a single clock cycle.

The Instruction Unit contains a PC incrementer and dedicated Branch Address adders to minimize delays during change of flow operations. Sequential prefetching is performed to ensure a supply of instructions into the execution pipeline. Branch target prefetching is performed to accelerate taken branches. Prefetched instructions are placed into an instruction buffer.

Branch target addresses are calculated in parallel with branch instruction decode, resulting in an execution time of two clocks (in z4 core) and four clocks (in z7 core) for correctly predicted branches. Conditional branches which are not taken execute in a single clock. Branches with successful BTB target prefetching have an effective execution time of one clock if correctly predicted.

Memory load and store operations are provided for byte, halfword, word (32-bit), and doubleword data with automatic zero or sign extension of byte and halfword load data as well as optional byte reversal of data. These instructions can be pipelined to allow effective single cycle throughput. Load and store multiple word instructions allow low overhead context save and restore operations. The load/store unit contains a dedicated effective address adder to allow effective address generation to be optimized.

The Condition Register unit supports the condition register (CR) and condition register operations defined by the Power architecture. The condition register consists of eight 4-bit fields that reflect the results of certain operations, such as move, integer and floating-point compare, arithmetic, and logical instructions, and provide a mechanism for testing and branching.

Vectored and autovectored interrupts are supported by the CPU. Vectored interrupt support is provided to allow multiple interrupt sources to have unique interrupt handlers invoked with no software overhead.

The SPE2 APU in e200z7260n3 supports vector instructions operating on 8, 16-, and 32-bit fixed-point data types, and scalar instructions operating on 64-bit fixed-point data types.

The EFPU2 APU supports 32-bit IEEE-754 single-precision floating-point formats, supports scalar and vector single-precision floating-point operations, and operates in a pipelined fashion. The general purpose register file is used for source and destination operands, and a unified storage model is used for scalar single-precision floating-point data types of 32-bits and the normal integer type. Low latency fixed-point and floating-point add, subtract, mixed add/subtract, sum, diff, min, max, multiply, multiply-add, multiply-sub, divide, square root, compare, and conversion operations are provided, and most operations can be pipelined.

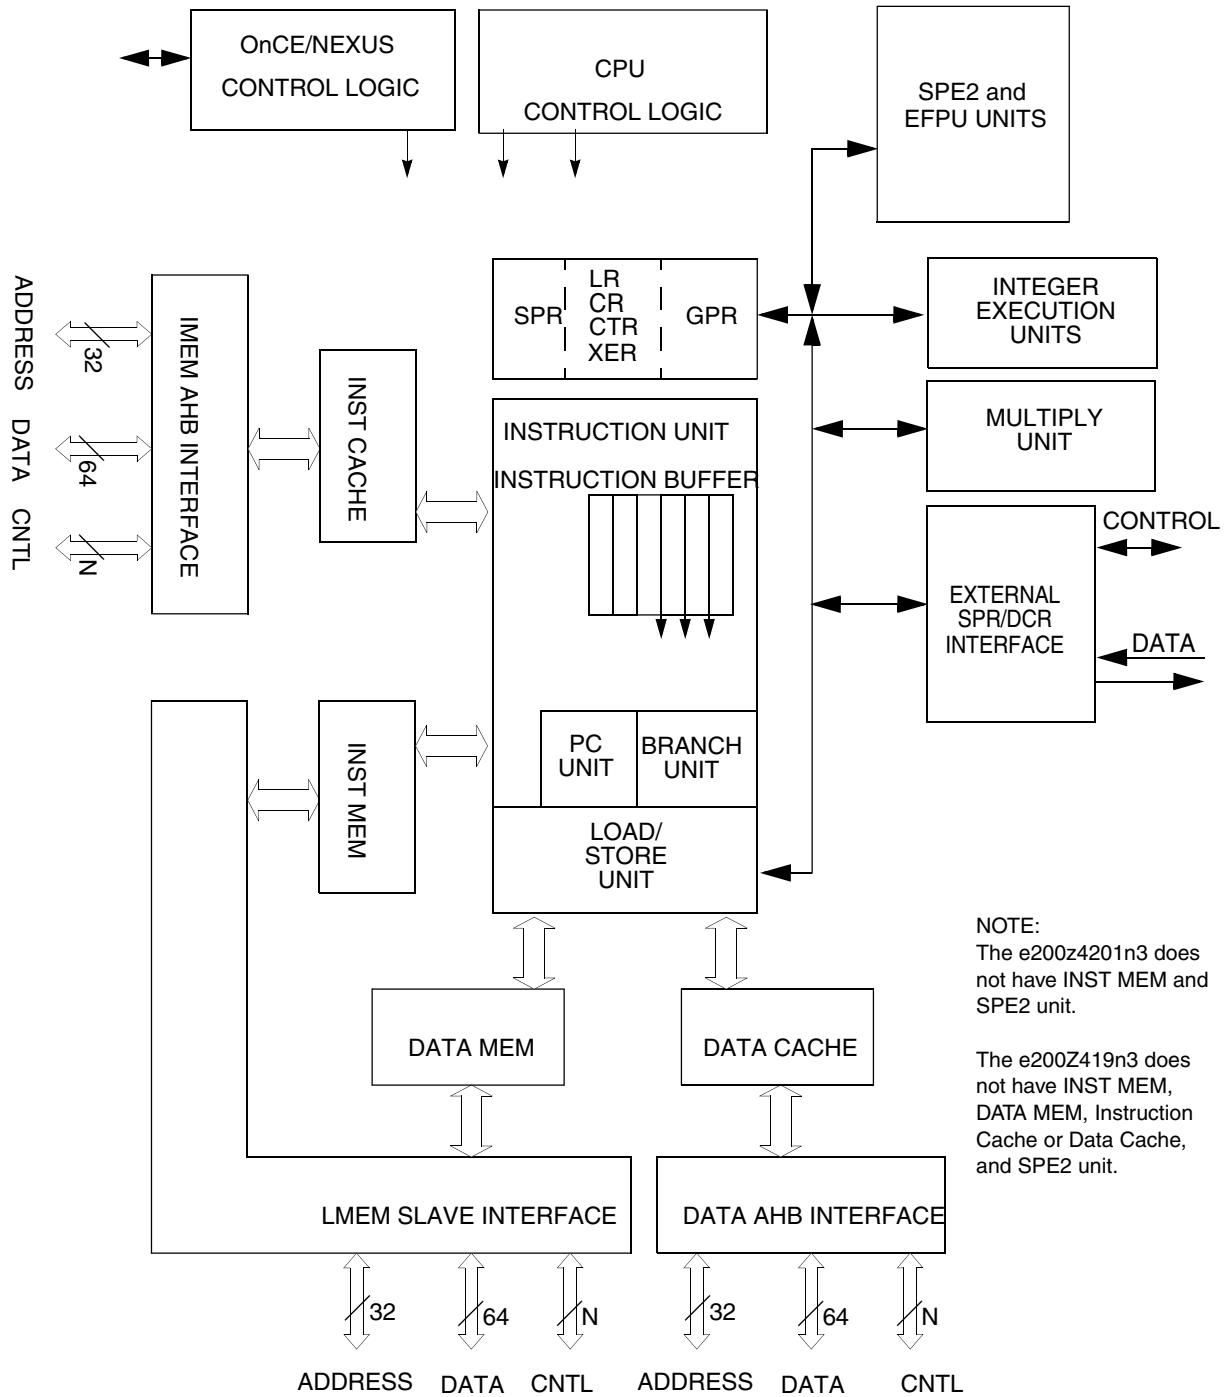

Figure 13-1. e200z block diagram

13.5 Instruction Unit Features

The features of the Instruction unit are:

- 64-bit path to cache supports fetching of two 32-bit instructions per clock
- Instruction buffer holds up to 8 32-bit instructions in e200z4201n3 and e200z419, and 10 32-bit instructions in e200z7260n3

- Dedicated PC incrementer supporting instruction prefetches
- Branch unit with dedicated branch address adder, and branch lookahead logic (BTB) supporting single cycle execution of successfully predicted branches

13.6 Integer Unit Features

The integer units support single cycle execution of most integer instructions:

- 32-bit AU for arithmetic and comparison operations
- 32-bit LU for logical operations
- 32-bit priority encoder for count leading zero's function
- 32-bit single cycle barrel shifter for shifts and rotates
- 32-bit mask unit for data masking and insertion
- Divider logic for signed and unsigned divide in 4-15 clocks (z4 core) and 4-14 clocks (z7 core) with minimized execution timing (EU1 only)
- Pipelined 32x32 hardware multiplier array supports 32x32->32 multiply with 2 clock latency, 1 clock throughput (EU1 only)

13.7 Load/Store Unit Features

The load/store unit supports load, store, and the load multiple / store multiple instructions:

- 32-bit effective address adder for data memory address calculations
- Dedicated 64-bit interface to memory supports saving and restoring of up to two registers per cycle for load multiple and store multiple word instructions and context save/restore instructions
- Pipelined operation supports throughput of one load or store operation per cycle

13.8 EFPU2 Floating-Point Unit Features

The EFPU2 embedded floating-point unit supports pipelined operation of most floating-point operations, allowing a throughput of one FP operation per cycle, and supports a variety of operations:

- Supports IEEE754 single-precision data format
- Supports IEEE754 half-precision format for conversion <->single-precision format
- EFPU2 instructions utilize the 32-bit GPRs for minimized context save/restore overhead
- Provides low latency pipelined scalar floating-point add, subtract, add/sub, sub/add, multiply, multiply-add, min, max, absolute value, compare, and conversion instructions with single-cycle throughput

- Default results mode for real-time applications allows for exception-free operations when underflow or overflows occur
- Trap Enable controls allow for trapping of various operation exceptions and emulation of IEEE754 boundary case results
- Floating-point Divide and Square root logic operating in 13 (FP div) and 11 (FP sqrt) clocks

13.9 SPE2 Signal Processing Unit Features

The SPE2 APU in e200z7260n3 is designed to accelerate signal processing applications normally suited to DSP operation.

- SPE2 instructions operate on the 64-bit GPRs
- Supports SIMD integer operations - arithmetic, logical, shift
- Supports SIMD rounding, saturation, pack, unpack, merge, extract, select for efficient data manipulation
- Supports SIMD multiply/ multiply accumulate/ dot product operations
- 8, 16-, 32-, and 64-bit signed and unsigned integer data types
- 16-, 32-, and 64-bit signed fractional support (1.15, 1.31, 1.63 representations)
- Guarded signed fractional support (33.31 and 17.47 representations)
- Single-cycle throughput for all instructions (except divide)
- Supports fractional divide operations (32/32->32 signed/unsigned int/frac, 64/64->64 signed/unsigned int)
- Specialized operations such as field manipulation, count-leading,
- Supports specialized load/store operations with integrated data manipulation
- Multiple addressing modes supported including circular and bit-reversed addressing
- Sustained throughput of up to 4 16x16-bit multiply/accumulate operations per cycle.

13.10 Memory Protection Unit (MPU) Features

The features of the MPU are as follows:

- 24-entry fully-associative Range Table
- Arbitrary range size support up to 4 GB
- 8-bit Process Identifier
- Bypass capability for individual access types
- Maskable Address and Process Identifier
- Programmable Memory Attributes
- Entry Invalidation Protection
- Per-Entry Write-Once Option
- Alternate Debug Breakpoint/Watchpoint function

13.11 Cache Features

The features of the Caches are as follows:

- 2-Way Set Associative Instruction and Data Caches
  - e200z4201n3—8 KB ICache, 4 KB DCache
  - e200z419—No ICache, No DCache
  - e200z7260n3—16 KB ICache, 16 KB DCache
- Writethrough Support
- 8-entry Store Buffer
- Linefill Buffer
- 32-bit address bus plus attributes and control
- Separate uni-directional 64-bit read data bus and 64-bit write data bus
- Supports Way locking
- Supports Write allocation policies
- Supports multi-bit EDC with Correction/Auto-invalidation capability
- Hardware Debug Cache Invalidate Support for the Data Cache
- Software and Hardware Debug access to cache tag, status and data storage via dedicated control registers

13.12 Local Memory Features

The features of the Local Data Memory are as follows:

- Local Data Memories (DMEM) with shared AHB 2.v6 64-bit slave interface
  - e200z4201n3 and e200z7260n3—64 KB DMEM
  - e200z419—No DMEM
- Two waitstate (z7) and one waitstate (z4) slave DMEM Read access
- Two waitstate (z7) and one waitstate (z4) slave DMEM Write access
- 64-bit local bus to CPU supporting zero wait-state CPU access
- Supports multi-bit (SECDED) ECC with correction/scrubbing capability
- 4-entry ECC R-M-W Store Buffer for DMEM
- 32-bit address bus plus attributes and control

13.13 Performance Monitor Unit Features

The features of the e200z4201n3 and e200z7260n3 performance monitor include:

- Four configurable 32-bit performance monitor counters each capable of counting selected CPU subsystem events
- Performance Monitor interrupt
- Ability to configure performance monitor resources for debugger use

- Hardware input signals for qualification of counting by individual counters
- Hardware output signals to indicate counter overflows
- Dedicated watchpoint outputs for each counter with programmable periodicity
- Trigger On/Off control for each counter based on subsystem events
- Multiple selectable event types including # of clocks, CPU stall cycles, # of instructions completed, # of interrupts taken, # of memory accesses (by type), # of instruction or data cache misses, # of cycles with 0, 1, or 2 instructions issued, # of instructions in a given class completed (ldst, branch, integer, FP, etc.), cache linefills, and many other event types.

13.14 e200z4201n3 and e200z7260n3 system bus features

The features of the e200z4201n3 and e200z7260n3 System Bus interface are as follows:

- Independent instruction and data interfaces
- Advanced microcontroller bus architecture (AMBA) AHB2.v6 protocol
- 32-bit address bus, 64-bit data bus, plus attributes and control
- Data interface provides separate uni-directional 64-bit read and write data buses
- Support for HCLK running at a slower rate than CPU clock

13.15 e200z419 system features

Checker Core_0 is implemented using an e200z419 core. When enabled, Checker Core_0s is used in Lock Step with Main_Core_0. The e200z419 core can only be enabled or disabled by the user. For this device, the Checker Core_0s has no system bus and cannot independently execute user code. The core is only used to execute the same instruction stream as Main Core 0.

The e200z419 core is identical to the e200z4201n3 with five exceptions:

- I MEM memory array is not present
- I CACHE memory array is not present
- D MEM memory array is not present
- D CACHE memory array is not present
- The e200z419 has a pair of system bus interfaces, which are driven/sampled by the delayed lockstep logic

13.16 Special Purpose Register Summary

PowerISA 2.06 and implementation-specific SPRs for the cores are listed in the following table. All registers are 32 bits in size. Register bits are numbered from bit 0 to bit 31 (most-significant to least-significant). Shaded entries represent optional registers. An SPR register may be read or written with the mfspr and mtspr instructions. In the instruction syntax, compilers should recognize the mnemonic name given in the following table.

Table 13-2. Special Purpose Registers

Mnemonic	Name	SPR Number	Access	Privileged	e200z Specific
XER	Integer Exception Register	1	R/W	No	No
LR	Link Register	8	R/W	No	No
CTR	Count Register	9	R/W	No	No
SRR0	Save/Restore Register 0	26	R/W	Yes	No
SRR1	Save/Restore Register 1	27	R/W	Yes	No
PID0	Process ID Register	48	R/W	Yes	No
CSRR0	Critical Save/ Restore Register 0	58	R/W	Yes	No
CSRR1	Critical Save/ Restore Register 1	59	R/W	Yes	No
DEAR	Data Exception Address Register	61	R/W	Yes	No
ESR	Exception Syndrome Register	62	R/W	Yes	No
IVPR	Interrupt Vector Prefix Register	63	R/W	Yes	No
SPRG0	SPR General 0	272	R/W	Yes	No
SPRG1	SPR General 1	273	R/W	Yes	No
SPRG2	SPR General 2	274	R/W	Yes	No
SPRG3	SPR General 3	275	R/W	Yes	No
PIR	Processor ID Register	286	R/W	Yes	No
PVR	Processor Version Register	287	Read-only	Yes	No
DBSR	Debug Status Register	304	Read/Clear[1]	Yes	No
DBCR0	Debug Control Register 0	308	R/W	Yes	No

Table continues on the next page...

Table 13-2. Special Purpose Registers (continued)

Mnemonic	Name	SPR Number	Access	Privileged	e200z Specific
DBCR1	Debug Control Register 1	309	R/W	Yes	No
DBCR2	Debug Control Register 2	310	R/W	Yes	No
IAC1	Instruction Address Compare 1	312	R/W	Yes	No
IAC2	Instruction Address Compare 2	313	R/W	Yes	No
IAC3	Instruction Address Compare 3	314	R/W	Yes	No
IAC4	Instruction Address Compare 4	315	R/W	Yes	No
DAC1	Data Address Compare 1	316	R/W	Yes	No
DAC2	Data Address Compare 2	317	R/W	Yes	No
DVC1	Data Value Compare 1[2]	318	R/W	Yes	No
DVC2	Data Value Compare 2[2]	319	R/W	Yes	No
SPEFSCR	LSP/EFP APU status and control register	512	R/W	No	No
L1CFG0	L1 cache config register 0	515	Read-only	No	Yes
L1CFG1	L1 cache config register 1	516	Read-only	No	Yes
NPIDR	Nexus 3 Process ID register	517	R/W	No	Yes
DBCR3	Debug control register 3	561	R/W	Yes	Yes
DBCR4	Debug control register 4	563	R/W	Yes	Yes
DBCR5	Debug control register 5	564	R/W	Yes	Yes
IAC5	Instruction Address Compare 5	565	R/W	Yes	Yes
IAC6	Instruction Address Compare 6	566	R/W	Yes	Yes
IAC7	Instruction Address Compare 7	567	R/W	Yes	Yes

Chapter 14
Core description

14.1 Overview of the e200z4201n3 core

The e200z4201n3 is a dual-issue 32-bit *Power ISA 2.06* VLE compliant design with 32-bit general-purpose registers (GPRs). The e200z4201n3 core implements the VLE (variable-length encoding) ISA, providing improved code density. The VLE ISA is further documented in *Power ISA 2.06*, a separate document.

An Embedded Floating-point (EFPU2) APU is provided to support real-time single-precision floating-point embedded numerics operations using the general-purpose registers.

The e200z4201n3 core integrates a pair of integer execution units, a branch control unit, instruction fetch unit, load/store unit, and a multi-ported register file capable of sustaining six read and three write operations per clock cycle. Most integer instructions execute in a single clock cycle. Branch target prefetching is performed by the branch unit to allow single-cycle branches in many cases.

The e200z4201n3 core contains an 8 KB Instruction Cache, and a 4 KB Data Cache, as well as a Nexus Class 3+ real-time debug module with support for program and data trace features as well as extensive trace controls.

A Memory Protection Unit that protects various instruction and data memory areas is also included.

14.2 Register model

This section describes the registers implemented in the e200z4201n3 core. The *Power ISA 2.06* architecture defines register-to-register operations for all computational instructions.

e200z4201n3 extends usage of the general purpose registers to support EFPU operations on the 32-bit GPR registers.

Figure 14-1 and Figure 14-2 show the complete e200z4201n3 register set, all of which are accessible in supervisor mode. Figure 14-3 and Figure 14-4 show the subset of registers accessible in user mode. The number to the right of the special-purpose registers (SPRs) is the decimal number used in the instruction syntax to access the register (for example, the integer exception register (XER) is SPR 1).

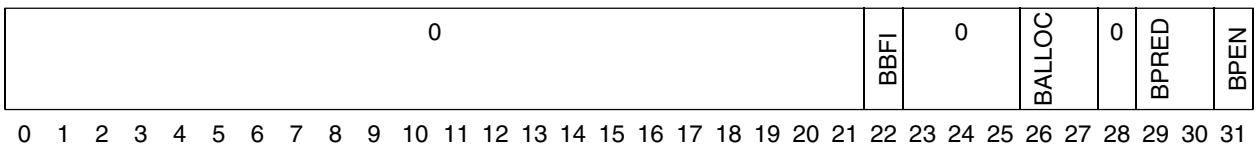
14.2.1 Branch Unit Control and Status Register (BUCSR)

The BUCSR register is used for general control and status of the branch target buffer (BTB). The BTB is detailed in Instruction prefetch buffers and branch target buffer. The BUCSR is shown in the following figure.



SPR — 1013; Read/Write; Reset — 0x0

Figure 14-5. Branch Unit Control and Status Register (BUCSR)

The BUCSR fields are defined in the following table.

Table 14-1. Branch Unit Control and Status Register (BUCSR)

Bits	Name	Description
0:21 [32:53]	-	Reserved
22 [54]	BBFI	Branch target buffer flash invalidate. When written to a '1', BBFI flash clears the valid bit of all entries in the branch target buffer; clearing occurs regardless of the value of the enable bit (BPEN). Note: BBFI is always read as 0.
23:25 [55:57]	-	Reserved
26:27 [58:59]	BALLOC	Branch Target Buffer Allocation Control. This field controls BTB allocation for branch acceleration when BPEN = 1. Note that BTB hits are not affected by the settings of this field. 00 Branch Target Buffer allocation for all branches is enabled. 01 Branch Target Buffer allocation is disabled for backward branches. 10 Branch Target Buffer allocation is disabled for forward branches. 11 Branch Target Buffer allocation is disabled for both branch directions.
28 [60]	-	Reserved
29:30 [61:62]	BPRED	Branch Prediction Control (Static). This field controls operation of static prediction mechanism on a BTB miss. When a branch is predicted as taken, fetching of the predicted target location will be performed for branch acceleration. BPRED operates independently of BPEN, and with a BPEN setting of 0, will be used to perform static prediction of all unresolved branches. 00 Branch predicted taken on BTB miss for all branches. 01 Branch predicted taken on BTB miss only for forward branches. 10 Branch predicted taken on BTB miss only for backward branches. 11 Branch predicted not taken on BTB miss for both branch directions. **NOTE:** BPRED functionality is not supported in e200z4xxx processor cores due to its short pipe stages.

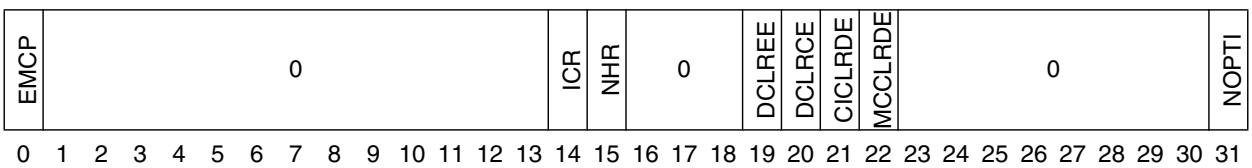
Table continues on the next page...

Table 14-1. Branch Unit Control and Status Register (BUCSR) (continued)

Bits	Name	Description
31 [63]	BPEN	Branch target buffer prediction enable. When the BPEN bit is cleared, no hits will be generated from the BTB, and no new entries will be allocated. Entries are not automatically invalidated when BPEN is cleared; the BBFI bit controls entry invalidation. BPEN operates independently of BPRED, and will be used even with a BPRED setting of 00. 0 Branch target buffer prediction disabled 1 Branch target buffer prediction enabled (enables BTB to predict branches)

14.2.2 Hardware Implementation Dependent Register 0 (HID0)

The HID0 register is a z4201n3 implementation dependent register used for various configuration and control functions. It is shown in the following figure.



SPR - 1008; Read/Write; Reset - 0x0

Figure 14-6. Hardware Implementation Dependent Register 0 (HID0)

The HID0 fields are defined in the following table.

Table 14-2. Hardware Implementation-Dependent Register 0

Bits	Name	Description
0 [32]	EMCP	Enable machine check pin (p_mcp_b) 0 p_mcp_b pin is disabled. 1 p_mcp_b pin is enabled. Asserting p_mcp_b causes a machine check interrupt to be reported.
1:13 [33:45]	-	Reserved
14 [46]	ICR	Interrupt Inputs Clear Reservation 0 External Input, Critical Input, and Non-Maskable Interrupts do not affect reservation status 1 External Input, Critical Input, and Non-Maskable Interrupts clear an outstanding reservation
15 [47]	NHR	Not hardware reset 0 indicates to a reset exception handler that a reset occurred if software had previously set this bit 1 indicates to a reset exception handler that no reset occurred if software had previously set this bit Provided for software use. Set anytime by software, cleared by reset.
16:18	-	Reserved

Table continues on the next page...

Table 14-2. Hardware Implementation-Dependent Register 0 (continued)

Bits	Name	Description
[48:50]		
19 [51]	DCLREE	Debug Interrupt Clears MSREE 0 MSREEunaffected by Debug Interrupt 1 MSREE cleared by Debug Interrupt This bit controls whether Debug interrupts force External Input interrupts to be disabled, or whether they remain unaffected.
20 [52]	DCLRCE	Debug Interrupt Clears MSRCE 0 MSRCE unaffected by Debug Interrupt 1 MSRCE cleared by Debug Interrupt This bit controls whether Debug interrupts force Critical interrupts to be disabled, or whether they remain unaffected.
21 [53]	CICLRDE	Critical Interrupt Clears MSRDE 0 MSRDE unaffected by Critical class interrupt 1 MSRDE cleared by Critical class interrupt This bit controls whether Critical interrupts force Debug interrupts to be disabled, or whether they remain unaffected. Machine Check interrupts have a separate control bit. Note that if Critical Interrupt Debug events are enabled (DBCR0CIRPT set), and MSRDE is set at the time of a Critical Input Critical interrupt, a debug event will be generated after the Critical Interrupt Handler has been fetched, and the Debug handler will be executed first. In this case, DSRR0DE will have been cleared, such that after returning from the debug handler, the Critical interrupt handler will not be run with MSRDE enabled.
22 [54]	MCCLRDE	Machine Check Interrupt Clears MSRDE 0 MSRDE unaffected by Machine Check interrupt 1 MSRDE cleared by Machine Check interrupt This bit controls whether Machine Check interrupts force Debug interrupts to be disabled, or whether they remain unaffected.
23:30 [58:62]	-	Reserved
31 [63]	NOPTI	No-op Touch Instructions 0 icbt, dcbt, dcbtst instructions operate normally 1 icbt, dcbt, dcbtst instructions are no-oped This bit only affects the icbt, dcbt, and dcbtst instructions.

14.2.3 Synchronization requirements for SPRs and DCRs

With the exception of the following registers, there are no synchronization requirements for accessing SPRs and DCRs beyond those stated in PowerISA 2.06. A complete description of Synchronization requirements are contained in Chapter 12 of BookIII-E of PowerISA 2.06. Software requirements for synchronization before/after accessing these

registers are shown in the following table. The notation CSI in the table refers to a Context Synchronizing instruction which include e_sc, se_sc, se_isync, se_rfi, se_rfci, se_rfmci, and se_rfdi.

Table 14-3. Additional synchronization requirements for SPRs and DCRs

Context altering event or instruction		Required before	Required after	Notes
mtmsr[PMM]		none	CSI	
mfspr, mfdcr				
DBSR	Debug Status register	msync	none	
E2EECSR0	End-to-End ECC Error Control and Status Register 0	msync	none	
HID0	Hardware Implementation-Dependent reg 0	none	none

L1FINV0, L1FINV1	L1 cache flush and invalidate control registers 0,1	msync	CSI	
MASx	MPU MAS registers	none	CSI	
MPU0CSR0	MPU control and status register 0	CSI	CSI	
PID (PID0)	PID0 register	CSI	CSI	
SPEFSCR	SPEFSCR register	none	CSI1	

Notes:

1. not required for status bit clearing, required for altering exception enable or rounding mode bits

14.3 Dual-issue operation

The instruction issue unit attempts to issue a pair of instructions to the execution units each cycle. Source operands for each of the instructions are provided from the GPRs or from the operand feed-forward muxes. Data or resource hazards may create stall conditions that cause instruction issue to be stalled for one or more cycles until the hazard is eliminated.

The execution units write the result of a finished instruction onto the proper result bus and into the destination registers. The writeback logic retires an instruction when the instruction has finished execution. As many as three results can be simultaneously written.

Two execution units are provided to allow dual issue of most instructions. Only a single load/store unit is provided. Only a single integer multiply and divide unit is provided, thus a pair of multiply or divide instructions cannot issue simultaneously. In addition, the divide unit is blocking.

The following table shows the concurrent instruction issue capabilities. Note that data dependencies between instructions will generally preclude dual-issue of those instructions.

Table 14-4. Concurrent instruction issue capabilities

Class of instruction	Branch	Load/Store	Scalar integer	Scalar float	Special
Branch	—	yes	yes	yes	—
Load/Store	yes	—	yes	yes	—
Scalar integer	yes	yes	yes[1]	yes[2]	—
Scalar float	yes	yes	yes[2]	—	—
Special	—	—	—	—	—

1. Excludes multiply or divide class instructions occurring in both issue slots.
2. Excludes divide/sqrt class instructions occurring in both issue slots

14.4 Instruction prefetch buffers and branch target buffer

An eight-entry instruction prefetch buffer supplies instructions into the Instruction Register (IR) for decoding. Each slot in the prefetch buffer is 32 bits wide, capable of holding a single 32-bit instruction, or a pair of 16-bit instructions.

Instruction prefetches request a 64-bit doubleword and the prefetch buffer is filled with a pair of instructions at a time, except for the case of a change of flow fetch where the target is to the second (odd) word. In that case only a 32-bit prefetch is performed to load the instruction prefetch buffer. This 32-bit fetch may be immediately followed by a 64-bit prefetch to fill Slots 0 and 1 in the event that the branch is resolved to be taken.

In normal sequential execution, instructions are loaded into the IR from prefetch buffer Slot 0 and 1, and as a pair of slots are emptied, they are refilled. Whenever a pair of slots is empty, a prefetch is initiated which fills the earliest empty slot pairs beginning with Slot 0.

If the instruction prefetch buffer empties, instruction issue stalls, and the buffer is refilled. The first returned instruction is forwarded directly to the IR. Open cycles on the memory bus are utilized to keep the buffer full when possible.

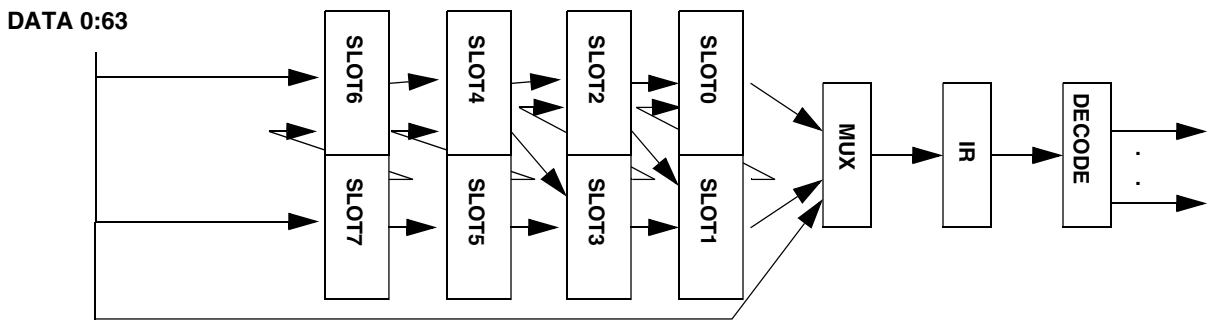

Figure 14-7. Instruction prefetch buffers

To resolve branch instructions and improve the accuracy of branch predictions, the z4201n3 implements a dynamic branch prediction mechanism using an 8-entry branch target buffer (BTB). An entry is allocated in the BTB whenever a branch resolves as taken and the BTB is enabled and misses. Certain branches do not allocate BTB entries: se_bctr, se_bctrl, and se_blrl. Entries in the BTB are allocated on taken branches using a FIFO replacement algorithm.

Each BTB entry holds a branch instruction address tag value, the branch target address, and a 2-bit branch history counter whose value is incremented or decremented on a BTB hit, depending on whether the branch was taken. The counters can assume four different values: strongly taken, weakly taken, weakly not taken, and strongly not taken. On initial allocation of an entry to the BTB for a taken branch, the counter is initialized to the weakly-taken state.

A branch will be predicted as taken on a hit in the BTB with a counter value of strongly or weakly taken. In this case the target address contained in the BTB is used to redirect the instruction fetch stream to the target of the branch prior to the branch reaching the

instruction decode stage. In the case of a BTB miss, static prediction is used to predict the outcome of the branch. In the case of a mispredicted branch, the instruction fetch stream will return to the proper instruction stream after the branch has been resolved.

When a branch is predicted taken and the branch is later resolved (in the branch execute stage), the value of the appropriate BTB counter is updated. If a branch whose counter indicates weakly taken is resolved as taken, the counter increments so that the prediction becomes strongly taken. If the branch resolves as not taken, the prediction changes to weakly not-taken. The counter saturates in the strongly taken states when the prediction is correct.

The z4201n3 does not implement the static branch prediction that is defined by the PowerISA architecture. The BO prediction information in branch encodings is ignored.

Dynamic branch prediction is enabled by setting $BUCSR_{BPEN}$. Allocation of branch target buffer entries may be controlled using the $BUCSR_{BALLOC}$ field to control whether forward or backward branches (or both) are candidates for entry into the BTB, and thus for branch prediction. Once a branch is in the BTB, $BUCSR_{ALLOC}$ has no further effect on that branch entry. Clearing $BUCSR_{BPEN}$ disables dynamic branch prediction, in which case the z4201n3 reverts to a static prediction mechanism using the $BUCSR_{BPRED}$ field to control whether forward or backward branches (or both) are predicted taken or not taken.

The BTB uses instruction fetch addresses for performing tag comparisons. On allocation of a BTB entry, the effective address of a taken branch is loaded into the entry as the tag value, and the counter value is set to weakly taken. The current PID value is not maintained as part of the tag information.

The z4201n3 does support automatic flushing of the BTB when the current PID value is updated by a mtcr PID0 instruction. Software is otherwise responsible for maintaining coherency in the BTB when a change in target address mapping is changed. This is supported by the $BUCSR_{BBFI}$ control bit.

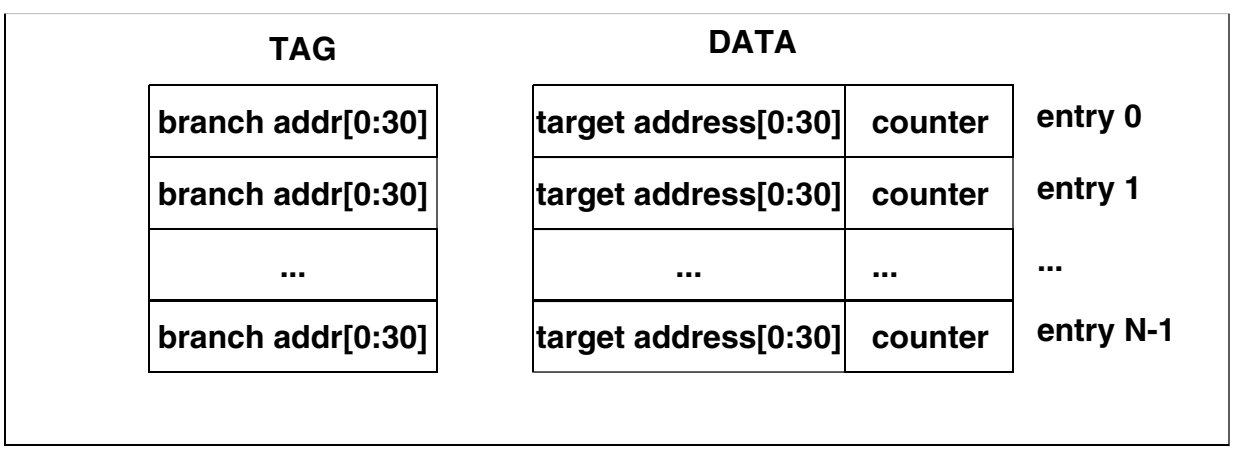

Figure 14-8. Branch target buffer

14.5 Instruction timing

Instruction timing in number of processor clock cycles for various instruction classes is shown in Table 14-5. Pipelined instructions are shown with cycles of total latency and throughput cycles. Divide instructions are not pipelined and block other instructions from executing during execution.

Timing for EFPU instructions is detailed in Table 14-8.

Load/store multiple instruction cycles are represented as a fixed number of cycles plus a variable number of cycles where *n* is the number of words accessed by the instruction. In addition, cycle times marked with & require variable number of additional cycles due to serialization.

Table 14-5. Instruction class cycle counts

Class of Instructions	Latency	Throughput	Special notes
integer: **add**, **sub**, **shift**, **rotate**, **logical**, **cntlzw**	1	1	—
integer: **compare**	1	1	—
Branch	3/2/1	3/2/1	Correct branch lookahead allows single-cycle execution. Worst-case mispredicted branch is 3 cycles.
multiply	2	1	—
divide	4–14	4–14	Data-dependent timing
CR logical	1	1	—
loads (non-multiple)	2	1	—
load multiple	2 + *n*/2 (max)	1 + *n*/2 (max)	Actual timing depends on *n* and address alignment.
stores (non-multiple)	2	1	—
store multiple	2 + *n*/2 (max)	1 + *n*/2 (max)	Actual timing depends on *n* and address alignment.
mtmsr, **wrtee**, **wrteei**	3&	3&	—
mcrf	1	1	—
mfspr, **mtspr**	4&	4&	Applies to Debug SPRs, optional unit SPRs

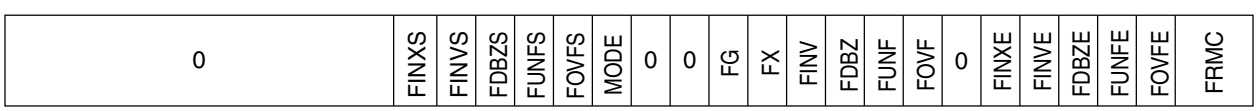
1. Destination register is also a source register, so for full throughput, back-to-back operations must use a different destination register.

14.6 Reservation instructions and cache interactions

If the CPU supports reservation instruction functionality, the CPU treats reservation instruction (**lbarx**, **lharx**, **lwarx**, **stbcx**, **sthcx**, and **stwcx**) accesses as though they were cache-inhibited, and forces a cache miss. A reservation access is always issued to the bus. This is done to allow external reservation logic to be built that properly signals a reservation failure. The bus access will be treated as a single-beat transfer.

14.7 Signal Processing Extension/Embedded Floating-point Status and Control Register (SPEFSCR)

Status and control for embedded floating-point operations use the SPEFSCR. The SPEFSCR is implemented as special-purpose register (SPR) number 512 and is read and written by the mfspr and mtspr instructions. The SPEFSCR is shown in the following figure.



SPR - 512; Read/Write; Reset - 0x0

Figure 14-9. EFPU Status and Control Register (SPEFSCR)

The SPEFSCR bits are defined in the following table.

Table 14-9. EFPU Status and Control Register field descriptions

Bits	Name	Description
0:9 (32:41)	—	Reserved
10	FINXS	Embedded Floating-point Inexact Sticky Flag

Table continues on the next page...

Table 14-9. EFPU Status and Control Register field descriptions (continued)

Bits	Name	Description
(42)		The FINXS bit is set to 1 whenever the execution of a floating-point instruction delivers an inexact result and no Floating-point Data exception is taken, or if the result of a Floating-point instruction results in overflow (FOVF = 1), but Floating-point Overflow exceptions are disabled (FOVFE = 0), or if the result of a Floating-point instruction results in underflow (FUNF = 1), but Floating-point Underflow exceptions are disabled (FUNFE = 0), and no Floating-point Data exception occurs. The FINXS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
11 (43)	FINVS	Embedded Floating-point Invalid Operation Sticky Flag The FINVS bit is set to a 1 when a floating-point instruction sets the FINV bit to 1. The FINVS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
12 (44)	FDBZS	Embedded Floating-point Divide by Zero Sticky Flag The FDBZS bit is set to 1 when a floating-point divide instruction sets the FDBZ bit to 1. The FDBZS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
13 (45)	FUNFS	Embedded Floating-point Underflow Sticky Flag The FUNFS bit is set to 1 when a floating-point instruction sets the FUNF bit to 1. The FUNFS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
14 (46)	FOVFS	Embedded Floating-point Overflow Sticky Flag The FOVFS bit is set to 1 when a floating-point instruction sets the FOVF bit to 1. The FOVFS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
15 (47)	MODE	Embedded Floating-point Operating Mode This bit controls the operating mode of the EFPU. e200z4201n3 Supports only mode 0. Software should read the value of this bit after writing it to determine if the implementation supports the selected mode. Implementations will return the value written if the selected mode is a supported mode, otherwise the value read will indicate the hardware supported mode. 0 Default hardware results operating mode 1 IEEE754 hardware results operating mode (not supported by e200 core)
16 (48)	—	Reserved
17 (49)	—	Reserved
18 (50)	FG	Embedded Floating-point Guard bit FG is supplied for use by the Floating-point Round exception handler. FG is zeroed if a Floating-point Data Exception occurs.
19 (51)	FX	Embedded Floating-point Sticky bit FX is supplied for use by the Floating-point Round exception handler. FX is zeroed if a Floating-point Data Exception occurs.
20 (52)	FINV	Embedded Floating-point Invalid Operation / Input error In mode 0, the FINV bit is set to 1 if the A or B operand of a floating-point instruction is Infinity, NaN, or Denorm, or if the operation is a divide and the dividend and divisor are both 0. In mode 1, the FINV bit is set on an IEEE754 invalid operation (IEEE754-1985 sec7.1).
21 (53)	FDBZ	Embedded Floating-point Divide by Zero The FDBZ bit is set to 1 when a floating-point divide instruction executed with divisor of 0, and the l dividend is a finite non-zero number.

Table continues on the next page...

Table 14-9. EFPU Status and Control Register field descriptions (continued)

Bits	Name	Description
22 (54)	FUNF	Embedded Floating-point Underflow The FUNF bit is set to 1 when the execution of a floating-point instruction results in an underflow.
23 (55)	FOVF	Embedded Floating-point Overflow The FOVF bit is set to 1 when the execution of a floating-point instruction results in an overflow.
24 (56)	—	Reserved
25 (57)	FINXE	Embedded Floating-point Inexact Exception Enable If the exception is enabled, a Floating-point Round exception is taken if the result of a Floating-point instruction does not result in overflow or underflow, and the result is inexact (FG | FX = 1), or if the result of a Floating-point instruction does result in overflow (FOVF = 1) but Floating-point Overflow exceptions are disabled (FOVFE = 0), or if the result of a Floating-point instruction results in underflow (FUNF = 1 or FUNFH = 1) but Floating-point Underflow exceptions are disabled (FUNFE = 0), and no Floating-point Data exception occurs. 0 Exception disabled 1 Exception enabled
26 (58)	FINVE	Embedded Floating-point Invalid Operation / Input Error Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FINV bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled
27 (59)	FDBZE	Embedded Floating-point Divide by Zero Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FDBZ bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled
28 (60)	FUNFE	Embedded Floating-point Underflow Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FUNF bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled
29 (61)	FOVFE	Embedded Floating-point Overflow Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FOVF bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled
30:31 (62:63)	FRMC	Embedded Floating-point Rounding Mode Control 00 Round to Nearest 01 Round toward Zero 10 Round toward +Infinity 11 Round toward -Infinity

14.8 Cache

This section describes the cache registers, cache control instructions, and various cache operations.

14.8.1 Cache overview

The e200z4201n3 processor supports an 8 KB 2-way set-associative instruction and 4KB 2-way set-associative data cache with a 32-byte line size. The caches improves system performance by providing low-latency data to the e200z4201n3 instruction and data pipelines, which decouples processor performance from system memory performance.

The e200z4201n3 processor also contains an 8-entry store buffer to decouple store completion to the processor from store completion on the data interface to further improve system performance.

Instruction and data addresses from the processor are used to index the cache arrays. If the access address matches a valid cache tag entry, the access hits in the cache.

14.8.2 L1 Cache Control and Status Register 0 (L1CSR0)

The L1 Cache Control and Status Register 0 (L1CSR0) is a 32-bit register used for general control of the data cache and for disabling ways in <u>both</u> caches. The L1CSR0 register is accessed using a **mfspr** or **mtspr** instruction. The L1CSR0 register is shown in the following figure.

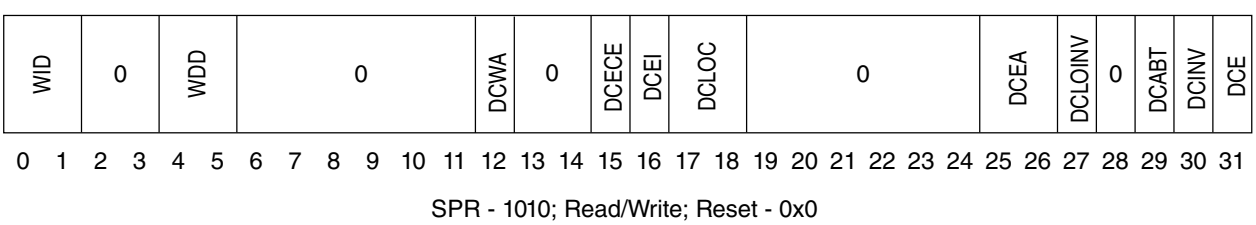


Figure 14-10. L1 Cache Control and Status Register 0 (L1CSR0)

The L1CSR0 fields are described in the following table.

Table 14-10. L1CSR0 field descriptions

Bits	Name	Description
0:1	WID	Way Instruction Disable

Table continues on the next page...

Table 14-10. L1CSR0 field descriptions (continued)

Bits	Name	Description
		Bit 0 corresponds to way 0. Bit 1 corresponds to way 1. The WID bits may be used for locking ways of the instruction cache, and also affect the replacement policy of the instruction cache. 0 The corresponding way in the instruction cache is available for replacement by instruction miss line fills. 1 The corresponding way instruction cache is not available for replacement by instruction miss line fills.
2:3	—	Reserved[1]
4:5	WDD	Way Data Disable Bit 4 corresponds to way 0. Bit 5 corresponds to way 1. The WDD bits may be used for locking ways of the data cache, and also affect the replacement policy of the data cache. 0 The corresponding way in the data cache is available for replacement by data miss line fills. 1 The corresponding way in the data cache is not available for replacement by data miss line fills.
8:11	—	Reserved[1]
12	DCWA	Data Cache Write Allocation Policy This bit also controls merging of store data into the linefill buffer while a cache linefill is in progress. Store data will not be merged when write allocation is disabled. 0 Cache line allocation on a cacheable write miss is disabled 1 Cache line allocation on a cacheable write miss is enabled
13:14	—	Reserved[1]
15	DCECE	Data Cache Error Checking Enable 0 Error Checking is disabled 1 Error Checking is enabled
16	DCEI	Data Cache Error Injection DCEI will cause injection of errors regardless of the setting of DCECE, although reporting of errors will be masked while DCECE = 0. 0 Cache Error Injection is disabled 1 A double-bit error will be injected on each write into the cache data array by inverting the two uppermost parity check bits (p_dchk[0:1]). This includes writes due to store hits as well as writes due to cache line refills.
17:18	DCLOC	Data Cache Lockout Control **Note:** For the **dcbi** and **dcbf** instructions, and for specialized load/store instructions, no lockout operation is performed, regardless of the occurrence of EDC/ECC error conditions, and errors are handled in the same manner as when lockout is disabled.

Table continues on the next page...

Table 14-10. L1CSR0 field descriptions (continued)

Bits	Name	Description
		Note: When operating in MC mode (DCEA = 00), detected errors on cache-inhibited accesses will not cause a data cache line to be locked out, instead the cache line contents are ignored. 00 Cache line lockout is disabled (and array LO indicators are ignored). 01 Cache line lockout is enabled. Cache lines with any tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. 10 Cache line lockout is enabled. Cache lines with any tag or data errors will have the corresponding lockout indicators set. A Machine check will still be generated for an error if the operation would have normally generated one. 11 Cache line lockout is enabled. Cache lines with uncorrectable tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. If a correctable tag error occurs, and is re-detected on recycling the access after a correction cycle for the tag is performed, the line is locked out regardless of detecting a single-bit or multi-bit error.
19:24	—	Reserved[1]
25:26	DCEA	Data Cache Error Action 00 Error Detection causes Machine Check exception. 01 Error Detection causes Correction/Auto-invalidation. No machine check is generated for most cases. Correction is performed for single-bit tag errors, and lines with multi-bit tag errors are invalidated. Correction is performed for single or multi-bit data errors on cache hits by reloading of the line. 10 Reserved 11 Reserved
27	DCLOINV	Data Cache Lockout Indicator Invalidate When written to a 1 in conjunction with writing DCINV to a 1, a cache lockout indicator invalidation operation is initiated by hardware, and the LO bits are cleared, removing all line lockout status. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. Cache lockout bit invalidation operations require approximately 66 cycles to complete. Invalidation occurs regardless of the data cache enable (DCE) value. When DCINV = 0: Reserved, do not set to 1 When DCINV = 1: 0 No cache lockout bit invalidate 1 Cache lockout indicator invalidation operation
28	—	Reserved[1]
29	DCABT	Data Cache Operation Aborted Indicates a Cache Invalidate operation was aborted prior to completion. This bit is set by hardware on an aborted condition, and will remain set until cleared by software writing 0 to this bit location.

Table continues on the next page...

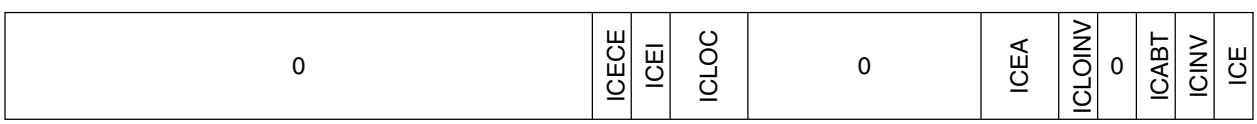
Table 14-10. L1CSR0 field descriptions (continued)

Bits	Name	Description
30	DCINV	Data Cache Invalidate When written to a 1, a cache invalidation operation is initiated by hardware. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. Cache invalidation operations require approximately 66 cycles to complete. Invalidation occurs regardless of the data cache enable (DCE) value. 0 No cache invalidate 1 Cache invalidation operation
31	DCE	Data Cache Enable When disabled, cache lookups are not performed for normal load or store accesses.Other L1CSR0 cache control operations are still available. Also, operation of the store buffer is not affected by DCE. 0 Cache is disabled 1 Cache is enabled

1. These bits are not implemented and should be written with zero for future compatibility.

14.8.3 L1 Cache Control and Status Register 1 (L1CSR1)

The L1 Cache Control and Status Register 1 (L1CSR1) is a 32-bit register used for general control of the instruction cache. The L1CSR1 register is accessed using a **mfspr** or **mtspr** instruction. The L1CSR1 register is shown in the following figure.



SPR - 1011; Read/Write; Reset - 0x0

Figure 14-11. L1 Cache Control and Status Register 1 (L1CSR1)

The L1CSR1 fields are described in the following table.

Table 14-11. L1CSR1 field descriptions

Bits	Name	Description
0:14	—	Reserved[1]
15	ICECE	Instruction Cache Error Checking Enable 0 Error Checking is disabled 1 Error Checking is enabled
16	ICEI	Instruction Cache Error Injection Enable

Table continues on the next page...

Table 14-11. L1CSR1 field descriptions (continued)

Bits	Name	Description
		ICEI will cause injection of errors regardless of the setting of ICECE, although reporting of errors will be masked when ICECE = 0. 0 Cache Error Injection is disabled 1 A double-bit error will be injected into each doubleword written into the cache by inverting the two uppermost parity check bits.
17:18	ICLOC	Instruction Cache Lockout Control **Note:** For the **icbi** instruction, no lockout operation is performed, regardless of the occurrence of EDC/ECC error conditions, and errors are handled in the same manner as when lockout is disabled. See ECC/EDC Error Handling for Cache Control Operations and Instructions. **Note:** When operating in MC mode (ICEA = 00), detected errors on cache-inhibited accesses will not cause an instruction cache line to be locked out, instead the cache line contents are ignored. 00 Cache line lockout is disabled (and array LO indicators are ignored). 01 Cache line lockout is enabled. Cache lines with any tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. 10 Cache line lockout is enabled. Cache lines with any tag or data errors will have the corresponding lockout indicators set. A Machine check will still be generated for an error if the operation would have normally generated one. 11 Cache line lockout is enabled. Cache lines with uncorrectable tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. If a correctable tag error occurs, and is re-detected on recycling the access after a correction cycle for the tag is performed, the line is locked out regardless of detecting a single-bit or multi-bit error.
19:24	—	Reserved[1]
25:26	ICEA	Instruction Cache Error Action 00 Error Detection causes Machine Check exception. 01 Error Detection causes Correction/Auto-invalidation. No machine check is generated for most cases. Correction is performed for single-bit tag errors, and lines with multi-bit tag errors are invalidated. Correction is performed for single or multi-bit data errors on cache hits by reloading of the line. 10 Reserved 11 Reserved
27	ICLOINV	Instruction Cache Lockout Indicator Invalidate When written to a 1 in conjunction with writing ICINV to a 1, a cache lockout indicator invalidation operation is initiated by hardware, and the LO bits are cleared, removing all line lockout status. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation

Table continues on the next page...

Table 14-11. L1CSR1 field descriptions (continued)

Bits	Name	Description
		operation is in progress will be ignored. Cache lockout bit invalidation operations require approximately 66 cycles to complete. Invalidation occurs regardless of the instruction cache enable (ICE) value. When ICINV = 0: Reserved, do not set to 1 When ICINV = 1: 0 No cache lockout bit invalidate 1 Cache lockout indicator invalidation operation
28	—	Reserved[1]
29	ICABT	Instruction Cache Operation Aborted Indicates a Cache Invalidate operation was aborted prior to completion. This bit is set by hardware on an aborted condition, and will remain set until cleared by software writing 0 to this bit location.
30	ICINV	Instruction Cache Invalidate When written to a 1, a cache invalidation operation is initiated by hardware. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. Cache invalidation operations require approximately 130 cycles to complete. Invalidation occurs regardless of the enable (ICE) value. 0 No cache invalidate 1 Cache invalidation operation
31	ICE	Instruction Cache Enable When disabled, cache lookups are not performed for instruction accesses. Other L1CSR1 cache control operations are still available and are not affected by ICE. 0 Cache is disabled 1 Cache is enabled

1. These bits are not implemented and should be written with zero for future compatibility.

14.8.4 L1 Cache Configuration Register 0 (L1CFG0)

The L1 Cache Configuration Register 0 (L1CFG0) is a 32-bit read-only register. L1CFG0 provides information about the configuration of the e200z4201n3 L1 data cache design. The contents of the L1CFG0 register can be read using a **mfspr** instruction. The L1CFG0 register is shown in the following figure.

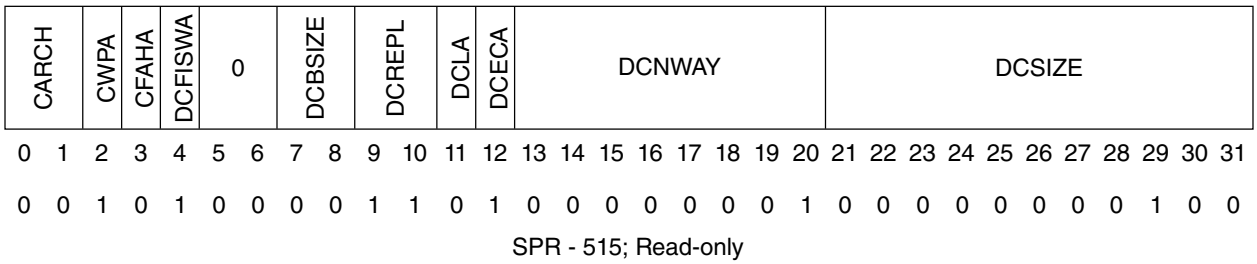


Figure 14-12. L1 Cache Configuration Register 0 (L1CFG0)

The L1CFG0 bits are described in the following table.

Table 14-12. L1CFG0 field descriptions

Bits	Name	Description
0:1	CARCH	Cache Architecture 00 The cache architecture is Harvard
2	CWPA	Cache Way Partitioning Available 1 The caches support partitioning of way availability for I/D accesses
3	DCFAHA	Data Cache Flush All by Hardware Available 0 The data cache does not support Flush All in Hardware
4	DCFISWA	Data Cache Flush/Invalidate by Set and Way Available 1 The data cache supports invalidation by Set and Way via L1FINV0
5:6	—	Reserved - read as zeros
7:8	DCBSIZE	Data Cache Block Size 00 The data cache implements a block size of 32 bytes
9:10	DCREPL	Data Cache Replacement Policy 11 The data cache implements a FIFO replacement policy
11	DCLA	Data Cache Locking APU Available 0 The data cache does not implement the line locking APU
12	DCECA	Data Cache Error Checking Available 1 The data cache implements error checking
13:20	DCNWAY	Data Cache Number of Ways 0x01 The data cache is 2-way set-associative
21:31	DCSIZE	Data Cache Size 0x004 The size of the data cache is 4 KB

14.8.5 L1 Cache Configuration Register 1 (L1CFG1)

The L1 Cache Configuration Register 1 (L1CFG1) is a 32-bit read-only register. L1CFG1 provides information about the configuration of the e200z4201n3 L1 instruction cache design. The contents of the L1CFG1 register can be read using a **mfspr** instruction. The L1CFG1 register is shown in the following figure.

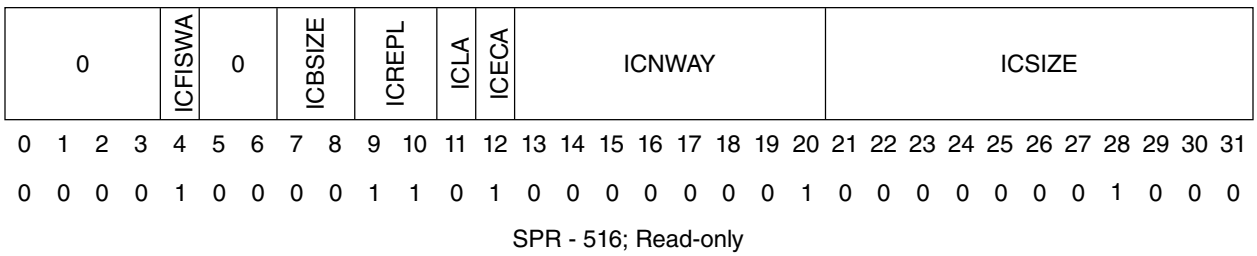

Figure 14-13. L1 Cache Configuration Register 1 (L1CFG1)

The L1CFG1 fields are described in the following table.

Table 14-13. L1CFG1 field descriptions

Bits	Name	Description
0:3	—	Reserved - read as zeros
4	ICFISWA	Instruction Cache Flush/Invalidate by Set and Way Available 1 The instruction cache supports invalidation by Set and Way via L1FINV1
5:6	—	Reserved - read as zeros
7:8	ICBSIZE	Instruction Cache Block Size 00 The instruction cache implements a block size of 32 bytes
9:10	ICREPL	Instruction Cache Replacement Policy 11 The instruction cache implements a FIFO replacement policy
11	ICLA	Instruction Cache Locking APU Available 0 The instruction cache does not implement the line locking APU
12	ICECA	Instruction Cache Error Checking Available 1 The instruction cache implements error checking
13:20	ICNWAY	Instruction Cache Number of Ways 0x01 The instruction cache is 2-way set-associative
21:31	ICSIZE	Instruction Cache Size 0x008 The size of the instruction cache is 8 KB

14.8.6 Data Cache Software Coherency

Data cache coherency is supported through software operations to invalidate lines using either a **dcbi** or **dcbf** instruction, or by using the L1FINV0 control register.

Data cache misses will force the store buffer to empty prior to performing the access.

14.8.7 Data Cache Hardware Coherency

Data cache coherency is not supported in hardware. Software operations must generally be used to maintain coherency. Debug support is provided, however, for a D-Cache line invalidation operation requested by an external hardware debugger. When requested by an external hardware debugger tool operating through the OnCE port, an individual cache line invalidation operation will be scheduled to occur at the next available D-Cache access cycle.

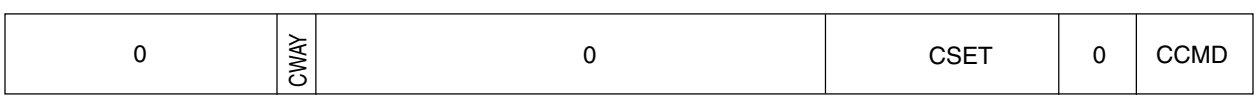
14.8.8 Cache Invalidate by Set and Way

e200z4201n3 supports cache set/way invalidation under software control. The caches may be invalidated by index and way through a **mtspr l1finv{0,1}** instruction.

The L1 Flush and Invalidate Control Registers (L1FINV{0,1}) are 32-bit SPRs used to select a cache set and way to be invalidated. This function is available even when a cache is disabled. L1FINV0 is used for data cache operations, while L1FINV1 is used for instruction cache operations.

14.8.8.1 L1FINV0

The SPR number for L1FINV0 is 1016 in decimal. The L1FINV0 register is shown in the following figure.



SPR - 1016; Read/Write; Reset - 0x0

Figure 14-14. L1 Flush/Invalidate Register 0 (L1FINV0)

The L1FINV0 bits are described in the following table.

Table 14-14. L1FINV0 field descriptions

Bits	Name	Description
0:6	—	Reserved[1] for way extension
7	CWAY	Cache Way Specifies the data cache way to be selected

Table continues on the next page...

Table 14-14. L1FINV0 field descriptions (continued)

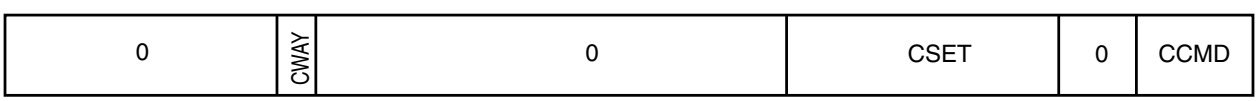
Bits	Name	Description
8: 20	—	Reserved[1] for set extension
21 :26	CSET	Cache Set Specifies the cache set to be selected
27:28	—	Reserved[1] for set/command extension
29:31	CCMD	Cache Command 000 = The data contained in this entry is invalidated. LO bits are unaffected 001 Reserved 01x Reserved 100 Reserved 101 The data contained in this entry is invalidated. LO bits are cleared 11x Reserved

1. These bits are not implemented and should be written with zero for future compatibility.

For invalidation operations via L1FINV0, tag ECC errors and data EDC errors are ignored, and the selected line will be invalidated regardless of any error. Invalidations conditionally affect the state of the lockout bits (LO).

14.8.8.2 L1FINV1

The L1FINV1 register is shown in following figure.



SPR - 959; Read/Write; Reset - 0x0

Figure 14-15. L1 Flush/Invalidate Register 1 (L1FINV1)

The L1FINV1 bits are described in the following table.

Table 14-15. L1FINV1 field descriptions

Bits	Name	Description
0:6	—	Reserved[1] for way extension
7	CWAY	Cache Way Specifies the instruction cache way to be selected
8: 19	—	Reserved[1] for set extension
20 :26	CSET	Cache Set

Table continues on the next page...

Table 14-15. L1FINV1 field descriptions (continued)

Bits	Name	Description
		Specifies the instruction cache set to be selected
27:28	—	Reserved[1] for set/command extension
29:31	CCMD	Cache Command 000 The data contained in this entry is invalidated. LO bits are unaffected 001 Reserved 01x Reserved 100 Reserved 101 The data contained in this entry is invalidated. LO bits are cleared 11x Reserved

1. These bits are not implemented and should be written with zero for future compatibility.

For invalidation operations via L1FINV1, tag ECC errors and data EDC errors are ignored, and the selected line will be invalidated regardless of any error. Invalidations conditionally affect the state of the lockout bits (LO).

14.8.9 Cache EDC/ECC Parity Protection

Cache parity protection is supported for both the tag and data arrays of each cache. Seven parity check bits are provided for each tag entry for the tag arrays of both caches to support error detection and correction (ECC - SECDED). Eight parity check bits are provided for each doubleword in the data arrays of the I-Cache, and each word in the data arrays of the D-Cache, which are used for single- and double-bit error detection (EDC - DED, double error detection). Utilizing ECC/EDC protection, many multi-bit errors are also detected.

The error detection codes also cover the cache index address of the cache line, providing additional protection against addressing errors. If any type of error (including a single-bit error in one of the index bits) is encountered in one of the index address bits, it is treated as an uncorrectable tag ECC error to protect against internal addressing failures. No attempt will be made to correct single-bit errors where the syndrome indicates an index address bit.

Tag ECC and data EDC checking is controlled by the L1CSR0[DCECE] and L1CSR1[ICECE] control fields. When error checking is enabled, checking is performed on each cache access. Errors are not signaled by the respective cache when cache error checking is disabled for that cache ($L1CSR\{0,1\}_{[D,I]CECE} = 0$).

If an uncorrectable tag ECC error is detected on any portion of a tag accessed during cache lookups performed because of instruction fetching, normal loads, or normal stores a tag ECC error is signaled, regardless of whether a cache hit or miss occurs. Otherwise, if a cache hit for an instruction fetch or a normal load occurs and a data EDC error is detected on any portion of the accessed data, a parity error is also signaled.

Store hits to the D-Cache will be placed into one of the RMW buffers to support EDC checkbit operation. If the store is a partial-width store, the cache data word corresponding to the address of the store is read into the next available buffer, the store data is merged, and the new EDC checkbits for the word are calculated. If the store is a full-width store, no read of the cache data is performed, since the store will overwrite the full EDC data granularity, and the EDC checkbits can be computed directly. Buffers are managed on a FIFO basis. If no buffer is available to hold the store data, a stall is incurred while a buffer (or two if possible) is written back to the cache to be freed for holding the new store. Buffers are written back to the D-Cache during otherwise idle cycles when two buffers are occupied, providing a simple form of store gathering.

Signaling of an ECC error or EDC error may cause a Machine Check exception to occur. One or more syndrome bits may be set in the Machine Check Syndrome register, or may instead result in a correction/auto-invalidation operation and not result in an exception being signaled. Both may occur, depending on the error action control setting in the appropriate cache control register.

14.8.9.1 Cache Line Lockout

In addition to the ECC/EDC protection employed for the caches, each cache line in the I-Cache and D-Cache has a lockout indicator composed of a redundant set of lockout bits. These lockout bits can selectively be set when certain errors occur in either the tag or the data portion of the cache line. Use of the lockout function and control over error conditions that cause a lockout to occur are controlled by $L1CSR\{0,1\}_{[D,I]CLOC}$. When the lockout function is enabled, lines that encounter selected tag ECC or data EDC errors on normal instruction fetch, load, or store accesses will have their lockout bits set. When the lockout indicator is set, the line will not be replaced and will remain in an invalid state, effectively disabling it. Also, future tag ECC or data EDC errors on the line are ignored. Cache-inhibited accesses will only set lockout indicators on lines not in a locked way. In addition, no lockout indicators are set by cache-inhibited accesses when operating in machine check mode.

When operating in machine check mode, if lockout controls are enabled via $L1CSR\{0,1\}_{[D,I]CLOC}$, lockout bit parity errors on any line detected on a cacheable cache lookup will generate a machine check exception.

If correction/auto-invalidation is instead enabled, on each cache lookup operation for an instruction fetch or normal load or store access, if a single- or double-bit lockout bit parity error is detected in one or more ways and lockout controls are enabled, the lockout error(s) will be corrected by rewriting all lockout bits to the asserted state, and no machine check is generated, unless the line is in a locked way. If a line in a locked way incurs a LO bit parity error, a machine check will be generated to ensure that any possible new lockout of the line is reported. For non-cacheable accesses, lockout bit parity errors will only be corrected for lines not in a locked way. Lockout bit parity errors do not generate a machine check for non-cacheable accesses in either error action mode, thus lockout bit correction is not performed for lockout bit parity errors detected on a line in a locked way.

In addition, to avoid certain exception conditions and for consistency with error reporting, specialized load/store accesses do not set LO bits; instead, cache contents are ignored for lines with those errors. Cache flush and invalidate instructions do not report or correct lockout bit parity errors. For both of these cases, a future cacheable normal access will perform the lockout function if required.

14.8.10 Cache Error Injection

Cache error injection provides a way to test error recovery by intentionally injecting parity errors into the instruction and/or data cache.

Error injection into the instruction cache operates as follows:

- If $L1CSR1_{ICEI}$ is set, any instruction cache line fill to the instruction cache data has the associated two most significant parity check bits inverted in the instruction cache data array for each doubleword loaded.

Error injection for the data cache operates as follows:

- If $L1CSR0_{DCEI}$ is set, any cache line fill to the data cache data array has the associated two most significant parity check bits inverted in the data array for each word loaded. Additionally, inverted parity bits are generated for any data stored into the data cache data array on a store hit.

Cache parity error injection is not performed for cache debug write accesses, since parity bit values written can be directly controlled.

In order to clear the parity errors, a cache invalidation or an invalidation of the lines that could have had an injected parity error may be performed. Line invalidation may be performed by an **icbi/dcbi** instruction or an L1FINV{0,1} invalidation operation.

14.9 Exceptions

Interrupts implemented in e200z4201n3 and the exception conditions that cause them are listed in the following table.

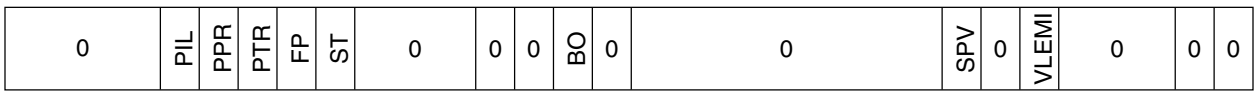
Table 14-16. Exceptions and Conditions

Interrupt type	Interrupt vector offset value	Causing conditions
System reset	none, vector to [p_rstbase[0:29]] || 2'b00	Reset
Critical Input	0x00[1]	**p_critint_b** is asserted and MSR_{CE} = 1.
Machine check	0x10	1. **p_mcp_b** transitions from negated to asserted 2. ISI or Bus Error on first instruction fetch for an exception handler 3. Parity Error signaled on Cache access 4. Parity Error signaled on Local Memory access 5. External bus error 6. Stack limit check failure
Machine check (NMI)	0x10	Non-Maskable Interrupt
Data Storage	0x20	Access control
Instruction Storage	0x30	Access control
External Input	0x40[2]	Interrupt Controller interrupt and MSR_{EE} = 1
Alignment	0x50	1. **lmw**, **stmw** not word aligned 2. **lwarx** or **stwcx.** not word aligned, **lharx** or **sthcx.** not halfword aligned 3. **dcbz**
Program	0x60	Illegal, Privileged, Trap
Performance Monitor	0x70	Performance Monitor Enabled Condition or Event w/$PMGC0_{UDI}$ = 0
System call	0x80	Execution of the System Call (**se_sc**) instruction
Debug	0x90	Trap, Instruction Address Compare, Data Address Compare, Instruction Complete, Branch Taken, Return from Interrupt, Interrupt Taken, Debug Counter, External Debug Event, Unconditional Debug Event, Performance Monitor Enabled Condition or Event w/$PMGC0_{UDI}$ = 1
EFPU Data Exception	0xA0	Embedded Floating-point Data Exception
EFPU Round Exception	0xB0	Embedded Floating-point Round Exception
TBD	0xC0–0xF0	Reserved for future processor use

1. Autovectored Critical Input interrupts use this offset value. Vectored interrupts supply an interrupt vector offset directly.
2. Autovectored External Input interrupts use this offset value. Vectored interrupts supply an interrupt vector offset directly.

14.9.1 Exception Syndrome Register (ESR)

The Exception Syndrome Register (ESR) provides a *syndrome* to differentiate between exceptions that can generate the same interrupt type.



SPR - 62; Read/Write; Reset - 0x0

Figure 14-16. Exception Syndrome Register (ESR)

The ESR bits are defined in the following table.

Table 14-17. ESR field descriptions

Bit(s)	Name	Description	Associated interrupt type
0:3	—	Reserved	—
4	PIL	Illegal Instruction exception For e200z4201n3, PIL is used for both illegal and unimplemented instructions.	Program
5	PPR	Privileged Instruction exception	Program
6	PTR	Trap exception	Program
7	FP	Floating-point operation	Program
8	ST	Store operation	Alignment Data Storage
9:11	—	Reserved	—
12	—	Reserved	—
13	—	Reserved	—
14	BO	Byte Ordering exception Mismatched Instruction Storage exception	Instruction Storage
15	—	Reserved	—
16:23	—	Reserved	—
24	SPV	EFPU APU Operation	EFPU Floating-point Data Exception EFPU Floating-point Round Exception Alignment Data Storage
25	—	Reserved	—
26	VLEMI	VLE Mode Instruction	EFPU Floating-point Data Exception EFPU Floating-point Round Exception Data Storage Instruction Storage

Table continues on the next page...

Bit(s)	Name	Description	Associated interrupt type
			Alignment Program System Call
27:29	—	Reserved	—
30	—	Reserved	—
31	—	Reserved	—

14.9.2 Machine State Register (MSR)

The Machine State Register defines the state of the processor. The e200z4201n3 MSR is shown in the following figure.

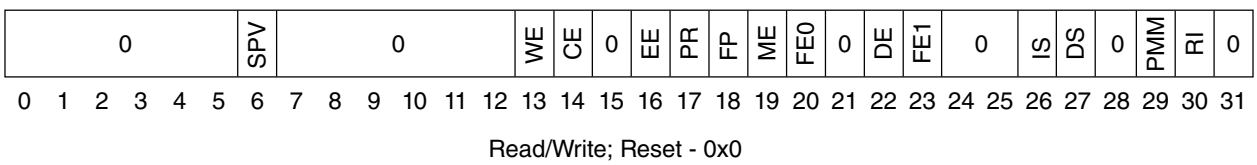

Figure 14-17. Machine State Register (MSR)

The MSR bits are defined in the following table.

Table 14-18. MSR field descriptions

Bit(s)	Name	Description
0:5	—	Reserved
6	SPV	SP/Embedded FP/Vector available 0 SP/Embedded FP Double/Vector unit is unavailable. The processor cannot execute SP/Embedded FP Double or Vector Unit instructions. 1 SP/Embedded FP Double/Vector unit is available. The processor can execute SP/Embedded FP Double or Vector Unit instructions. **NOTE:** The e200z4201n3 processor does not support these units in hardware. An Illegal Instruction exception is generated for attempted execution of these instructions regardless of the setting of SPV. SPV is ignored, but cleared on exceptions.
7:12	—	Reserved
13	WE	Wait State (Power management) enable. **NOTE:** this bit is implementation dependent and is being phased out. It will be removed in a future release. Currently it is implemented as a writeable bit, and is ignored, but cleared on exceptions.
14	CE	Critical Interrupt Enable 0 Critical Input interrupts are disabled. 1 Critical Input interrupts are enabled.

Table continues on the next page...

Table 14-18. MSR field descriptions (continued)

Bit(s)	Name	Description
15	—	Reserved
16	EE	External Interrupt Enable 0 External Input interrupts are disabled. 1 External Input interrupts are enabled.
17	PR	Problem State 0 The processor is in supervisor mode, can execute any instruction, and can access any resource (e.g. GPRs, SPRs, MSR, etc.). 1 The processor is in user mode, cannot execute any privileged instruction, and cannot access any privileged resource.
18	FP	Floating-Point Available 0 Floating point unit is unavailable. The processor cannot execute floating-point instructions, including floating-point loads, stores, and moves. 1 Floating Point unit is available. The processor can execute floating-point instructions. **NOTE:** The e200z4201n3 processor does not support the PowerISA 2.06 floating point unit in hardware, and an Illegal Instruction exception is generated for attempted execution of PowerISA 2.06 floating point instructions regardless of the setting of FP. FP is ignored, but cleared on exceptions.
19	ME	Machine Check Enable 0 Asynchronous Machine Check interrupts are disabled. 1 Asynchronous Machine Check interrupts are enabled.
20	FE0	Floating-point exception mode 0 (not used) **NOTE:** The e200z4201n3 processor does not support the PowerISA 2.06 floating point unit in hardware, thus FE0 is ignored, but cleared on exceptions.
21	—	Reserved
22	DE	Debug Interrupt Enable 0 Debug interrupts are disabled. 1 Debug interrupts are enabled.
23	FE1	Floating-point exception mode 1 (not used) **NOTE:** The e200z4201n3 processor does not support the PowerISA 2.06 floating point unit in hardware, thus FE1 is ignored, but cleared on exceptions.
24:25	—	Reserved
26	IS	Instruction Address Space 0 The processor directs all instruction fetches to address space 0. 1 The processor directs all instruction fetches to address space 1. **NOTE:** The e200z4201n3 processor does not support Address Spaces, thus the IS bit is ignored, but cleared on exceptions.
27	DS	Data Address Space 0 The processor directs all data storage accesses to address space 0. 1 The processor directs all data storage accesses to address space 1.

Table continues on the next page...

Table 14-18. MSR field descriptions (continued)

Bit(s)	Name	Description
		NOTE: The e200z4201n3 processor does not support Address Spaces, thus the DS bit is ignored, but cleared on exceptions.
28	—	Reserved
29	PMM	PMM Performance monitor mark bit System software can set PMM when a marked process is running to enable statistics to be gathered only during the execution of the marked process. MSR_{PR} and MSR_{PMM} together define a state that the processor (supervisor or user) and the process (marked or unmarked) may be in at any time. If this state matches an individual state specified in the PMLCa*n* Performance Monitor registers, the state for which monitoring is enabled, counting is enabled.
30	RI	Recoverable Interrupt This bit is provided for software use to detect nested machine check exception conditions. This bit is cleared by hardware when a Machine Check interrupt is taken.
31	—	Reserved

14.9.3 Machine Check Syndrome Register (MCSR)

When the processor takes a machine check interrupt, it updates the Machine Check Syndrome Register (MCSR) to differentiate between machine check conditions. The MCSR is shown in the following figure.

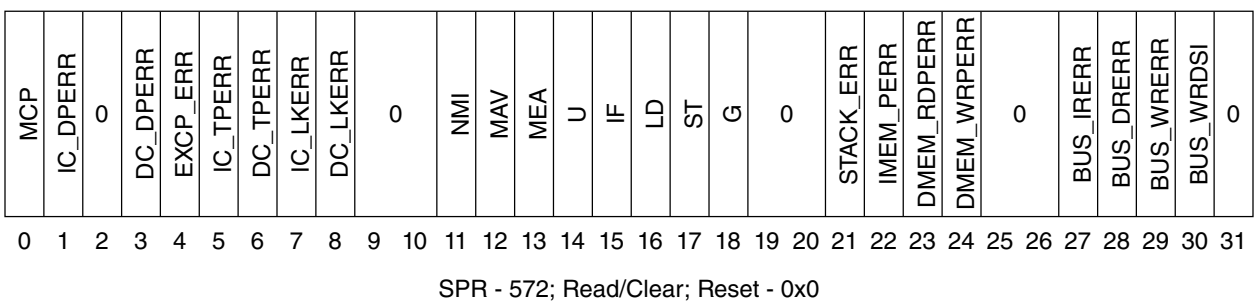

Figure 14-18. Machine Check Syndrome Register (MCSR)

The following table describes MCSR fields. The MCSR indicates the source of a machine check condition.

All bits in the MCSR are implemented as "write 1 to clear." Software in the machine check handler is expected to clear the MCSR bits it has sampled prior to re-enabling MSR_{ME} to avoid a redundant machine check exception and to prepare for updated status bit information on the next machine check interrupt.

Note that any set bit in the MCSR other than status-type bits will cause a subsequent machine check interrupt once $MSR_{ME} = 1$.

Table 14-19. Machine Check Syndrome Register (MCSR) field descriptions

Bit	Name	Description	Exception type[1]	Recoverable
0	MCP	Machine check input pin	Async Mchk	Maybe
1	IC_DPERR	Instruction Cache data array parity error	Async Mchk	Precise
2	—	Reserved	—	—
3	DC_DPERR	Data Cache data array parity error	Async Mchk	Maybe
4	EXCP_ERR	ISI or Bus Error on first instruction fetch for an exception handler	Async Mchk	Precise
5	IC_TPERR	Instruction Cache Tag parity error	Async Mchk	Precise
6	DC_TPERR	Data Cache Tag parity error	Async Mchk	Maybe
7	IC_LKERR	Instruction Cache Lock error Indicates a cache control operation or invalidation operation invalidated one or more lines in a locked way of the I-Cache for certain situations. May also be set on locked line refill error.	Async Mchk	—
8	DC_LKERR	Data Cache Lock error Indicates a cache control operation or invalidation operation invalidated one or more lines in a locked way of the D-Cache for certain situations. May also be set on locked line refill error.	Async Mchk	—
9:10	—	Reserved	—	—
11	NMI	NMI input pin	NMI	—
12	MAV	MCAR Address Valid Indicates that the address contained in the MCAR was updated by hardware to correspond to the first detected Async Mchk error condition	Status	—
13	MEA	MCAR holds Effective Address If MAV = 1, MEA = 1 indicates that the MCAR contains an effective address and MEA = 0 indicates that the MCAR contains a physical address[2]	Status	—
14	U	User Indicates the value captured in MCAR was generated in user mode.	Status	—
15	IF	Instruction Fetch Error Report An error occurred during the fetch of an instruction and the instruction attempted to execute. This could be due to an internal parity error, or an external bus error. MCSRR0 contains the instruction address.	Error Report	Precise
16	LD	Load type instruction Error Report An error occurred during the attempt to execute the load type instruction located at the address stored in MCSRR0. This could be due to an internal parity error, stack limit check error, or an external bus error.	Error Report	Precise

Table continues on the next page...

Table 14-19. Machine Check Syndrome Register (MCSR) field descriptions (continued)

Bit	Name	Description	Exception type[1]	Recoverable
17	ST	Store type instruction Error Report An error occurred during the attempt to execute the store type instruction located at the address stored in MCSRR0. This could be due to an internal parity error, stack limit check error, or on certain external bus errors.	Error Report	Precise
18	G	Guarded instruction Error Report An error occurred during the attempt to execute the load or store type instruction located at the address stored in MCSRR0 and the access was guarded and encountered an error on the external bus, or an uncorrectable DMEM error.	Error Report	Precise
19:20	—	Reserved	—	—
21	STACK_ERR	Stack Access Limit Check Error Indicates a limit check failure on a CPU data access using R1 in the <EA> calculation.	Async Mchk	Precise
22	IMEM_PERR[3]	Instruction Mem (IMEM) Parity Error Indicates an uncorrectable error in the IMEM on a CPU port access.	Async Mchk	Precise
23	DMEM_RDPERR	Data Mem (DMEM) Parity Error Indicates an uncorrectable error in the DMEM on a CPU port read access.	Async Mchk	Precise
24	DMEM_WRPERR	Data Mem (DMEM) Write Parity Error Indicates an uncorrectable error in the DMEM on a CPU port write access.	Async Mchk	Maybe
25:26	—	Reserved	—	—
27	BUS_IRERR	Read bus error on Instruction recovery linefill	Async Mchk	Precise if data used
28	BUS_DRERR	Read bus error on data load or linefill	Async Mchk	Precise if data used
29	BUS_WRERR	Write bus error on store to bus or DMEM imprecise write error	Async Mchk	Unlikely
30	BUS_WRDSI	Write bus error on buffered store to bus with DSI signaled. Set concurrently with BUS_WRERR for this case	Async Mchk	Unlikely
31	—	Reserved	—	—

1. The Exception Type indicates the exception type associated with a given syndrome bit.
   - "Error Report" indicates that this bit is only set for error report exceptions which cause machine check interrupts. These bits are only updated when the machine check interrupt is actually taken. Error report exceptions are not gated by MSR_{ME}. These are synchronous exceptions. These bits will remain set until cleared by software writing a '1' to the bit position(s) to be cleared.
   - "Status" indicates that this bit provides additional status information regarding the logging of a machine check exception. These bits will remain set until cleared by software writing a '1' to the bit position(s) to be cleared.

- "NMI" indicates that this bit is only set for the non-maskable interrupt type exception which causes a machine check interrupt. This bit is only updated when the machine check interrupt is actually taken. NMI exceptions are not gated by MSR_{ME}. This is an asynchronous exception. This bit will remain set until cleared by software writing a '1' to the bit position.
- "Async Mchk" indicates that this bit is set for an asynchronous machine check exception. These bits are set immediately upon detection of the error. Once any "Async Mchk" bit is set in the MCSR, a machine check interrupt will occur if MSR_{ME} = 1. If MSR_{ME} = 0, the machine check exception will remain pending. These bits will remain set until cleared by software writing a '1' to the bit position(s) to be cleared.

2. Note that since no address translation mechanism is present on e200z4201n3, the MEA value is always set to '0'.
3. Will not be set by e200z4201n3 since no local instruction memory is present.

14.9.4 Interrupt Vector Prefix Registers (IVPR)

The Interrupt Vector Prefix Register is used during interrupt processing for determining the starting address of a software handler used to handle an interrupt. The value of the Vector Offset selected for a particular interrupt type is concatenated with the Vector Base value held in the IVPR to form an instruction address from which execution is to begin. The format of IVPR is shown in the following figure.

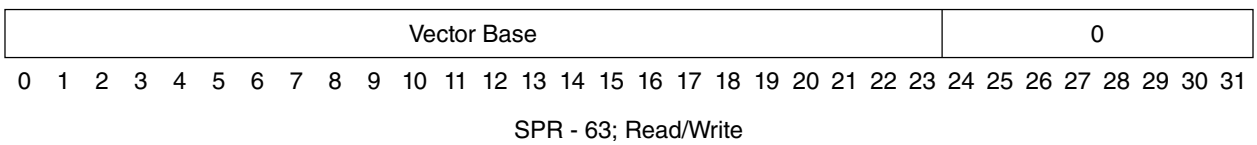

Figure 14-19. Interrupt Vector Prefix Register (IVPR)

The IVPR fields are defined in the following table.

Table 14-20. IVPR field descriptions

Bit(s)	Name	Description
0:23 (32:55)	Vector Base	Vector Base This field is used to define the base location of the vector table, aligned to a 256-byte boundary. This field provides the high-order 24 bits of the location of all interrupt handlers (unless hardware vectoring is used). The vector offset value appropriate for the type of exception being processed is concatenated with the IVPR Vector Base to form the address of the handler in memory. For hardware-vectored interrupts, the value of the supplied interrupt vector is logically OR'ed with the low order bits of the Vec Base Field to determine the interrupt handler address.
24:31 (56:63)	—	Reserved

14.9.5 Interrupt Definitions

14.9.5.1 Critical Input Interrupt (offset 0x00)

A Critical Input exception is signaled to the processor by the assertion of the critical interrupt pin. If the exception is enabled by MSR_{CE}, the Critical Input interrupt is taken.

A Critical Input interrupt may be delayed by other higher priority exceptions or if MSR_{CE} is cleared when the exception occurs.

The following table lists register settings when a Critical Input interrupt is taken.

Table 14-21. Critical Input Interrupt—register settings

Register	Setting description					
CSRR0	Set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.					
CSRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0
	WE	0	ME	—	IS	0
	CE	0	FE0	0	DS	0
	EE	0	DE	—/0[1]	PMM	0
	PR	0			RI	—
ESR	Unchanged					
MCSR	Unchanged					
DEAR	Unchanged					
Vector	$IVPR_{0:23}$ || 0x00 (autovectored) $IVPR_{0:15}$ || (IVPR16:29 | **p_voffset[0:13]**) || 2'b00 (non-autovectored)					

1. Clearing of DE is optionally supported by control in HID0.

The MSR_{DE} bit is not automatically cleared by a Critical Input interrupt, but it can be configured to be cleared via the HID0 register ($HID0_{CICLRDE}$).

14.9.5.2 Machine Check Interrupt (offset 0x10)

The EIS Machine Check APU defines a separate set of save/restore registers (MCSRR0/1), a Machine Check Syndrome Register (MCSR) to record the source(s) of machine checks, and a Machine Check Address Register (MCAR) to hold an address associated with a machine check for certain classes of machine checks. Return from Machine Check instructions (**se_rfmci**) are also provided to support returns using MCSRR0/1.

The MSR_{DE} bit is not automatically cleared by a Machine Check exception, but it can be configured to be cleared or left unchanged via the HID0 register ($HID0_{MCCLRDE}$).

When a Machine Check interrupt is taken, registers are updated as shown in the following table.

Table 14-22. Machine Check Interrupt—register settings

Register	Setting description					
MCSRR0	On a best-effort basis, set to the address of some instruction that was executing or about to be executing when the machine check condition occurred.					
MCSRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0
	WE	0	ME	0	IS	0
	CE	0	FE0	0	DS	0
	EE	0	DE	0/—[1]	PMM	0
	PR	0			RI	0
ESR	Unchanged					
MCSR	Updated to reflect the source(s) of a machine check. Hardware only sets appropriate bits, no previously set bits are cleared by hardware.					
Vector	$IVPR_{0:23}$ || 0x10					

1. Clearing of DE is optionally supported by control in HID0.

14.9.5.3 Data Storage Interrupt (offset 0x20)

A Data Storage interrupt (DSI) may occur if no higher priority exception exists and a Read or Write Access Control exception condition exists.

The following table lists register settings when a DSI is taken.

Table 14-23. Data Storage Interrupt—register settings

Register	Setting description					
SRR0	Set to the effective address of the excepting load/store instruction.					
SRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0
	WE	0	ME	—	IS	0
	CE	—	FE0	0	DS	0
	EE	0	DE	—	PMM	0
	PR	0			RI	—
ESR	Access:		[ST], [SPV], VLEMI. All other bits cleared.			
MCSR	Unchanged					
DEAR	For Access Control exceptions, set to the effective address of the access that caused the violation.					
Vector	$IVPR_{0:23}$ || 0x20					

14.9.5.4 Instruction Storage Interrupt (offset 0x30)

An Instruction Storage interrupt (ISI) occurs when no higher priority exception exists and an Execute Access Control exception occurs.

The following table lists register settings when an ISI is taken.

Table 14-24. Instruction Storage Interrupt—register settings

Register	Setting description					
SRR0	Set to the effective address of the excepting instruction.

DEAR	Unchanged					
Vector	$IVPR_{0:23}$ || 0x30					

14.9.5.5 External Input Interrupt (offset 0x40)

An External Input exception is signaled to the processor by the assertion of an interrupt from the interrupt controller. The input is a level-sensitive signal expected to remain asserted until the core acknowledges the external interrupt. If the input is negated early, recognition of the interrupt request is not guaranteed. When the core detects the exception, if the exception is enabled by MSR_{EE}, it takes the External Input interrupt.

An External Input interrupt may be delayed by other higher priority exceptions or if MSR_{EE} is cleared when the exception occurs.

The following table lists register settings when an External Input interrupt is taken.

Table 14-25. External Input Interrupt—Register Settings

Register	Setting description					
SRR0	Set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.

14.9.5.6 Alignment Interrupt (offset 0x50)

An Alignment exception is generated when any of the following occurs:

- The operand of **lmw** or **stmw** is not word aligned.
- The operand of **lwarx** or **stwcx.** is not word aligned.
- The operand of **lharx** or **sthcx.** is not halfword aligned.
- Execution of a **dcbz** instruction is attempted.

The following table lists register settings when an alignment interrupt is taken.

Table 14-26. Alignment Interrupt—register settings

Vector	$IVPR_{0:23}$ || 0x50					

14.9.5.7 Program Interrupt (offset 0x60)

A program interrupt occurs when no higher priority exception exists and one or more of the following exception conditions occur:

- Illegal Instruction exception
- Privileged Instruction exception
- Trap exception

The e200z4201n3 will invoke an Illegal Instruction program exception on attempted execution of the following instructions:

- Unimplemented instructions
- An instruction from the illegal instruction class
- **mtspr** and **mfspr** instructions with an undefined SPR specified
- **mtdcr** and **mfdcr** instructions with an undefined DCR specified

The e200z4201n3 will invoke a Privileged Instruction program exception on attempted execution of the following instructions when $MSR_{PR} = 1$ (user mode):

- A privileged instruction
- **mtspr** and **mfspr** instructions that specify a SPRN value with $SPRN_5 = 1$ (even if the SPR is undefined)

The e200z4201n3 will invoke a Trap exception on execution of the **tw** instruction if the trap conditions are met and the exception is not also enabled as a Debug interrupt.

The core will invoke an Illegal instruction program exception on attempted execution of the instructions **lswi**, **lswx**, **stswi**, **stswx**, **mfapidi**, **mfdcrx**, **mtdcrx**, or on any *Power ISA 2.06* floating-point instruction. All other defined or allocated instructions that are not implemented by core will cause an illegal instruction program exception.

The following table lists register settings when a Program interrupt is taken.

Table 14-27. Program Interrupt—register settings

Register	Setting description
SRR0	Set to the effective address of the excepting instruction.
SRR1	Set to the contents of the MSR at the time of the interrupt

14.9.5.8 Performance Monitor Interrupt (offset 0x70)

A performance monitor interrupt that may be generated by an enabled condition or event. An enabled condition or event is as follows:

A PMC*x* register overflow condition occurs with the following settings:

- PMLCax_{CE} = 11; that is, for the given counter the overflow condition is enabled.
- PMCx_{OV} = 11; that is, the given counter indicates an overflow.

For a performance monitor interrupt to be signaled on an enabled condition or event, $PMGC0_{PMIE}$ must be set.

Although an exception condition may occur with MSR_{EE} = 0, the interrupt cannot be taken until MSR_{EE} = 1.

The priority of the performance monitor interrupt is below all other asynchronous interrupts.

The following table lists register settings when an performance monitor interrupt is taken.

Table 14-28. Performance Monitor Interrupt—Register Settings

Register	Setting description
SRR0/ DSRR0[1]	Set to the effective address of the next instruction to be executed.

14.9.5.13 System Reset Interrupt

The System Reset exception is a non-maskable, asynchronous exception signaled to the processor through the assertion of system-defined signals.

A System Reset may be initiated by either a software reset or during power-on reset.

When a reset request occurs, the processor branches to the system reset exception vector without attempting to reach a recoverable state. If reset occurs during normal operation, all operations cease and the machine state is lost.

The following table lists register settings when a System Reset interrupt is taken.

Table 14-33. System Reset Interrupt—register settings

14.10 Memory Protection Unit (MPU)

14.10.1 MPU Overview

The e200z4201n3 Memory Protection Unit (MPU) protects regions of memory, with the following feature set:

- 24-entry region descriptor table with support for 6 arbitrary-sized instruction memory regions, 12 arbitrary-sized data memory regions, and 6 additional arbitrary-sized regions programmable as instruction or data memory regions
- Ability to set access permissions and memory attributes on a per-region basis
- Process ID aware, with per-bit masking of TID values
- Capability for masking upper address bits in the range comparison
- Capability of bypassing permissions checking for selected access types
- Per-entry write-once logic for entry protection
- Hardware flash invalidation support and per-entry invalidation protection controls
- Ability to optionally utilize region descriptors for generating debug events and watchpoints
- Software managed by **mpure** and **mpuwe** instructions

14.10.2 Software Interface and MPU Instructions

The MPU entries are accessed indirectly through several MPU Assist (MAS) registers. Software can write and read the MAS registers with **mtspr** and **mfspr** instructions. These registers contain information related to reading and writing a given entry within the MPU. Data is read from the MPU into the MAS registers with an **mpure** (MPU read entry) instruction. Data is written to the MPU from the MAS registers with an **mpuwe** (MPU write entry) instruction.

The **mpure**, **mpuwe**, and **mpusync** instructions are privileged.

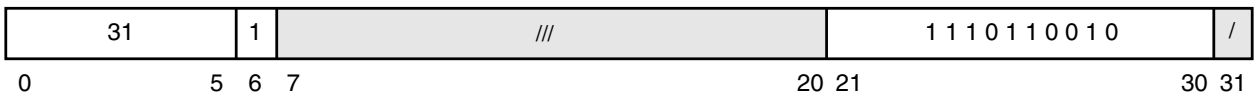
14.10.3 MPU Read Entry Instruction (mpure)

The MPU read entry instruction causes the content of a single MPU entry to be placed in the MPU assist registers. The entry is specified by the INST, SHD, and ESEL fields of the MAS0 register. The entry contents are placed in the MAS0, MAS1, MAS2, and MAS3 registers.

mpure

mpu read entry

mpure



```
mpu_entry_id = MAS0(INST, SHD, ESEL)
result = MPU(mpu_entry_id)
MAS0, MAS1, MAS2, MAS3 = result
```

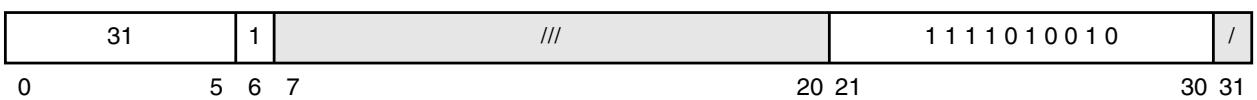
14.10.4 MPU Write Entry Instruction (mpuwe)

The MPU write entry instruction causes the contents of certain fields within the MPU assist registers MAS0, MAS1, MAS2, and MAS3 to be written into a single MPU entry in the MPU. The entry written is specified by the INST, SHD, and ESEL fields of the MAS0 register.

mpuwe

mpu write entry

mpuwe



```
mpu_entry_id = MAS0(INST, SHD, ESEL)
MPU(mpu_entry_id) = MAS0, MAS1, MAS2, MAS3
```

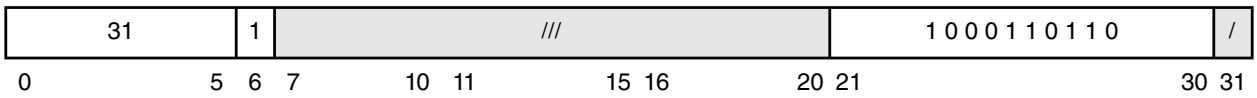
14.10.5 MPU Synchronize Instruction (mpusync)

The MPU Synchronize instruction is treated as a privileged no-op by the core.

mpusync

MPU Synchronize
mpusync

mpusync



14.10.6 MMU/MPU Configuration Register (MMUCFG)

The MMU/MPU Configuration Register (MMUCFG) is a 32-bit read-only register. The SPR number for MMUCFG is 1015 in decimal. MMUCFG provides information about the configuration of the e200z4201n3 MPU design. The MMUCFG register is shown in the following figure.

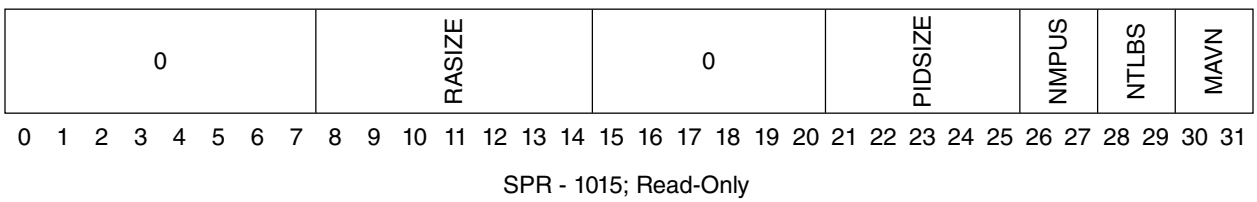


Figure 14-20. MMU/MPU Configuration Register (MMUCFG)

The MMUCFG bits are described in the following table.

Table 14-34. MMUCFG field descriptions

Bits	Name	Function
0:7	—	Reserved
8:14	RASIZE	Number of Bits of Real Address supported 0100000 This version of the MPU implements 32 real address bits
15:16	—	Reserved
17:20	—	Reserved
21:25	PIDSIZE	PID Register Size 00111 PID registers contain 8 bits in this version of the MPU
26:27	NMPUS	Number of MPUs 01 This version of the MMU implements one MPU structure: a fully associative MPU for MPU0
28:29	NTLBS	Number of TLBs 00 This version of the MMU implements no TLB structures
30:31	MAVN	MMU Architecture Version Number 11 This version of the MMU implements Version 3.1 of the EIS MMU Architecture

14.10.7 MPU0 Configuration Register (MPU0CFG)

The MPU0 Configuration Register (MPU0CFG) is a 32-bit read-only register. The SPR number for MPU0CFG is 692 in decimal. MPU0CFG provides information about the configuration of MPU0 in the e200z4201n3 MPU. The MPU0CFG register is shown in following figure.

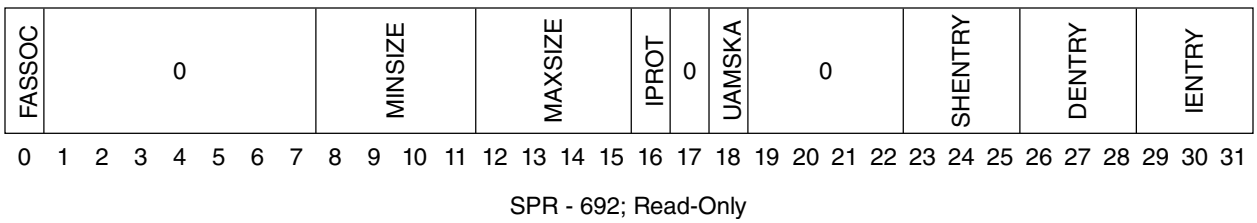

Figure 14-21. MPU0 Configuration Register (MPU0CFG)

The MPU0CFG bits are described in the following table.

Table 14-35. MPU0CFG field descriptions

Bits	Name	Function
0	FASSOC	Fully Associative 1 Indicates that MPU0 is fully associative
1:7	—	Reserved for non-fully associative implementation use
8:11	MINSIZE	Minimum Region Size Due to the use of access address matching, the effective smallest region size is 8 bytes 0x0 Smallest region size is 1 byte
12:15	MAXSIZE	Maximum Region Size 0xB Largest region size is 4 GB
16	IPROT	Invalidate Protect Capability 1 Invalidate Protect Capability is supported in MPU0
17	—	Reserved
18	UAMSKA	Upper Address Masking Availability 1 Upper Address Masking is Available
19:22	—	Reserved
23:25	SHENTRY	Number of Shared (configurable for I or D) Entries 0x2 Indicates that MPU0 contains six shared entries
26:28	DENTRY	Number of Data Entries 0x4 Indicates that MPU0 contains 12 dedicated data entries
29:31	IENTRY	Number of Instruction Entries 0x2 Indicates that MPU0 contains six dedicated Instruction entries

14.10.8 MPU0 Control and Status Register 0 (MPU0CSR0)

The MPU0 Control and Status Register 0 (MPU0CSR0) is a 32-bit register. The SPR number for MPU0CSR0 is 1014 in decimal. MPU0CSR0 controls the operation of the MPU. The MPU0CSR0 register is shown in the following figure.

SPR - 1014; Read/ Write; Reset - 0x0[1]

Figure 14-22. MPU0 Control and Status Register 0 (MPU0CSR0)

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM} = 0$, as well as unconditionally by an internal power-on reset signal. If $EDBCR0_{EDM} = 1$, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**. Specifically, this applies to the DRDEN, DWDEN, and IDEN control bits.

The MPU0CSR0 bits are described in the following table.

Table 14-36. MPU0CSR0 field descriptions

Bits	Name	Description
0:15	—	Reserved
16	BYPSR	Bypass MPU protections for Supervisor Read accesses This bit controls whether supervisor-mode read accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode read accesses do not generate a DSI when no MPU match occurs. Supervisor-mode read accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for Supervisor Read accesses 1 Bypass MPU protections for Supervisor Read accesses
17	BYPSW	Bypass MPU protections for Supervisor Write accesses This bit controls whether supervisor-mode write accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode write accesses do not generate a DSI when no MPU match occurs. Supervisor-mode write accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for Supervisor Write accesses 1 Bypass MPU protections for Supervisor Write accesses
18	BYPSX	Bypass MPU protections for Supervisor Instruction accesses

Table continues on the next page...

Table 14-36. MPU0CSR0 field descriptions (continued)

Bits	Name	Description
		This bit controls whether supervisor-mode instruction accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode instruction accesses do not generate an ISI when no MPU match occurs. Supervisor-mode instruction accesses are still compared to MPU entries, and a hit will provide access attributes (CI). 0 No Bypass of MPU protections for Supervisor Instruction accesses 1 Bypass MPU protections for Supervisor Instruction accesses
19	BYPUR	Bypass MPU protections for User Read accesses This bit controls whether user-mode read accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode read accesses do not generate a DSI when no MPU match occurs. User-mode read accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for User Read accesses 1 Bypass MPU protections for User Read accesses
20	BYPUW	Bypass MPU protections for User Write accessesThis bit controls whether user-mode write accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode write accesses do not generate a DSI when no MPU match occurs. User-mode write accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for User Write accesses 1 Bypass MPU protections for User Write accesses
21	BYPUX	Bypass MPU protections for User Instruction accesses This bit controls whether user-mode instruction accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode instruction accesses do not generate an ISI when no MPU match occurs. User-mode instruction accesses are still compared to MPU entries, and a hit will provide access attributes (CI). 0 No Bypass of MPU protections for User Instruction accesses 1 Bypass MPU protections for User Instruction accesses
22:23	—	Reserved
24	DRDEN	Data Read Debug Enable This bit controls whether data read accesses are enabled to generate MPU debug events. When disabled, no data read access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG = 1. If such a match occurs, no MPU debug event is generated, and no access protection is performed. When enabled, data read accesses are not blocked from generating MPU debug events. 0 MPU debug events are disabled for data read accesses 1 MPU debug events are enabled for data read accesses
25	DWDEN	Data Write Debug Enable This bit controls whether data write accesses are enabled to generate MPU debug events. When disabled, no data write access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG = 1. If such a match occurs, no MPU debug event is generated, and no access protection is performed. When enabled, data write accesses are not blocked from generating MPU debug events. 0 MPU debug events are disabled for data write accesses

Table continues on the next page...

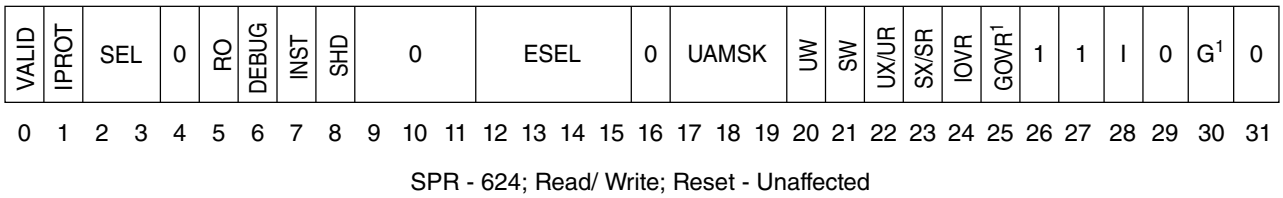
Table 14-36. MPU0CSR0 field descriptions (continued)

Bits	Name	Description
		1 MPU debug events are enabled for data write accesses
26	IDEN	Instruction Debug Enable This bit controls whether instruction accesses are enabled to generate MPU debug events. When disabled, no instruction access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG = 1. When enabled, instruction accesses are not blocked from generating MPU debug events. 0 MPU debug events are disabled for instruction accesses 1 MPU debug events are enabled for instruction accesses
27	—	Reserved
28	TIDCTL	TID usage Control When TIDCTL is set to 1, the TID match is disabled (forced match) in Supervisor mode. 0 TID comparisons performed normally 1 No TID comparisons are performed for matching while in Supervisor mode
29	—	Reserved
30	MPUFI	MPU flash invalidate When written to a 1, a MPU invalidation operation is initiated by hardware. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. MPU invalidation operations require 3 cycles to complete. 0 No flash invalidate 1 MPU1 invalidation operation **Note:** Entries that have the IPROT bit set will not be invalidated.
31	MPUEN	MPU Enable This bit enables operation of the MPU. When enabled, access addresses are compared to each entry in the MPU for a match condition. If no match condition occurs, and the access type is not enabled to bypass the MPU protections, then an ISI or DSI condition is signaled for the access. Note that this bit is ignored for matching entries with DEBUG = 1 if in EDM and hardware owns MPU Debug entries. 0 MPU is disabled 1 MPU is enabled

14.10.9 MPU Assist Registers (MAS)

The core uses four special-purpose registers (MAS0, MAS1, MAS2, and MAS3) to facilitate reading and writing MPU entries. The MAS registers can be read or written using the **mfspr** and **mtspr** instructions.

The MAS0 register is shown in Figure 14-23. Fields are defined in Table 14-37.



SPR - 624; Read/ Write; Reset - Unaffected

Figure 14-23. MPU Assist Register 0 (MAS0)

Note

[1] This bit is not implemented in dedicated instruction entries, and is ignored in shared entries with INST = 1

Table 14-37. MAS0—MPU Read/Write and Replacement Control

Bit	Name	Comments, or Function when Set
0	VALID	MPU Entry Valid 0 = This MPU entry is invalid 1 = This MPU entry is valid
1	IPROT	Invalidation Protect 0 = Entry is not protected from invalidation 1 = Entry is protected from invalidation
2:3	SEL	Selects MPU for access: 00 = Reserved, no access 01 = Reserved, no access 10 = Select MPU 11 = Reserved, no access
4	—	Reserved
5	RO	Read-Only When set to 1, the entry is no longer writable by software. Once set, this bit will remain set until a processor reset occurs. 0 = This MPU entry is writable 1 = This MPU entry is Read-only
6	DEBUG	Debug Control for Entry This bit is used to assign an entry for debug event use instead of normal access protection use. When used for debug purposes, an MPU debug event is generated when a hit to the entry occurs and the access permissions allow the access. 0 = This MPU entry is used for access protections and allows accesses when matched based on protection attributes 1 = This MPU entry is used for generating a debug event when a match occurs and the access protections would allow access
7	INST	Instruction Entry When SHD = 0, this bit is used to select the INST entry portion of the region descriptor table for **mpure** and **mpuwe** instruction operations.

Table continues on the next page...

Table 14-37. MAS0—MPU Read/Write and Replacement Control (continued)

Bit	Name	Comments, or Function when Set
		When SHD = 1, this bit is used to indicate whether the entry in the Shared portion of the region descriptor table is assigned as an entry for either instruction access or data access matching. Only one of these access types is monitored for matching by a given shared region descriptor entry. 0 = This MPU entry is used for matching data accesses only 1 = This MPU entry is used for matching instruction accesses only
8	SHD	Shared Entry Select This bit is used to control selection of the Shared portion of the region descriptor table. 0 = The shared portion of the region descriptor table is not accessed on a **mpure** or **mpuwe** operation. Either the instruction portion or the data portion is accessed based on the setting of INST. The entry within the selected portion is based on ESEL. 1 = The shared portion of the region descriptor table is accessed on a **mpure** or **mpuwe** operation. The instruction and data portions are not accessed. The INST bit is used to indicate whether the entry in the Shared portion of the region descriptor table is assigned as an entry for instruction access or data access matching. Only one of these access types is monitored for matching by a given shared region descriptor entry. ESEL defines which shared entry is selected.
9:11	—	Reserved
12 :15	ESEL	Entry select for MPU. This field is used to select an entry for reading or writing in conjunction with the settings of SHD and INST. Only valid entry numbers should be used in this field, otherwise the result of an operation is boundedly undefined.
16	—	Reserved
17:19	UAMSK	Upper Address Mask Control This field is used to support masking of upper address bits before performing range comparisons. Masked bits will be forced to 0 for the purposes of the range compare. Range upper and lower bounds should be set accordingly. 000 = No upper address bits are masked, address matching uses all 32 address bits for accesses 001 = The most significant access address bit is forced to zero before matching 010 = The two most significant access address bits are forced to zero before matching 011 = The three most significant access address bits are forced to 0 before matching 100 = The four most significant access address bits are forced to 0 before matching 101 = The upper five access address bits are forced to zero before matching 11x = Reserved, do not use
20	UW	User Mode Write PermissionDetermines User mode Write (W) permission when INST = 0. Ignored when INST = 1. 0 = No User mode Write permission 1 = User mode has Write permission
21	SW	Supervisor Mode Write / Read Permission Determines Supervisor mode Write (W) permission when INST = 0. Ignored when INST = 1. 0 = No Supervisor mode Write permission

Table continues on the next page...

Table 14-37. MAS0—MPU Read/Write and Replacement Control (continued)

Bit	Name	Comments, or Function when Set
		1 = Supervisor mode has Write permission

14.10.10 MAS Registers Summary

The MAS registers are summarized in the following figure.

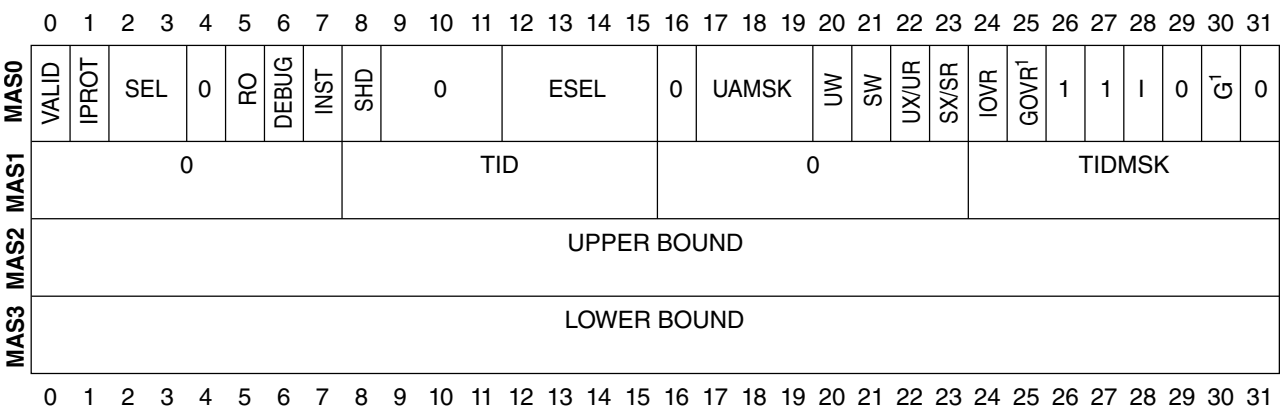

Figure 14-27. MPU Assist Registers Summary

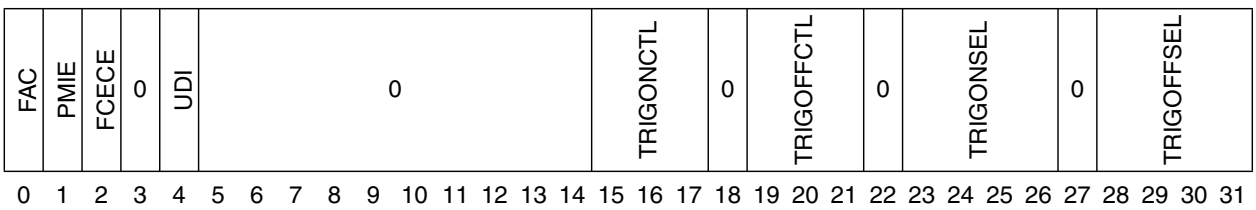
Note

[1] This bit is not implemented in dedicated instruction entries, and is ignored in shared entries with INST = 1

14.11 Performance Monitor

14.11.1 Global Control Register 0 (PMGC0)

The performance monitor global control register PMGC0 shown in the following figure controls all performance monitor counters.



PMR - 400; Read/Write; Reset[1] - 0x0

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

Figure 14-28. Performance Monitor Global Control Register (PMGC0)

The following table describes PMGC0 fields.

Table 14-41. PMGC0 field descriptions

Bits	Name	Description
0 (32)	FAC	Freeze All Counters. 0 The PMCs are incremented (if permitted by other PMGC/PMLC control bits). 1 The PMCs are not incremented. When FAC is set to 1 by hardware or software, it has no effect on PMLCaxFC; PMLCaxFC maintains its current value until changed by software. FAC setting by hardware is controlled by PMGC0FCECE.
1 (33)	PMIE	Performance monitor interrupt enable 0 Performance monitor interrupts are disabled. 1 Performance monitor interrupts are enabled and occur when an enabled condition or event occurs, at which time PMGC0PMIE is cleared Software can clear PMIE to prevent performance monitor interrupts. Performance monitor interrupts are caused by PMCx counter overflows.
2 (34)	FCECE	Freeze Counters on Enabled Condition or Event An enabled condition or event is defined as one of the following: • When the msb = 1 in PMCx and PMLCaxCE = 1. 0 The PMCs can be incremented (if permitted by other PM control bits). 1 The PMCs can be incremented (if permitted by other PM control bits) only until an enabled condition or event occurs. When an enabled condition or event occurs, PMGC0FAC is set to 1. It is up to software to clear PMGC0FAC to 0.
3 (35)	-	Reserved, should be cleared.

Table continues on the next page...

Table 14-41. PMGC0 field descriptions (continued)

Bits	Name	Description
4 (36)	UDI	Use Debug Interrupt **NOTE:** This bit is ignored when EDBCR0EDM=1 and Performance Monitor Resources are assigned to an external debugger via the DBECR0PMI control bit. **NOTE:** If UDI is set and DBCR0IDM=0, no software performance monitor debug interrupts will be taken. 0 Performance Monitor Interrupts use the SRR0/1 registers and the Performance Monitor interrupt vector offset, or if the Performance Monitor Resources are assigned to an external debugger via the DBECR0PMI control bit, can set the EDBSR0PMI to conditionally enter debug halted mode 1 Performance Monitor Interrupts set the DBSRPMI status bit when DBCR0IDM=1, and can thus use the DSRR0/1 registers and the Debug interrupt vector offset when Debug Interrupts are not masked, or if EDBCR0EDM=1 and the Performance Monitor Resources are assigned to an external debugger via the DBECR0PMI control bit, can set the EDBSR0PMI to conditionally enter debug halted mode.
5:14 (37:46)	-	Reserved, should be cleared.
15:17 (47:49)	TRIGONCNTL	Trigger-on Control Class - Class of Trigger-on source 000 Trigger-on control is disabled if TRIGONSEL is 0000 (i.e. counting is not affected by triggers). All other values for TRIGONSEL are reserved. 001 Reserved 010 Trigger-on based on selected processor event(s) 011 Trigger-on based on selected hardware signal(s) 100 Trigger-on based on selected watchpoint occurrence (watchpoint #0-15) 101 Trigger-on based on selected watchpoint occurrence (extension for watchpoint #16-31) 11*x* Reserved. Indicates the condition under which triggering to start counting occurs. No triggering will occur while PMGC0FAC or PMLCanFC is set to '1'.
18 (50)	-	Reserved, should be cleared.
19:21 (51:53)	TRIGOFFCNTL	Trigger-off Control Class - Class of Trigger-off source. Indicates the condition under which triggering to stop counting occurs. No triggering will occur while PMGC0FAC or PMLCanFC is set to '1'. 000 Trigger-off control is disabled if TRIGOFFSEL is 0000 (i.e. counting is not affected by triggers) All other values for TRIGOFFSEL are reserved. 001 Reserved 010 Trigger-off based on selected processor event(s) 011 Trigger-off based on selected hardware signal(s) 100 Trigger-off based on selected watchpoint occurrence (watchpoint #0-15) 101 Trigger-off based on selected watchpoint occurrence (extension for watchpoint #16-31) 11*x* Reserved
22 (54)	-	Reserved, should be cleared.
23:26 (55:58)	TRIGONSEL	Trigger-on Source Select - Source Select based on setting of TRIGONCTL TRIGONCTL = 000:

14.12 Local memories

14.12.1 Local Data memory overview

Local Data (DMEM) memory has been added to provide low latency access for critical instruction routines and data operands. Access latency (zero wait-states) is similar to that of a data cache, but does not suffer from the overhead of cache miss or cache writethrough operations. Instead, it provides a large capacity tightly coupled storage.

The local memory has one dedicated port for CPU accesses and another shared slave port for external accesses. DMEM provides a dedicated port to the CPU's load/store unit. Access via the dedicated CPU port is referred to as *front door* access. Access via the slave port is referred to as *back door* access.

Local memory occupies a portion of the processor's address space and is conditionally accessed in parallel with the corresponding cache (if present) when a CPU request is made, based on an address decode comparison early in the access pipeline.

External masters use the shared slave port, which is implemented as an AHB 2.v6 slave interface, to access the DMEM. Slave port accesses are arbitrated with the CPU port in a round-robin fashion to prevent starvation from occurring on either port.

NOTE

DMEM, by default, is always accessed through the front door (CPU) interface, regardless of whether the program uses Decorated Access, Non-decorated Cache Bypass, Atomic Load and Reserve instructions, as well as regular load/store instructions (stw, lwz, for example). The only exception is when the core's DMEMCTL0 register is set to bypass the type of DMEM access used onto AHB back door slave interface. Regular load/store instructions always access DMEM through the front door interface since no bypass control is available for these kinds of instructions.

14.12.2 Local memory control and configuration

DMEM local memory configuration information is provided by a set of privileged read-only SPRs that are accessed using **mfspr** instructions. DMEM local memory operation is controlled by a set of privileged device control registers (DCRs) that are accessed using the **mfdcr** and **mtdcr** instructions. These registers and a description of the operation of various features are described in the following subsections.

14.12.2.1 DMEM Configuration Register 0 (DMEMCFG0)

The DMEM Configuration Register 0 (DMEMCFG0) is a 32-bit read-only register. DMEMCFG0 provides information about the configuration of the e200z4201n3 local data memory design. The contents of the DMEMCFG0 register can be read using a **mfspr** instruction. The SPR number for DMEMCFG0 is 694 in decimal. The DMEMCFG0 register is shown in the following figure.

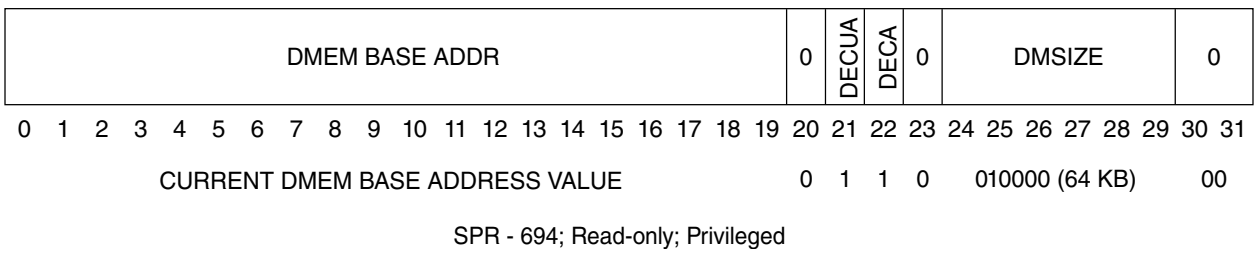

Figure 14-29. DMEM Configuration Register 0 (DMEMCFG0)

The DMEMCFG0 fields are described in the following table.

Table 14-42. DMEMCFG0 field descriptions

Bits	Name	Description
0:19	DMEM BASE ADDR	DMEM BASE ADDRESS (CPU Port) This field defines the current Base Address value being used for the CPU port to the DMEM. This field reflects the value of the external DMEM base address port inputs when the external base address port inputs are enabled via the DBAPD control bit, or the value of the BASE ADDRESS field of DMEMCTL0 when the external base address port inputs are disabled via the DBAPD control bit. **Note:** Low order bits of this field are driven to 0s when the DMEM size is > 4 KB
20	—	Reserved
21	DECUA	DMEM Error Correction Update Available DECUA indicates an error scrubbing function for the DMEM is available. 0 Error Correction Update is not available. 1 Error Correction Update is available for correction of a correctable single-bit error detected on a read access.
22	DECA	DMEM Error Correction Available DECA indicates an error correction function for the DMEM is available. 0 Error Correction is not available. 1 Error Correction is available.
23	—	Reserved
24:29	DMSIZE	DMEM Size 010000 The size of the DMEM is 64 KB.
30:31	—	Reserved

14.12.2.2 DMEM Control Register 0 (DMEMCTL0)

The DMEM Control Register 0 (DMEMCTL0) controls operation of certain functions of the DMEM logic.

DMEM BASE ADDR	0	DBYPCB	DBYPAT	DBYPDEC	DECUE	0	DBAPD	DPEIE	DICWE	DSWCE	DDAUEC	DCPECE	DSECE
0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15	16 17 18	19	20	21	22	23	24	25	26	27 28	29	30	31
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	0 0 0	0	0	1	0	0	0	0	0	1 1	0	1	1

DCR - 496; Read/Write; Reset[1] - 0x0000_041B; Privileged

Figure 14-30. DMEM Control Register 0 (DMEMCTL0)

NOTE

[1] Reset by an internal power-on reset signal or by an internal destructive reset signal. Unaffected by **p_reset_b**.

Table 14-43. DMEMCTL0 field descriptions

Bits	Name	Description
0:15	DMEM BASEADDR	DMEM BASE ADDRESS Field (CPU Port) This field defines the Base Address used for the CPU port to the DMEM when the external base address port inputs are disabled via the DBAPD control bit. **NOTE:** Changes to this value and to the BAPD control bit must be performed carefully by software to ensure coherency is maintained. Specifically, software must ensure that no cached entries are present in the D-Cache for the memory space to be occupied by the DMEM.
16 :18	—	Reserved
19	DBYPCB	DMEM Bypass Cache Bypass CPU accesses DBYPCB can be used to force Non-decorated Cache Bypass loads and Store with Writethrough (**lbcbx**, **lhcbx**, **lwcbx**, and **stwwtx**, **sthwtx**, **stbwtx**) accesses that target the DMEM address space to be presented to the external bus. Note that the protection settings in DMEMCTL1 are still applied to these accesses. 0 Non-decorated Cache Bypass loads and Store with Writethrough CPU accesses do not bypass the DMEM CPU port. 1 Non-decorated Cache Bypass loads and Store with Writethrough CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface. **NOTE:** This field is updated by Reset from an internal power-on reset signal or by an internal destructive reset signal.
20	DBYPAT	DMEM Bypass Atomic CPU accesses DBYPAT can be used to force atomic (load and reserve, store conditional) accesses to the DMEM address space to be presented to external reservation hardware in systems that support reservation and/or decoration functionality, since no internal reservation hardware is present in the CPU for the DMEM. In general, software must not rely on normal CPU write accesses to clear a reservation, since they are not monitored by

Table continues on the next page...

Table 14-43. DMEMCTL0 field descriptions (continued)

Bits	Name	Description
		reservation hardware; instead only store conditional accesses should be used for this purpose. Note that the protection settings in DMEMCTL1 are still applied to these accesses. 0 Atomic CPU accesses do not bypass the DMEM CPU port. 1 Atomic CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface. **NOTE:** This field is updated by Reset from an internal power-on reset signal or by an internal destructive reset signal.
21	DBYPDEC	DMEM Bypass Decorated CPU accesses DBYPDEC can be used to force decorated accesses (**lbdx, lhdx, lwdx, lbdcbx, lhdcbx, lwdcbx, stbdx, sthdx, stwdx, stbdcbx, sthdcbx, stwdcbx, dsn, dsncb**) to the DMEM address space to be presented to external decoration hardware for systems that support this functionality, since no internal decoration hardware is present in the CPU. Note that the protection settings in DMEMCTL1 are still applied to these accesses. 0 Decorated Load and Store CPU accesses do not bypass the DMEM CPU port. 1 Decorated Load and Store CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface. **NOTE:** This field is updated by Reset from an internal power-on reset signal or by an internal destructive reset signal.
22	DECUE	DMEM Error Correction Update Enable DECUE can be used in conjunction with DCPECE and DSECE to provide an error scrubbing function for the DMEM. 0 Error Correction Update is disabled. 1 Error Correction Update is enabled. A correctable single-bit error detected on a read access from either the CPU or the slave port will cause the DMEM to be rewritten with the corrected data if the corresponding error checking enable bit is set (DCPECE for CPU accesses, DSECE for slave port accesses). (Write accesses perform this correction automatically during partial-width writes when error checking is enabled.) **NOTE:** This field is updated by Reset from an internal power-on reset signal or by an internal destructive reset signal.
23	—	Reserved
24	DBAPD	DMEM Base Address Port Disable This bit controls usage of the external Base Address port to define the base address of the DMEM for CPU port accesses. It has no effect on DMEM slave port accesses. 0 The external DMEM base address port is used to define the base address of the DMEM for CPU accesses. 1 The external DMEM base address port is disabled for use, and instead the BASE ADDR field value is used to define the base address of the DMEM for CPU accesses.
25	DPEIE	DMEM Processor Error Injection Enable DPEIE will cause injection of errors regardless of the setting of DCPECE, although reporting of errors to the CPU will be masked while DCPECE = 0. 0 Error Injection is disabled. 1 A double-bit error will be injected on each CPU port write into the DMEM data array by inverting the two uppermost parity check bits.

Table continues on the next page...

Table 14-43. DMEMCTL0 field descriptions (continued)

Bits	Name	Description
26	DICWE	DMEM Imprecise CPU Write Enable DICWE may allow for increased partial-width write performance when set. 0 Imprecise writes by the CPU are disabled. All partial-width write ECC errors are reported precisely (error report machine check). 1 Imprecise writes by the CPU are enabled. In certain cases, partial-width write errors may be reported imprecisely (async machine check only).
27:28	DSWCE	DMEM Slave port Write Check/Correct Enable 00 Slave write data is not checked or corrected for errors. 01 Slave write data is checked but not corrected for errors. Detected errors generate a slave port ERROR response and no Write is performed to the DMEM. 10 Slave write data is checked and corrected for errors on all writes. Single-bit correctable errors do not automatically generate an ERROR response, but are instead corrected. 11 Slave write data is checked and corrected for errors on partial-width (1, 2, 3, 5, 6, or 7 byte, or misaligned 4-byte) writes. Single-bit correctable errors on partial-width writes do not automatically generate an ERROR response, but are instead corrected. Aligned word or doubleword writes are not checked or corrected for errors. **NOTE:** This field is updated by Reset from an internal power-on reset signal or by an internal destructive reset signal.
29	DDAUEC	DMEM Disable Address Use in Error Check This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portions are not used for checkbit/syndrome generation for DMEM CPU or slave port accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation. **NOTE:** This field is updated by Reset from an internal power-on reset signal or by an internal destructive reset signal.
30	DCPECE	DMEM CPU Port ECC Enable (CPU port) 0 End-to-End ECC is disabled for the CPU interface. No checking of read data is performed by the CPU. Writes will still generate the proper check bit values to be written. 1 End-to-End ECC is enabled for performing ECC on the CPU interface. Error checking of read data is performed with single-bit error correction. Detection of uncorrectable single- or multi-bit errors on a CPU port access cause a machine check to be generated. **NOTE:** This field is updated by Reset from an internal power-on reset signal or by an internal destructive reset signal.
31	DSECE	DMEM Slave port Error Checking Enable (Slave port) 0 End-to-End ECC checking logic is disabled for the Slave interface. No checking of read data is performed during read-modify-write operations for Slave port partial-width writes. Writes will still generate the proper check bit values to be written.

Table 14-43. DMEMCTL0 field descriptions

Bits	Name	Description
		1 End-to-End ECC is enabled for performing ECC on the Slave Port interface. Error checking of read data is performed with single-bit error correction during read-modify-write operations for partial-width writes. Detection of uncorrectable single- or multi-bit errors on a Slave port partial-width write access causes a bus error ERROR response to be generated. **NOTE:** This field is updated by Reset from an internal power-on reset signal or by an internal destructive reset signal.

14.12.2.3 DMEM Control Register 1 (DMEMCTL1)

The DMEM Control Register 1 (DMEMCTL1) provides protection functions for the DMEM. Separate Supervisor-mode and User-mode read and write access controls allow accesses to be granted, denied, or conditionally granted independently for four equally sized blocks of DMEM. Conditional granting of access permissions causes the MPU memory protection functions to be employed. All other settings override MPU settings. The DMEMCTL1 settings are applied to all accesses that target DMEM address range, regardless of whether access may bypass the DMEM based on settings in DMEMCTL0$_{DBYPCB,\ DBYPATF,\ DBYPDEC}$.

14.13 End-to-End ECC Support

This section describes end-to-end error detection and correction capability (e2eECC) enhancements to address additional diagnostic capabilities for the next generation of embedded designs.

14.13.1 End-to-End ECC control and configuration

e2eECC is controlled by a set of privileged device control registers (DCRs) accessed using the **mfdcr** and **mtdcr** instructions. These registers and the operation of various features are described in the following subsections.

14.13.1.1 End-to-End ECC Control Register 0 (E2ECTL0)

The End-to-End ECC Control Register 0 (E2ECTL0) controls operation of the e2eECC logic.

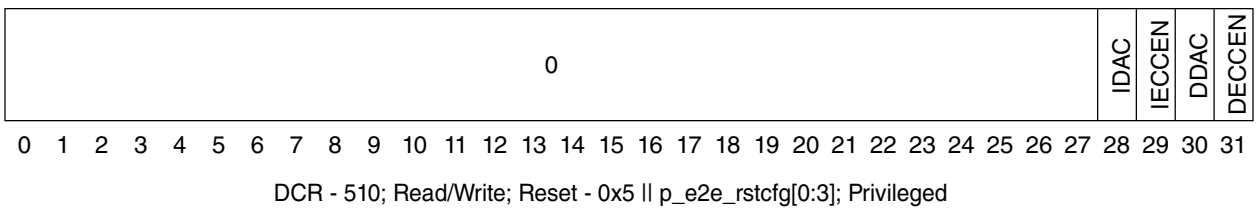

Figure 14-32. e2eECC Control Register 0 (E2ECTL0)

Table 14-45. E2ECTL0 field descriptions

Bits	Name	Description
0:27	—	Reserved
28	IDAC	Instruction Disable Address Checking This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portion is not used for checkbit/syndrome generation for Instruction AHB accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[0]** input.
29	IECCEN	Instruction ECC Enable Field 0 End-to-End ECC is disabled for the Instruction interface. No checking of instruction fetch data is performed. 1 End-to-End ECC is enabled for performing error detection and correction on the Instruction interface. Checking of instruction fetch data is performed with correction of single-bit data errors. Detection of any address errors or uncorrectable multi-bit data errors cause a machine check to be generated if the instruction fetch information is attempted to be used for instruction decoding and execution. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[1]** input.
30	DDAC	Data Disable Address Checking This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portion is not used for checkbit/syndrome generation for Data AHB accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[2]** input.
31	DECCEN	Data ECC Enable Field 0 End-to-End ECC is disabled for the Data interface. No checking of read data is performed. Writes will still generate the proper check bit values to be supplied to external storage devices.

Table 14-45. E2ECTL0 field descriptions

Bits	Name	Description
		1 End-to-End ECC is enabled for performing error detection and correction on the Data interface. Checking of read data is performed with correction of single-bit data errors. Detection of any address errors, or uncorrectable multi-bit data errors cause a machine check to be generated. Writes generate the proper check bit values to be supplied to external storage devices. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[3]** input.

e2eECC is enabled by setting the [I,D]ECCEN bit of the E2ECTL0 DCR to a 1. On reset, e2eECC operation may be disabled from detecting or correcting errors based on reset configuration inputs, and no exceptions will be signaled for nonzero calculated syndrome values. This allows for the proper initialization of stored checkbits in any volatile storage by the CPU without causing error conditions due to uninitialized storage. Following the initialization, software may enable e2eECC operation by writing the appropriate values to the $E2ECTL0_{[I,D]ECCEN}$ control bits.

The $E2ECTL0_{[I,D]DAC}$ control bits can be used to remove the address checking component of the ECC logic for the Instruction AHB and Data AHB when address inclusion is not desired.

14.13.1.2 End-to-End ECC fault injection by software

Fault injection provides a way to test error recovery and portions of the error detection/ correction logic by intentionally injecting parity errors into the driven checkbit information on the external bus during write operations. No provision is made to generate internal errors on read data due to timing issues; instead, software may intentionally generate errors in the checkbit values to emulate data, address, or checkbit error on external bus write cycles, and read back the written data to cause an error to be detected.

The End-to-End ECC Error Control/Status Register (E2EECSR0) controls operation of the e2eECC error injection logic. It allows for generation of a single error injection operation on the next CPU data write to the external bus only, or for a series of error injection write operations to the external bus, using the WRC and INVC control fields. The WRCHKBIT/CHKINVT field controls which of the **p_hwchkbit[7:0]** outputs are affected.

Control is provided to allow for either inverting the value(s) of one or more of the checkbit outputs **p_hwchkbit[7:0]** in hardware on one or more external write accesses, or for software to directly supply checkbit values to be used for the external write access(es).

The End-to-End ECC Error Control/Status Register (E2EECSR0) also supports access to raw checkbit values via the RCHKBIT status field. This field is updated with checkbit values received on each CPU data read operation to either the DMEM or to the external bus (but not on cache hits). For the case of an external read access that receives an ERROR response (HRESP=ERR), the RCHKBIT field is written with all zeros.

Note that Nexus 3 accesses do not cause error injection or the capture of read checkbits, regardless of the settings of the E2EECSR0 register.

The following figure shows the layout of E2EECSR0.

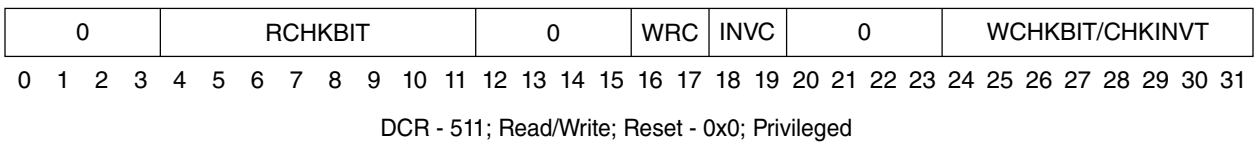

Figure 14-33. e2eECC Error Control/Status Register 0 (E2EECSR0)

Table 14-46. E2EECSR0 field descriptions

Bits	Name	Description
0:3	—	Reserved
4:11	RCHKBIT	Read Checkbits This field provides the raw checkbits received on the last CPU data access to the DMEM or to external memory via the Data BIU. This field corresponds bit-wise to **p_hrchkbit[7:0]**. for external reads and to **p_dchk[0:7]** for DMEM read accesses. Software may use this information to determine the stored checkbits of external memories or the DMEM by performing CPU load operations and then accessing this field prior to the next load operation (assuming interrupts are masked). If the CPU receives an ERROR response (HRESP=ERR) on an external read access, the RCHKBIT field is written with all zeros.
12:15	—	Reserved
16:17	WRC	Write Control 00 No write checkbit substitution is performed by this control bit 01 Checkbit substitution is performed for the next CPU external write access (only) by driving **p_hwchkbit[7:0]** with the values in the WCHKBIT control field. Software must clear this field before rewriting to 01 in order to generate a subsequent checkbit substitution operation. 10 Checkbit substitution is performed for each CPU external write access while this field remains set to 10 by driving **p_hwchkbit[7:0]** with the values in the WCHKBIT control field. This field must be cleared by software to discontinue further checkbit substitution. 11 Reserved Note: Checkbit substitution has priority over Error injection
18:19	INVC	Invert Control 00 No error injection is performed by this control bit 01 Error injection is performed for the next CPU external write access (only) by modifying **p_hwchkbit[7:0]** based on CHKINVT. Software must clear this field before rewriting to 01 in order to generate a subsequent error injection operation.

Table continues on the next page...

Table 14-46. E2EECSR0 field descriptions (continued)

Bits	Name	Description
		10 Error injection is performed for each CPU external write access while this field remains set to 10 by modifying **p_hwchkbit[7:0]** based on CHKINVT. This field must be cleared by software to discontinue further fault injection. 11 Reserved Note: Checkbit substitution has priority over Error injection
20:23	—	Reserved
24:31	WCHKBIT/ CHKINVT	Write Checkbits / Checkbit Invert Mask This field provides the checkbit substitution values when performing checkbit substitution via the WRC control field, and controls which checkbits are inverted when performing error injection via the INVC control field. This field corresponds bit-wise to **p_hwchkbit[7:0]**. For Checkbit inversion operations via error injection: 0 Checkbit is driven normally 1 Checkbit is inverted before being driven out on **p_hwchkbit[7:0]** when error injection occurs.

Chapter 15
z7 Core Description

15.1 Overview of the e200z7260n3 core

The e200z7260n3is a dual-issue 32-bit Power ISA 2.06 Revision B VLE compliant design with 32-bit general-purpose registers (GPRs). The e200z7260n3 core implements the VLE (variable-length encoding) ISA, providing improved code density. The VLE ISA is further documented in Power ISA 2.06 Revision B, a separate document.

An Embedded Floating-point (EFPU2) APU is provided to support real-time single-precision floating-point embedded numerics operations using the general-purpose registers.

The e200z7260n3 processor integrates a pair of integer execution units, a branch control unit, instruction fetch unit, load/store unit, and a multi-ported register file capable of sustaining six read and three write operations per clock cycle. Most integer instructions execute in a single clock cycle. Branch target prefetching is performed by the branch unit to allow single-cycle branches in many cases.

e200z7260n3 contains a16 KB Instruction Cache, and a 16 KB Data Cache, as well as a Nexus Class 3+ real-time debug module with support for program and data trace features as well as extensive trace controls.

A Memory Protection Unit that protects various instruction and data memory areas is also included.

15.2 Register model

This section describes the registers implemented in the e200z7260n3 core. The Power ISA 2.06 Revision B architecture defines register-to-register operations for all computational instructions.

e200z7260n3 extends usage of the general purpose registers to support EFPU operations on the 32-bit GPR registers.

Figure 15-1 and Figure 15-2 show the complete e200z7260n3 register set, all of which are accessible in supervisor mode. Figure 15-3 and Figure 15-4 show the subset of registers accessible in user mode. The number to the right of the special-purpose registers (SPRs) is the decimal number used in the instruction syntax to access the register (for example, the integer exception register (XER) is SPR 1).

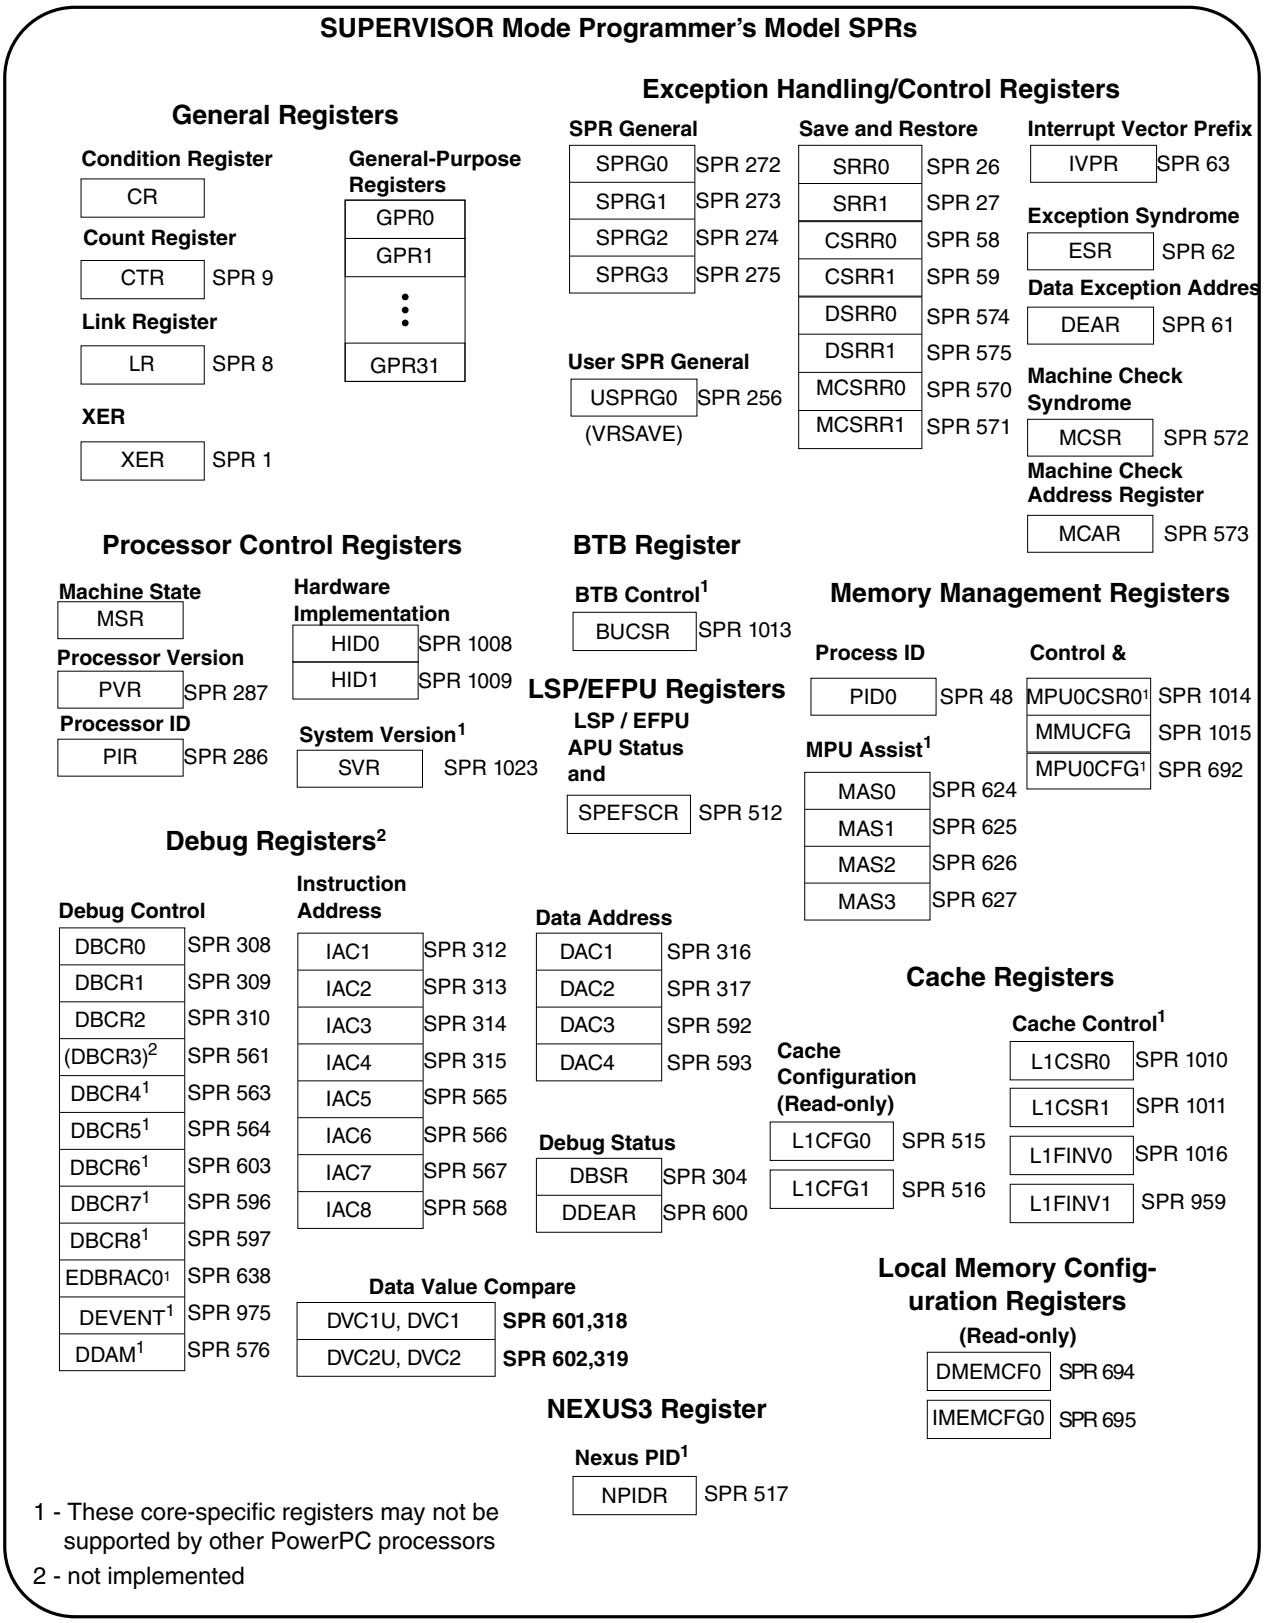

Figure 15-1. e200z7260n3 Supervisor Mode Programmer's Model SPRs

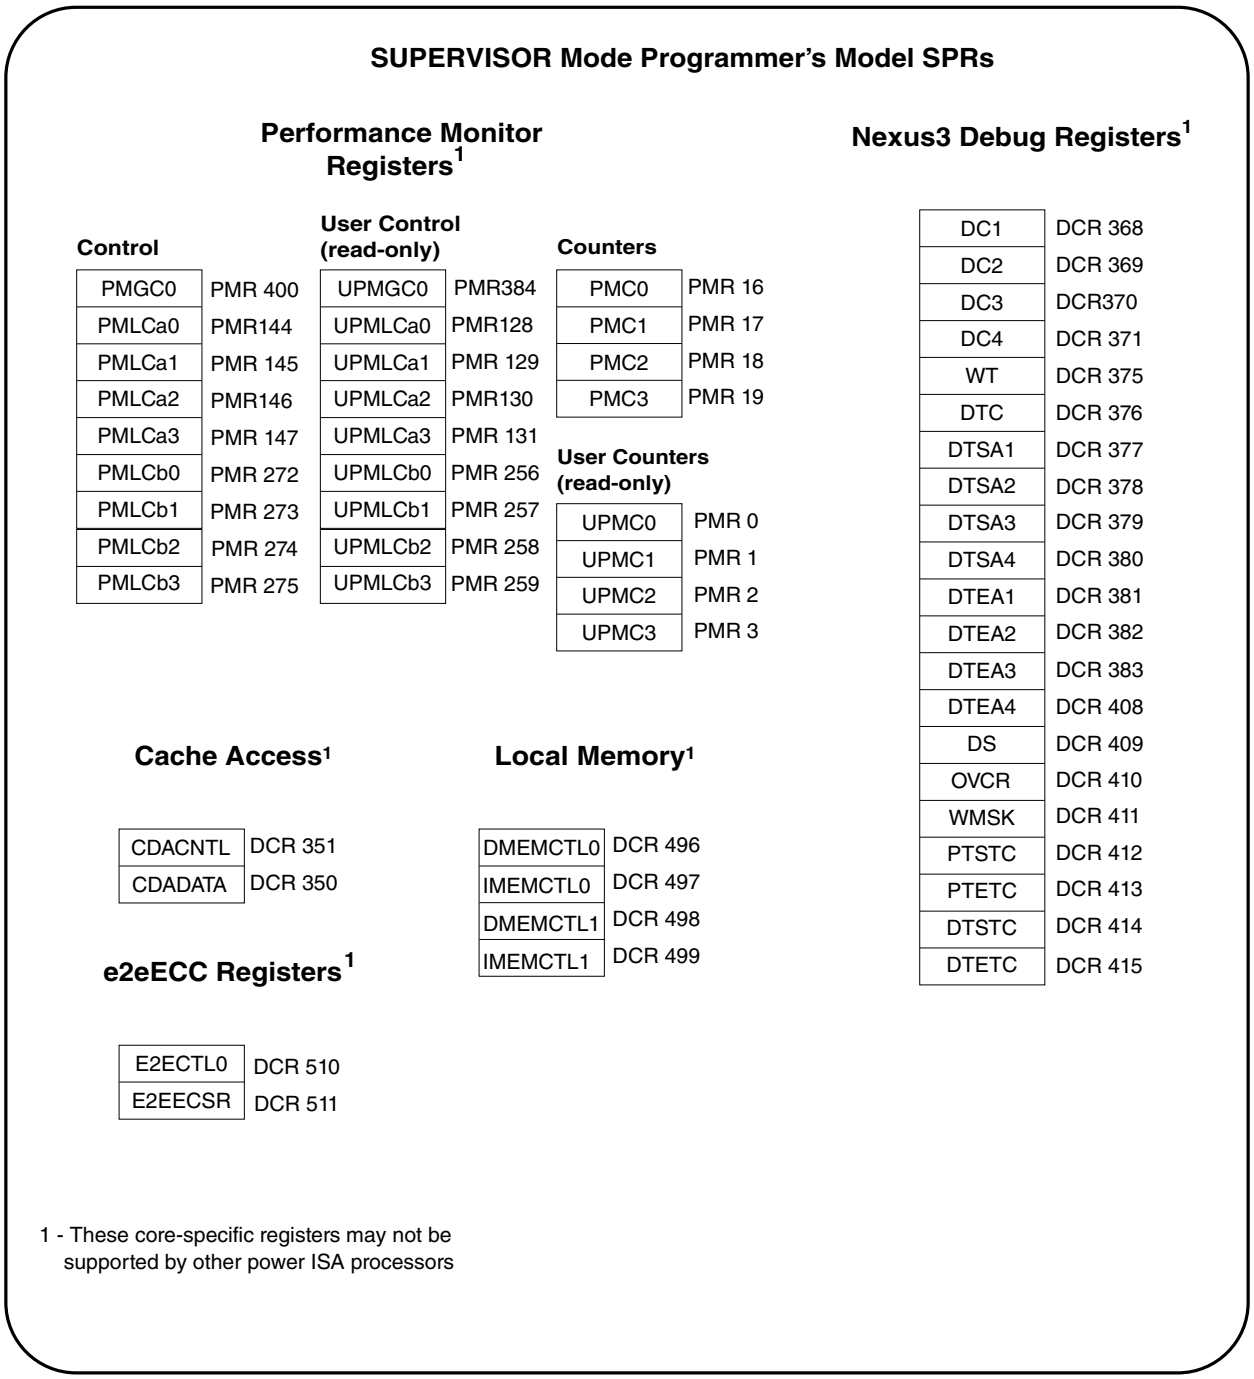

Figure 15-2. e200z7260n3 Supervisor Mode Programmer's Model DCRs and PMRs

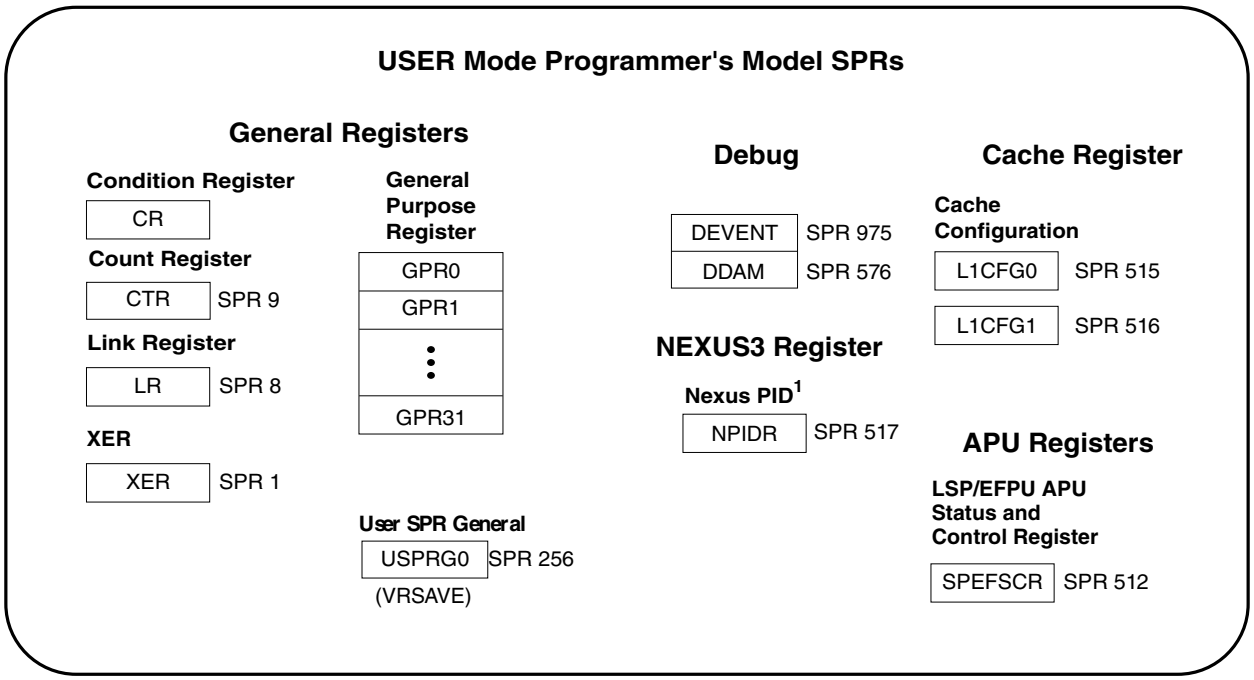

Figure 15-3. e200z7260n3 User Mode Programmer's Model SPRs

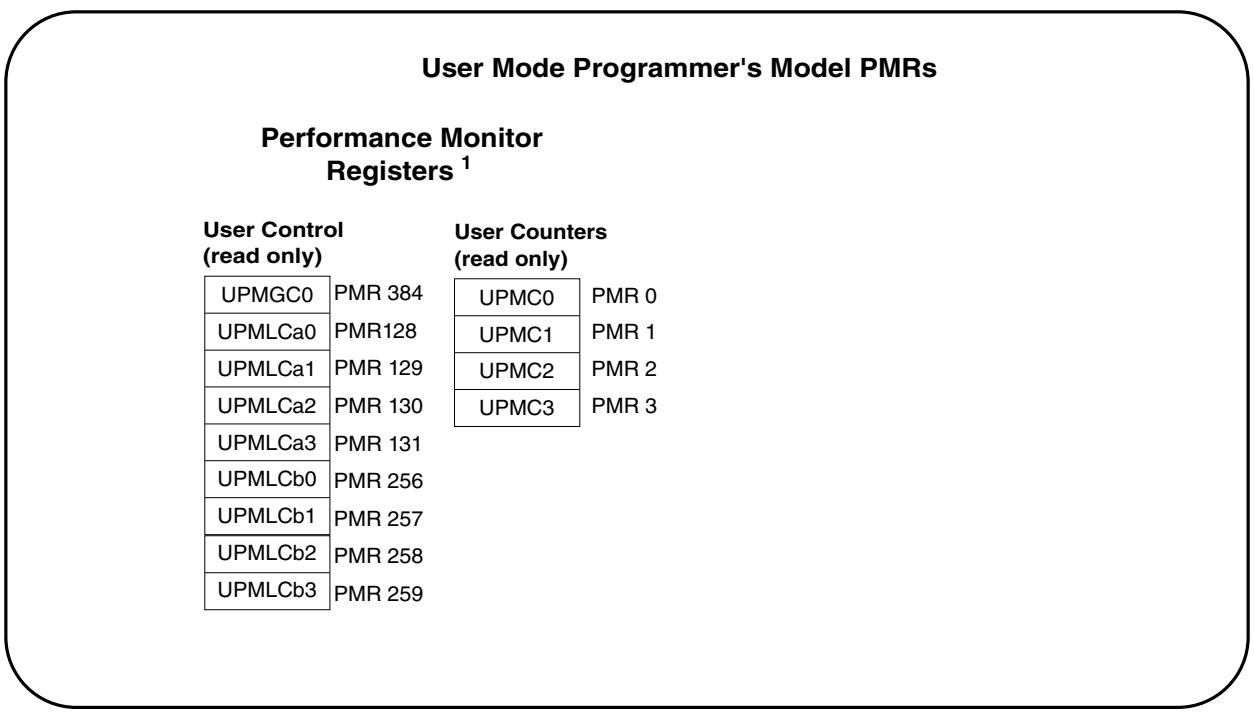

Figure 15-4. e200z7260n3 User Mode Programmer's Model PMRs

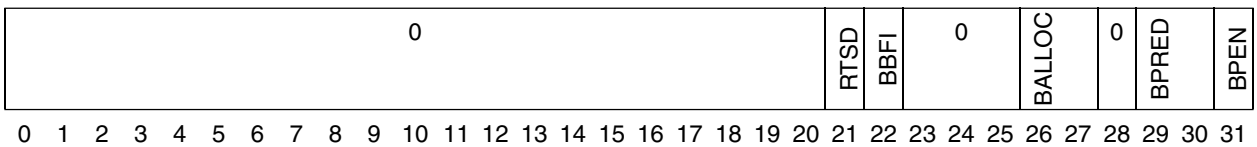
15.2.1 Branch Unit Control and Status Register (BUCSR)

The BUCSR register is used for general control and status of the branch target buffer (BTB). The BTB is detailed in Instruction prefetch buffers and branch target buffer. The BUCSR is shown in the following figure.



SPR — 1013; Read/Write; Reset — 0x0

Figure 15-5. Branch Unit Control and Status Register (BUCSR)

The BUCSR fields are defined in the following table.

Table 15-1. Branch Unit Control and Status Register (BUCSR)

Bits	Name	Description
0:20 [32:52]	-	Reserved
21 [53]	RTSD	Return Stack Disable 0 - Return Stack is enabled. 1 - Return Stack is disabled and invalidated. When written to a '1', the Return Stack is disabled, and the valid bit of all entries is cleared regardless of the value of the enable bit (BPEN). The Return Stack is only enabled when BPEN=1 and RTSD=0.
22 [54]	BBFI	Branch target buffer flash invalidate. When written to a '1', BBFI flash clears the valid bit of all entries in the branch target buffer, as well as return stack entries; clearing occurs regardless of the value of the enable bit (BPEN). Note: BBFI is always read as 0.
23:25 [55:57]	-	Reserved
26:27 [58:59]	BALLOC	Branch Target Buffer Allocation Control. This field controls BTB allocation for branch acceleration when BPEN = 1. Note that BTB hits are not affected by the settings of this field. 00 Branch Target Buffer allocation for all branches is enabled. 01 Branch Target Buffer allocation is disabled for backward branches. 10 Branch Target Buffer allocation is disabled for forward branches. 11 Branch Target Buffer allocation is disabled for both branch directions.
28 [60]	-	Reserved
29:30 [61:62]	BPRED	Branch Prediction Control (Static). This field controls operation of static prediction mechanism on a BTB miss. When a branch is predicted as taken, fetching of the predicted target location will be performed for branch acceleration. BPRED operates independently of BPEN, and with a BPEN setting of 0, will be used to perform static prediction of all unresolved branches. 00 Branch predicted taken on BTB miss for all branches. 01 Branch predicted taken on BTB miss only for forward branches.

Table continues on the next page...

Table 15-1. Branch Unit Control and Status Register (BUCSR) (continued)

Bits	Name	Description
		10 Branch predicted taken on BTB miss only for backward branches. 11 Branch predicted not taken on BTB miss for both branch directions. **NOTE:** BTB hits are not affected by the settings of this field. Note also that for certain applications, setting BPRED to a non-default value may result in improved performance.
31 [63]	BPEN	Branch target buffer prediction enable. When the BPEN bit is cleared, no hits will be generated from the BTB, and no new entries will be allocated. Entries are not automatically invalidated when BPEN is cleared; the BBFI bit controls entry invalidation. BPEN operates independently of BPRED, and will be used even with a BPRED setting of 00. 0 Branch target buffer prediction disabled 1 Branch target buffer prediction enabled (enables BTB to predict branches)

15.2.2 Hardware Implementation Dependent Register 0 (HID0)

The HID0 register is a z7260n3 implementation dependent register used for various configuration and control functions. It is shown in the following figure.

SPR - 1008; Read/Write; Reset - 0x0

Figure 15-6. Hardware Implementation Dependent Register 0 (HID0)

The HID0 fields are defined in the following table.

Table 15-2. Hardware Implementation-Dependent Register 0

Bits	Name	Description
0 [32]	EMCP	Enable machine check pin (p_mcp_b) 0 p_mcp_b pin is disabled. 1 p_mcp_b pin is enabled. Asserting p_mcp_b causes a machine check interrupt to be reported.
1:13 [33:45]	-	Reserved
14 [46]	ICR	Interrupt Inputs Clear Reservation 0 External Input, Critical Input, and Non-Maskable Interrupts do not affect reservation status 1 External Input, Critical Input, and Non-Maskable Interrupts clear an outstanding reservation
15 [47]	NHR	Not hardware reset 0 indicates to a reset exception handler that a reset occurred if software had previously set this bit

Table continues on the next page...

Table 15-2. Hardware Implementation-Dependent Register 0 (continued)

Bits	Name	Description
		1 indicates to a reset exception handler that no reset occurred if software had previously set this bit Provided for software use. Set anytime by software, cleared by reset.
16:18 [48:50]	-	Reserved
19 [51]	DCLREE	Debug Interrupt Clears MSREE 0 MSREEunaffected by Debug Interrupt 1 MSREE cleared by Debug Interrupt This bit controls whether Debug interrupts force External Input interrupts to be disabled, or whether they remain unaffected.
20 [52]	DCLRCE	Debug Interrupt Clears MSRCE 0 MSRCE unaffected by Debug Interrupt 1 MSRCE cleared by Debug Interrupt This bit controls whether Debug interrupts force Critical interrupts to be disabled, or whether they remain unaffected.
21 [53]	CICLRDE	Critical Interrupt Clears MSRDE 0 MSRDE unaffected by Critical class interrupt 1 MSRDE cleared by Critical class interrupt This bit controls whether Critical interrupts force Debug interrupts to be disabled, or whether they remain unaffected. Machine Check interrupts have a separate control bit. Note that if Critical Interrupt Debug events are enabled (DBCR0CIRPT set), and MSRDE is set at the time of a Critical Input Critical interrupt, a debug event will be generated after the Critical Interrupt Handler has been fetched, and the Debug handler will be executed first. In this case, DSRR0DE will have been cleared, such that after returning from the debug handler, the Critical interrupt handler will not be run with MSRDE enabled.
22 [54]	MCCLRDE	Machine Check Interrupt Clears MSRDE 0 MSRDE unaffected by Machine Check interrupt 1 MSRDE cleared by Machine Check interrupt This bit controls whether Machine Check interrupts force Debug interrupts to be disabled, or whether they remain unaffected.
23:30 [58:62]	-	Reserved
31 [63]	NOPTI	No-op Touch Instructions 0 icbt, dcbt, dcbtst instructions operate normally 1 icbt, dcbt, dcbtst instructions are no-oped This bit only affects the icbt, dcbt, and dcbtst instructions.

15.2.3 Synchronization requirements for SPRs and DCRs

With the exception of the following registers, there are no synchronization requirements for accessing SPRs and DCRs beyond those stated in PowerISA 2.06. A complete description of Synchronization requirements are contained in Chapter 12 of BookIII-E of PowerISA 2.06. Software requirements for synchronization before/after accessing these registers are shown in the following table. The notation CSI in the table refers to a Context Synchronizing instruction which include e_sc, se_sc, se_isync, se_rfi, se_rfci, se_rfmci, and se_rfdi.

Table 15-3. Additional synchronization requirements for SPRs and DCRs

Context altering event or instruction		Required before	Required after	Notes
mtmsr[PMM]		none	CSI	
mfspr, mfdcr				
DBSR	Debug Status register	msync	none	
E2EECSR0	End-to-End ECC Error Control and Status Register 0	msync	none	
HID0	Hardware Implementation-Dependent reg 0	none	none	
HID1	Hardware Implementation-Dependent reg 1	msync	none	
L1CSR0, L1CSR1, L1CSR2	L1 cache control and status registers 0,1,2	msync	none	
L1FINV0, L1FINV1	L1 cache flush and invalidate control registers 0,1	msync	none	
MPU0CSR0	MPU control and status register 0	CSI	none	
mtspr, mtdcr				
BUCSR	Branch Unit Control and Status Register	none	CSI	
DBCR0-10	Debug Control Register 0-10	none	CSI	
DBSR	Debug Status Register	msync	none	
DMEMCTL0,1	Local Data Memory Control Register 0 and 1	msync, isync	CSI	
E2ECTL0	End-to-End ECC Control and Status Register 0	msync, isync	CSI	
E2EECSR0	End-to-End ECC Error Control and Status Register 0	msync	CSI	
HID0	Hardware Implementation-Dependent reg 0	CSI	isync	
HID1	Hardware Implementation-Dependent reg 1	msync, isync	CSI	
L1CSR0	L1 cache control and status register 0	msync, isync	CSI	
L1CSR1	L1 cache control and status register 1	msync, isync	CSI	
L1CSR2	L1 cache control and status register 2	msync, isync	CSI	
L1FINV0, L1FINV1	L1 cache flush and invalidate control registers 0,1	msync	CSI	
MASx	MPU MAS registers	none	CSI	
MPU0CSR0	MPU control and status register 0	CSI	CSI	
PID (PID0)	PID0 register	CSI	CSI	
SPEFSCR	SPEFSCR register	none	CSI1	
Notes: 1. not required for status bit clearing, required for altering exception enable or rounding mode bits				

15.3 Dual-issue operation

The instruction issue unit attempts to issue a pair of instructions to the execution units each cycle. Source operands for each of the instructions are provided from the GPRs or from the operand feed-forward muxes. Data or resource hazards may create stall conditions that cause instruction issue to be stalled for one or more cycles until the hazard is eliminated.

The execution units write the result of a finished instruction onto the proper result bus and into the destination registers. The writeback logic retires an instruction when the instruction has finished execution. Up to three results can be simultaneously written.

Two execution units are provided to allow dual issue of most instructions. Only a single load/store unit is provided. Only a single integer multiply and divide unit is provided, thus a pair of multiply or divide instructions cannot issue simultaneously. In addition, the divide unit is blocking.

The following table shows the e200z7260n3 concurrent instruction issue capabilities. Note that data dependencies between instructions will generally preclude z7260_dual-issue of those instructions.

Table 15-4. Concurrent instruction issue capabilities for e200z425n3/e200z720n3

Class of instruction	Branch	Load/ Store	Scalar integer	Scalar float	Vector integer non-MAC	Vector integer MAC	Special
Branch	—	yes	yes	yes	yes	yes	—
Load/Store	yes	—	yes	yes	yes	yes	—
Scalar integer	yes	yes	yes[1]	yes	yes	yes[2]	—
Scalar float	yes	yes	yes	—	yes	yes	—
Vector integer non-MAC	yes	yes	yes	yes	yes	yes	—
Vector integer MAC	yes	yes	yes[2]	yes	yes	—	—
Special	—	—	—	—	—	—	—

1. Excludes multiply or divide class instructions occurring in both issue slots.
2. Excludes vector MAC/multiply class instructions occurring with scalar multiply, or divide class instructions.

15.4 Instruction prefetch buffers and branch target buffer

A ten-entry instruction prefetch buffer supplies instructions into the Instruction Register (IR) for decoding. Each slot in the prefetch buffer is 32 bits wide, capable of holding a single 32-bit instruction, or a pair of 16-bit instructions.

Instruction prefetches request a 64-bit doubleword and the prefetch buffer is filled with a pair of instructions at a time, except for the case of a change of flow fetch where the target is to the second (odd) word. In that case only a 32-bit prefetch is performed to load the instruction prefetch buffer. This 32-bit fetch may be immediately followed by a 64-bit prefetch to fill Slots 0 and 1 in the event that the branch is resolved to be taken.

In normal sequential execution, instructions are loaded into the IR from prefetch buffer Slot 0 and 1, and as a pair of slots are emptied, they are refilled. Whenever a pair of slots is empty, a prefetch is initiated which fills the earliest empty slot pairs beginning with Slot 0.

If the instruction prefetch buffer empties, instruction issue stalls, and the buffer is refilled. The first returned instruction is forwarded directly to the IR. Open cycles on the memory bus are utilized to keep the buffer full when possible.

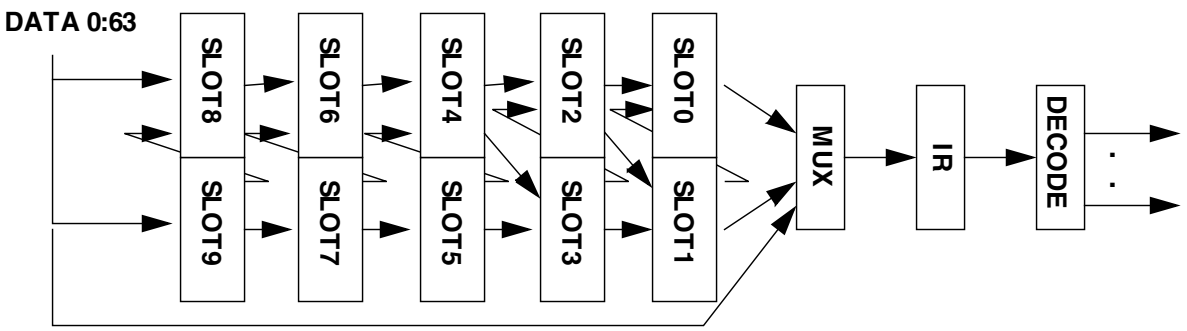


Figure 15-7. Instruction prefetch buffers

To resolve branch instructions and improve the accuracy of branch predictions, the z7260n3 implements a dynamic branch prediction mechanism using a 32/32-entry branch target buffer (BTB) and a 3-entry Return Stack used for subroutine return address prediction.

An entry is allocated in the BTB whenever a branch resolves as taken and the BTB is enabled and misses. Certain branches do not allocate BTB entries: se_bctr, se_bctrl, and se_blrl. Entries in the BTB are allocated on taken branches using a FIFO replacement algorithm.

The 32/32-entry branch target buffer structure is composed of two portions, each having 32 entries. The first portion holds non-return type branches (non-se_blr), while the second portion holds return-type instructions (se_blr) and works in conjunction with the return stack. Each BTB entry in the first portion holds a branch instruction address tag value, the branch target address, and a 2-bit branch history counter whose value is incremented or decremented on a BTB hit, depending on whether the branch was taken. Each BTB entry in the second portion holds only a branch instruction address tag value and a 2-bit branch history counter, and the branch return address is obtained from the

return stack. The counters can assume four different values: strongly taken, weakly taken, weakly not taken, and strongly not taken. On initial allocation of an entry to the BTB for a taken branch, the counter is initialized to the weakly-taken state.

The return stack is a 3-entry LIFO used to predict return addresses when a branch to link register instruction is encountered. A return stack entry is pushed whenever a branch with link instruction (e_bl, e_bcl, se_bl) is executed, or is pushed speculatively when one hits in the BTB. Return stack entries are popped when a branch to link register instruction (se_blr) is encountered. Return address predictions are validated with the current value of the link register when the se_blr instruction reaches the decode pipeline stage, and mispredictions result in a re-fetch of the correct target instruction stream.

A branch will be predicted as taken on a hit in the BTB with a counter value of strongly or weakly taken. In this case the target address contained in the BTB or return stack is used to redirect the instruction fetch stream to the target of the branch prior to the branch reaching the instruction decode stage. In the case of a BTB miss, static prediction is used to predict the outcome of the branch. In the case of a mispredicted branch, the instruction fetch stream will return to the proper instruction stream after the branch has been resolved.

When a branch is predicted taken and the branch is later resolved (in the branch execute stage), the value of the appropriate BTB counter is updated. If a branch whose counter indicates weakly taken is resolved as taken, the counter increments so that the prediction becomes strongly taken. If the branch resolves as not taken, the prediction changes to weakly not-taken. The counter saturates in the strongly taken states when the prediction is correct.

The z7260n3 does not implement the static branch prediction that is defined by the PowerISA architecture. The BO prediction information in branch encodings is ignored.

Dynamic branch prediction is enabled by setting $BUCSR_{BPEN}$. Allocation of branch target buffer entries may be controlled using the $BUCSR_{BALLOC}$ field to control whether forward or backward branches (or both) are candidates for entry into the BTB, and thus for branch prediction. Once a branch is in the BTB, $BUCSR_{ALLOC}$ has no further effect on that branch entry. Clearing $BUCSR_{BPEN}$ disables dynamic branch prediction, in which case the z7260n3 reverts to a static prediction mechanism using the $BUCSR_{BPRED}$ field to control whether forward or backward branches (or both) are predicted taken or not taken.

The BTB uses instruction fetch addresses for performing tag comparisons. On allocation of a BTB entry, the effective address of a taken branch is loaded into the entry as the tag value, and the counter value is set to weakly taken. The current PID value is not maintained as part of the tag information.

The z7260n3 does support automatic flushing of the BTB when the current PID value is updated by a mtcr PID0 instruction. Software is otherwise responsible for maintaining coherency in the BTB when a change in target address mapping is changed. This is supported by the $BUCSR_{BBFI}$ control bit.

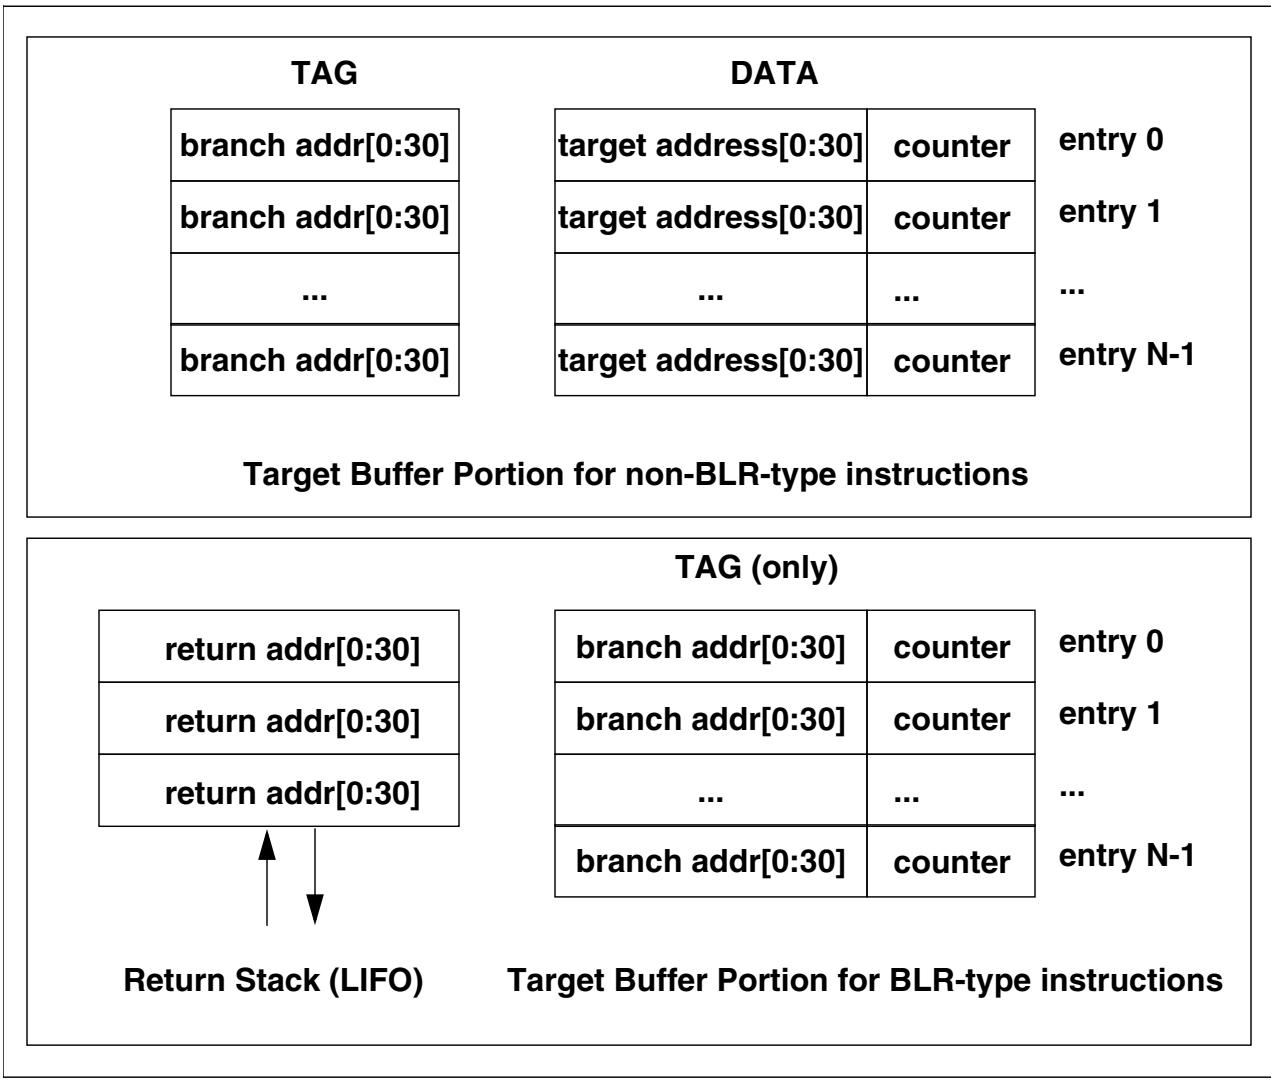

Figure 15-8. Branch target buffer with return stack

15.5 Reservation instructions and cache interactions

The CPU treats reservation instruction (**lbarx**, **lharx**, **lwarx**, **stbcx**, **sthcx**, and **stwcx**) accesses as though they were cache-inhibited, and forces a cache miss. A reservation access is always issued to the bus. This is done to allow external reservation logic to be built that properly signals a reservation failure. The bus access will be treated as a single-beat transfer.

15.6 Signal Processing Extension/Embedded Floating-point Status and Control Register (SPEFSCR)

Status and control for embedded floating-point operations use the SPEFSCR. The SPEFSCR is implemented as special-purpose register (SPR) number 512 and is read and written by the mfspr and mtspr instructions. The SPEFSCR is shown in the following figure.

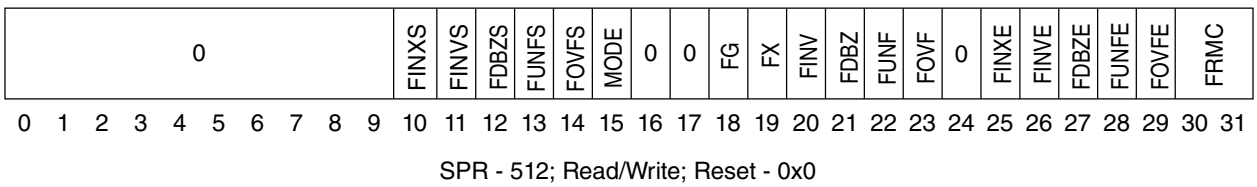

Figure 15-9. EFPU Status and Control Register (SPEFSCR)

The SPEFSCR bits are defined in the following table.

Table 15-5. EFPU Status and Control Register field descriptions

Bits	Name	Description
0:9 (32:41)	—	Reserved
10 (42)	FINXS	Embedded Floating-point Inexact Sticky Flag The FINXS bit is set to 1 whenever the execution of a floating-point instruction delivers an inexact result and no Floating-point Data exception is taken, or if the result of a Floating-point instruction results in overflow (FOVF = 1), but Floating-point Overflow exceptions are disabled (FOVFE = 0), or if the result of a Floating-point instruction results in underflow (FUNF = 1), but Floating-point Underflow exceptions are disabled (FUNFE = 0), and no Floating-point Data exception occurs. The FINXS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
11 (43)	FINVS	Embedded Floating-point Invalid Operation Sticky Flag The FINVS bit is set to a 1 when a floating-point instruction sets the FINV bit to 1. The FINVS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
12 (44)	FDBZS	Embedded Floating-point Divide by Zero Sticky Flag The FDBZS bit is set to 1 when a floating-point divide instruction sets the FDBZ bit to 1. The FDBZS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
13 (45)	FUNFS	Embedded Floating-point Underflow Sticky Flag The FUNFS bit is set to 1 when a floating-point instruction sets the FUNF bit to 1. The FUNFS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
14 (46)	FOVFS	Embedded Floating-point Overflow Sticky Flag The FOVFS bit is set to 1 when a floating-point instruction sets the FOVF bit to 1. The FOVFS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
15 (47)	MODE	Embedded Floating-point Operating Mode This bit controls the operating mode of the EFPU. e200z7260n3 supports only mode 0.

Table continues on the next page...

Table 15-5. EFPU Status and Control Register field descriptions (continued)

Bits	Name	Description
		Software should read the value of this bit after writing it to determine if the implementation supports the selected mode. Implementations will return the value written if the selected mode is a supported mode, otherwise the value read will indicate the hardware supported mode. 0 Default hardware results operating mode 1 IEEE754 hardware results operating mode (not supported by Zen)
16 (48)	—	Reserved
17 (49)	—	Reserved
18 (50)	FG	Embedded Floating-point Guard bit FG is supplied for use by the Floating-point Round exception handler. FG is zeroed if a Floating-point Data Exception occurs.
19 (51)	FX	Embedded Floating-point Sticky bit FX is supplied for use by the Floating-point Round exception handler.FX is zeroed if a Floating-point Data Exception occurs.
20 (52)	FINV	Embedded Floating-point Invalid Operation / Input error In mode 0, the FINV bit is set to 1 if the A or B operand of a floating-point instruction is Infinity, NaN, or Denorm, or if the operation is a divide and the dividend and divisor are both 0. In mode 1, the FINV bit is set on an IEEE754 invalid operation (IEEE754-1985 sec7.1).
21 (53)	FDBZ	Embedded Floating-point Divide by Zero The FDBZ bit is set to 1 when a floating-point divide instruction executed with divisor of 0, and the l dividend is a finite non-zero number.
22 (54)	FUNF	Embedded Floating-point Underflow The FUNF bit is set to 1 when the execution of a floating-point instruction results in an underflow.
23 (55)	FOVF	Embedded Floating-point Overflow The FOVF bit is set to 1 when the execution of a floating-point instruction results in an overflow.
24 (56)	—	Reserved
25 (57)	FINXE	Embedded Floating-point Inexact Exception Enable If the exception is enabled, a Floating-point Round exception is taken if the result of a Floating-point instruction does not result in overflow or underflow, and the result is inexact (FG | FX = 1), or if the result of a Floating-point instruction does result in overflow (FOVF = 1) but Floating-point Overflow exceptions are disabled (FOVFE = 0), or if the result of a Floating-point instruction results in underflow (FUNF = 1 or FUNFH = 1) but Floating-point Underflow exceptions are disabled (FUNFE = 0), and no Floating-point Data exception occurs. 0 Exception disabled 1 Exception enabled
26 (58)	FINVE	Embedded Floating-point Invalid Operation / Input Error Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FINV bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled

Table continues on the next page...

Table 15-5. EFPU Status and Control Register field descriptions (continued)

Bits	Name	Description
27 (59)	FDBZE	Embedded Floating-point Divide by Zero Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FDBZ bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled
28 (60)	FUNFE	Embedded Floating-point Underflow Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FUNF bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled
29 (61)	FOVFE	Embedded Floating-point Overflow Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FOVF bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled

15.7 Cache

This section describes the cache registers, cache control instructions, and various cache operations.

15.7.1 Cache overview

The e200z7260n3 processor supports a 16 KB 2-way set-associative instruction and 16KB 2-way set-associative data cache with a 32-byte line size. The caches improves system performance by providing low-latency data to the e200z7260n3 instruction and data pipelines, which decouples processor performance from system memory performance.

The e200z7260n3 processor also contains an 8-entry store buffer to decouple store completion to the processor from store completion on the data interface to further improve system performance.

Instruction and data addresses from the processor are used to index the cache arrays. If the access address matches a valid cache tag entry, the access hits in the cache.

15.7.2 L1 Cache Control and Status Register 0 (L1CSR0)

The L1 Cache Control and Status Register 0 (L1CSR0) is a 32-bit register used for general control of the a data cache and for disabling ways in both caches. The L1CSR0 register is accessed using a **mfspr** or **mtspr** instruction. The SPR number for L1CSR0 is 1010 in decimal. The L1CSR0 register is shown in the following figure.

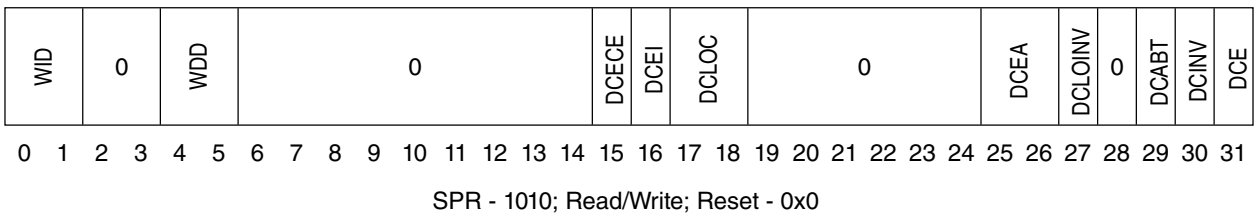

Figure 15-10. L1 Cache Control and Status Register 0 (L1CSR0)

The L1CSR0 fields are described in the following table.

Table 15-6. L1CSR0 field descriptions

Bits	Name	Description
0:1	WID	Way Instruction Disable Bit 0 corresponds to way 0. Bit 1 corresponds to way 1. The WID bits may be used for locking ways of the instruction cache, and also affect the replacement policy of the instruction cache. 0 The corresponding way in the instruction cache is available for replacement by instruction miss line fills. 1 The corresponding way instruction cache is not available for replacement by instruction miss line fills.
2:3	—	Reserved[1]
4:5	WDD	Way Data Disable Bit 4 corresponds to way 0. Bit 5 corresponds to way 1. The WDD bits may be used for locking ways of the data cache, and also affect the replacement policy of the data cache. 0 The corresponding way in the data cache is available for replacement by data miss line fills. 1 The corresponding way in the data cache is not available for replacement by data miss line fills.
8:11	—	Reserved[2]
12	DCWA	Data Cache Write Allocation Policy

Table continues on the next page...

Table 15-6. L1CSR0 field descriptions (continued)

Bits	Name	Description
		This bit also controls merging of store data into the linefill buffer while a cache linefill is in progress. Store data will not be merged when write allocation is disabled. 0 Cache line allocation on a cacheable write miss is disabled 1 Cache line allocation on a cacheable write miss is enabled
13:14	—	Reserved[2]
15	DCECE	Data Cache Error Checking Enable 0 Error Checking is disabled 1 Error Checking is enabled
16	DCEI	Data Cache Error Injection DCEI will cause injection of errors regardless of the setting of DCECE, although reporting of errors will be masked while DCECE = 0. 0 Cache Error Injection is disabled 1 A double-bit error will be injected on each write into the cache data array by inverting the two uppermost parity check bits (p_dchk[0:1]). This includes writes due to store hits as well as writes due to cache line refills.
17:18	DCLOC	Data Cache Lockout Control **Note:** For the **dcbi** and **dcbf** instructions, and for specialized load/store instructions, no lockout operation is performed, regardless of the occurrence of EDC/ECC error conditions, and errors are handled in the same manner as when lockout is disabled. **Note:** When operating in MC mode (DCEA = 00), detected errors on cache-inhibited accesses will not cause a data cache line to be locked out, instead the cache line contents are ignored. 00 Cache line lockout is disabled (and array LO indicators are ignored). 01 Cache line lockout is enabled. Cache lines with any tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. 10 Cache line lockout is enabled. Cache lines with any tag or data errors will have the corresponding lockout indicators set. A Machine check will still be generated for an error if the operation would have normally generated one. 11 Cache line lockout is enabled. Cache lines with uncorrectable tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. If a correctable tag error occurs, and is re-detected on recycling the access after a correction cycle for the tag is performed, the line is locked out regardless of detecting a single-bit or multi-bit error.
19:24	—	Reserved[2]
25:26	DCEA	Data Cache Error Action 00 Error Detection causes Machine Check exception.

Table continues on the next page...

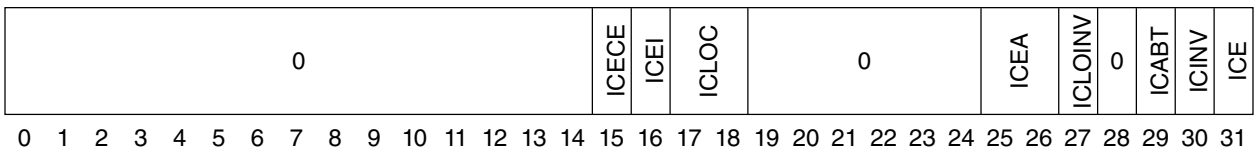
Table 15-6. L1CSR0 field descriptions (continued)

Bits	Name	Description
		01 Error Detection causes Correction/Auto-invalidation. No machine check is generated for most cases. Correction is performed for single-bit tag errors, and lines with multi-bit tag errors are invalidated. Correction is performed for single or multi-bit data errors on cache hits by reloading of the line. 10 Reserved 11 Reserved
27	DCLOINV	Data Cache Lockout Indicator Invalidate When written to a 1 in conjunction with writing DCINV to a 1, a cache lockout indicator invalidation operation is initiated by hardware, and the LO bits are cleared, removing all line lockout status. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. Cache lockout bit invalidation operations require approximately 66 cycles to complete. Invalidation occurs regardless of the data cache enable (DCE) value. When DCINV = 0: Reserved, do not set to 1 When DCINV = 1: 0 No cache lockout bit invalidate 1 Cache lockout indicator invalidation operation
28	—	Reserved[2]
29	DCABT	Data Cache Operation Aborted Indicates a Cache Invalidate operation was aborted prior to completion. This bit is set by hardware on an aborted condition, and will remain set until cleared by software writing 0 to this bit location.
30	DCINV	Data Cache Invalidate When written to a 1, a cache invalidation operation is initiated by hardware. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. Cache invalidation operations require approximately 66 cycles to complete. Invalidation occurs regardless of the data cache enable (DCE) value. 0 No cache invalidate 1 Cache invalidation operation
31	DCE	Data Cache Enable When disabled, cache lookups are not performed for normal load or store accesses.Other L1CSR0 cache control operations are still available. Also, operation of the store buffer is not affected by DCE. 0 Cache is disabled 1 Cache is enabled

1. These bits are not implemented and should be written with zero for future compatibility.

15.7.3 L1 Cache Control and Status Register 1 (L1CSR1)

The L1 Cache Control and Status Register 1 (L1CSR1) is a 32-bit register used for general control of the instruction cache. The L1CSR1 register is accessed using a **mfspr** or **mtspr** instruction. The SPR number for L1CSR1 is 1011 in decimal. The L1CSR1 register is shown in the following figure.



SPR - 1011; Read/Write; Reset - 0x0

Figure 15-11. L1 Cache Control and Status Register 1 (L1CSR1)

The L1CSR1 fields are described in the following table.

Table 15-7. L1CSR1 field descriptions

Bits	Name	Description
0:14	—	Reserved[1]
15	ICECE	Instruction Cache Error Checking Enable 0 Error Checking is disabled 1 Error Checking is enabled
16	ICEI	Instruction Cache Error Injection Enable ICEI will cause injection of errors regardless of the setting of ICECE, although reporting of errors will be masked when ICECE = 0. 0 Cache Error Injection is disabled 1 A double-bit error will be injected into each doubleword written into the cache by inverting the two uppermost parity check bits (p_chk[0:1]).
17:18	ICLOC	Instruction Cache Lockout Control **Note:** For the **icbi** instruction, no lockout operation is performed, regardless of the occurrence of EDC/ECC error conditions, and errors are handled in the same manner as when lockout is disabled. See ECC/EDC Error Handling for Cache Control Operations and Instructions. **Note:** When operating in MC mode (ICEA = 00), detected errors on cache-inhibited accesses will not cause an instruction cache line to be locked out, instead the cache line contents are ignored. 00 Cache line lockout is disabled (and array LO indicators are ignored). 01 Cache line lockout is enabled. Cache lines with any tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. 10 Cache line lockout is enabled. Cache lines with any tag or data errors will have the corresponding lockout indicators set. A Machine check will still be generated for an error if the operation would have normally generated one.

No constraints on alignment or requirement to be contiguous. External bus write accesses for gathered stores may have non-contiguous byte strobes asserted. 10 - Store Gathering is enabled. Gathered stores are required to be contiguous once gathered. Cache hit data from a store access lookup may be used to provide adjacent store data to increase gathering opportunities. External bus write accesses for gathered stores will not have non-contiguous byte strobes asserted. 11 - No Store Gathering is Performed
4:31	—	Reserved

15.7.5 L1 Cache Configuration Register 0 (L1CFG0)

The L1 Cache Configuration Register 0 (L1CFG0) is a 32-bit read-only register. L1CFG0 provides information about the configuration of the e200z7260n3 L1 data cache design. The contents of the L1CFG0 register can be read using a **mfspr** instruction. The SPR number for L1CFG0 is 515 in decimal. The L1CFG0 register is shown in the following figure.

Figure 15-13. L1 Cache Configuration Register 0 (L1CFG0)

The L1CFG0 bits are described in the following table.

Table 15-9. L1CFG0 field descriptions

Bits	Name	Description
0:1	CARCH	Cache Architecture 00 The cache architecture is Harvard
2	CWPA	Cache Way Partitioning Available 1 The caches support partitioning of way availability for I/D accesses
3	DCFAHA	Data Cache Flush All by Hardware Available 0 The data cache does not support Flush All in Hardware
4	DCFISWA	Data Cache Flush/Invalidate by Set and Way Available 1 The data cache supports invalidation by Set and Way via L1FINV0
5:6	—	Reserved - read as zeros
7:8	DCBSIZE	Data Cache Block Size 00 The data cache implements a block size of 32 bytes
9:10	DCREPL	Data Cache Replacement Policy 11 The data cache implements a FIFO replacement policy
11	DCLA	Data Cache Locking APU Available 0 The data cache does not implement the line locking APU
12	DCECA	Data Cache Error Checking Available 1 The data cache implements error checking
13:20	DCNWAY	Data Cache Number of Ways 0x01 The data cache is 2-way set-associative
21:31	DCSIZE	Data Cache Size 0x010 The size of the data cache is 10 KB

15.7.6 L1 Cache Configuration Register 1 (L1CFG1)

The L1 Cache Configuration Register 1 (L1CFG1) is a 32-bit read-only register. L1CFG1 provides information about the configuration of the e200z7260n3 L1 instruction cache design. The contents of the L1CFG1 register can be read using a **mfspr** instruction. The SPR number for L1CFG1 is 516 in decimal. The L1CFG1 register is shown in the following figure.

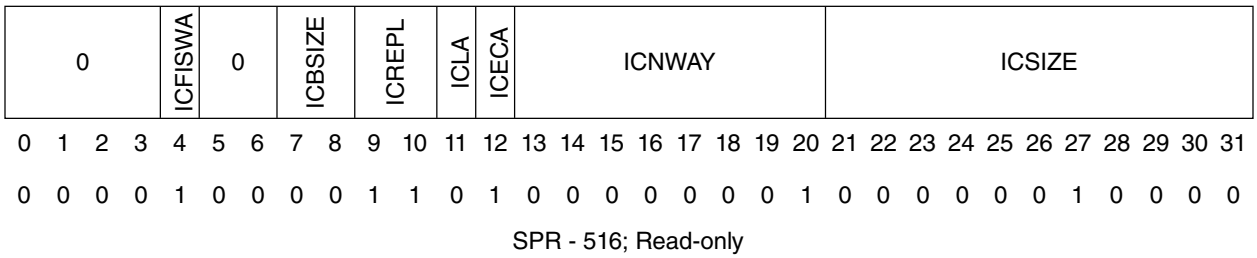

Figure 15-14. L1 Cache Configuration Register 1 (L1CFG1)

The L1CFG1 fields are described in the following table.

Table 15-10. L1CFG1 field descriptions

Bits	Name	Description
0:3	—	Reserved - read as zeros
4	ICFISWA	Instruction Cache Flush/Invalidate by Set and Way Available 1 The instruction cache supports invalidation by Set and Way via L1FINV1
5:6	—	Reserved - read as zeros
7:8	ICBSIZE	Instruction Cache Block Size 00 The instruction cache implements a block size of 32 bytes
9:10	ICREPL	Instruction Cache Replacement Policy 11 The instruction cache implements a FIFO replacement policy
11	ICLA	Instruction Cache Locking APU Available 0 The instruction cache does not implement the line locking APU
12	ICECA	Instruction Cache Error Checking Available 1 The instruction cache implements error checking
13:20	ICNWAY	Instruction Cache Number of Ways 0x01 The instruction cache is 2-way set-associative
21:31	ICSIZE	Instruction Cache Size 0x010 The size of the instruction cache is 16 KB

15.7.7 Data Cache Software Coherency

Data cache coherency is supported through software operations to invalidate lines using either a **dcbi** or **dcbf** instruction, or by using the L1FINV0 control register.

Data cache misses will force the store buffer to empty prior to performing the access.

15.7.8 Data Cache Hardware Coherency

Data cache coherency is not supported in hardware. Software operations must generally be used to maintain coherency. Debug support is provided, however, for a D-Cache line invalidation operation requested by an external hardware debugger. When requested by an external hardware debugger tool operating through the OnCE port, an individual cache line invalidation operation will be scheduled to occur at the next available D-Cache access cycle.

15.7.9 Cache Invalidate by Set and Way

e200z7260n3 supports cache set/way invalidation under software control. The caches may be invalidated by index and way through a **mtspr l1finv{0,1}** instruction.

The L1 Flush and Invalidate Control Registers (L1FINV{0,1}) are 32-bit SPRs used to select a cache set and way to be invalidated. This function is available even when a cache is disabled. L1FINV0 is used for data cache operations, while L1FINV1 is used for instruction cache operations.

15.7.9.1 L1FINV0

The SPR number for L1FINV0 is 1016 in decimal. The L1FINV0 register is shown in the following figure.

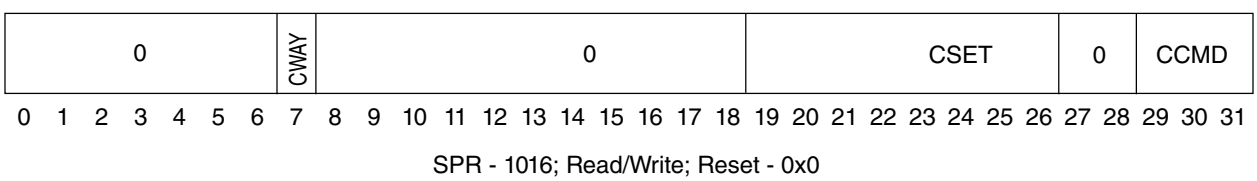

Figure 15-15. L1 Flush/Invalidate Register 0 (L1FINV0)

The L1FINV0 bits are described in the following table.

Table 15-11. L1FINV0 field descriptions

Bits	Name	Description
0:6	—	Reserved[1] for way extension
7	CWAY	Cache Way Specifies the data cache way to be selected
8: 18	—	Reserved[1] for set extension
19:26	CSET	Cache Set Specifies the cache set to be selected
27:28	—	Reserved[1] for set/command extension
29:31	CCMD	Cache Command 000 = The data contained in this entry is invalidated. LO bits are unaffected 001 Reserved 01x Reserved 100 Reserved 101 The data contained in this entry is invalidated. LO bits are cleared 11x Reserved

1. These bits are not implemented and should be written with zero for future compatibility.

For invalidation operations via L1FINV0, tag ECC errors and data EDC errors are ignored, and the selected line will be invalidated regardless of any error. Invalidations conditionally affect the state of the lockout bits (LO).

15.7.9.2 L1FINV1

The SPR number for L1FINV1 is 959 in decimal. The L1FINV1 register is shown in following figure.

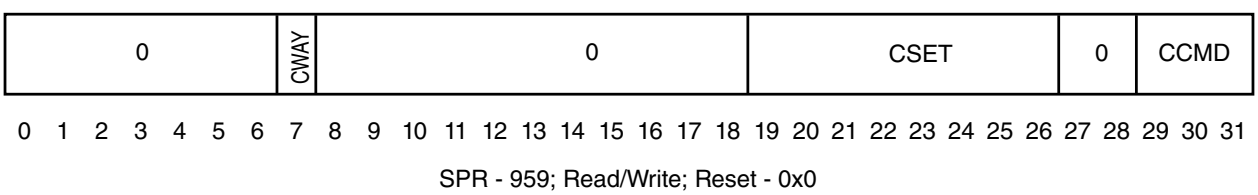

Figure 15-16. L1 Flush/Invalidate Register 1 (L1FINV1)

The L1FINV1 bits are described in the following table.

Table 15-12. L1FINV1 field descriptions

29:31	CCMD	Cache Command 000 The data contained in this entry is invalidated. LO bits are unaffected 001 Reserved 01x Reserved 100 Reserved 101 The data contained in this entry is invalidated. LO bits are cleared 11x Reserved

1. These bits are not implemented and should be written with zero for future compatibility.

For invalidation operations via L1FINV1, tag ECC errors and data EDC errors are ignored, and the selected line will be invalidated regardless of any error. Invalidations conditionally affect the state of the lockout bits (LO).

15.7.10 Cache EDC/ECC Parity Protection

Cache parity protection is supported for both the tag and data arrays of each cache. Seven parity check bits are provided for each tag entry for the tag arrays of both caches to support error detection and correction (ECC - SECDED). Eight parity check bits are provided for each doubleword in the data arrays of the I-Cache, and each word in the data arrays of the D-Cache, which are used for single- and double-bit error detection (EDC - DED, double error detection). Utilizing ECC/EDC protection, many multi-bit errors are also detected.

The error detection codes also cover the cache index address of the cache line, providing additional protection against addressing errors. If any type of error (including a single-bit error in one of the index bits) is encountered in one of the index address bits, it is treated as an uncorrectable tag ECC error to protect against internal addressing failures. No attempt will be made to correct single-bit errors where the syndrome indicates an index address bit.

Tag ECC and data EDC checking is controlled by the $L1CSR0_{DCECE}$and $L1CSR1_{ICECE}$ control fields. When error checking is enabled, checking is performed on each cache access. Errors are not signaled by the respective cache when cache error checking is disabled for that cache ($L1CSR\{0,1\}_{[D,I]CECE} = 0$).

If an uncorrectable tag ECC error is detected on any portion of a tag accessed during cache lookups performed because of instruction fetching, normal loads, or normal stores, a tag ECC error is signaled, regardless of whether a cache hit or miss occurs. Otherwise, if a cache hit for an instruction fetch or a normal load occurs and a data EDC error is detected on any portion of the accessed data, a parity error is also signaled.

Store hits to the D-Cache will be placed into one of the RMW buffers to support EDC checkbit operation. If the store is a partial-width store, the cache data word corresponding to the address of the store is read into the next available buffer, the store data is merged, and the new EDC checkbits for the word are calculated. If the store is a full-width store, no read of the cache data is performed, since the store will overwrite the full EDC data granularity, and the EDC checkbits can be computed directly. Buffers are managed on a FIFO basis. If no buffer is available to hold the store data, a stall is incurred while a buffer (or two if possible) is written back to the cache to be freed for holding the new store. Buffers are written back to the D-Cache during otherwise idle cycles when two buffers are occupied, providing a simple form of store gathering.

Signaling of an ECC error or EDC error may cause a Machine Check exception to occur. One or more syndrome bits may be set in the Machine Check Syndrome register, or may instead result in a correction/auto-invalidation operation and not result in an exception being signaled. Both may occur, depending on the error action control setting in the appropriate cache control register.

15.7.10.1 Cache Line Lockout

In addition to the ECC/EDC protection employed for the caches, each cache line in the I-Cache and D-Cache has a lockout indicator composed of a redundant set of lockout bits. These lockout bits can selectively be set when certain errors occur in either the tag or the data portion of the cache line. Use of the lockout function and control over error conditions that cause a lockout to occur are controlled by $L1CSR\{0,1\}_{[D,I]CLOC}$. When the lockout function is enabled, lines that encounter selected tag ECC or data EDC errors on normal instruction fetch, load, or store accesses will have their lockout bits set. When the lockout indicator is set, the line will not be replaced and will remain in an invalid state, effectively disabling it. Also, future tag ECC or data EDC errors on the line are

ignored. Cache-inhibited accesses will only set lockout indicators on lines not in a locked way. In addition, no lockout indicators are set by cache-inhibited accesses when operating in machine check mode.

When operating in machine check mode, if lockout controls are enabled via L1CSR{0,1}$_{[D,I]CLOC}$, lockout bit parity errors on any line detected on a cacheable cache lookup will generate a machine check exception.

If correction/auto-invalidation is instead enabled, on each cache lookup operation for an instruction fetch or normal load or store access, if a single- or double-bit lockout bit parity error is detected in one or more ways and lockout controls are enabled, the lockout error(s) will be corrected by rewriting all lockout bits to the asserted state, and no machine check is generated, unless the line is in a locked way. If a line in a locked way incurs a LO bit parity error, a machine check will be generated to ensure that any possible new lockout of the line is reported. For non-cacheable accesses, lockout bit parity errors will only be corrected for lines not in a locked way. Lockout bit parity errors do not generate a machine check for non-cacheable accesses in either error action mode, thus lockout bit correction is not performed for lockout bit parity errors detected on a line in a locked way.

In addition, to avoid certain exception conditions and for consistency with error reporting, specialized load/store accesses do not set LO bits; instead, cache contents are ignored for lines with those errors. Cache flush and invalidate instructions do not report or correct lockout bit parity errors. For both of these cases, a future cacheable normal access will perform the lockout function if required.

15.7.11 Cache Fault Injection

Cache error injection provides a way to test error recovery by intentionally injecting parity errors into the instruction and/or data cache.

Error injection into the instruction cache operates as follows:

- If L1CSR1$_{ICEI}$ is set, any instruction cache line fill to the instruction cache data has the associated two most significant parity check bits inverted in the instruction cache data array for each doubleword loaded.

Error injection for the data cache operates as follows:

- If $L1CSR0_{DCEI}$ is set, any cache line fill to the data cache data array has the associated two most significant parity check bits inverted in the data array for each word loaded. Additionally, inverted parity bits are generated for any data stored into the data cache data array on a store hit.

Cache parity error injection is not performed for cache debug write accesses, since parity bit values written can be directly controlled.

In order to clear the parity errors, a cache invalidation or an invalidation of the lines that could have had an injected parity error may be performed. Line invalidation may be performed by an **icbi/dcbi** instruction, or an L1FINV{0,1} invalidation operation.

15.8 Exceptions

Interrupts implemented in e200z7260n3 and the exception conditions that cause them are listed in the following table.

Table 15-13. Exceptions and Conditions

Interrupt type	Interrupt vector offset value	Causing conditions
System reset	none, vector to [p_rstbase[0:29]] || 2'b00	Reset
Critical Input	0x00[1]	**p_critint_b** is asserted and MSR_{CE} = 1.
Machine check	0x10	1. **p_mcp_b** transitions from negated to asserted 2. ISI or Bus Error on first instruction fetch for an exception handler 3. Parity Error signaled on Cache access 4. Parity Error signaled on Local Memory access 5. External bus error 6. Stack limit check failure
Machine check (NMI)	0x10	Non-Maskable Interrupt
Data Storage	0x20	Access control
Instruction Storage	0x30	Access control
External Input	0x40[2]	Interrupt Controller interrupt and MSR_{EE} = 1
Alignment	0x50	1. **lmw**, **stmw** not word aligned 2. **lwarx** or **stwcx.** not word aligned, **lharx** or **sthcx.** not halfword aligned 3. **dcbz**
Program	0x60	Illegal, Privileged, Trap
Performance Monitor	0x70	Performance Monitor Enabled Condition or Event w/$PMGC0_{UDI}$ = 0

Table continues on the next page...

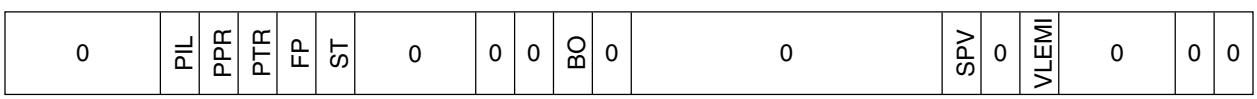
Table 15-13. Exceptions and Conditions (continued)

Interrupt type	Interrupt vector offset value	Causing conditions
System call	0x80	Execution of the System Call (**se_sc**) instruction
Debug	0x90	Trap, Instruction Address Compare, Data Address Compare, Instruction Complete, Branch Taken, Return from Interrupt, Interrupt Taken, Debug Counter, External Debug Event, Unconditional Debug Event, Performance Monitor Enabled Condition or Event w/$PMGC0_{UDI}$ = 1, MPU
EFPU Data Exception	0xA0	See core specification about Embedded Floating-point Data Exception
EFPU Round Exception	0xB0	See core specification about Embedded Floating-point Round Exception
SPE/EFPU Unavailable Exception	0xC0	See core specification about SPE/EFPU Unavailable Exception
TBD	0xD0–0xF0	Reserved for future processor use

1. Autovectored Critical Input interrupts use this offset value. Vectored interrupts supply an interrupt vector offset directly.
2. Autovectored External Input interrupts use this offset value. Vectored interrupts supply an interrupt vector offset directly.

15.8.1 Exception Syndrome Register (ESR)

The Exception Syndrome Register (ESR) provides a *syndrome* to differentiate between exceptions that can generate the same interrupt type.



SPR - 62; Read/Write; Reset - 0x0

Figure 15-17. Exception Syndrome Register (ESR)

The ESR bits are defined in the following table.

Table 15-14. ESR field descriptions

Bit(s)	Name	Description	Associated interrupt type
0:3	—	Reserved	—
4	PIL	Illegal Instruction exception For e200z7260n3, PIL is used for both illegal and unimplemented instructions.	Program
5	PPR	Privileged Instruction exception	Program
6	PTR	Trap exception	Program
7	FP	Floating-point operation	Program
8	ST	Store operation	Alignment Data Storage
9:11	—	Reserved	—

Table continues on the next page...

Table 15-14. ESR field descriptions (continued)

Bit(s)	Name	Description	Associated interrupt type
12	—	Reserved	—
13	—	Reserved	—

15	—	Reserved	—
16:23	—	Reserved	—
24	SPV	EFPU APU Operation	EFPU Floating-point Data Exception EFPU Floating-point Round Exception Alignment Data Storage
25	—	Reserved	—
26	VLEMI	VLE Mode Instruction	EFPU Floating-point Data Exception EFPU Floating-point Round Exception Data Storage Instruction Storage Alignment Program System Call
27:29	—	Reserved	—
30	—	Reserved	—
31	—	Reserved	—

15.8.2 Machine State Register (MSR)

The Machine State Register defines the state of the processor. The e200z7260n3 MSR is shown in the following figure.

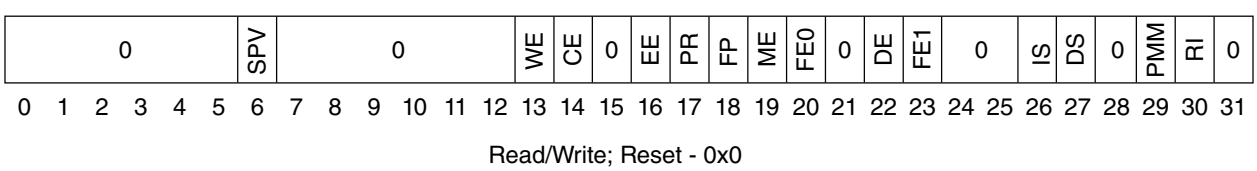

Figure 15-18. Machine State Register (MSR)

The MSR bits are defined in the following table.

Table 15-15. MSR field descriptions

Bit(s)	Name	Description
0:5	—	Reserved
6	SPV	SP/Embedded FP/Vector available 0 SP/Embedded FP Double/Vector unit is unavailable. The processor cannot execute SP/Embedded FP Double or Vector Unit instructions. 1 SP/Embedded FP Double/Vector unit is available. The processor can execute SP/Embedded FP Double or Vector Unit instructions. **NOTE:** The e200z7260n3 processor does not support these units in hardware. An Illegal Instruction exception is generated for attempted execution of these instructions regardless of the setting of SPV. SPV is ignored, but cleared on exceptions.
7:12	—	Reserved
13	WE	Wait State (Power management) enable. **NOTE:** this bit is implementation dependent and is being phased out. It will be removed in a future release. Currently it is implemented as a writeable bit, and is ignored, but cleared on exceptions.
14	CE	Critical Interrupt Enable 0 Critical Input interrupts are disabled. 1 Critical Input interrupts are enabled.
15	—	Reserved
16	EE	External Interrupt Enable 0 External Input interrupts are disabled. 1 External Input interrupts are enabled.
17	PR	Problem State 0 The processor is in supervisor mode, can execute any instruction, and can access any resource (e.g. GPRs, SPRs, MSR, etc.). 1 The processor is in user mode, cannot execute any privileged instruction, and cannot access any privileged resource.
18	FP	Floating-Point Available 0 Floating point unit is unavailable. The processor cannot execute floating-point instructions, including floating-point loads, stores, and moves. 1 Floating Point unit is available. The processor can execute floating-point instructions. **NOTE:** The e200z7260n3 processor does not support the PowerISA 2.06 floating point unit in hardware, and an Illegal Instruction exception is generated for attempted execution of PowerISA 2.06 floating point instructions regardless of the setting of FP. FP is ignored, but cleared on exceptions.
19	ME	Machine Check Enable 0 Asynchronous Machine Check interrupts are disabled. 1 Asynchronous Machine Check interrupts are enabled.
20	FE0	Floating-point exception mode 0 (not used) **NOTE:** The e200z7260n3 processor does not support the PowerISA 2.06 floating point unit in hardware, thus FE0 is ignored, but cleared on exceptions.
21	—	Reserved
22	DE	Debug Interrupt Enable

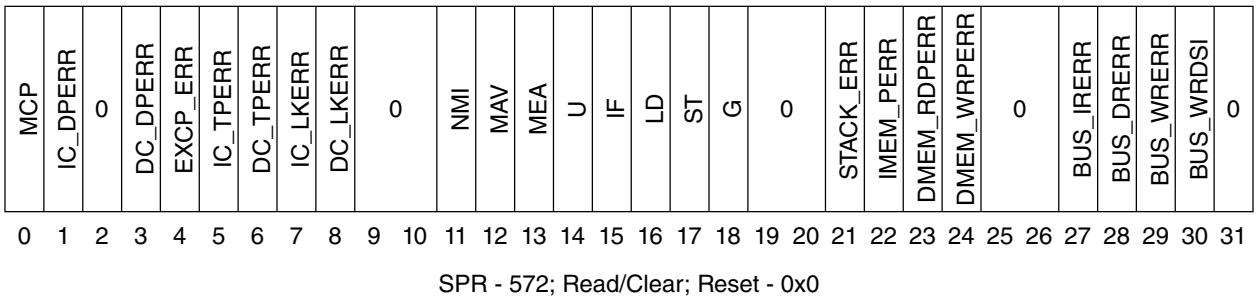
Table continues on the next page...

Table 15-15. MSR field descriptions (continued)

Bit(s)	Name	Description
		0 Debug interrupts are disabled. 1 Debug interrupts are enabled.
23	FE1	Floating-point exception mode 1 (not used) **NOTE:** The e200z7260n3 processor does not support the PowerISA 2.06 floating point unit in hardware, thus FE1 is ignored, but cleared on exceptions.
24:25	—	Reserved
26	IS	Instruction Address Space 0 The processor directs all instruction fetches to address space 0. 1 The processor directs all instruction fetches to address space 1. **NOTE:** The e200z7260n3 processor does not support Address Spaces, thus the IS bit is ignored, but cleared on exceptions.
27	DS	Data Address Space 0 The processor directs all data storage accesses to address space 0. 1 The processor directs all data storage accesses to address space 1. **NOTE:** The e200z7260n3 processor does not support Address Spaces, thus the DS bit is ignored, but cleared on exceptions.
28	—	Reserved
29	PMM	PMM Performance monitor mark bit System software can set PMM when a marked process is running to enable statistics to be gathered only during the execution of the marked process. MSR_{PR} and MSR_{PMM} together define a state that the processor (supervisor or user) and the process (marked or unmarked) may be in at any time. If this state matches an individual state specified in the PMLCa*n* Performance Monitor registers, the state for which monitoring is enabled, counting is enabled.
30	RI	Recoverable Interrupt This bit is provided for software use to detect nested machine check exception conditions. This bit is cleared by hardware when a Machine Check interrupt is taken.
31	—	Reserved

15.8.3 Machine Check Syndrome Register (MCSR)

When the processor takes a machine check interrupt, it updates the Machine Check Syndrome Register (MCSR) to differentiate between machine check conditions. The MCSR is shown in the following figure.



SPR - 572; Read/Clear; Reset - 0x0

Figure 15-19. Machine Check Syndrome Register (MCSR)

The following table describes MCSR fields. The MCSR indicates the source of a machine check condition.

All bits in the MCSR are implemented as "write 1 to clear." Software in the machine check handler is expected to clear the MCSR bits it has sampled prior to re-enabling MSR_{ME} to avoid a redundant machine check exception and to prepare for updated status bit information on the next machine check interrupt.

Note that any set bit in the MCSR other than status-type bits will cause a subsequent machine check interrupt once $MSR_{ME} = 1$.

Table 15-16. Machine Check Syndrome Register (MCSR) field descriptions

Bit	Name	Description	Exception type[1]	Recoverable
0	MCP	Machine check input pin	Async Mchk	Maybe
1	IC_DPERR	Instruction Cache data array parity error	Async Mchk	Precise
2	—	Reserved	—	—
3	DC_DPERR	Data Cache data array parity error	Async Mchk	Maybe
4	EXCP_ERR	ISI or Bus Error on first instruction fetch for an exception handler	Async Mchk	Precise
5	IC_TPERR	Instruction Cache Tag parity error	Async Mchk	Precise
6	DC_TPERR	Data Cache Tag parity error	Async Mchk	Maybe
7	IC_LKERR	Instruction Cache Lock error Indicates a cache control operation or invalidation operation invalidated one or more lines in a locked way of the I-Cache for certain situations. May also be set on locked line refill error.	Async Mchk	—
8	DC_LKERR	Data Cache Lock error Indicates a cache control operation or invalidation operation invalidated one or more lines in a locked way of the D-Cache for certain situations. May also be set on locked line refill error.	Async Mchk	—
9:10	—	Reserved	—	—
11	NMI	NMI input pin	NMI	—
12	MAV	MCAR Address Valid	Status	—

Table continues on the next page...

Table 15-16. Machine Check Syndrome Register (MCSR) field descriptions (continued)

Bit	Name	Description	Exception type[1]	Recoverable
		Indicates that the address contained in the MCAR was updated by hardware to correspond to the first detected Async Mchk error condition		
13	MEA	MCAR holds Effective Address If MAV = 1,MEA = 1 indicates that the MCAR contains an effective address and MEA = 0 indicates that the MCAR contains a physical address[2]	Status	—
14	U	User Indicates the value captured in MCAR was generated in user mode.	Status	—
15	IF	Instruction Fetch Error Report An error occurred during the fetch of an instruction and the instruction attempted to execute. This could be due to an internal parity error, or an external bus error. MCSRR0 contains the instruction address.	Error Report	Precise
16	LD	Load type instruction Error Report An error occurred during the attempt to execute the load type instruction located at the address stored in MCSRR0. This could be due to an internal parity error, stack limit check error, or an external bus error.	Error Report	Precise
17	ST	Store type instruction Error Report An error occurred during the attempt to execute the store type instruction located at the address stored in MCSRR0. This could be due to an internal parity error, stack limit check error, or on certain external bus errors.	Error Report	Precise
18	G	Guarded instruction Error Report An error occurred during the attempt to execute the load or store type instruction located at the address stored in MCSRR0 and the access was guarded and encountered an error on the external bus, or an uncorrectable DMEM error.	Error Report	Precise
19:20	—	Reserved	—	—
21	STACK_ERR	Stack Access Limit Check Error Indicates a limit check failure on a CPU data access using R1 in the <EA> calculation.	Async Mchk	Precise
22	IMEM_PERR3	Instruction Mem (IMEM) Parity Error Indicates an uncorrectable error in the IMEM on a CPU port access.	Async Mchk	Precise
23	DMEM_RDPERR	Data Mem (DMEM) Parity Error Indicates an uncorrectable error in the DMEM on a CPU port read access.	Async Mchk	Precise
24	DMEM_WRPERR	Data Mem (DMEM) Write Parity Error	Async Mchk	Maybe

Table continues on the next page...

Table 15-16. Machine Check Syndrome Register (MCSR) field descriptions (continued)

Bit	Name	Description	Exception type[1]	Recoverable
		Indicates an uncorrectable error in the DMEM on a CPU port write access.		
25:26	—	Reserved	—	—
27	BUS_IRERR	Read bus error on Instruction recovery linefill	Async Mchk	Precise if data used
28	BUS_DRERR	Read bus error on data load or linefill	Async Mchk	Precise if data used
29	BUS_WRERR	Write bus error on store to bus or DMEM imprecise write error	Async Mchk	Unlikely
30	BUS_WRDSI	Write bus error on buffered store to bus with DSI signaled. Set concurrently with BUS_WRERR for this case	Async Mchk	Unlikely
31	—	Reserved	—	—

1. The Exception Type indicates the exception type associated with a given syndrome bit.
   - "Error Report" indicates that this bit is only set for error report exceptions which cause machine check interrupts. These bits are only updated when the machine check interrupt is actually taken. Error report exceptions are not gated by MSR_{ME}. These are synchronous exceptions. These bits will remain set until cleared by software writing a '1' to the bit position(s) to be cleared.
   - "Status" indicates that this bit is provides additional status information regarding the logging of a machine check exception. These bits will remain set until cleared by software writing a '1' to the bit position(s) to be cleared.
   - "NMI" indicates that this bit is only set for the non-maskable interrupt type exception which causes a machine check interrupt. This bit is only updated when the machine check interrupt is actually taken. NMI exceptions are not gated by MSR_{ME}. This is an asynchronous exception. This bit will remain set until cleared by software writing a '1' to the bit position.
   - "Async Mchk" indicates that this bit is set for an asynchronous machine check exception. These bits are set immediately upon detection of the error. Once any "Async Mchk" bit is set in the MCSR, a machine check interrupt will occur if MSR_{ME} = 1. If MSR_{ME} = 0, the machine check exception will remain pending. These bits will remain set until cleared by software writing a '1' to the bit position(s) to be cleared.
2. Note that since no address translation mechanism is present on Zen Z420n3, the MEA value is always set to \0'.
3. Will not be set by e200z7260n3 since no local instruction memory is present.

15.8.4 Interrupt Vector Prefix Registers (IVPR)

The Interrupt Vector Prefix Register is used during interrupt processing for determining the starting address of a software handler used to handle an interrupt. The value of the Vector Offset selected for a particular interrupt type is concatenated with the Vector Base value held in the IVPR to form an instruction address from which execution is to begin. The format of IVPR is shown in the following figure.

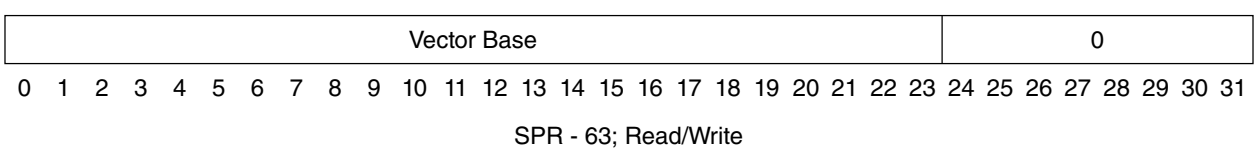


Figure 15-20. Zen Interrupt Vector Prefix Register (IVPR)

The IVPR fields are defined in the following table.

Table 15-17. IVPR field descriptions

Bit(s)	Name	Description
0:23 (32:55)	Vector Base	Vector Base This field is used to define the base location of the vector table, aligned to a 256 byte boundary. This field provides the high-order 24 bits of the location of all interrupt handlers (unless hardware vectoring is used). The vector offset value appropriate for the type of exception being processed is concatenated with the IVPR Vector Base to form the address of the handler in memory. For hardware-vectored interrupts, the value of the supplied interrupt vector is logically OR'ed with the low order bits of the Vec Base Field to determine the interrupt handler address.
24:31 (56:63)	—	Reserved

15.8.5 Interrupt Definitions

15.8.5.1 Critical Input Interrupt (offset 0x00)

A Critical Input exception is signaled to the processor by the assertion of the critical interrupt pin. If the exception is enabled by MSR_{CE}, the Critical Input interrupt is taken.

A Critical Input interrupt may be delayed by other higher priority exceptions or if MSR_{CE} is cleared when the exception occurs.

The following table lists register settings when a Critical Input interrupt is taken.

Table 15-18. Critical Input Interrupt—register settings

Register	Setting description					
CSRR0	Set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.					
CSRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0
	WE	0	ME	—	IS	0
	CE	0	FE0	0	DS	0
	EE	0	DE	—/0[1]	PMM	0
	PR	0			RI	—
ESR	Unchanged					
MCSR	Unchanged					
DEAR	Unchanged					
Vector	$IVPR_{0:23}$ || 0x00 (autovectored) $IVPR_{0:15}$ || (IVPR16:29 | **p_voffset[0:13]**) || 2'b00 (non-autovectored)					

1. Clearing of DE is optionally supported by control in HID0.

The MSR_{DE} bit is not automatically cleared by a Critical Input interrupt, but it can be configured to be cleared via the HID0 register ($HID0_{CICLRDE}$).

15.8.5.2 Machine Check Interrupt (offset 0x10)

The EIS Machine Check APU defines a separate set of save/restore registers (MCSRR0/1), a Machine Check Syndrome Register (MCSR) to record the source(s) of machine checks, and a Machine Check Address Register (MCAR) to hold an address associated with a machine check for certain classes of machine checks. Return from Machine Check instructions (**se_rfmci**) are also provided to support returns using MCSRR0/1.

The MSR_{DE} bit is not automatically cleared by a Machine Check exception, but it can be configured to be cleared or left unchanged via the HID0 register ($HID0_{MCCLRDE}$).

When a Machine Check interrupt is taken, registers are updated as shown in the following table.

Table 15-19. Machine Check Interrupt—register settings

Register	Setting description					
MCSRR0	On a best-effort basis, set to the address of some instruction that was executing or about to be executing when the machine check condition occurred.					
MCSRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0
	WE	0	ME	0	IS	0
	CE	0	FE0	0	DS	0
	EE	0	DE	0/—[1]	PMM	0
	PR	0			RI	0
ESR	Unchanged					
MCSR	Updated to reflect the source(s) of a machine check. Hardware only sets appropriate bits, no previously set bits are cleared by hardware.					
Vector	$IVPR_{0:23}$ || 0x10					

1. Clearing of DE is optionally supported by control in HID0.

15.8.5.3 Data Storage Interrupt (offset 0x20)

A Data Storage interrupt (DSI) may occur if no higher priority exception exists and a Read or Write Access Control exception condition exists.

The following table lists register settings when a DSI is taken.

Table 15-20. Data Storage Interrupt—register settings

Register	Setting description					
SRR0	Set to the effective address of the excepting load/store instruction.					
SRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0
	WE	0	ME	—	IS	0
	CE	—	FE0	0	DS	0
	EE	0	DE	—	PMM	0
	PR	0			RI	—
ESR	Access:		[ST], [SPV], VLEMI. All other bits cleared.			
MCSR	Unchanged					
DEAR	For Access Control exceptions, set to the effective address of the access that caused the violation.					
Vector	$IVPR_{0:23}$ || 0x20					

15.8.5.4 Instruction Storage Interrupt (offset 0x30)

An Instruction Storage interrupt (ISI) occurs when no higher priority exception exists and an Execute Access Control exception occurs.

The following table lists register settings when an ISI is taken.

Table 15-21. Instruction Storage Interrupt—register settings

Register	Setting description					
SRR0	Set to the effective address of the excepting instruction.					
SRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0
	WE	0	ME	—	IS	0
	CE	—	FE0	0	DS	0
	EE	0	DE	—	PMM	0
	PR	0			RI	—
ESR	VLEMI. All other bits cleared.					
MCSR	Unchanged					
DEAR	Unchanged					
Vector	$IVPR_{0:23}$ || 0x30					

15.8.5.5 External Input Interrupt (offset 0x40)

An External Input exception is signaled to the processor by the assertion of an interrupt from the interrupt controller. The input is a level-sensitive signal expected to remain asserted until the core acknowledges the external interrupt. If the input is negated early, recognition of the interrupt request is not guaranteed. When the core detects the exception, if the exception is enabled by MSR_{EE}, it takes the External Input interrupt.

An External Input interrupt may be delayed by other higher priority exceptions or if MSR_{EE} is cleared when the exception occurs.

The following table lists register settings when an External Input interrupt is taken.

Table 15-22. External Input Interrupt—Register Settings

Register	Setting description					
SRR0	Set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.					
SRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0
	WE	0	ME	—	IS	0
	CE	—	FE0	0	DS	0
	EE	0	DE	—	PMM	0
	PR	0			RI	—
ESR	Unchanged					
MCSR	Unchanged					
DEAR	Unchanged					
Vector	$IVPR_{0:23}$ || 0x40 (autovectored) IVPR0:15 || (IVPR16:29 | **p_voffset[0:13]**) || 2'b00 (non-autovectored)					

15.8.5.6 Alignment Interrupt (offset 0x50)

An Alignment exception is generated when any of the following occurs:

- The operand of **lmw** or **stmw** is not word aligned.
- The operand of **lwarx** or **stwcx.** is not word aligned.
- The operand of **lharx** or **sthcx.** is not halfword aligned.
- Execution of a **dcbz** instruction is attempted.

The following table lists register settings when an alignment interrupt is taken.

Table 15-23. Alignment Interrupt—register settings

Register	Setting description					
SRR0	Set to the effective address of the excepting load/store/dcbz instruction.					
SRR1	Set to the contents of the MSR at the time of the interrupt					
MSR	SPV	0	FP	0	FE1	0
	WE	0	ME	—	IS	0
	CE	—	FE0	0	DS	0
	EE	0	DE	—	PMM	0
	PR	0			RI	—
ESR	[ST], VLEMI. All other bits cleared.					
MCSR	Unchanged					
DEAR	Set to the effective address of a byte of the load or store access causing the violation.					
Vector	$IVPR_{0:23}$ || 0x50					

15.8.5.7 Program Interrupt (offset 0x60)

A program interrupt occurs when no higher priority exception exists and one or more of the following exception conditions occur:

- Illegal Instruction exception
- Privileged Instruction exception
- Trap exception

The e200z7260n3 will invoke an Illegal Instruction program exception on attempted execution of the following instructions:

- Unimplemented instructions
- An instruction from the illegal instruction class
- **mtspr** and **mfspr** instructions with an undefined SPR specified
- **mtdcr** and **mfdcr** instructions with an undefined DCR specified

The e200z7260n3 will invoke a Privileged Instruction program exception on attempted execution of the following instructions when $MSR_{PR} = 1$ (user mode):

- A privileged instruction
- **mtspr** and **mfspr** instructions that specify a SPRN value with $SPRN_5 = 1$ (even if the SPR is undefined)

The e200z7260n3 will invoke an Trap exception on execution of the **tw** instruction if the trap conditions are met and the exception is not also enabled as a Debug interrupt.

The core will invoke an Illegal instruction program exception on attempted execution of the instructions **lswi**, **lswx**, **stswi**, **stswx**, **mfapidi**, **mfdcrx**, **mtdcrx**, or on any Power ISA 2.06 Revision B floating-point instruction. All other defined or allocated instructions that are not implemented by core will cause an illegal instruction program exception.

The following table lists register settings when a Program interrupt is taken.

Table 15-24. Program Interrupt—register settings

Register	Setting description

15.8.5.8 Performance Monitor Interrupt (offset 0x70)

A performance monitor interrupt that may be generated by an enabled condition or event. An enabled condition or event is as follows:

A PMC*x* register overflow condition occurs with the following settings:

- PMLCax_{CE} = 11; that is, for the given counter the overflow condition is enabled.
- PMCx_{OV} = 11; that is, the given counter indicates an overflow.

For a performance monitor interrupt to be signaled on an enabled condition or event, $PMGC0_{PMIE}$ must be set.

Although an exception condition may occur with MSR_{EE} = 0, the interrupt cannot be taken until MSR_{EE} = 1.

The priority of the performance monitor interrupt is below all other asynchronous interrupts.

The following table lists register settings when an performance monitor interrupt is taken.

Table 15-25. Performance Monitor Interrupt—Register Settings

Register	Setting description					
SRR0/ DSRR0[1]	Set to the effective address of the next instruction to be executed.					
SRR1/ DSRR1[1]	Set to the contents of the MSR at the time of the interrupt.

15.8.5.11 Embedded Floating-point Data Interrupt (offset 0xA0)

The Embedded Floating-point Data interrupt is taken if no higher priority exception exists and an EFPU Floating-point Data exception is generated. When a Floating-point Data exception occurs, the processor suppresses execution of the instruction causing the exception.

The following table lists register settings when an EFPU Floating-point Data interrupt is taken.

Table 15-28. Embedded Floating-point Data Interrupt—register settings

Register	Setting description					
SRR0	Set to the effective address of the excepting EFPU instruction.

15.8.5.13 System Reset Interrupt

The System Reset exception is a non-maskable, asynchronous exception signaled to the processor through the assertion of system-defined signals.

A System Reset may be initiated by either a software reset or during power-on reset.

When a reset request occurs, the processor branches to the system reset exception vector without attempting to reach a recoverable state. If reset occurs during normal operation, all operations cease and the machine state is lost.

The following table lists register settings when a System Reset interrupt is taken.

Table 15-30. System Reset Interrupt—register settings

15.9 Memory Protection Unit (MPU)

15.9.1 MPU Overview

The e200z7260n3 Memory Protection Unit (MPU) protects regions of memory, with the following feature set:

- 24-entry region descriptor table with support for 6 arbitrary-sized instruction memory regions, 12 arbitrary-sized data memory regions, and 6 additional arbitrary-sized regions programmable as instruction or data memory regions
- Ability to set access permissions and memory attributes on a per-region basis
- Process ID aware, with per-bit masking of TID values
- Capability for masking upper address bits in the range comparison
- Capability of bypassing permissions checking for selected access types
- Per-entry write-once logic for entry protection
- Hardware flash invalidation support and per-entry invalidation protection controls
- Ability to optionally utilize region descriptors for generating debug events and watchpoints
- Software managed by **mpure** and **mpuwe** instructions

15.9.2 Software Interface and MPU Instructions

The MPU entries are accessed indirectly through several MPU Assist (MAS) registers. Software can write and read the MAS registers with **mtspr** and **mfspr** instructions. These registers contain information related to reading and writing a given entry within the MPU. Data is read from the MPU into the MAS registers with an **mpure** (MPU read entry) instruction. Data is written to the MPU from the MAS registers with an **mpuwe** (MPU write entry) instruction.

The **mpure**, **mpuwe**, and **mpu**sy**n**c instructions are privileged.

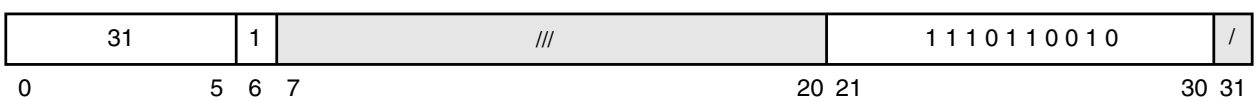
15.9.3 MPU Read Entry Instruction (mpure)

The MPU read entry instruction causes the content of a single MPU entry to be placed in the MPU assist registers. The entry is specified by the INST, SHD, and ESEL fields of the MAS0 register. The entry contents are placed in the MAS0, MAS1, MAS2, and MAS3 registers.

mpure

mpu read entry

mpure



```
mpu_entry_id = MAS0(INST, SHD, ESEL)
result = MPU(mpu_entry_id)
MAS0, MAS1, MAS2, MAS3 = result
```

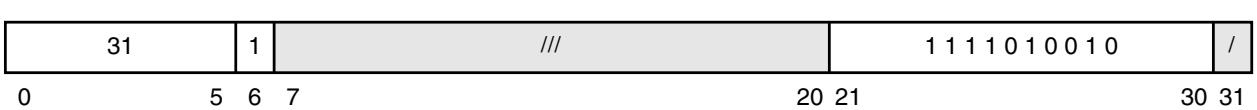
15.9.4 MPU Write Entry Instruction (mpuwe)

The MPU write entry instruction causes the contents of certain fields within the MPU assist registers MAS0, MAS1, MAS2, and MAS3 to be written into a single MPU entry in the MPU. The entry written is specified by the INST, SHD, and ESEL fields of the MAS0 register.

mpuwe

mpu write entry

mpuwe



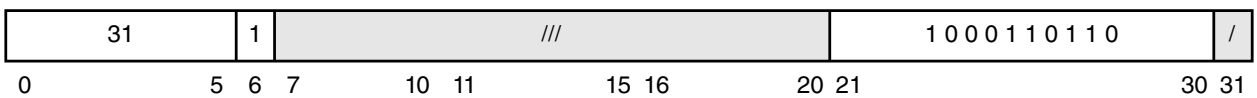
```
mpu_entry_id = MAS0(INST, SHD, ESEL)
MPU(mpu_entry_id) = MAS0, MAS1, MAS2, MAS3
```

15.9.5 MPU Synchronize Instruction (mpusync)

The MPU Synchronize instruction is treated as a privileged no-op by the e200z7260n3.

mpusync mpusync

MPU Synchronize
mpusync



15.9.6 MMU/MPU Configuration Register (MMUCFG)

The MMU/MPU Configuration Register (MMUCFG) is a 32-bit read-only register. The SPR number for MMUCFG is 1015 in decimal. MMUCFG provides information about the configuration of the e200z7260n3 MPU design. The MMUCFG register is shown in the following figure.

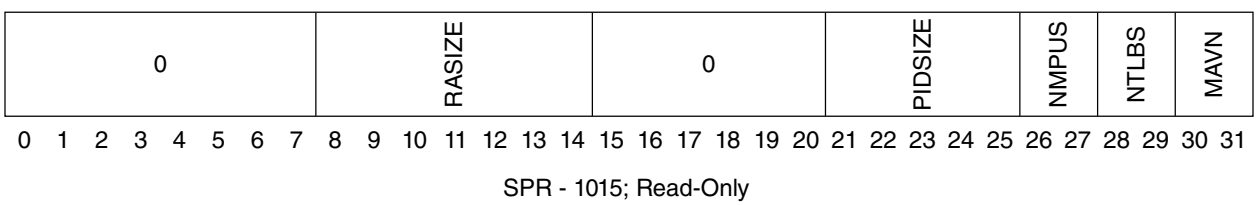


Figure 15-21. MMU/MPU Configuration Register (MMUCFG)

The MMUCFG bits are described in the following table.

Table 15-31. MMUCFG field descriptions

Bits	Name	Function
0:7	—	Reserved
8:14	RASIZE	Number of Bits of Real Address supported 0100000 This version of the MPU implements 32 real address bits
15:16	—	Reserved
17:20	—	Reserved
21:25	PIDSIZE	PID Register Size 00111 PID registers contain 8 bits in this version of the MPU

Table continues on the next page...

Table 15-31. MMUCFG field descriptions (continued)

Bits	Name	Function
26:27	NMPUS	Number of MPUs 01 This version of the MMU implements one MPU structure: a fully associative MPU for MPU0
28:29	NTLBS	Number of TLBs 00 This version of the MMU implements no TLB structures
30:31	MAVN	MMU Architecture Version Number 11 This version of the MMU implements Version 3.1 of the EIS MMU Architecture

15.9.7 MPU0 Configuration Register (MPU0CFG)

The MPU0 Configuration Register (MPU0CFG) is a 32-bit read-only register. The SPR number for MPU0CFG is 692 in decimal. MPU0CFG provides information about the configuration of MPU0 in the e200z7260n3 MPU. The MPU0CFG register is shown in following figure.

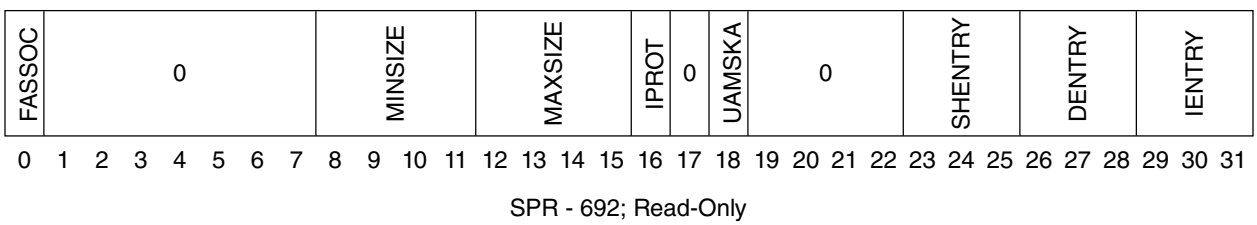

Figure 15-22. MPU0 Configuration Register (MPU0CFG)

The MPU0CFG bits are described in the following table.

Table 15-32. MPU0CFG field descriptions

Bits	Name	Function
0	FASSOC	Fully Associative 1 Indicates that MPU0 is fully associative
1:7	—	Reserved for non-fully associative implementation use
8:11	MINSIZE	Minimum Region Size Due to the use of access address matching, the effective smallest region size is 8 bytes 0x0 Smallest region size is 1 byte
12:15	MAXSIZE	Maximum Region Size 0xB Largest region size is 4 GB
16	IPROT	Invalidate Protect Capability 1 Invalidate Protect Capability is supported in MPU0
17	—	Reserved

Table continues on the next page...

Table 15-32. MPU0CFG field descriptions (continued)

Bits	Name	Function
18	UAMSKA	Upper Address Masking Availability 1 Upper Address Masking is Available
19:22	—	Reserved
23:25	SHENTRY	Number of Shared (configurable for I or D) Entries 0x2 Indicates that MPU0 contains six shared entries
26:28	DENTRY	Number of Data Entries 0x4 Indicates that MPU0 contains 12 dedicated data entries
29:31	IENTRY	Number of Instruction Entries 0x2 Indicates that MPU0 contains six dedicated Instruction entries

15.9.8 MPU0 Control and Status Register 0 (MPU0CSR0)

The MPU0 Control and Status Register 0 (MPU0CSR0) is a 32-bit register. The SPR number for MPU0CSR0 is 1014 in decimal. MPU0CSR0 controls the operation of the MPU. The MPU0CSR0 register is shown in the following figure.

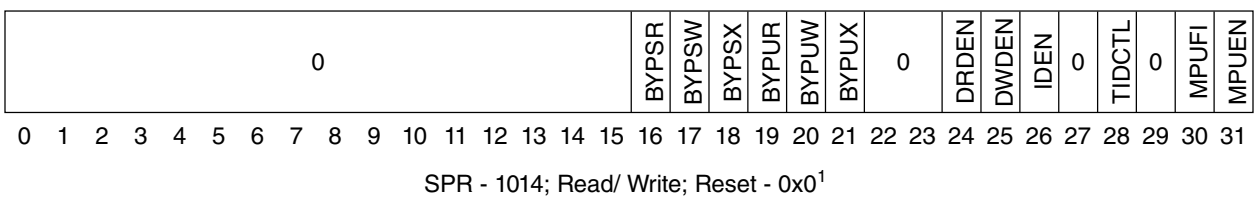

Figure 15-23. MPU0 Control and Status Register 0 (MPU0CSR0)

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM} = 0$, as well as unconditionally by **m_por**. If $EDBCR0_{EDM} = 1$, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**. Specifically, this applies to the DRDEN, DWDEN, and IDEN control bits.

The MPU0CSR0 bits are described in the following table.

Table 15-33. MPU0CSR0 field descriptions

Bits	Name	Description
0:15	—	Reserved
16	BYPSR	Bypass MPU protections for Supervisor Read accesses

Table continues on the next page...

Table 15-33. MPU0CSR0 field descriptions (continued)

Bits	Name	Description
		This bit controls whether supervisor-mode read accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode read accesses do not generate a DSI when no MPU match occurs. Supervisor-mode read accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for Supervisor Read accesses 1 Bypass MPU protections for Supervisor Read accesses
17	BYPSW	Bypass MPU protections for Supervisor Write accesses This bit controls whether supervisor-mode write accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode write accesses do not generate a DSI when no MPU match occurs. Supervisor-mode write accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for Supervisor Write accesses 1 Bypass MPU protections for Supervisor Write accesses
18	BYPSX	Bypass MPU protections for Supervisor Instruction accesses This bit controls whether supervisor-mode instruction accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode instruction accesses do not generate an ISI when no MPU match occurs. Supervisor-mode instruction accesses are still compared to MPU entries, and a hit will provide access attributes (CI). 0 No Bypass of MPU protections for Supervisor Instruction accesses 1 Bypass MPU protections for Supervisor Instruction accesses
19	BYPUR	Bypass MPU protections for User Read accesses This bit controls whether user-mode read accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode read accesses do not generate a DSI when no MPU match occurs. User-mode read accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for User Read accesses 1 Bypass MPU protections for User Read accesses
20	BYPUW	Bypass MPU protections for User Write accessesThis bit controls whether user-mode write accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode write accesses do not generate a DSI when no MPU match occurs. User-mode write accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for User Write accesses 1 Bypass MPU protections for User Write accesses
21	BYPUX	Bypass MPU protections for User Instruction accesses This bit controls whether user-mode instruction accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode instruction accesses do not generate an ISI when no MPU match occurs. User-mode instruction accesses are still compared to MPU entries, and a hit will provide access attributes (CI). 0 No Bypass of MPU protections for User Instruction accesses 1 Bypass MPU protections for User Instruction accesses
22:23	—	Reserved
24	DRDEN	Data Read Debug Enable

Table continues on the next page...

Table 15-33. MPU0CSR0 field descriptions (continued)

Bits	Name	Description
		This bit controls whether data read accesses are enabled to generate MPU debug events. When disabled, no data read access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG = 1. If such a match occurs, no MPU debug event is generated, and no access protection is performed. When enabled, data read accesses are not blocked from generating MPU debug events. 0 MPU debug events are disabled for data read accesses 1 MPU debug events are enabled for data read accesses
25	DWDEN	Data Write Debug Enable This bit controls whether data write accesses are enabled to generate MPU debug events. When disabled, no data write access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG = 1. If such a match occurs, no MPU debug event is generated, and no access protection is performed. When enabled, data write accesses are not blocked from generating MPU debug events. 0 MPU debug events are disabled for data write accesses 1 MPU debug events are enabled for data write accesses
26	IDEN	Instruction Debug Enable This bit controls whether instruction accesses are enabled to generate MPU debug events. When disabled, no instruction access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG = 1. When enabled, instruction accesses are not blocked from generating MPU debug events. 0 MPU debug events are disabled for instruction accesses 1 MPU debug events are enabled for instruction accesses
27	—	Reserved
28	TIDCTL	TID usage Control When TIDCTL is set to 1, the TID match is disabled (forced match) in Supervisor mode. 0 TID comparisons performed normally 1 No TID comparisons are performed for matching while in Supervisor mode
29	—	Reserved
30	MPUFI	MPU flash invalidate When written to a 1, a MPU invalidation operation is initiated by hardware. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. MPU invalidation operations require 3 cycles to complete. 0 No flash invalidate 1 MPU1 invalidation operation **Note:)** Entries that have the IPROT bit set will not be invalidated.
31	MPUEN	MPU Enable

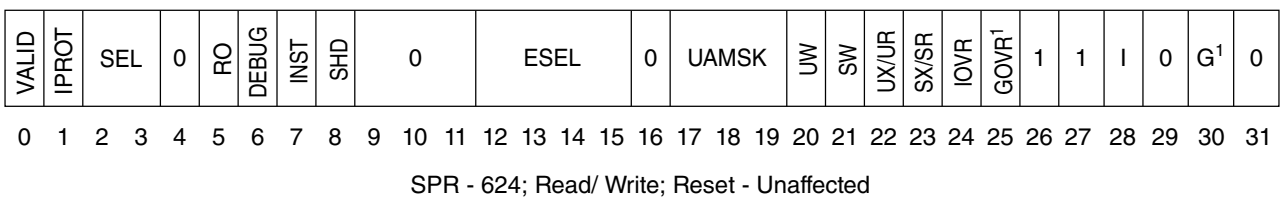
Table 15-33. MPU0CSR0 field descriptions

Bits	Name	Description
		This bit enables operation of the MPU. When enabled, access addresses are compared to each entry in the MPU for a match condition. If no match condition occurs, and the access type is not enabled to bypass the MPU protections, then an ISI or DSI condition is signaled for the access. Note that this bit is ignored for matching entries with DEBUG = 1 if in EDM and hardware owns MPU Debug entries. 0 MPU is disabled 1 MPU is enabled

15.9.9 MPU Assist Registers (MAS)

The e200z7260n3 uses four special-purpose registers (MAS0, MAS1, MAS2, and MAS3) to facilitate reading and writing MPU entries. The MAS registers can be read or written using the **mfspr** and **mtspr** instructions.

The MAS0 register is shown in Figure 15-24. Fields are defined in Table 15-34.



SPR - 624; Read/ Write; Reset - Unaffected

Figure 15-24. MPU Assist Register 0 (MAS0)

Note

[1] This bit is not implemented in dedicated instruction entries, and is ignored in shared entries with INST = 1

Note

[2] This bit is not implemented in dedicated instruction entries, and is ignored in shared entries with INST = 1

Table 15-34. MAS0—MPU Read/Write and Replacement Control

Bit	Name	Comments, or Function when Set
0	VALID	MPU Entry Valid 0 = This MPU entry is invalid 1 = This MPU entry is valid
1	IPROT	Invalidation Protect 0 = Entry is not protected from invalidation

Table continues on the next page...

Table 15-34. MAS0—MPU Read/Write and Replacement Control (continued)

Bit	Name	Comments, or Function when Set
		1 = Entry is protected from invalidation
2:3	SEL	Selects MPU for access: 00 = Reserved, no access 01 = Reserved, no access 10 = Select MPU 11 = Reserved, no access
4	—	Reserved
5	RO	Read-Only When set to 1, the entry is no longer writable by software. Once set, this bit will remain set until a processor reset occurs. 0 = This MPU entry is writable 1 = This MPU entry is Read-only
6	DEBUG	Debug Control for Entry This bit is used to assign an entry for debug event use instead of normal access protection use. When used for debug purposes, an MPU debug event is generated when a hit to the entry occurs and the access permissions allow the access. 0 = This MPU entry is used for access protections and allows accesses when matched based on protection attributes 1 = This MPU entry is used for generating a debug event when a match occurs and the access protections would allow access
7	INST	Instruction Entry When SHD = 0, this bit is used to select the INST entry portion of the region descriptor table for **mpure** and **mpuwe** instruction operations. When SHD = 1, this bit is used to indicate whether the entry in the Shared portion of the region descriptor table is assigned as an entry for either instruction access or data access matching. Only one of these access types is monitored for matching by a given shared region descriptor entry. 0 = This MPU entry is used for matching data accesses only 1 = This MPU entry is used for matching instruction accesses only
8	SHD	Shared Entry Select This bit is used to control selection of the Shared portion of the region descriptor table. 0 = The shared portion of the region descriptor table is not accessed on a **mpure** or **mpuwe** operation. Either the instruction portion or the data portion is accessed based on the setting of INST. The entry within the selected portion is based on ESEL. 1 = The shared portion of the region descriptor table is accessed on a **mpure** or **mpuwe** operation. The instruction and data portions are not accessed. The INST bit is used to indicate whether the entry in the Shared portion of the region descriptor table is assigned as an entry for instruction access or data access matching. Only one of these access types is monitored for matching by a given shared region descriptor entry. ESEL defines which shared entry is selected.
9:11	—	Reserved
12 :15	ESEL	Entry select for MPU.

Table continues on the next page...

Table 15-34. MAS0—MPU Read/Write and Replacement Control (continued)

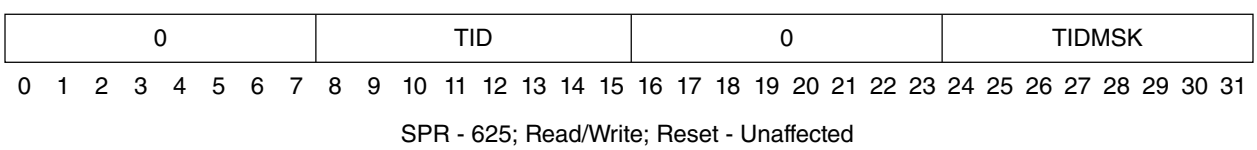
Bit	Name	Comments, or Function when Set
		This field is used to select an entry for reading or writing in conjunction with the settings of SHD and INST. Only valid entry numbers should be used in this field, otherwise the result of an operation is boundedly undefined.
16	—	Reserved
17:19	UAMSK	Upper Address Mask Control This field is used to support masking of upper address bits before performing range comparisons. Masked bits will be forced to 0 for the purposes of the range compare. Range upper and lower bounds should be set accordingly. 000 = No upper address bits are masked, address matching uses all 32 address bits for accesses 001 = The most significant access address bit is forced to zero before matching 010 = The two most significant access address bits are forced to zero before matching 011 = The three most significant access address bits are forced to 0 before matching 100 = The four most significant access address bits are forced to 0 before matching 101 = The upper five access address bits are forced to zero before matching 11x = Reserved, do not use
20	UW	User Mode Write PermissionDetermines User mode Write (W) permission when INST = 0. Ignored when INST = 1. 0 = No User mode Write permission 1 = User mode has Write permission
21	SW	Supervisor Mode Write / Read Permission Determines Supervisor mode Write (W) permission when INST = 0. Ignored when INST = 1. 0 = No Supervisor mode Write permission 1 = Supervisor mode has Write permission
22	UX/UR	User Mode Execute / Read Permission Determines User mode Execute (X) permission when INST = 1, or User mode Read (R) permission when INST = 0. 0 = No User mode Execute/ Read permission 1 = User mode has Execute/ Read permission
23	SX/SR	Supervisor Mode Execute / Read Permission Determines Supervisor mode Execute (X) permission when INST = 1, or Supervisor mode Read (R) permission when INST = 0. 0 = No Supervisor mode Execute/ Read permission 1 = Supervisor mode has Execute/ Read permission
24	IOVR	Cache-Inhibit attribute OverrideDetermines whether this matching entry overrides the I bit settings of other matching entries and the cache-inhibited region configuration signals 0 = No override of I attribute by entry 1 = Entry I bit overrides I attribute
25	GOVR/—	G attribute Override

Table continues on the next page...

Table 15-34. MAS0—MPU Read/Write and Replacement Control (continued)

Bit	Name	Comments, or Function when Set
		Determines whether this entry overrides the G bit settings of other matching entries and the Guarded region configuration signals This bit is not implemented in dedicated instruction entries, and is ignored in shared entries with INST = 1. 0 = No override of G attribute by entry 1 = Entry G bit overrides G attribute
26	—	Reserved
27	—	Reserved
28	I	Cache Inhibited This attribute may be overridden by the cache-inhibited region configuration input settings. 0 = This region is considered cacheable 1 = This region is considered cache-inhibited
29	—	Reserved
30	G/—	Guarded This attribute may be overridden by the guarded region configuration input settings.This bit is not implemented in dedicated instruction entries, and is ignored in shared entries with INST = 1. 0 = Accesses to this region are not guarded, and can be performed before it is known if they are required by the sequential execution model 1 = All loads and stores to this region are performed without speculation (i.e. they are known to be required)
31	—	Reserved

The MAS1 register is shown in Figure 15-25. Fields are defined in Table 15-35.



SPR - 625; Read/Write; Reset - Unaffected

Bit	Name	Comments, or Function when Set
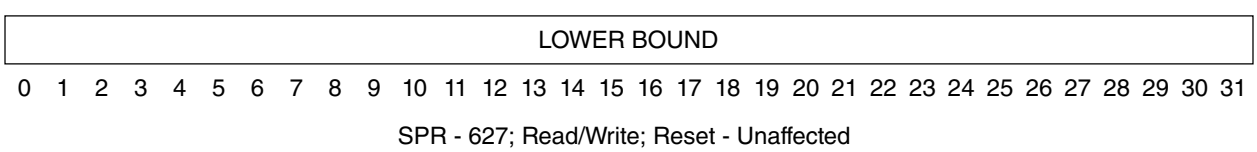
0:31	UPPER BOUND	Upper bound of address range covered by entry. Entry match requires LOWER_BOUND <= EA <= UPPER_BOUND

The MAS3 register is shown in Figure 15-27. Fields are defined in Table 15-37.



SPR - 627; Read/Write; Reset - Unaffected

Figure 15-27. MPU Assist Register 3 (MAS3)

Table 15-37. MAS3—Lower Bound Control

Bit	Name	Comments, or Function when Set
0:31	LOWER BOUND	Lower bound of address range covered by entry. Entry match requires LOWER_BOUND <= EA <= UPPER_BOUND

15.9.10 MAS Registers Summary

The MAS registers are summarized in the following figure.

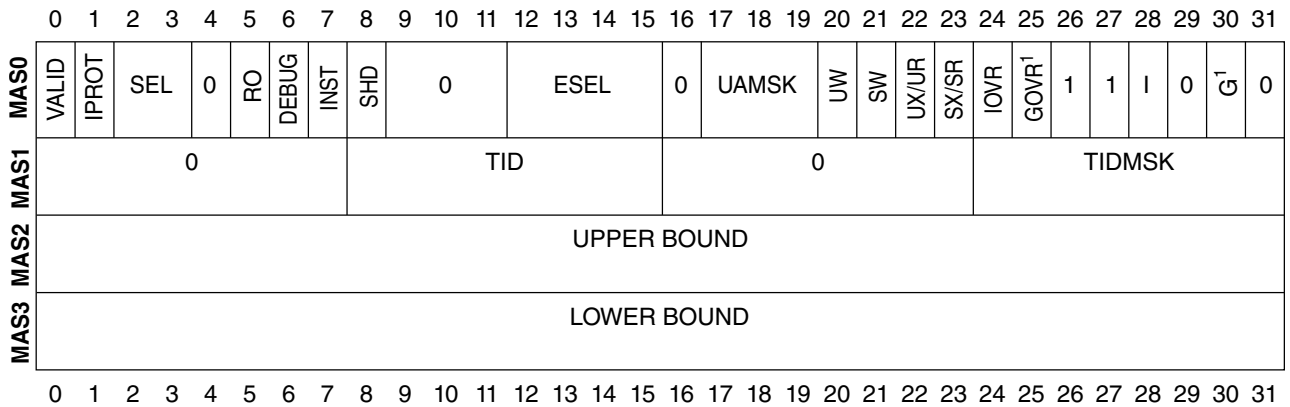


Figure 15-28. MPU Assist Registers Summary

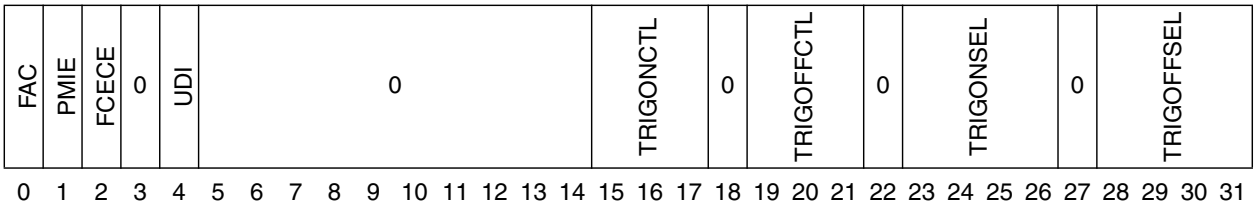
Note

[1] This bit is not implemented in dedicated instruction entries, and is ignored in shared entries with INST = 1

15.10 Performance Monitor

15.10.1 Global Control Register 0 (PMGC0)

The performance monitor global control register PMGC0 shown in the following figure controls all performance monitor counters.



PMR - 400; Read/Write; Reset[1] - 0x0

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

Figure 15-29. Performance Monitor Global Control Register (PMGC0)

The following table describes PMGC0 fields.

Table 15-38. PMGC0 field descriptions

Bits	Name	Description
0 (32)	FAC	Freeze All Counters. 0 The PMCs are incremented (if permitted by other PMGC/PMLC control bits). 1 The PMCs are not incremented. When FAC is set to 1 by hardware or software, it has no effect on PMLCaxFC; PMLCaxFC maintains its current value until changed by software. FAC setting by hardware is controlled by PMGC0FCECE.
1 (33)	PMIE	Performance monitor interrupt enable 0 Performance monitor interrupts are disabled. 1 Performance monitor interrupts are enabled and occur when an enabled condition or event occurs, at which time PMGC0PMIE is cleared Software can clear PMIE to prevent performance monitor interrupts. Performance monitor interrupts are caused by PMCx counter overflows.
2 (34)	FCECE	Freeze Counters on Enabled Condition or Event An enabled condition or event is defined as one of the following: • When the msb = 1 in PMCx and PMLCaxCE = 1. 0 The PMCs can be incremented (if permitted by other PM control bits). 1 The PMCs can be incremented (if permitted by other PM control bits) only until an enabled condition or event occurs. When an enabled condition or event occurs, PMGC0FAC is set to 1. It is up to software to clear PMGC0FAC to 0.
3 (35)	-	Reserved, should be cleared.
4 (36)	UDI	Use Debug Interrupt **NOTE:** This bit is ignored when EDBCR0EDM=1 and Performance Monitor Resources are assigned to an external debugger via the DBECR0PMI control bit. **NOTE:** If UDI is set and DBCR0IDM=0, no software performance monitor debug interrupts will be taken.

Table continues on the next page...

Table 15-38. PMGC0 field descriptions (continued)

Bits	Name	Description
		0 Performance Monitor Interrupts use the SRR0/1 registers and the Performance Monitor interrupt vector offset, or if the Performance Monitor Resources are assigned to an external debugger via the DBECR0PMI control bit, can set the EDBSR0PMI to conditionally enter debug halted mode 1 Performance Monitor Interrupts set the DBSRPMI status bit when DBCR0IDM=1, and can thus use the DSRR0/1 registers and the Debug interrupt vector offset when Debug Interrupts are not masked, or if EDBCR0EDM=1 and the Performance Monitor Resources are assigned to an external debugger via the DBECR0PMI control bit, can set the EDBSR0PMI to conditionally enter debug halted mode.
5:14 (37:46)	-	Reserved, should be cleared.
15:17 (47:49)	TRIGONCNTL	Trigger-on Control Class - Class of Trigger-on source 000 Trigger-on control is disabled if TRIGONSEL is 0000 (i.e. counting is not affected by triggers). All other values for TRIGONSEL are reserved. 001 Reserved 010 Trigger-on based on selected processor event(s) 011 Trigger-on based on selected hardware signal(s) 100 Trigger-on based on selected watchpoint occurrence (watchpoint #0-15) 101 Trigger-on based on selected watchpoint occurrence (extension for watchpoint #16-31) 11*x* Reserved. Indicates the condition under which triggering to start counting occurs. No triggering will occur while PMGC0FAC or PMLCanFC is set to '1'.
18 (50)	-	Reserved, should be cleared.
19:21 (51:53)	TRIGOFFCNTL	Trigger-off Control Class - Class of Trigger-off source. Indicates the condition under which triggering to stop counting occurs. No triggering will occur while PMGC0FAC or PMLCanFC is set to '1'. 000 Trigger-off control is disabled if TRIGOFFSEL is 0000 (i.e. counting is not affected by triggers) All other values for TRIGOFFSEL are reserved. 001 Reserved 010 Trigger-off based on selected processor event(s) 011 Trigger-off based on selected hardware signal(s) 100 Trigger-off based on selected watchpoint occurrence (watchpoint #0-15) 101 Trigger-off based on selected watchpoint occurrence (extension for watchpoint #16-31) 11*x* Reserved
22 (54)	-	Reserved, should be cleared.
23:26 (55:58)	TRIGONSEL	Trigger-on Source Select - Source Select based on setting of TRIGONCTL TRIGONCTL = 000: 0000 Trigger-on control is disabled 0001 - 1111 : Reserved TRIGONCTL = 010: 0000 Trigger-on when next processor interrupt occurs (software may want to set PMGC0PMIE = 0 for this setting).

Table continues on the next page...

Table 15-38. PMGC0 field descriptions (continued)

Bits	Name	Description
		0001 - 1111 : Reserved TRIGONCTL = 011: 0000 Trigger on rise of p_pmc0_qual input 0001 Trigger on rise of p_pmc1_qual input 0010 Trigger on rise of p_pmc2_qual input 0011 Trigger on rise of p_pmc3_qual input TRIGONCTL = 100: 0000 Trigger-on based on watchpoint #0 occurrence 0001 Trigger-on based on watchpoint #1 occurrence 0010 Trigger-on based on watchpoint #2 occurrence . . . 1110 Trigger-on based on watchpoint #14 occurrence 1111 Trigger-on based on watchpoint #15 occurrence TRIGONCTL = 101: 0000 Trigger-on based on watchpoint #16 occurrence 0001 Trigger-on based on watchpoint #17 occurrence 0010 Trigger-on based on watchpoint #18 occurrence . . . 1100 Trigger-on based on watchpoint #28 occurrence 1101 Trigger-on based on watchpoint #29 occurrence 1110 Trigger-on based on watchpoint #30 occurrence 1111 Trigger-on based on watchpoint #31 occurrence

15.11 Local memories

15.11.1 Local Data memory overview

Local Data (DMEM) memory has been added to provide low latency access for critical instruction routines and data operands. Access latency (zero wait-states) is similar to that of a data cache, but does not suffer from the overhead of cache miss or cache writethrough operations. Instead, it provides a large capacity tightly coupled storage.

The local memory has one dedicated port for CPU accesses and another shared slave port for external accesses. DMEM provides a dedicated port to the CPU's load/store unit. Access via the dedicated CPU port is referred to as *front door* access. Access via the slave port is referred to as *back door* access.

Local memory occupies a portion of the processor's address space and is conditionally accessed in parallel with the corresponding cache (if present) when a CPU request is made, based on an address decode comparison early in the access pipeline.

External masters use the shared slave port, which is implemented as an AHB 2.v6 slave interface, to access the DMEM. Slave port accesses are arbitrated with the CPU port in a round-robin fashion to prevent starvation from occurring on either port.

NOTE

DMEM, by default, is always accessed through the front door (CPU) interface, regardless of whether the program uses Decorated Access, Non-decorated Cache Bypass, Atomic Load and Reserve instructions, as well as regular load/store instructions (stw, lwz, for example). The only exception is when the core's DMEMCTL0 register is set to bypass the type of DMEM access used onto AHB back door slave interface. Regular load/store instructions always access DMEM through the front door interface since no bypass control is available for these kinds of instructions.

15.11.2 Local memory control and configuration

DMEM local memory configuration information is provided by a set of privileged read-only SPRs that are accessed using **mfspr** instructions. DMEM local memory operation is controlled by a set of privileged device control registers (DCRs) that are accessed using the **mfdcr** and **mtdcr** instructions. These registers and a description of the operation of various features are described in the following subsections.

15.11.2.1 DMEM Configuration Register 0 (DMEMCFG0)

The DMEM Configuration Register 0 (DMEMCFG0) is a 32-bit read-only register. DMEMCFG0 provides information about the configuration of the e200z7260n3 local data memory design. The contents of the DMEMCFG0 register can be read using a **mfspr** instruction. The SPR number for DMEMCFG0 is 694 in decimal. The DMEMCFG0 register is shown in the following figure.

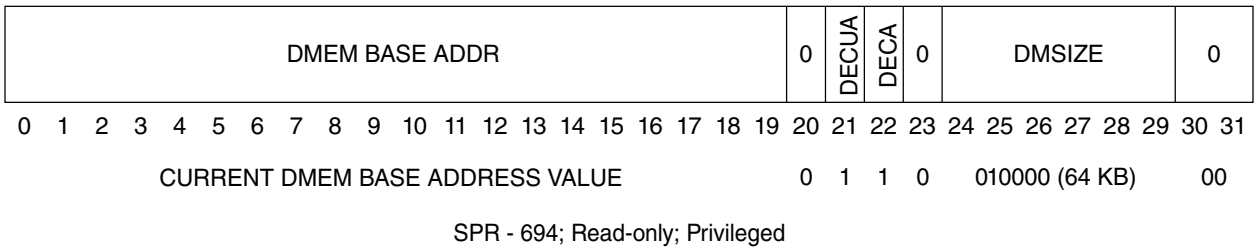

Figure 15-30. DMEM Configuration Register 0 (DMEMCFG0)

The DMEMCFG0 fields are described in the following table.

Table 15-39. DMEMCFG0 field descriptions

Bits	Name	Description
0:19	DMEM BASE ADDR	DMEM BASE ADDRESS (CPU Port) This field defines the current Base Address value being used for the CPU port to the DMEM. This field reflects the value of the external DMEM base address port inputs when the external base address port inputs are enabled via the DBAPD control bit, or the value of the BASE ADDRESS field of DMEMCTL0 when the external base address port inputs are disabled via the DBAPD control bit. **Note:** Low order bits of this field are driven to 0s when the DMEM size is > 4 KB
20	—	Reserved
21	DECUA	DMEM Error Correction Update Available DECUA indicates an error scrubbing function for the DMEM is available. 0 Error Correction Update is not available. 1 Error Correction Update is available for correction of a correctable single-bit error detected on a read access.
22	DECA	DMEM Error Correction Available DECA indicates an error correction function for the DMEM is available. 0 Error Correction is not available. 1 Error Correction is available.
23	—	Reserved
24:29	DMSIZE	DMEM Size 010000 The size of the DMEM is 64 KB.
30:31	—	Reserved

15.11.2.2 DMEM Control Register 0 (DMEMCTL0)

The DMEM Control Register 0 (DMEMCTL0) controls operation of certain functions of the DMEM logic.

DMEM BASE ADDR	0	DBYPCB	DBYPAT	DBYPDEC	DECUE	0	DBAPD	DPEIE	DICWE	DSWCE	DDAUEC	DCPECE	DSECE

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	1	1	0	1	1

DCR - 496; Read/Write; Reset[1] - 0x0000_041B; Privileged

Figure 15-31. DMEM Control Register 0 (DMEMCTL0)

Note

[1] Reset by **m_por** and **slv_reset_b**. Unaffected by **p_reset_b**.

Table 15-40. DMEMCTL0 field descriptions

Bits	Name	Description
0:15	DMEM BASEADDR	DMEM BASE ADDRESS Field (CPU Port) This field defines the Base Address used for the CPU port to the DMEM when the external base address port inputs are disabled via the DBAPD control bit. **Note:** Changes to this value and to the BAPD control bit must be performed carefully by software to ensure coherency is maintained. Specifically, software must ensure that no cached entries are present in the D-Cache for the memory space to be occupied by the DMEM.
16 :18	—	Reserved
19	DBYPCB	DMEM Bypass Cache Bypass CPU accesses DBYPCB can be used to force Non-decorated Cache Bypass loads and Store with Writethrough (**lbcbx**, **lhcbx**, **lwcbx**, and **stwwtx**, **sthwtx**, **stbwtx**) accesses that target the DMEM address space to be presented to the external bus. Note that the protection settings in DMEMCTL1 are still applied to these accesses. 0 Non-decorated Cache Bypass loads and Store with Writethrough CPU accesses do not bypass the DMEM CPU port. 1 Non-decorated Cache Bypass loads and Store with Writethrough CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface. **Note:** This field is updated on **m_por** and **slv_reset_b**.
20	DBYPAT	DMEM Bypass Atomic CPU accesses DBYPAT can be used to force atomic (load and reserve, store conditional) accesses to the DMEM address space to be presented to external reservation hardware in systems that support reservation and/or decoration functionality, since no internal reservation hardware is present in the CPU for the DMEM. In general, software must not rely on normal CPU write accesses to clear a reservation, since they are not monitored by reservation hardware; instead only store conditional accesses should be used for this purpose. Note that the protection settings in DMEMCTL1 are still applied to these accesses. 0 Atomic CPU accesses do not bypass the DMEM CPU port. 1 Atomic CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface. **Note:** This field is updated on **m_por** and **slv_reset_b**.
21	DBYPDEC	DMEM Bypass Decorated CPU accesses

Table continues on the next page...

Table 15-40. DMEMCTL0 field descriptions (continued)

Bits	Name	Description
		DBYPDEC can be used to force decorated accesses (**lbdx, lhdx, lwdx, lbdcbx, lhdcbx, lwdcbx, stbdx, sthdx, stwdx, stbdcbx, sthdcbx, stwdcbx, dsn, dsncb**) to the DMEM address space to be presented to external decoration hardware for systems that support this functionality, since no internal decoration hardware is present in the CPU. Note that the protection settings in DMEMCTL1 are still applied to these accesses. 0 Decorated Load and Store CPU accesses do not bypass the DMEM CPU port. 1 Decorated Load and Store CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface. **Note:** This field is updated on **m_por** and **slv_reset_b**.
22	DECUE	DMEM Error Correction Update Enable DECUE can be used in conjunction with DCPECE and DSECE to provide an error scrubbing function for the DMEM. 0 Error Correction Update is disabled. 1 Error Correction Update is enabled. A correctable single-bit error detected on a read access from either the CPU or the slave port will cause the DMEM to be rewritten with the corrected data if the corresponding error checking enable bit is set (DCPECE for CPU accesses, DSECE for slave port accesses). (Write accesses perform this correction automatically during partial-width writes when error checking is enabled.) **Note:** This field is updated on **m_por** and **slv_reset_b**.
23	—	Reserved
24	DBAPD	DMEM Base Address Port Disable This bit controls usage of the external Base Address port (**p_dmem_baseaddr[0:n]**) to define the base address of the DMEM for CPU port accesses. It has no effect on DMEM slave port accesses. 0 The external DMEM base address port (**p_dmem_baseaddr[0:n]**) is used to define the base address of the DMEM for CPU accesses. 1 The external DMEM base address port (**p_dmem_baseaddr[0:n]**) is disabled for use, and instead the BASE ADDR field value is used to define the base address of the DMEM for CPU accesses.
25	DPEIE	DMEM Processor Error Injection Enable DPEIE will cause injection of errors regardless of the setting of DCPECE, although reporting of errors to the CPU will be masked while DCPECE = 0. 0 Error Injection is disabled. 1 A double-bit error will be injected on each CPU port write into the DMEM data array by inverting the two uppermost parity check bits (p_dchk[0:1]).
26	DICWE	DMEM Imprecise CPU Write Enable DICWE may allow for increased partial-width write performance when set. 0 Imprecise writes by the CPU are disabled. All partial-width write ECC errors are reported precisely (error report machine check). 1 Imprecise writes by the CPU are enabled. In certain cases, partial-width write errors may be reported imprecisely (async machine check only).
27:28	DSWCE	DMEM Slave port Write Check/Correct Enable 00 Slave write data is not checked or corrected for errors.

Table continues on the next page...

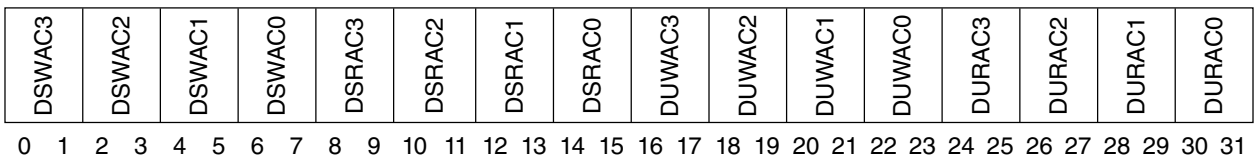
Table 15-40. DMEMCTL0 field descriptions (continued)

Bits	Name	Description
		01 Slave write data is checked but not corrected for errors. Detected errors generate a slave port ERROR response and no Write is performed to the DMEM. 10 Slave write data is checked and corrected for errors on all writes. Single-bit correctable errors do not automatically generate an ERROR response, but are instead corrected. 11 Slave write data is checked and corrected for errors on partial-width (1, 2, 3, 5, 6, or 7 byte, or misaligned 4-byte writes) writes. Single-bit correctable errors on partial-width writes do not automatically generate an ERROR response, but are instead corrected. Aligned word or doubleword writes are not checked or corrected for errors. **Note:** This field is updated on **m_por** and **slv_reset_b**.
29	DDAUEC	DMEM Disable Address Use in Error Check This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portions are not used for checkbit/syndrome generation for DMEM CPU or slave port accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation. **Note:** This field is updated on **m_por** and **slv_reset_b**.
30	DCPECE	DMEM CPU Port ECC Enable (CPU port) 0 End-to-End ECC is disabled for the CPU interface. No checking of read data is performed by the CPU. Writes will still generate the proper check bit values to be written. 1 End-to-End ECC is enabled for performing ECC on the CPU interface. Error checking of read data is performed with single-bit error correction. Detection of uncorrectable single- or multi-bit errors on a CPU port access cause a machine check to be generated. **Note:** This field is updated on **m_por** and **slv_reset_b**.
31	DSECE	DMEM Slave port Error Checking Enable (Slave port) 0 End-to-End ECC checking logic is disabled for the Slave interface. No checking of read data is performed during read-modify-write operations for Slave port partial-width writes. Writes will still generate the proper check bit values to be written. 1 End-to-End ECC is enabled for performing ECC on the Slave Port interface. Error checking of read data is performed with single-bit error correction during read-modify-write operations for partial-width writes. Detection of uncorrectable single- or multi-bit errors on a Slave port partial-width write access causes a bus error ERROR response to be generated. **Note:** This field is updated on **m_por** and **slv_reset_b**.

15.11.2.3 DMEM Control Register 1 (DMEMCTL1)

The DMEM Control Register 1 (DMEMCTL1) provides protection functions for the DMEM. Separate Supervisor-mode and User-mode read and write access controls allow accesses to be granted, denied, or conditionally granted independently for four equally sized blocks of DMEM. Conditional granting of access permissions causes the MPU

memory protection functions to be employed, all other settings override MPU settings. The DMEMCTL1 settings are applied to all accesses that target DMEM address range, regardless of whether access may bypass the DMEM based on settings in DMEMCTL0$_{DBYPCB, DBYPATF, DBYPDEC}$.



DCR - 498; Read/Write; Reset[1] - 32'b0; Privileged

		Note: Individual control fields are provided for four equal sized sections of DMEM regardless of DMEM size. A single control field is used for each access based on the upper two address bits used to index into the DMEM. DURAC0 is used when these two bits = 2'b00

15.12 End-to-End ECC Support

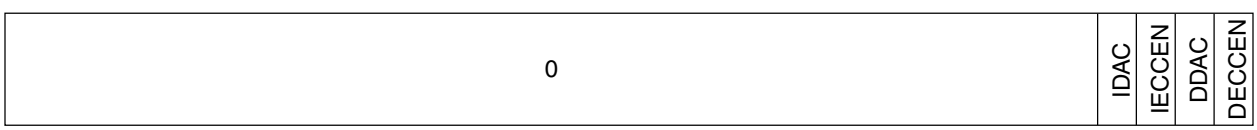
This section describes end-to-end error detection and correction capability (e2eECC) enhancements to address additional diagnostic capabilities for the next generation of embedded designs.

15.12.1 End-to-End ECC control and configuration

e2eECC is controlled by a set of privileged device control registers (DCRs) accessed using the **mfdcr** and **mtdcr** instructions. These registers and the operation of various features are described in the following subsections.

15.12.1.1 End-to-End ECC Control Register 0 (E2ECTL0)

The End-to-End ECC Control Register 0 (E2ECTL0) controls operation of the e2eECC logic.



DCR - 510; Read/Write; Reset - 0x5 || p_e2e_rstcfg[0:3]; Privileged

Figure 15-33. e2eECC Control Register 0 (E2ECTL0)

Table 15-42. E2ECTL0 field descriptions

Bits	Name	Description
0:27	—	Reserved
28	IDAC	Instruction Disable Address Checking This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portion is not used for checkbit/syndrome generation for Instruction AHB accesses.

Table continues on the next page...

Table 15-42. E2ECTL0 field descriptions (continued)

Bits	Name	Description
		0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[0]** input.
29	IECCEN	Instruction ECC Enable Field 0 End-to-End ECC is disabled for the Instruction interface. No checking of instruction fetch data is performed. 1 End-to-End ECC is enabled for performing error detection and correction on the Instruction interface. Checking of instruction fetch data is performed with correction of single-bit data errors. Detection of any address errors or uncorrectable multi-bit data errors cause a machine check to be generated if the instruction fetch information is attempted to be used for instruction decoding and execution. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[1]** input.
30	DDAC	Data Disable Address Checking This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portion is not used for checkbit/syndrome generation for Data AHB accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[2]** input.
31	DECCEN	Data ECC Enable Field 0 End-to-End ECC is disabled for the Data interface. No checking of read data is performed. Writes will still generate the proper check bit values to be supplied to external storage devices. 1 End-to-End ECC is enabled for performing error detection and correction on the Data interface. Checking of read data is performed with correction of single-bit data errors. Detection of any address errors, or uncorrectable multi-bit data errors cause a machine check to be generated. Writes generate the proper check bit values to be supplied to external storage devices. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[3]** input.

e2eECC is enabled by setting the [I,D]ECCEN bit of the E2ECTL0 DCR to a 1. On reset, e2eECC operation may be disabled from detecting or correcting errors based on reset configuration inputs, and no exceptions will be signaled for nonzero calculated syndrome values. This allows for the proper initialization of stored checkbits in any volatile storage by the CPU without causing error conditions due to uninitialized storage. Following the initialization, software may enable e2eECC operation by writing the appropriate values to the $E2ECTL0_{[I,D]ECCEN}$ control bits.

The $E2ECTL0_{[I,D]DAC}$ control bits can be used to remove the address checking component of the ECC logic for the Instruction AHB and Data AHB when address inclusion is not desired.

15.12.1.2 End-to-End ECC fault injection by software

Fault injection provides a way to test error recovery and portions of the error detection/correction logic by intentionally injecting parity errors into the driven checkbit information on the external bus during write operations. No provision is made to generate internal errors on read data due to timing issues; instead, software may intentionally generate errors in the checkbit values to emulate data, address, or checkbit error on external bus write cycles, and read back the written data to cause an error to be detected.

The End-to-End ECC Error Control/Status Register (E2EECSR0) controls operation of the e2eECC error injection logic. It allows for generation of a single error injection operation on the next CPU data write to the external bus only, or for a series of error injection write operations to the external bus, using the WRC and INVC control fields. The WRCHKBIT/CHKINVT field controls which of the **p_hwchkbit[7:0]** outputs are affected.

Control is provided to allow for either inverting the value(s) of one or more of the checkbit outputs **p_hwchkbit[7:0]** in hardware on one or more external write accesses, or for software to directly supply checkbit values to be used for the external write access(es).

The End-to-End ECC Error Control/Status Register (E2EECSR0) also supports access to raw checkbit values via the RCHKBIT status field. This field is updated with checkbit values received on each CPU data read operation to either the DMEM or to the external bus (but not on cache hits).

Note that Nexus 3 accesses do not cause error injection or the capture of read checkbits, regardless of the settings of the E2EECSR0 register.

The following figure shows the layout of E2EECSR0.

0	RCHKBIT	0	WRC	INVC	0	WCHKBIT/CHKINVT
0 1 2 3	4 5 6 7 8 9 10 11	12 13 14 15	16	17	18 19 20 21	22 23 24 25 26 27 28 29 30 31

DCR - 511; Read/Write; Reset - 0x0; Privileged

Figure 15-34. e2eECC Error Control/Status Register 0 (E2EECSR0)

Table 15-43. E2EECSR0 field descriptions

Bits	Name	Description
0:3	—	Reserved
4:11	RCHKBIT	Read Checkbits This field provides the raw checkbits received on the last CPU data access to the DMEM or to external memory via the Data BIU. This field corresponds bit-wise to **p_hrchkbit[7:0]**. for external reads and to **p_dchk[0:7]** for DMEM read accesses. Software may use this information to determine the stored checkbits of external memories or the DMEM by performing CPU load operations and then accessing this field prior to the next load operation (assuming interrupts are masked).
12:15	—	Reserved
16:17	WRC	Write Control 00 No write checkbit substitution is performed by this control bit 01 Checkbit substitution is performed for the next CPU external write access (only) by driving **p_hwchkbit[7:0]** with the values in the WCHKBIT control field. Software must clear this field before rewriting to 01 in order to generate a subsequent checkbit substitution operation. 10 Checkbit substitution is performed for each CPU external write access while this field remains set to 10 by driving **p_hwchkbit[7:0]** with the values in the WCHKBIT control field. This field must be cleared by software to discontinue further checkbit substitution. 11 Reserved Note: Checkbit substitution has priority over Error injection
18:19	INVC	Invert Control 00 No error injection is performed by this control bit 01 Error injection is performed for the next CPU external write access (only) by modifying **p_hwchkbit[7:0]** based on CHKINVT. Software must clear this field before rewriting to 01 in order to generate a subsequent error injection operation. 10 Error injection is performed for each CPU external write access while this field remains set to 10 by modifying **p_hwchkbit[7:0]** based on CHKINVT. This field must be cleared by software to discontinue further error generation. 11 Reserved Note: Checkbit substitution has priority over Error injection
20:23	—	Reserved
24:31	WCHKBIT/ CHKINVT	Write Checkbits / Checkbit Invert Mask This field provides the checkbit substitution values when performing checkbit substitution via the WRC control field, and controls which checkbits are inverted when performing error injection via the INVC control field. This field corresponds bit-wise to **p_hwchkbit[7:0]**. For Checkbit inversion operations via error injection: 0 Checkbit is driven normally 1 Checkbit is inverted before being driven out on **p_hwchkbit[7:0]** when error injection occurs.

Chapter 16
Nexus Module

16.1 Introduction

The e200z4201n3Nexus 3 module provides real-time development capabilities for corresponding core processors in compliance with the IEEE-ISTO 5001 standard. This module provides development support capabilities without requiring the use of address and data pins for internal visibility.

A portion of the pin interface (the JTAG port) is also shared with the OnCE / Nexus 1 unit. The IEEE-ISTO 5001 standard defines an extensible auxiliary port which is used in conjunction with the JTAG port in these processors.

16.1.1 General description

This chapter defines the auxiliary pin functions, transfer protocols and standard development features of a Class 3 device in compliance with the IEEE-ISTO 5001 standard. The development features supported are Program Trace, Data Trace, Watchpoint Messaging, Ownership Trace, Data Acquisition Messaging, and Read/Write Access via the JTAG interface. The Nexus 3 module also supports two Class 4 features: Watchpoint Triggering, and Processor Overrun Control.

16.1.2 Terms and definitions

The following table contains a set of terms and definitions associated with the Nexus 3 module.

Table 16-1. Terms and definitions

Term	Description
IEEE-ISTO 5001	Consortium & standard for real-time embedded system design. World wide Web documentation at http://www.ieee-isto.org/Nexus5001
Auxiliary Port	Refers to Nexus auxiliary port. Used as auxiliary port to the IEEE 1149.1 JTAG interface.
Branch Trace Messaging (BTM)	Visibility of addresses for taken branches and exceptions, and the number of sequential instructions executed between each taken branch.
Data Read Message (DRM)	External visibility of data reads to memory-mapped resources.
Data Write Message (DWM)	External visibility of data writes to memory-mapped resources.
Data Trace Messaging (DTM)	External visibility of how data flows through the embedded system. This may include DRM and/or DWM.
Data Acquisition Messaging (DQM)	Data Acquisition Messaging (DQM) allows code to be instrumented to export customized information to the Nexus Auxiliary Output Port.
JTAG Compliant	Device complying to IEEE 1149.1 JTAG standard
JTAG IR & DR Sequence	JTAG Instruction Register (IR) scan to load an opcode value for selecting a development register. The JTAG IR corresponds to the OnCE command register (OCMD). The selected development register is then accessed via a JTAG Data Register (DR) scan.
Nexus1	The (OnCE) debug module. This module integrated with each processor provides all static (core halted) debug functionality. This module is compliant with Class1 of the IEEE-ISTO 5001 standard.
Ownership Trace Message (OTM)	Visibility of process/function that is currently executing.
Public Messages	Messages on the auxiliary pins for accomplishing common visibility and controllability requirements
SoC	"System-on-a-Chip". SoC signifies all of the modules on a single die. This generally includes one or more processors with associated peripherals, interfaces & memory modules.
Standard	The phrase "according to the standard" is used to indicate according to the IEEE-ISTO 5001 standard.
Transfer Code (TCODE)	Message header that identifies the number and/or size of packets to be transferred, and how to interpret each of the packets.
Watchpoint	A Data or Instruction Breakpoint or other debug event that does not cause the processor to halt. Instead, a pin is used to signal that the condition occurred. A Watchpoint Message may also be generated.

16.1.3 Feature list

The Nexus 3 module is compliant with Class 3 of the IEEE-ISTO 5001 standard, with additional Class 4 features available. The following features are implemented:

- Program Trace via Branch Trace Messaging (BTM). Branch trace messaging displays program flow discontinuities (direct and indirect branches, exceptions, etc.), allowing the development tool to interpolate what transpires between the discontinuities. Thus static code may be traced.
- Data Trace via Data Write Messaging (DWM) and Data Read Messaging (DRM). This provides the capability for the development tool to trace reads and/or writes to selected internal memory resources.
- Ownership Trace via Ownership Trace Messaging (OTM). OTM facilitates ownership trace by providing visibility of which process ID or operating system task is activated. An Ownership Trace Message is transmitted when a new process/task is activated, allowing the development tool to trace ownership flow.
- Run-time access to embedded processor memory map via the JTAG port. This allows for enhanced download/upload capabilities.
- Watchpoint Messaging via the auxiliary pins
- Watchpoint Trigger enable of Program and/or Data Trace Messaging
- Auxiliary interface for higher data
  - Configurable (min/max) Message Data Out pins (**nex_mdo[n:0]**)
  - One (1) or two (2) Message Start/End Out pins (**nex_mseo_b[1:0]**)
  - One (1) Read/Write Ready pin (**nex_rdy_b**) pin
  - One (1) Read/Write Error pin (**nex_err_b**) pin
  - One (1) Watchpoint Event output pin (**evto_b**)
  - Four (4) additional Watchpoint Event output pins (**nex_wevto[3:0]**) for SoC use
  - One (1) Event In pin (**nex_evti_b**)
  - One (1) MCKO (Message Clock Out) pin
- Registers for Program Trace, Data Trace, Ownership Trace and Watchpoint Trigger
- All features controllable and configurable via the JTAG port
- Conditional software control of the module via SoC signaling input (**nex_sfwcntl_en**)
- Indicates to the FCCU whether it becomes active during functional mode.

Note

For multi-Nexus implementations, the configuration of the Message Data Out pins is controlled by the Port Control Register (at the SoC level). For single Nexus implementations (not normally implemented on an SoC), this configuration is controlled by Development Control Register 1 (DC1) within the Nexus 3 module.

In either implementation, Full Port Mode (FPM - maximum number of MDO pins) or Reduced Port Mode (RPM - minimum number of MDO pins) are supported. This setting should not be changed while the system is running.

Note

The configuration of the Message Start/End Out pins (1 or 2) is determined at the SOC integration level. This option will be hard-wired based on SOC bandwidth requirements.

16.1.4 Functional block diagram

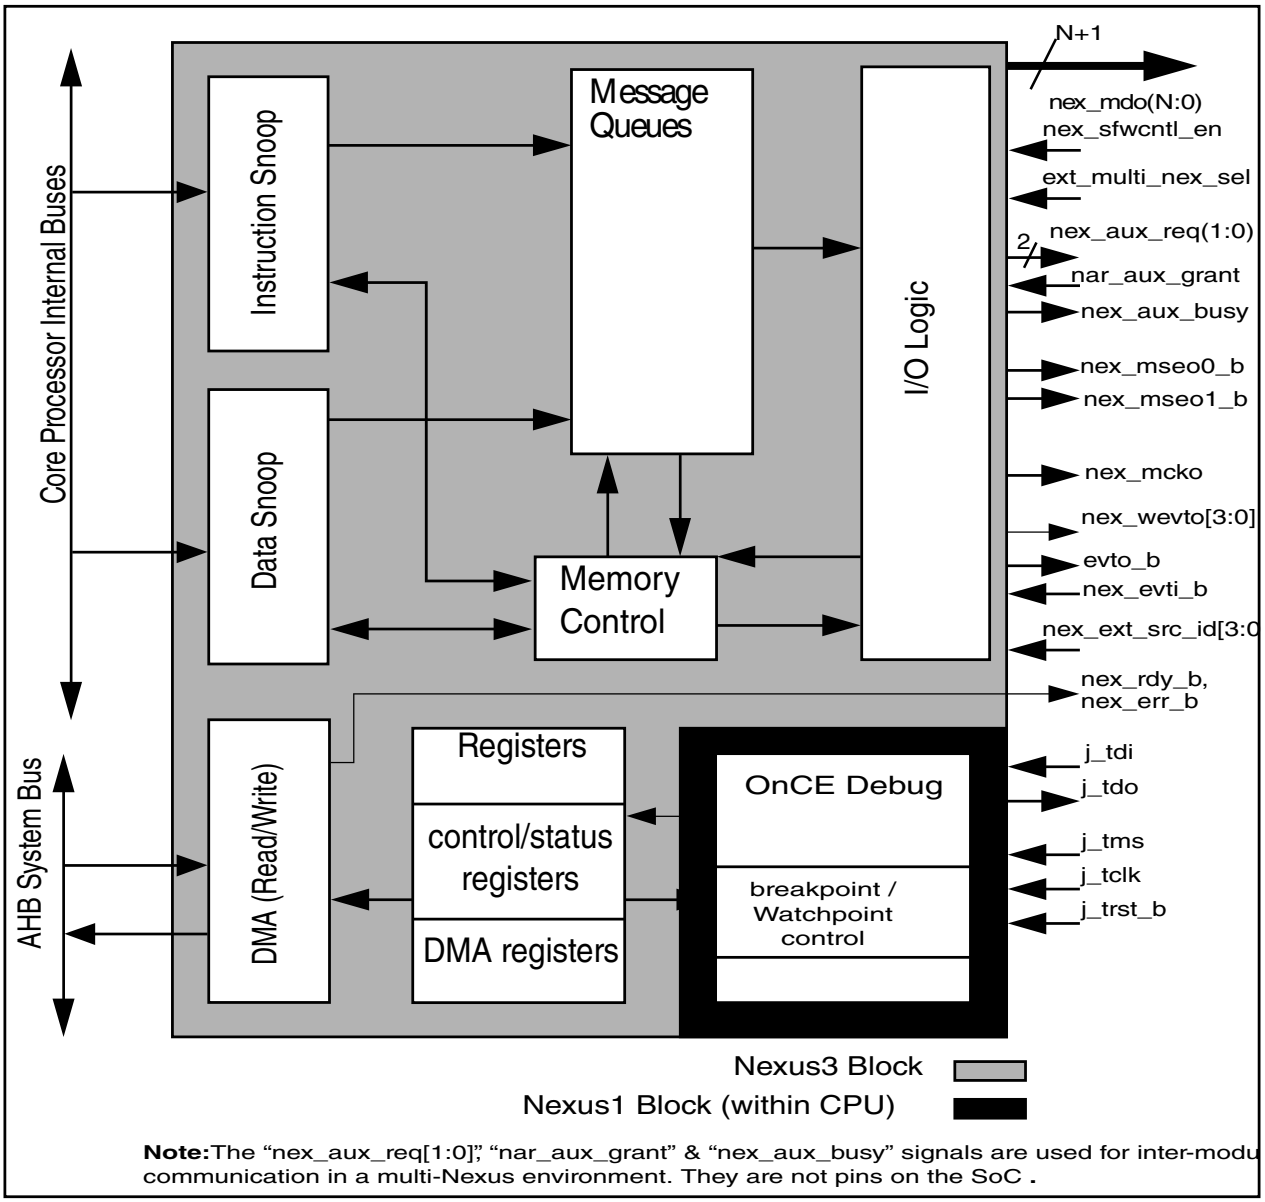


Figure 16-1. Nexus 3 functional block diagram

16.2 Enabling Nexus 3 operation

The Nexus module is enabled by loading a single instruction (*NEXUS3-ACCESS*) into the JTAG Instruction Register (IR) (OnCE OCMD register). For the Nexus3 module, the OCMD value is 0b0001111100. The Nexus 3 module may alternately be enabled if the nex_evti_b input signal is asserted at the time that j_trst_b is initially negated, or is asserted during the Test-Logic-Reset TAP state. Once enabled, the module will be ready to accept control input via the JTAG/OnCE pins.

Enabling the Nexus 3 module automatically enables the generation of Debug Status Messages.

The Nexus 3 module is disabled when the JTAG state machine initially reaches the Test-Logic-Reset state from any other state. This state can be reached by the assertion of the **j_trst_b** pin or by cycling through the state machine using the **j_tms** pin. The Nexus module will also be disabled if a Power-on-Reset (POR) event occurs. If the Nexus 3 module is disabled, no trace output will be provided, and the module will disable (drive inactive) auxiliary port output pins (**nex_mdo[n:0]**, **nex_mseo[1:0]**, **nex_mcko**). Nexus registers will not be available for reads or writes.

In order to support software control of the Nexus 3 module when no external development tool is present, the Nexus 3 module is not forced to be disabled when the JTAG state remains in the Test-Logic-Reset state. Software is allowed to control the Nexus 3 module when the input signal **nex_sfwcntl_en** is asserted by the SoC. This signal is intended to provide a mechanism for allowing software to use the Nexus 3 module to fill on-chip trace buffers or other visibility mechanisms. It is up to the SoC to determine whether a top-level Nexus 3 controller has been enabled by a hardware debugger, or whether appropriate security mechanisms have granted the capability for software to use these resources, and to drive the appropriate value to the **nex_sfwcntl_en** input. Software can enable the module by a write to any of the module's DCRs when **nex_sfwcntl_en** is asserted.

Reset of the Nexus 3 module is accomplished by a transition on **j_trst_b**, on initial entry into the Test_Logic_Reset state from another state, or if a Power-on-Reset (POR) event occurs. The module is not reset by the CPU's **p_reset_b** signal, even when software has control of the module.

16.2.1 Interaction with Low Power Modes

The Nexus 3 module will continue to operate in the Waiting and Halted states, as long as **nex_clk** remains active. In the Stopped state, **nex_clk** is gated off internally to the Nexus 3 logic, therefore watchpoint or hardware triggering recognition, message generation, and Nexus 3 read-write access to memory is suspended. The Nexus 3 logic will wait to enter the Stopped state until the message FIFOs are empty and any in-progress Nexus R/W transfer has completed. If a block transfer has been requested, the remainder of the block transfer is not completed, and the RWCS AC bit is cleared, and the ERR bit is set. Once the Stopped state has been entered, no further messages are queued and no triggering conditions are monitored. Also, Nexus R/W accesses are no longer available. Upon exiting the Stopped state, normal functions will resume assuming **nex_clk** is active.

16.3 TCODEs supported

The Nexus 3 pins allow for flexible transfer operations via Public Messages. A TCODE defines the transfer format, the number and/or size of the packets to be transferred, and the purpose of each packet. The IEEE-ISTO 5001-2003 standard defines a set of public messages and allocates additional TCODEs for vendor-specific features outside the scope of the public messages. The Nexus 3 block supports the TCODEs shown in Table 16-2.

Table 16-2. Supported TCODEs

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Debug Status	6	6	TCODE	fixed	TCODE number = 0
	4	4	SRC	fixed	source processor identifier
	8	8	STATUS	fixed	Development Status Register (DS[31:24])
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)
Ownership Trace Message	6	6	TCODE	fixed	TCODE number = 2
	4	4	SRC	fixed	source processor identifier
	1	32	PROCESS	variable	Task/Process ID tag
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)
Program Trace - Direct Branch Message	6	6	TCODE	fixed	TCODE number = 3
	4	4	SRC	fixed	source processor identifier
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)
Program Trace - Indirect Branch Message	6	6	TCODE	fixed	TCODE number = 4
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	U-ADDR	variable	unique part of target address for taken branches/ exceptions
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)
Data Trace - Data Write Message	6	6	TCODE	fixed	TCODE number = 5
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to Table 16-7)
	1	32	U-ADDR	variable	unique portion of the data write address
	1	64	DATA	variable	data write value(s) (see Data Trace section for details)

Table continues on the next page...

Table 16-2. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)
Data Trace - Data Read Message	6	6	TCODE	fixed	TCODE number = 6
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to Table 16-7)
	1	32	U-ADDR	variable	unique portion of the data read address
	1	64	DATA	variable	data read value(s) (see Data Trace section for details)
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)
Data Acquisition Message	6	6	TCODE	fixed	TCODE number = 7
	4	4	SRC	fixed	source processor identifier
	8	8	DQTAG	fixed	identification tag taken from $DEVENT_{DQTAG}$ register field
	1	32	DQDATA	variable	exported data taken from DDAM register
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)
Error Message	6	6	TCODE	fixed	TCODE number = 8
	4	4	SRC	fixed	source processor identifier
	4	4	ETYPE	fixed	error type
	8	8	ECODE	fixed	error code
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)
Program Trace - Synchronization Message	6	6	TCODE	fixed	TCODE number = 9
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow. Cleared for most sync conditions.
	1	32	F-ADDR	variable	full target address (leading zero (0) truncated)
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)
Program Trace - Direct Branch Message w/ Sync	6	6	TCODE	fixed	TCODE number = 11
	4	4	SRC	fixed	source processor identifier
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zeros truncated)
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)
Program Trace - Indirect Branch Message w/Sync	6	6	TCODE	fixed	TCODE number = 12
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)

Table continues on the next page...

Table 16-2. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description

	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zero (0) truncated)
	1	32	HIST	variable	branch / predicate instruction history (See Branch Trace Messaging types.)
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)
Program Trace - Program Correlation Message	6	6	TCODE	fixed	TCODE number = 33
	4	4	SRC	fixed	source processor identifier
	4	4	EVCODE	fixed	event correlated w/ program flow (Refer to Table 16-6)
	2	2	CDF	fixed	# fields of information in CDATA. 00 - reserved, 01 - one field (CDATA1) (reserved), 10 - two fields (CDATA1 + CDATA2), 11 - three fields (reserved)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	CDATA1	variable	correlation data field 1 - [branch / predicate instruction history] (See Program Correlation Messages.)
	0	32	CDATA2	variable	correlation data field 2- PID info (See Program Correlation Messages.)
	0	30	TSTAMP	variable	Timestamp value (optionally generated field)

Note

Program Trace can be implemented using either Branch History/Predicate Instruction Messages, or traditional Direct/ Indirect Branch Messages. The user can select between the two types of Program Trace. The advantages for each are discussed in Branch Trace Messaging types. If the Branch History method is selected, the shaded TCODES above will not be messaged out.

Table 16-3 shows the error code encodings used when reporting an error via the Nexus 3 Error Message.

Table 16-3. Error Code (ECODE) Encoding (TCODE = 8)

Error Code	Description
xxxxxxx1	Watchpoint Trace Message(s) Lost
xxxxxx1x	Data Trace Message(s) Lost
xxxxx1xx	Program Trace Message(s) Lost
xxxx1xxx	Ownership Trace Message(s) Lost
xxx1xxxx	Status Message(s) Lost (Debug Status messages, etc.)
xx1xxxxx	Data Acquisition Message(s) Lost
x1xxxxxx	Reserved
1xxxxxxx	Reserved

Table 16-4 shows the error type encodings used when reporting an error via the Nexus 3 Error Message.

Table 16-4. Error Type (ETYPE) Encoding (TCODE = 8)

Error Type	Description
0000	Message Queue Overrun caused one or more messages to be lost
0001	Contention with higher priority messages caused one or more messages to be lost
0010	Reserved
0011	Reserved
0100	Reserved
0101	Invalid access opcode (Nexus Register unimplemented)
0110 - 1111	Reserved

Table 16-5 shows the encodings used for resource codes for certain messages.

Table 16-5. Resource Code (RCODE) values (TCODE = 27)

Resource Code	Description
0000	Program Trace Instruction counter reached 255 and was reset.
0001	Program Trace, Branch / Predicate Instruction History full. This type of packet is terminated by a stop bit set to 1 after the last history bit.

Table 16-6 shows the event code encodings used for certain messages.

Table 16-6. Event Code (EVCODE) Encoding (TCODE = 33)

Event Code	Description
0000	Entry into Debug Mode
0001	Entry into Low Power Mode (CPU only)
0010-0011	Reserved for future functionality
0100	Disabling Program Trace

Table continues on the next page...

Table 16-6. Event Code (EVCODE) Encoding (TCODE = 33) (continued)

Event Code	Description
0101	Process ID value is established in PID0/NPIDR via **mtspr PID0/NPIDR**
0110-1000	Reserved for future functionality
1001	Begin masking of program trace messages due to MSR_{PMM}=0 and $DC4_{PTMARK}$=1
1010	Branch and link occurrence (direct branch function call)
1011-1111	Reserved for future functionality

Table 16-7 shows the data trace size encodings used for certain messages.

Table 16-7. Data Trace Size (DSZ) Encodings (TCODE = 5,6,13,14)

DTM Size Encoding	Transfer Size
0000	0 - no data
0001	Byte
0010	Halfword (2 bytes)
0011	Three bytes
0100	Word (4 bytes)
0101	Five bytes
0110	Six bytes
0111	Seven bytes
1000	Doubleword (8 bytes)
1001-1111	Reserved

16.4 Nexus 3 Programmer's model

This section describes the Nexus 3 programmer's model. Nexus 3 registers are accessed using the JTAG/OnCE port in compliance with IEEE 1149.1, or by software via DCRs. See Nexus 3 Register Access via JTAG/OnCE and Nexus 3 Register Access via Software for details on Nexus 3 register access.

Note

Nexus 3 registers and output signals are numbered using bit 0 as the least significant bit. This bit ordering is consistent with the ordering defined by the IEEE-ISTO 5001 standard.

The following table details the register map for the Nexus 3 module.

Table 16-8. Nexus 3 register map

Nexus Register	Nexus Access Opcode	Read/ Write	Read Address	Write Address	DCR #[1]
Client Select Control (CSC)[2]	0x1	R	0x02	-

1. Software access via the **mfdcr** and **mtdcr** instructions use these values for the DCR number. Software writes to these registers via **mtdcr** when **nex_sfwcntl_en** is negated are ignored.
2. The CSC and PCR registers are shown in this table as part of the Nexus programmer's model. They are only present at the top level SoC Nexus controller in a multi-Nexus implementation, not in the Nexus 3 module. The SoC's CSC Register is readable through Nexus, but the PCR is shown for reference only here.

3. The "PCR_INDEX" is a parameter determined by the SoC.

16.4.1 Client Select Control (CSC) register

The CSC Register determines which Nexus client is under development. This register is present at the top-level SOC Nexus 3 controller to select one of multiple on-chip Nexus 3 units.

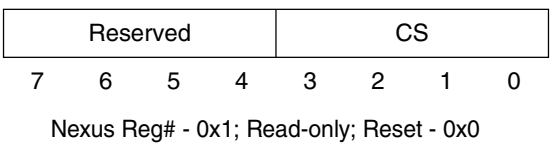

Figure 16-2. Client Select Control (CSC) register

Table 16-9. CSC field descriptions

Bits	Description
CSC[7:4]	Reserved for future Nexus Clients (read as 0)
CSC[3:0]	Client Select Control 0xx - Nexus client (SoC level)

16.4.2 Port Configuration Register (PCR) - reference only

The Port Configuration Register (PCR) controls the basic port functions for all Nexus modules in a multi-Nexus environment. This includes clock control and auxiliary port width. All bits in this register are writable only once after system reset.

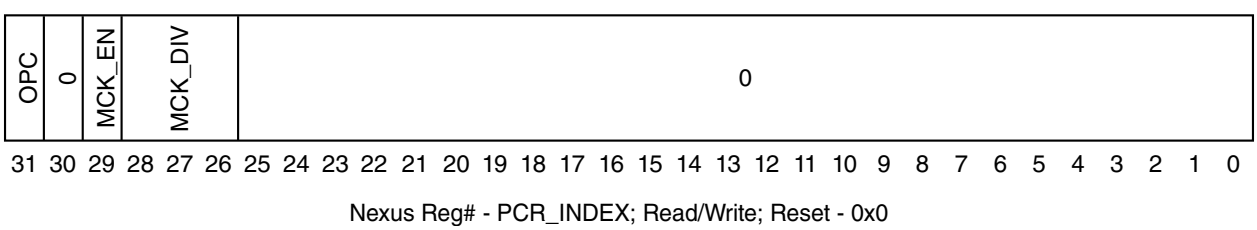

Figure 16-3. Port Configuration Register

Table 16-10. PCR field descriptions

Bit	Name	Description
31	OPC	Output Port Mode Control (SoC Level) 0 Reduced Port Mode configuration (min# **nex_mdo[n:0]** pins defined by SOC) 1 Full Port Mode configuration (max# **nex_mdo[n:0]** pins defined by SOC)
30	—	Reserved for future functionality

Table continues on the next page...

Table 16-10. PCR field descriptions (continued)

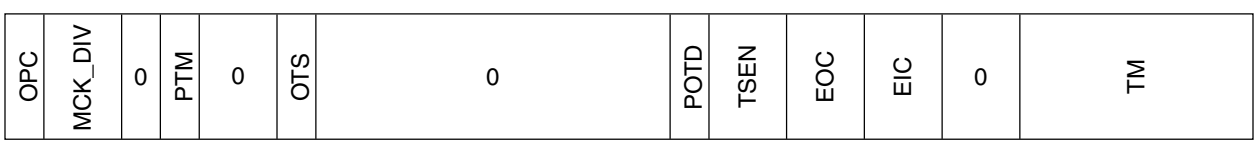
Bit	Name	Description
29	MCK_EN	MCKO Clock Enable (SoC Level) 0 **nex_mcko** is disabled 1 **nex_mcko** is enabled
28:26	MCK_DIV	MCKO Clock Divide Ratio (see note below) (SoC Level) 000 **nex_mcko** is 1x processor clock freq. 001 **nex_mcko** is 1/2x processor clock freq. 010 Reserved (default to 1/2x processor clock freq.) 011 **nex_mcko** is 1/4x processor clock freq. 100 Reserved (default to 1/2x processor clock freq.) 101 Reserved (default to 1/2x processor clock freq.) 110 Reserved (default to 1/2x processor clock freq.) 111 **nex_mcko** is 1/8x processor clock freq.
25:0	—	Reserved for future functionality

Note

The CSC and PCR Registers exist in a separate module at the SoC level in a multi-Nexus environment. If the core Nexus 3 module is the only Nexus module, these registers are not implemented and the Nexus 3 defined Development Control Register 1 (DC1) is used to control the SoC-level Nexus port functionality.

16.4.3 Nexus Development Control Register 1 (DC1)

Nexus Development Control Register 1 is used to control the basic development features of the Nexus 3 module. Development Control Register 1 is shown in Figure 16-4 and its fields are described in Table 16-11.



Nexus Reg# - 0x2; DCR - 368; Read/Write; Reset - 0x0

Figure 16-4. Development Control Register 1

Table 16-11. DC1 field descriptions

Bits	Name	Description

1. This field may be updated by hardware in response to watchpoint triggering if not already enable for tracing by a previous direct write to DC1. Direct writes to this field to enable one or more trace types take precedence over hardware updates. Refer to Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers for more information on watchpoint triggering.
1. This field may be updated by hardware in response to watchpoint triggering if not already enable for tracing by a previous direct write to DC1. Direct writes to this field to enable one or more trace types take precedence over hardware updates. Refer to Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers for more information on watchpoint triggering.
1. This field may be updated by hardware in response to watchpoint triggering if not already enable for tracing by a previous direct write to DC1. Direct writes to this field to enable one or more trace types take precedence over hardware updates. Refer to Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers for more information on watchpoint triggering.

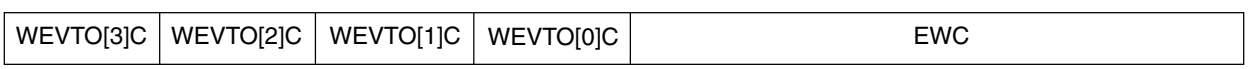
Note

The Output Port Mode Control bit (OPC) and MCKO Clock Divide Ratio bits (MCK_DIV) MUST ONLY be modified during system reset or debug mode to insure correct output port and output clock functionality. It is also recommended that all other bits of the DC1 also only be modified in one of these two modes.

16.4.4 Nexus Development Control Registers 2 & 3 (DC2, DC3)

Nexus Development Control Registers 2 and 3 are used to control output signaling on the Nexus 3 module. A table of watchpoints can be found in the Core (e200z4201n3) Core Debug Support chapter.

Development Control Register 2 is shown in Figure 16-5 and its fields are described in Table 16-12.



Nexus Reg# - 0x3; DCR - 369; Read/Write; Reset - 0x0

1. EOC bits in DC1 must be programmed to trigger $\overline{\text{EVTO}}$ on Watchpoint occurrence for EWC bits to have any effect.

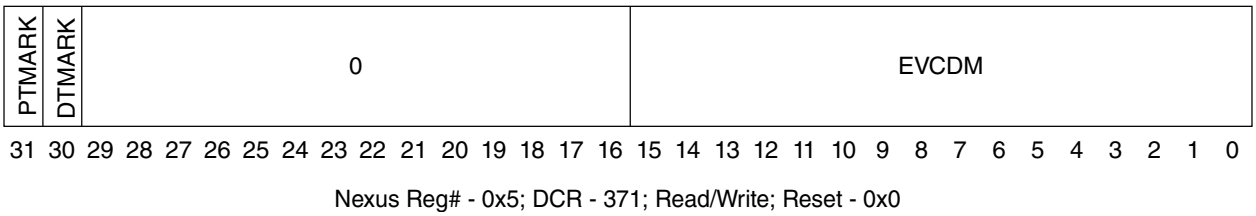
16.4.5 Nexus Development Control Register 4 (DC4)

Nexus Development Control Register 4 is used to control mark selection for Program and Data Trace Messaging, as well as masking of events that initiate Program Correlation Messages on the Nexus 3 module.

Development Control Register 4 is shown in Figure 16-7 and its fields are described in Table 16-14.



Nexus Reg# - 0x5; DCR - 371; Read/Write; Reset - 0x0

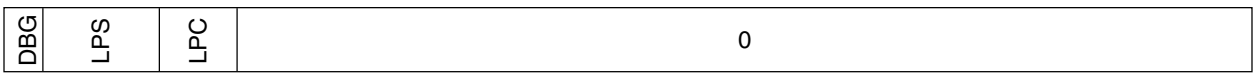
16.4.6 Development Status Register (DS)

The Development Status Register is used to report system debug status. When Debug Mode is entered or exited, or an SoC- or core-defined Low Power Mode is entered (see note below), a Debug Status Message is transmitted with DS[31:24]. The external tool can read this register at any time.



31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

25:0	—	Reserved for future functionality (read as 0)

16.4.7 Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers

The Watchpoint Trigger Registers allows the watchpoints defined within the Nexus1 logic to trigger actions. These watchpoints can control Program and/or Data Trace enable and disable. The control bits can be used to produce a related "window" for triggering Trace Messages. Watchpoint trigger register WT is used to control triggering by a single selected watchpoint. The Program Trace Start Trigger Control (PTSTC), Program Trace End Trigger Control (PTETC), Data Trace Start Trigger Control (DTSTC), and Data

Trace End Trigger Control (DTETC) are used for extended trigger controls for the respective function. If multiple watchpoints are desired for triggering, or a watchpoint beyond watchpoint #13 is required, then one or more of the extended watchpoint trigger registers may be used. A field encoding of 4'b1111 in one of the WT register fields enables the corresponding extended trigger register. For all other WT field encodings, the corresponding extended trigger register is disabled and the contents are ignored. Note that direct writes to enable program trace and/or data trace in DC1 will override these controls, and trace will remain enabled until another direct write to DC1 to disable program and/or data trace occurs.

When a start trigger is detected, the designated trace features become enabled, and the corresponding enable bits of the DC1 register are set. Whenever a stop trigger is detected, the designated trace features become disabled, and the corresponding enable bits of the DC1 register are cleared. If the same trigger condition is used for both start and stop triggering, then the designated trace features will toggle between being enabled and disabled at each occurrence of the trigger condition. Similarly, if start and stop triggers for a trace feature occur simultaneously, then the designated trace feature will toggle between enabled and disabled depending on the enable state at the time of the trigger events. For example, if tracing is enabled, and a start and stop trigger occur simultaneously, then tracing will be disabled. Direct writes of the DC1 register take precedence over any trace feature enable state that is derived from watchpoint triggering. A table of watchpoints can be found in the Core (e200z4201n3) Core Debug Support chapter.

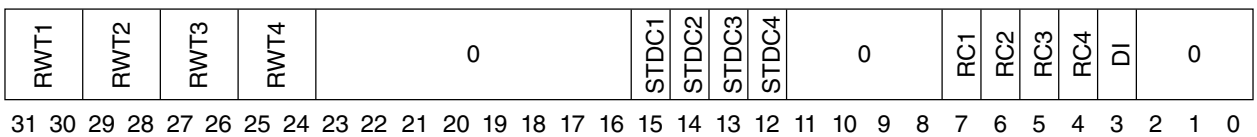
Figure 16-16. Nexus Overrun Control Register Fields

16.4.10 Data Trace Control Register (DTC) register

The Data Trace Control Register controls whether DTM Messages are restricted to reads, writes, or both for a user programmable address range. In addition, control is provided to restrict data trace message generation to only those load or store accesses that are not stack-related, in order to minimize required data trace message bandwidth.

There are four Data Trace channels controlled by the DTC for the Nexus 3 module. Channels can be programmed to trace data accesses or instruction accesses, but not independently.



Nexus Reg# - 0xD; DCR - 376; Read/Write; Reset - 0x0

Figure 16-17. Data Trace Control Register

The following table details the Data Trace Control register fields.

Figure 16-25. Data Trace End Address 4 (DTEA4) register

Table 16-23 illustrates the range that will be selected for Data Trace for various cases of DTSA being less than, greater than, or equal to DTEA.

Table 16-23. Data trace - address range options

Programmed values	Range Control Bit Value	Range Selected	
DTSA < DTEA	0	DTSA ->	<- DTEA
DTSA < DTEA	1	<- DTSA	DTEA ->
DTSA > DTEA	N/A	Invalid Range - no trace	
DTSA = DTEA	N/A	Invalid Range - no trace	

Note

DTSA must be less than DTEA in order to guarantee correct Data Write/Read Traces. Data Trace ranges are *inclusive* of the DTSA and DTEA addresses for Range Control settings indicating "within range," and are *exclusive* of the DTSA and DTEA addresses for Range Control settings indicating "outside of range."

Accesses that meet the range and access type qualifiers will cause assertion of a watchpoint output for Ranges 1, 2, and 3. There are three dedicated watchpoint outputs, one for each DTSA/DTEA sets 1, 2, and 3. Range 4 does not provide a watchpoint output. Note that when DTC_{DI}=1, all instruction fetches and prefetches (including discarded prefetches) are monitored, and thus these range watchpoints differ from the IACx watchpoint outputs, which are not asserted for instructions that are not executed (i.e. when the instruction prefetch is discarded).

16.4.13 Read/Write Access Control/Status (RWCS) register

The Read Write Access Control/Status Register provides control for Read/Write Access. Read/Write access provides DMA-like access to memory-mapped resources on the AHB System bus either while the processor is halted, or during runtime. Control is provided over access type, size, count, and certain bus attributes.

Note that the internal CPU interfaces to the caches and local memory are not accessible or utilized by this mechanism. Since the external interface is used, base address port settings are used to access local memory, and not the settings of local memory control register base address values.

The RWCS Register also provides Read/Write Access Status information per Table 16-25.

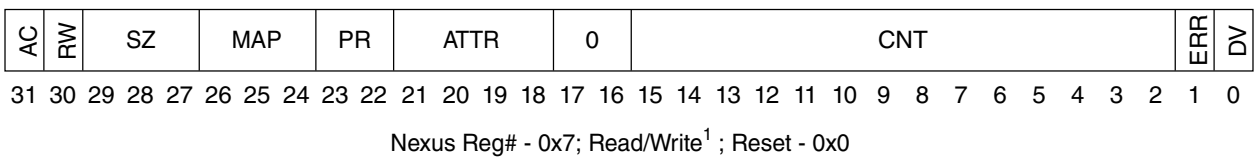

Figure 16-26. Read/Write Access Control/Status (RWCS) register

NOTES:

[1]ERR and DV are read-only

Table 16-24. RWCS field description

Bits	Name	Description
RWCS[31]	AC	Access Control 0 End access/ Access has completed 1 Start access
RWCS[30]	RW	Read/Write Select 0 Read access 1 Write access
RWCS[29:27]	SZ	Word Size 000 8-bit (byte) 001 16-bit (half-word) 010 32-bit (word) 011 64-bit (doubleword, requires two passes through RWD) 100 - 111 Reserved (default to word)
RWCS[26:24]	MAP	MAP Select 000 Primary memory map 001-111 Reserved
RWCS[23:22]	PR[1]	Read/Write Access Priority

Table continues on the next page...

Table 16-24. RWCS field description (continued)

Bits	Name	Description
		00 Reserved (default to highest priority) 01 Reserved (default to highest priority) 10 Reserved (default to highest priority) 11 Highest access priority
RWCS[21:18]	ATTR	Access Attributes 0xxx Reserved 1xxx Reserved x0xx **p_d_hprot[4]** driven to 0 for accesses x1xx **p_d_hprot[4]** driven to 1 for accesses xx0x **p_d_hprot[3]** driven to 0 for accesses xx1x **p_d_hprot[3]** driven to 1 for accesses xxx0 **p_d_hprot[2]** driven to 0 for accesses xxx1 **p_d_hprot[2]** driven to 1 for accesses
RWCS[17:16]	—	RES - Reserved for future functionality
RWCS[15:2]	CNT	Access Control Count hhhh Number of accesses of word size SZ
RWCS[1]	ERR[2]	Read/Write Access Error (see Table 16-25)
RWCS[0]	DV[2]	Read/Write Access Data Valid (see Table 16-25)

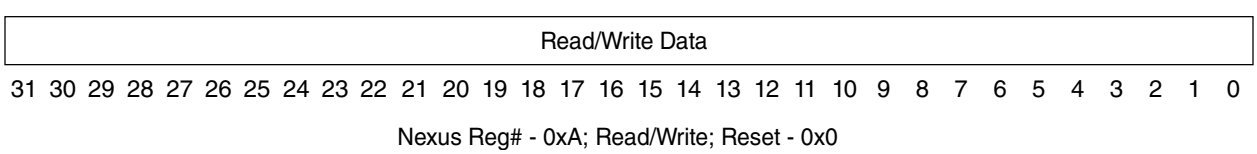
1. The priority functionality is not currently implemented.
2. ERR and DV are read-only.

Table 16-25. Read/Write Access Status Bit Encoding

Read Action	Write Action	ERR	DV
Read Access has not completed	Write Access completed without error	0	0
Read Access error has occurred	Write Access error has occurred	1	0
Read Access completed without error	Write Access has not completed	0	1
Not Allowed	Not allowed	1	1

16.4.14 Read/Write Access Data (RWD) register

The Read/Write Access Data (RWD) register provides the data to/from system bus memory-mapped locations when initiating a read or a write access.



Nexus Reg# - 0xA; Read/Write; Reset - 0x0

Figure 16-27. Read/Write Access Data (RWD) register

Read/Write accesses to the AHB require that the debug firmware properly retrieve/place the data in the RWD. Table 16-26 shows the proper placement of data into the RWD. Note that doubleword transfers require two passes through RWD.

Table 16-26. RWD data placement for ransfers

Transfer Size and byte offset	RWA(2:0)	RWCS[SZ]	RWD			
			31:24	23:16	15:8	7:0
Byte	x x x	0 0 0	-	-	-	X
Half	x x 0	0 0 1	-	-	X	X
Word	x 0 0	0 1 0	X	X	X	X
Doubleword	0 0 0	0 1 1				
first RWD pass (low order data)			X	X	X	X
second RWD pass (high order data)			X	X	X	X

Table Notes:

"X" indicates byte lanes with valid data

"-" indicates byte lanes that will contain unused data.

Table 16-27 shows the mapping of RWD bytes to byte lanes of the AHB read and write data buses.

Table 16-27. RWD byte lane mapping

Transfer Size and byte offset	RWA(2:0)	RWD			
		31:24	23:16	15:8	7:0
Byte @000	0 0 0	-	-	-	AHB[7:0]
Byte @001	0 0 1	-	-	-	AHB[15:8]
Byte @010	0 1 0	-	-	-	AHB[23:16]
Byte @011	0 1 1	-	-	-	AHB[31:24]

Byte @111	1 1 1	-	-	-	AHB[63:56]
Half @000	0 0 0	-	-	AHB[15:8]	AHB[7:0]
Half @010	0 1 0	-	-	AHB[31:24]	AHB[23:16]
Half @100	1 0 0	-	-	AHB[47:40]	AHB[39:32]
Half @110	1 1 0	-	-	AHB[63:56]	AHB[55:48]
Word @000	0 0 0	AHB[31:24]	AHB[23:16]	AHB[15:8]	AHB[7:0]
Word @100	1 0 0	AHB[63:56]	AHB[55:48]	AHB[47:40]	AHB[39:32]
Doubleword @000	0 0 0				
first RWD pass		AHB[31:24]	AHB[23:16]	AHB[15:8]	AHB[7:0]
second RWD pass		AHB[63:56]	AHB[55:48]	AHB[47:40]	AHB[39:32]

Table Notes:

"-" indicates byte lanes that will contain unused data.

16.4.15 Read/Write Access Address (RWA)

The Read/Write Access Address Register provides the system bus address to be accessed when initiating a read or a write access.

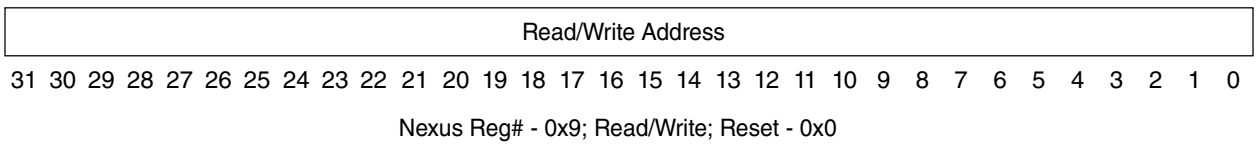

Figure 16-28. Read/Write Access Address (RWA) register

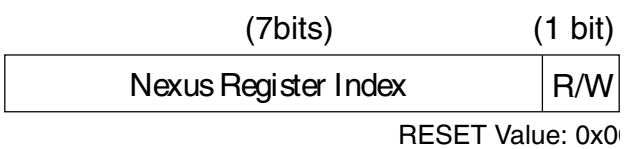
16.5 Nexus 3 Register Access via JTAG/OnCE

Access to Nexus 3 register resources is enabled by loading a single instruction ("*NEXUS3-ACCESS*") into the JTAG Instruction Register (IR) (OnCE OCMD register). For the Nexus 3 block, the OCMD value is 0b0001111100.

Once the NEXUS3-ACCESS instruction has been loaded, the JTAG/OnCE port allows tool/target communications with all Nexus 3 registers according to the register map in Table 16-8.

Reading/writing of a Nexus 3 register then requires two (2) passes through the Data-Scan (DR) path of the JTAG state machine. (See IEEE 1149.1 (JTAG) RD/WR sequences.)

1. The first pass through the DR selects the Nexus 3 register to be accessed by providing an index (see Table 16-8), and the direction (read/write). This is achieved by loading an 8-bit value into the JTAG Data Register (DR). This register has the following format:



Nexus Register Index	Selected from values in Table 16-8
Read/Write (R/W):	0 - Read 1 - Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.
   a. During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the "Capture-DR" state.
   b. During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the "Update-DR" state.

16.6 Nexus 3 Register Access via Software

Access to most Nexus 3 register resources by software is supported by mapping the Nexus 3 registers to privileged DCRs (device control registers) that are accessible via the **mfdcr** and **mtdcr** instructions. It is intended that these access only occur when no possible conflicts with hardware-based accesses are possible. A conflict between hardware and software accesses will produce undefined results. Table 16-8 shows the mappings of Nexus 3 registers to DCR numbers. Software writes to Nexus 3 register resources are blocked when the **nex_sfwcntl_en** input signal is negated, without signaling an exception. Note that the Nexus 3 Read/Write Access functionality is not available to software, since software can use load and store instructions to access memory.

16.7 Nexus message fields

Nexus messages are composed of fields. Each field contains a distinct piece of information within a message, and each message contains multiple fields. Messages are transferred in packets over the Auxiliary Output protocol. A packet is a collection of fields. A packet may contain any number of fixed length fields, but may contain at most one variable length field. The variable length field must be the last field in a packet. The following sub-sections describe a subset of the message field types.

16.7.1 TCODE Field

The TCODE field is a 6-bit fixed length field that identifies the type of message and its format. The field encodings are assigned by IEEE-ISTO 5001.

16.7.2 Source ID Field (SRC)

Each Nexus module in a device is identified by a unique Client Source Identification Number. The number assigned to each Nexus module is determined by the SoC integrator, and is provided on the **nex3_ext_src_id[0:3]** input signals. Multi-threaded processors may assign additional source ID information to indicate which thread a message is associated with. The Nexus 3 module implements a 4-bit fixed length Source ID field consisting of a Client Source ID.

16.7.3 Relative Address Field (U-ADDR)

The non-sync forms of the Program and Data Trace messages include addresses that are relative to the address that was transmitted in the previous Program or Data Trace message, respectively. The relative address format is compliant with IEEE-ISTO 5001 and is designed to reduce the number of bits transmitted for address fields.

The relative address is generated by XORing the new address with the previous, and then using only the results up to the most significant '1'. To recreate the original address, the relative address is XORed with the previously decoded address.

The relative address of a Program Trace message is calculated with respect to the previous Program Trace message, regardless of any address information that may have been sent in any other trace messages in the interim between the two Program Trace messages.

The relative address of a Data Trace message is calculated with respect to the previous Data Trace message, regardless of any address information that may have been sent in any other trace messages in the interim between the two Data Trace messages.

Program trace messages also provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

Previous Address (A1) =0x0003FC01, New Address (A2) = 0x0003F365

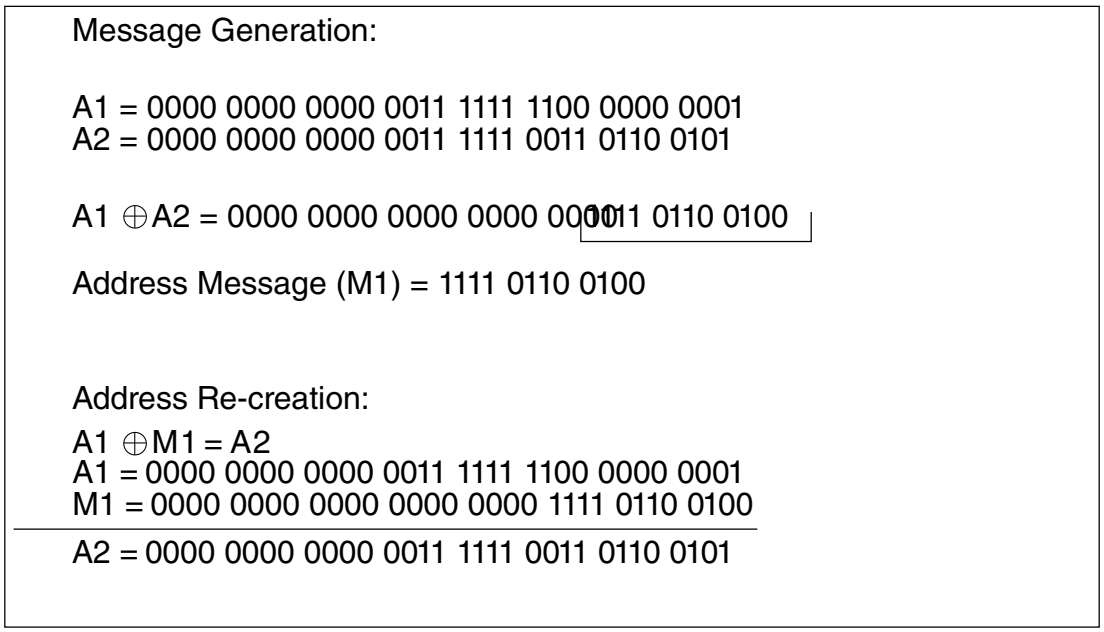


Figure 16-29. Relative address generation and recreation

16.7.4 Full Address Field (F-ADDR)

Program Trace synchronization messages provide the full address associated with the trace event (leading zeroes may be truncated) with the intent of providing a reference point for development tools to operate from when reconstructing relative addresses. Synchronization messages are generated at significant mode switches and are also generated periodically to ensure that development tools are guaranteed to have a reference address given a sufficiently large sample of trace messages. Program trace messages also provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

16.7.5 Timestamp field (TSTAMP)

Timestamps may be optionally applied to messages. Enabling of timestamping is controlled by the nex_tsen input signal. The timestamping mode (timestamp frequency of occurrence) is controlled by the value of nex_tsmode[0:1] and the timestamp value is based on the nex_timebase[0:29] inputs. These signals are first synchronized to the nex_clk clock domain, and for nex_timebase[0:29], a gray-code to binary value

conversion is performed. The timestamp value is applied to messages as they exit the message queues. Leading zeros in the timestamp value are removed. The table shows the nex_tsmode[0:1] encodings used for the timestamp mode.

Table 16-28. nex_tsmode[0:1] timestamp mode encoding

nex_tsmode[0:1]	Timestamp Mode
00	Timestamp applied to every message
01	Timestamp applied to every 4th message
10	Timestamp applied to every 16th message
11	Timestamp applied to every 64th message

16.8 Nexus Message Queues

The Nexus 3 module implements internal message queues capable of storing up to three messages per cycle into a small initial queue, which then fills a larger queue at up to two messages per cycle. Messages that enter the queues are transmitted in the order in which they are received.

If more than three messages attempt to enter the queue in the same cycle, the highest priority messages are stored and the remaining message(s) will be dropped due to a collision. Collision events are expected to be rare.

The Overrun Control register (OVCR) controls the Nexus behavior as the message queue fills. The Nexus block may be programmed to:

- Allow the queue to overflow, drain the contents, queue an overrun error message and resume tracing.
- Stall the processor when the queue utilization reaches the selected threshold.
- Suppress selected message types when the queue utilization reaches the selected threshold.

16.8.1 Message Queue Overrun

In this mode, the message queue will stop accepting messages when an overrun condition is detected. The contents of the queues will be allowed to drain until empty. Incoming messages are discarded until the queue is emptied. Once empty, an overrun error message is enqueued that contains information about the types of messages that were discarded due to the overrun condition.

16.8.2 CPU Stall

In this mode, processor instruction issue is stalled when the queue utilization reaches the selected threshold. The processor is stalled long enough to drop one threshold level below the level that triggered the stall. For example, if stalling the processor is triggered at 1/4 full, the stall will stay in effect until the queue utilization drops to empty. There may be significant skid from the time that the stall request is made until the processor is able to stop completing instructions. This skid should be taken into consideration when programming the threshold. Refer to Nexus Overrun Control Register (OVCR) for complete programming options.

16.8.3 Message Suppression

In this mode, the message queue will disable selected message types when the queue utilization reaches the selected threshold. This allows lower bandwidth tracing to continue and possibly avoid an overrun condition. If an overrun condition occurs despite this message suppression, the queue will respond according to the behavior described in Message Queue Overrun. Suppressed message types are reported in the error message if they occur after overrun in addition to other discarded message types. Once triggered, message suppression will remain in effect until queue utilization drops to the threshold below the level selected to trigger suppression.

16.8.4 Nexus Message Priority

Nexus messages may be lost due to contention with other message types under the following circumstances:

- More than three messages are generated in the same cycle

Table 16-29 lists the various message types and their relative priority from highest to lowest.

Up to three message requests can be queued into the message buffer in a given cycle. If more than three message requests exist in a given cycle, the three highest priority message classes are queued into the message buffer. The remaining messages that did not successfully queue into the message buffer in that cycle will generate subsequent responses, as detailed in Table 16-29.

The CPU is capable of completing two instructions per cycle. If multiple trace messages need to be queued at the same time, they will be queued with the following priority: Instruction 0 (oldest instruction) (WPM ->DQM -> PCM_{PIDMSG} -> OTM -> BTM -> DTM)-> Instruction1 (newer instruction) (WPM -> DQM -> OTM -> BTM -> DTM). As many as three messages may be simultaneously queued. Note that for the cycle following a dropped PTM, non-periodic OTM, or DQM message, only two other messages may be queued in addition to the dropped Error Message.

Watchpoint Messages from instructions that complete at the same time or events that occur during the same cycle will be combined.

Table 16-29. Message Type Priority and Message Dropped Responses

Message Type	Message	Priority	Message Dropped Response
Error	Error	0 (highest)	N/A[1]
WP (Watchpoint Trace)	WPM (Watchpoint Message)	1	N/A[1]
DQ (Data Acquisition)	DQM (Data Acquisition Message)	2	DQM Error Message
Program Trace (PID MSG)	PCM - PID/NPIDR update (Program Correlation Message)	2	OTM Error Message
OT (Ownership)	OTM - PID/NPIDR update (Ownership Trace Message)	2	OTM Error Message[2]
Program Trace	BTM (Branch Trace Message)	2	BTM Error Message, Sync upgrade next BTM
	Sync (Program Sync Message)	3	Sync upgrade next BTM
	RFM (Resource Full for Instruction counter or history buffer)	4	BTM Error Message Sync upgrade next BTM
	DS (Debug Status Message)	5	Sync upgrade next BTM
	PCM (Program Correlation Message)	6	BTM Error Message Sync upgrade next BTM
DT (Data Trace)	DTM (Data Trace Message)	7	Sync upgrade next DTM
OT (Ownership)	OTM - Periodic update (Ownership Trace Message)	8 (lowest)	none

1. Error and Watchpoint messages are not dropped due to collisions, due to their priority.
2. Message will always be dropped if program trace is enabled, and program correlation messages for PID messages are not masked (Event Code = 0101). No error message is sent for this case since the PID value is contained in the higher priority message.

16.8.5 Data Acquisition Message Priority Loss Response

If a Data Acquisition Message (DQM) loses arbitration due to contention with higher priority messages, an error message will be generated to indicate that a DQM has been lost due to contention.

16.8.6 Ownership Trace Message Priority Loss Response

If an Ownership Trace message (OTM) due to software updates to the Process ID state loses arbitration due to contention with higher priority messages other than a program correlation message with EVCODE = 0101 (PID update), an error message will be generated to indicate that a OTM has been lost due to contention. If the pending OTM is a periodic update, the event is dropped without generating an error message.

16.8.7 Program Trace Message Priority Loss Response

If a Program Trace message (PTM) loses arbitration due to contention with higher priority messages, and the discarded PTM is a Program Correlation message, a Resource Full message for instruction count or history buffer, or a Branch Trace message, then an Error message is generated to indicate that branch trace information has been lost, and the next Branch Trace message will be upgraded to a sync-type message.

If the discarded PTM is a Program Correlation message with PID information (EVCODE=0101), the Error message will indicate a dropped OTM and a dropped Program Trace (Error code = xxxx11xx).

16.8.8 Program Trace Sync Message Priority Loss Response

If a Program Trace Sync message (SYNC) loses arbitration due to contention with higher priority messages, the Sync event is discarded, and the next Branch Trace message will be upgraded to a sync-type message.

16.8.9 Data Trace Message Priority Loss Response

If a Data Trace message (DTM) loses arbitration due to contention with higher priority messages, the DTM event is discarded, and the next DTM will be upgraded to a sync-type message.

16.9 Debug Status messages

Debug Status Messages report low power mode and debug status. Debug Status messages are enabled when Nexus 3 is enabled. Entering/exiting Debug Mode as well as entering, exiting, or changing Low Power Mode(s) will trigger a Debug Status message, indicating the value of the most significant byte in the Development Status register. Debug status information is sent out in the following format:

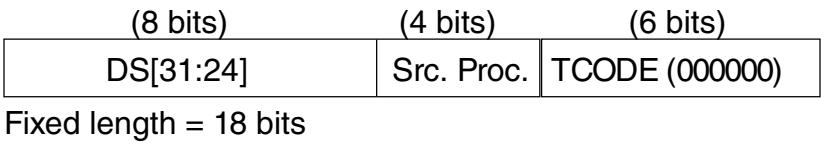

Figure 16-30. Debug Status message format

16.10 Error messages

Error messages are enabled whenever the debug logic is enabled. There are two conditions that will produce an error message, each receiving a separate error type designation:

- A message is discarded due to contention with other (higher priority) message types. These errors will have an Error Type value of 1.
- The message queue overruns. After the queue is drained, an error message is enqueued with an error code that indicates what types of messages were discarded during the interim. These errors will have an Error Type value of 0.

Note

The OVCR Register can be used in order to alleviate potential overrun situations.

Error information is messaged out in the following format (also see Table 16-3 and Table 16-4):

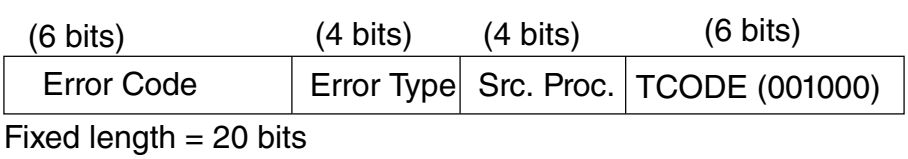

Figure 16-31. Error message format

16.11 Ownership trace

This section details the ownership trace features of the Nexus 3 module.

16.11.1 Overview

Ownership trace provides a macroscopic view, such as task flow reconstruction, when debugging software written in a high level (or object-oriented) language. It offers the highest level of abstraction for tracking operating system software execution. This is especially useful when the developer is not interested in debugging at lower levels.

16.11.2 Ownership Trace Messaging (OTM)

Ownership trace information is messaged via the auxiliary port using an Ownership Trace Message (OTM). Core (e200z4201n3) processors contain a *Power ISA 2.06* defined "Process ID" register within the CPU. It is updated by the operating system software to provide task/process ID information. The contents of this register are replicated on the pins of the processor and connected to Nexus. The Process ID (PID) register value can be accessed using the **mfspr/mtspr** instructions.

Note

The CPU includes a Process ID register (PID0), thus the Nexus UBA functionality is not implemented.

In addition, to decouple trace information from the PID0 register and to provide a full independent 32-bit process ID for debug use, the Nexus PID Register (NPIDR) may be used instead of PID0 to provide OTM process ID information. It is updated by the operating system software to provide task/process ID information. The Nexus Process ID (NPIDR) register value can be accessed using the **mfspr/mtspr** instructions. This register is accessible in user or supervisor mode.

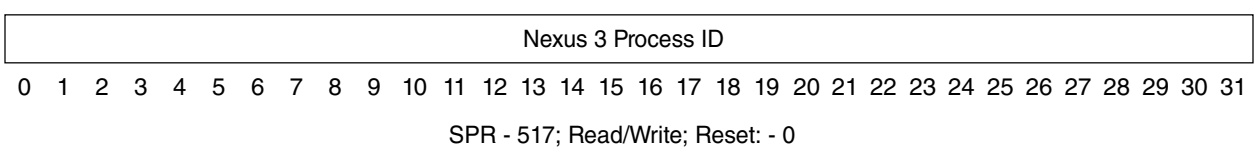

Figure 16-32. Nexus 3 Process ID Register (NPIDR)

Note

OS updates to NPIDR should be performed in addition to normal PID0 updates when a process switch occurs, in order to properly generate OTM messages with new process ID information when NPIDR is selected for OTM use.

The process ID source (PID0 or NPIDR) is selected by the setting of the $DC1_{OTS}$ control bit.

There are two conditions that will cause an Ownership Trace Message when Ownership Trace is enabled:

- When the PID0 register is written to by the processor and $DC1_{OTS}$ indicates PID0 should be used, or when the NPIDR register is written to by the processor and $DC1_{OTS}$ indicates NPIDR should be used, the data is latched within Nexus, and is messaged out via the auxiliary port, allowing development tools to trace ownership flow. However, if Program Trace is enabled, and program correlation messages for PID updates are not masked (Event Code = 0101), then an OTM will not be generated for an update to the selected process ID register, since the program correlation message will provide this process ID update information.
- Periodically, at least once every 256 messages, the most recent state of the selected process ID register is messaged out. The resulting Ownership Trace message will indicate in the PID Index sub-field that PID0/NPIDR status is being reported and the most recent value of the PID0/NPIDR register will be conveyed in the Process ID value sub-field. These periodic Ownership Trace message events can be disabled by setting $DC1_{POTD}$.

Ownership trace information is messaged out in the following format:

(1-32 bits)	(4 bits)	(4 bits)	(6 bits)
Process ID	PID Index (0000)	Src. Proc.	TCODE (000010)

Variable length = 15-46 bits

Figure 16-33. Ownership Trace Message format

16.12 Program trace

This section details the program trace mechanism supported by Nexus3 for the e200z4201n3 processor. Program trace is implemented via Branch Trace Messaging (BTM) as per the **IEEE-ISTO 5001** standard definition. Branch Trace Messaging for

Core (e200z4201n3) processors is accomplished by snooping the internal address bus (between the CPU and Cache), attribute signals, and CPU Status (**p_mode[0:3]**, **p_pstat_pipe{0,1}[0:5]**).

16.12.1 Branch Trace Messaging types

Traditional Branch Trace Messaging facilitates program trace by providing the following types of information:

- Messaging for taken direct branches includes how many sequential instructions were executed since the last taken branch or exception, including the taken direct branch. Branch instructions are included in the count of sequential instructions.
- Messaging for taken indirect branches and exceptions includes how many sequential instructions were executed since the last taken branch or exception and the unique portion of the branch target address or exception vector address. Branch instructions are included in the count of sequential instructions. For taken indirect branches that trigger generation of a message, the branch is also included in the count.

Branch History Messaging facilitates program trace by providing the following information.

- Messaging for taken indirect branches and exceptions includes a) how many sequential instructions (I-CNT) were executed since the last predicate instruction, taken/not taken direct branch, taken/not-taken indirect branch, or exception, b) the unique portion of the branch target address or exception vector address, and c) a branch/predicate instruction history field. Each bit in the history field represents a direct branch or predicated instruction where a value of one (1) indicates taken, and a value of zero (0) indicates not taken. Not-taken indirect branches will generate a history bit with a value of zero (0). Instructions that generate history bits are not included in instruction counts. For taken indirect branches that trigger generation of this message type, the branch is included in the count, but not in the history field.

16.12.1.1 Indirect Branch Message instructions

Table 16-30 shows the types of instructions and events that cause Indirect Branch Messages or Branch History Messages to be encoded.

Table 16-30. Indirect Branch Message sources

Source of Indirect Branch Message	Instructions / Detail
Taken branch relative to a register value	**bcctr, bcctrl, bclr, bclrl, se_bctr, se_bctrl, se_blr, se_blrl**
System Call / Trap exceptions taken	**se_sc, tw**
Return from interrupts / exceptions	**se_rfi, se_rfci, se_rfdi**
Exit from reset with Program Trace Enabled	**Indirect branch with Sync, target address is initial instruction, count = 1**

16.12.1.2 Direct Branch Message Instructions

Table 16-31 shows the types of instructions that will cause Direct Branch Messages or will toggle a bit in the instruction history buffer to be messaged out in a Resource Full Message or Branch History Message.

Table 16-31. Direct Branch Message sources

Source of Direct Branch Message	Instructions
Taken direct branch instructions Instruction Synchronize	**b, ba, bl, bla, bc, bca, bcl, bcla, se_b. se_bc, se_bl, e_b, e_bc, e_bl, e_bcl, se_isync**

16.12.1.3 BTM using Branch History Messages

Traditional BTM Messaging can accurately track the number of sequential instructions between branches, but cannot accurately indicate which instructions were conditionally executed, and which were not.

Branch History Messaging solves this problem by providing a predicated instruction history field in each Indirect Branch Message. Each bit in the history represents a predicated instruction or direct branch, or a not-taken indirect branch. A value of one (1) indicates the conditional instruction was executed or the direct branch was taken. A value of zero (0) indicates the conditional instruction was not executed or the branch was not taken.

Branch History Messages solve predicated instruction tracking and save bandwidth since only indirect branches cause messages to be queued.

16.12.1.4 BTM using Traditional Program Trace Messages

Based on the PTM bit in the DC1 Register, Program Tracing can utilize either Branch History Messages (PTM = 1) or traditional Direct/Indirect Branch Messages (PTM = 0).

Branch History will save bandwidth and keep consistency between methods of Program Trace, yet may lose temporal order between BTM messages and other types of messages. Since direct branches are not messaged, but are instead included in the history field of the Indirect Branch History Message, other types of messages may enter the FIFO between Branch History Messages. The development tool cannot determine the ordering of "events" that occurred with respect to direct branches simply by the order in which messages are sent out.

Traditional BTM messages maintain their temporal ordering because each event that can cause a message to be queued will enter the FIFO in the order it occurred and will be messaged out maintaining that order.

16.12.2 BTM Message For mats

The Nexus 3 block supports three types of traditional BTM Messages - Direct, Indirect, and Synchronization Messages. It supports two types of branch history BTM Messages - Indirect Branch History, and Indirect Branch History with Synchronization Messages.

16.12.2.1 Indirect branch messages (history)

Indirect branches include all taken branches whose destination is determined at run time, interrupts, and exceptions. If $DC1_{PTM}$ is set to '1', indirect branch information is messaged out in the following format:

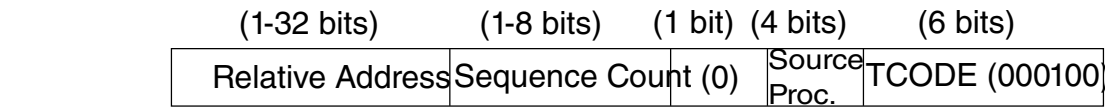
(1-32 bits)	(1-32 bits)	(1-8 bits)	(1 bit)	(4 bits)	(6 bits)
Branch History	Relative Address	Sequence Count	(0)	Source Proc.	TCODE (011100)

Max length = 83 bits; Min length = 14 bits

Figure 16-34. Indirect branch message (history) format

16.12.2.2 Indirect branch messages (traditional)

If $DC1_{PTM}$ is cleared to '0', indirect branch information is messaged out in the following format:

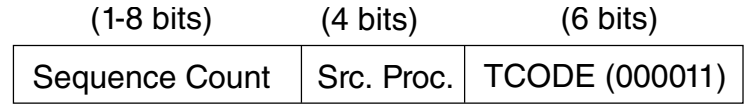


Max length = 51 bits; Min length = 13 bits

Figure 16-35. Indirect branch message format

16.12.2.3 Direct branch messages (traditional)

Direct branches (conditional or unconditional) are all taken branches whose destination is fixed in the instruction opcode. Direct branch information is messaged out in the following format:



Max length = 18 bits; Min length = 11bits

Figure 16-36. Direct Branch message format

Note

When $DC1_{PTM}$ is set, Direct Branch Messages will not be transmitted. Instead, each direct branch, not-taken indirect branch, or predicated instruction will be recorded in the history buffer.

16.12.3 Program Trace Message Fields

The following subsections describe specific fields used for Program Trace messages.

16.12.3.1 Sequential Instruction Count Field (ICNT)

Most of the program trace messages include an instruction count field. For traditional Branch messages, ICNT represents the number of sequential instructions including non-taken branches since the last Direct/Indirect Branch messages. Branch instructions that trigger message generation are included in the ICNT.

For Branch History messages, ICNT represents the number of instructions executed since the last taken/non-taken direct branch, predicate instruction, last taken/not-taken indirect branch, or exception. Branch instructions that trigger message generation are included in the ICNT. Instructions that generate history bits are not included in the ICNT.

The sequential instruction counter overflows after its value reaches 255 and is reset to 0. In addition, the next BTM Message (corresponding to the 256th or later instruction) will be converted to a w/sync type message.

The instruction counter is reset every time the instruction count is transmitted in a message or whenever there is a branch/predicate history event, as well as on exiting from debug mode.

16.12.3.2 Branch/Predicate Instruction History (HIST)

If $DC1_{PTM}$ is set, BTM messaging will use the Branch History format. The branch history (HIST) field in these messages provides a history of branch execution used for reconstructing the program flow. The branch/predicate history buffer stores information about branch and predicate instruction execution. The buffer is implemented as a left-shifting register. The buffer is preloaded with a one (1), which acts as a stop bit (the most significant 1 in the history field is a termination bit for the field). The pre-loaded bit itself is not part of the history, but is transmitted with the packet.

A value of one (1) is shifted into the history buffer for each taken direct branch (program counter relative branch) or predicate instruction whose condition evaluates to true. A value of zero (0) is shifted into the history buffer for each not-taken branch (including indirect branch instructions) or predicate instruction whose condition evaluates to false.

This history buffer information is transmitted as part of an Indirect Branch with History message, as part of a Program Correlation message, or as part of a Resource Full message if the history buffer becomes full. The history buffer is reset every time the history information is transmitted in a message, as well as on exiting from debug mode.

Table 16-32. Branch/Predicate history events

Branch/Predicate History Event	History Bit(s)	Relevant Instructions
Not taken register indirect branches	0	**bcctr, bcctrl, bclr, bclrl**
Not taken direct branches	0	**b, ba, bc, bca, bla, bcla, bl, bcl**
Taken direct branches	1	**b, ba, bc, bca, bla, bcla, bl, bcl**[1]

1. If the EVCODE for direct branch function calls is not masked in DC4, taken **bl** and **bcl** instructions will generate Program Correlation Messages and will not be logged in the history buffer.1

16.12.3.3 Execution Mode Indication

In order for a development tool to properly interpret instruction count and history information, it must be aware of the execution mode context of that information. VLE instructions will be interpreted differently from non-VLE instructions.

Program trace messages provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

16.12.4 Resource Full Messages

The Resource Full Message is used in conjunction with Branch Trace and Branch History Messages. The Resource Full Message is generated when either the internal branch/ predicate history buffer is full, or if the BTM Instruction sequence counter (I-CNT) overflows. If synchronization is needed at the time this message is generated, the synchronization is delayed until the next Branch Trace Message that is not a Resource Full Message.

For history buffer overflow, the Resource Full Message transmits a Resource Code (RCODE) of 0b0001 and the current contents of the history buffer, including the stop bit, are transmitted in the Resource Data (RDATA) field. This history information can be concatenated by the development tool with the branch/predicate history information from subsequent messages to obtain the complete branch/predicate history between indirect changes of flow.

For instruction counter overflow, the Resource Full Message transmits an RCODE of 0b0000 and a value of 0xFF is transmitted in the RDATA field, indicating that 255 sequential instructions have been executed since the last change of flow, or, if program trace is in history mode, since the last instruction that recorded history information.

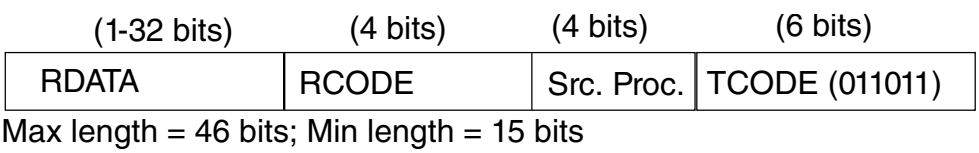


Figure 16-37. Resource Full Message format

The following table shows the RCODE encodings and RDATA information used for Resource Full Messages.

Table 16-33. RCODE encoding

RCODE	Description	RDATA field
0000	Program Trace Instruction counter reached 255 and was reset.	0xFF
0001	Program Trace, Branch / Predicate Instruction History full.	Branch HIstory. This type of packet is terminated by a stop bit set to 1 after the last history bit.

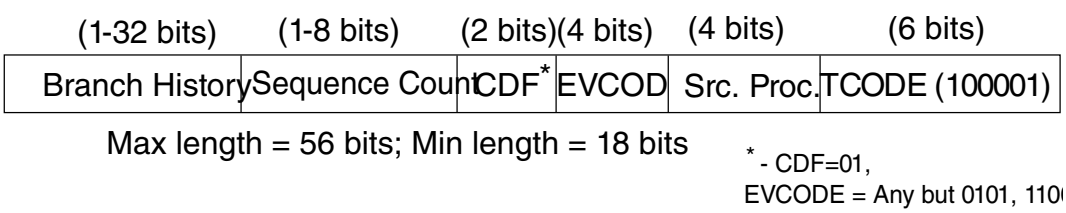
16.12.5 Program Correlation Messages

Program Correlation Messages (PCMs) are used to correlate events to the program flow that may or may not be associated with the instruction stream. The following events will result in a PCM when program trace is enabled:

- When the CPU enters debug mode, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to debug mode entry.
- When the CPU first enters a low power mode in which instructions are no longer executed, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to low power mode entry.
- Whenever program trace is disabled by any means, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to disabling program trace.
- When a "Branch and Link" instruction executes (direct branch function call — **bl/bcl/bla/bcla**-type instructions)
- When program trace becomes masked due to MSR_{PMM}='0' and $DC4_{PTMARK}$='1'.
- When a write to the process ID register selected by $DC1_{OTS}$ (PID0 or NPIDR) is made via a **mtspr** PID0 or **mtspr** NPIDR.

Refer to Table 16-6 for the event codes that are supported in this implementation. Event code masking is available via the EVCDM field of the DC4 register to allow for control over generation of Program Correlation messages for each event type.

Program Correlation is messaged out in the following formats:



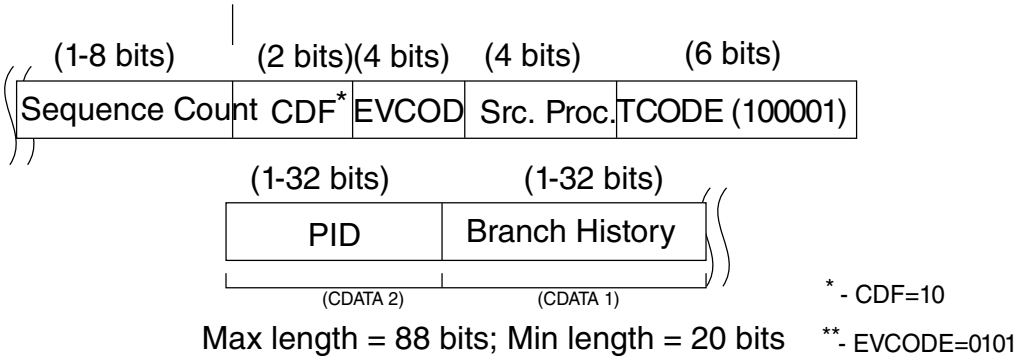


Figure 16-38. Program Correlation message formats

16.12.5.1 Program Correlation message generation for PID updates

When a (potentially) new value is established in the selected process ID register via a **mtspr** PID0/NPIDR, a Program Correlation message is generated containing the information regarding the new process ID value. This PCM also contains the current history and instruction count. The message is provided so that address translation information can be processed by the development tool in the proper program flow. The **mtspr** PID0/NPIDR is included in the instruction count information. Note that Ownership Trace Messages (other than the periodic OTM) are redundant with the information provided, and may be disabled to avoid unnecessary message bandwidth or collisions.

16.12.6 Program Trace Overflow Error messages

An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard incoming messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied.

16.12.7 Program Trace Synchronization messages

By default, program trace messages will perform XOR compression on the branch target address to produce the address field for the message. This compression is consistent with the specification in IEEE-ISTO 5001.

Under some conditions an uncompressed address is sent to provide development tools with a baseline reference address. A Program Trace Synchronization message is messaged via the auxiliary port (provided Program Trace is enabled) for the following conditions (see Table 16-34):

- Initial Program Trace message after exit from system reset or whenever program trace is enabled.
- Upon exiting from a CPU Low Power state.
- Upon exiting from Debug Mode.
- Upon occurrence of queue overrun (can be caused by any trace message) or suppression, provided Program Trace is enabled.
- Upon assertion of the Event In (**nex_evti_b**) pin if the EIC bits within the DC1 Register have enabled this feature.
- When program trace becomes unmasked due to $MSR_{PMM} \rightarrow$ '1' with $DC4_{PTMARK}$='1'.

Note that the ICNT information for these messages is driven to zero, thus will not always be meaningful for some of these cases.

The format for Program Trace Synchronization messages is as follows:

(1-32 bits)	(1-8 bits)	(1 bit)	(4 bits)	(6 bits)
Full Target Address	Seq. Count (0)	(0)	Source Proc.	TCODE (001001)

Max length = 51 bits; Min length = 13 bits

Exception conditions that result in Program Trace Synchronization are summarized in Table 16-34.

Table 16-34. Program Trace exception summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (**j_trst_b**), queue pointers, counters, state machines, and registers within the Nexus 3 module are reset. Upon exiting system reset (**p_reset_b**), if Program Trace is already enabled, a Program Trace Sync Message is sent.
Program Trace Enabled	The first Program Trace Message (after Program Trace has been enabled or re-enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a Low Power mode or Debug mode, a Program Trace Sync Message is sent.
Queue Overrun	An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied. The next BTM message in the queue will be a Program Trace Sync Message.

Table continues on the next page...

Table 16-34. Program Trace exception summary (continued)

Exception Condition	Exception Handling
Event In	If the Nexus module is enabled, a **nex_evti_b** assertion initiates a Program Trace Sync Message if Program Trace is enabled and the EIC bits of the DC1 Register have enabled this feature.

Note that for cases where program trace sync messages are generated due to program trace being enabled, the address contained in the sync message may either be the address of the instruction that caused program trace to be enabled, or may be the address of the first instruction of an exception handler that is executed in response to unsuccessful completion of that instruction.

16.12.8 Program Trace Direct/Indirect Branch with Sync messages

Under some conditions an uncompressed address is sent to provide development tools with a baseline reference address. A Program Trace Synchronization or a Direct/Indirect Branch with Sync message is messaged via the auxiliary port (provided Program Trace is enabled) for the following conditions (see Table 16-34):

- Upon direct/indirect branch after a Program Sync Message was lost due to a collision while attempting to enter the message queue.
- Upon direct/indirect branch after the sequential instruction counter has expired indicating 255 instructions have occurred since the last change of flow.
- When the periodic program trace counter has expired indicating 255 *without-sync* Program Trace messages have occurred since the last *with-sync* message occurred.

Note that the ICNT and History information for the first message will not always be meaningful, since the temporary masking of program trace may result in ambiguous values. Subsequent w/sync messages will not have this issue.

The format for Program Trace Direct/Indirect Branch with Sync Messages is as follows:

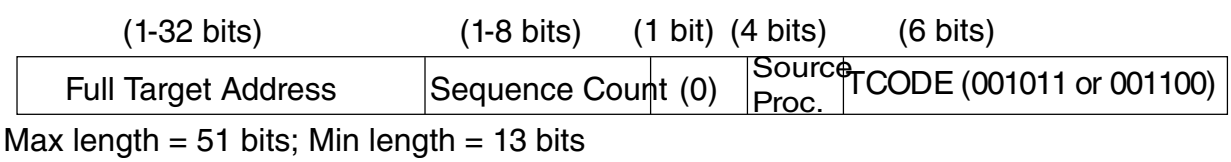

Figure 16-39. Direct/Indirect Branch with Sync message format

The format for Program Trace Indirect Branch History with Sync. messages is as follows:

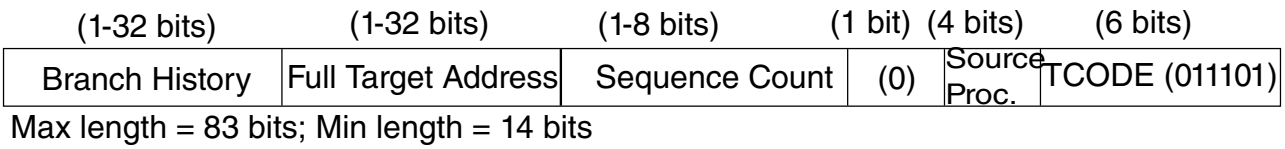

Figure 16-40. Indirect Branch History w/ Sync. message format

Exception conditions that result in Program Trace Synchronization using a w/Sync message type are summarized in Table 16-35.

Table 16-35. Program Trace Exception Summary for w/Sync BTM messages

Exception Condition	Exception Handling
Periodic Program Trace Sync.	A forced synchronization occurs periodically after 255 non-sync Program Trace Messages have been queued. A Direct/Indirect Branch w/ Sync. Message is queued. The periodic program trace message counter then resets.
Sequential Instruction Count Overflow	After the sequential instruction counter reaches its maximum count (up to 255 sequential instructions may be executed), a forced synchronization occurs. The sequential counter then resets. A Program Trace Direct/Indirect Branch w/ Sync.Message is queued upon execution of the next branch. A Resource Full Message is Queued on the overflow event. If a branch instruction is the 255th instruction to occur, and causes a Program Trace message to be queued, then no Resource Full Message is queued, and the w/Sync message will be queued for the *next* Program Trace Direct/Indirect Branch Message.
Collision Priority	All Messages have the following priority: Instruction 0 (WPM -> DQM -> PCM_{PIDMSG} → OTM → BTM → DTM) → Instruction1 (WPM → DQM → OTM → BTM → DTM), where instruction0 is the oldest instruction. A BTM Message from Instruction1 that attempts to enter the queue at the same time as three higher priority messages from either instruction will be lost. An Error Message will be sent indicating the BTM was lost. The following direct/indirect branch will queue a Direct/Indirect Branch w/ Sync. Message. The count value within this message will reflect the number of sequential instructions executed after the last successful BTM Message was generated. This count will include the branch that did not generate a message due to the collision.

16.12.9 Enabling Program Trace

Program Trace Messaging can be enabled in one of three ways:

- Setting the TM field of the DC1 Register to enable Program Trace
- Using the PTS field of the WT Register to enable Program Trace on Watchpoint hits (watchpoints are configured within the CPU)
- Filtering of Program Trace messages may be performed using the MSR_{PMM} bit and the setting of $DC4_{PTMARK}$

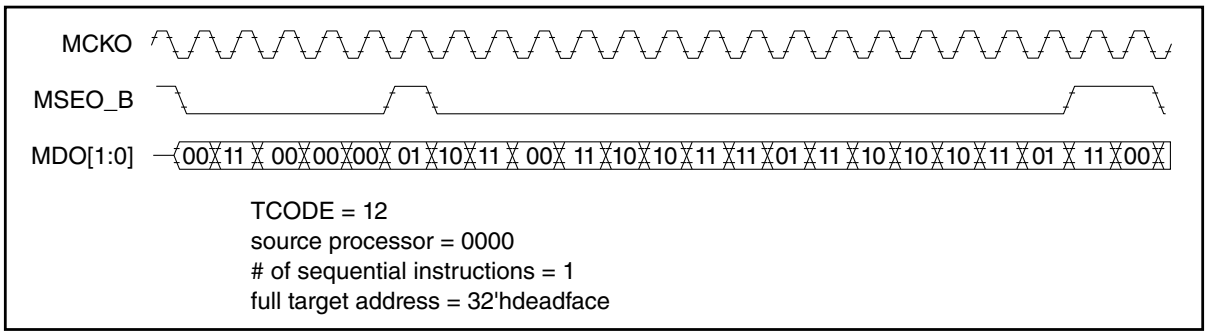

Figure 16-44. Program Trace - Indirect Branch w/ Sync. message

16.13 Data Trace

This section deals with the Data Trace mechanism supported by the Nexus 3 module. Data Trace is implemented via Data Write Messaging (DWM) and Data Read Messaging (DRM), as per the **IEEE-ISTO 5001** standard.

16.13.1 Data Trace Messaging (DTM)

Data Trace Messaging is accomplished by snooping the internal address and data buses, and storing the information for qualifying accesses (based on enabled features and matching target addresses). The Nexus 3 module traces all data access that meet the selected range and attributes.

Note

Data Trace is only performed on the internal data buses. This allows for data visibility for Core (e200z4201n3) processors that incorporate a data cache. Only CPU initiated accesses will be traced. No DMA accesses to the AHB system bus will be traced.

Data Trace Messaging can be enabled in one of the following ways:

- Setting the TM field of the DC1 Register to enable Data Trace.
- Using the DTS field of the WT Register to enable Data Trace on Watchpoint hits (watchpoints are configured within the Nexus1 module).

16.13.2 DTM Message formats

The Nexus 3 block supports five types of DTM Messages — Data Write, Data Read, Data Write Synchronization, Data Read Synchronization and Error Messages.

16.13.2.1 Data Write messages

The Data Write message contains the data write value and the address of the write access, relative to the previous Data Trace Message. Data Write message information is messaged out in the following format:

(1-64 bits)	(1-32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value(s)*	Relative Address	Data Size	(0)	Src. Proc	TCODE (000101)

Max length = 111 bits; Min length = 17 bits

Figure 16-45. Data Write message format

16.13.2.2 Data Read messages

The Data Read message contains the data read value and the address of the read access, relative to the previous Data Trace message. Data Read message information is messaged out in the following format:

(1-64 bits)	(1-32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value(s)*	Relative Address	Data Size	(0)	Src. Proc	TCODE (000110)

Max length = 111 bits; Min length = 17 bits

Figure 16-46. Data Read fessage format

Note

* Core (e200z4201n3)-based CPUs are capable of generating two (2) reads or writes per clock cycle in cases where multiple registers are accessed with a single instruction (lmw/stmw). These will have a double word pair size encoding (**p_tsiz** = 0b000). In these cases, the Nexus 3 module will send one (1) Data Trace Message with the two 32-bit data values as one combined 64-bit value for each message.

For Core (e200z4201n3)-based CPUs, the doubleword encoding (**p_tsiz** = 0b000) may also indicate a doubleword access and will be sent out as a single Data Trace Message with a single 64-bit data value.

The debug/development tool will need to distinguish the two cases based on the family of processor.

16.13.2.3 Data Trace Synchronization messages

A Data Trace Write/Read with Sync. message is messaged via the auxiliary port (provided Data Trace is enabled) for the following conditions (see Table 16-36):

- Initial Data Trace Message after exit from system reset or whenever Data Trace is enabled.
- Upon returning from a CPU Low Power state.
- Upon returning from Debug Mode.
- After occurrence of queue overrun (can be caused by any trace message) or suppression, provided Data Trace is enabled.
- After the periodic data trace counter has expired indicating 255 *without-sync* Data Trace messages have occurred since the last *with-sync* message occurred.
- Upon assertion of the Event In (**nex_evti_b**) pin, the first Data Trace Message will be a synchronization message if the EIC bits of the DC1 Register have enabled this feature.
- Upon Data Trace Write/Read after the previous DTM message was lost due to an attempted access to a secure memory location (for SOC's w/ security).
- Upon Data Trace Write/Read after the previous DTM message was lost due to a collision entering the FIFO between the DTM message and any two of the following: Watchpoint message, Ownership Trace message, or Program Trace message.

Data Trace Synchronization Messages provide the full address (without leading zeros) and insure that development tools fully synchronize with Data Trace regularly. Synchronization messages provide a reference address for subsequent DTMs, in which only the unique portion of the Data Trace address is transmitted. The format for Data Trace Write/Read with Sync. Messages is as follows:

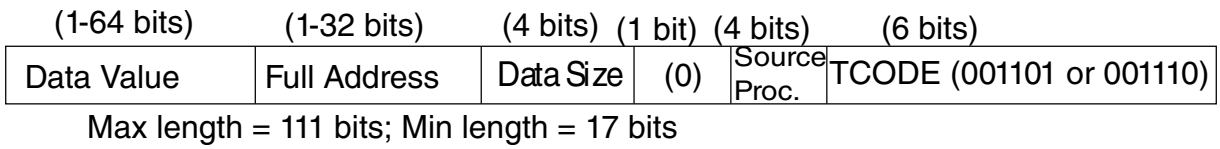

Figure 16-47. Data Write/Read with Sync. message format

Exception conditions that result in Data Trace Synchronization are summarized in Table 16-36.

Table 16-36. Data Trace Exception summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (**j_trst_b**), queue pointers, counters, state machines, and registers within the Nexus 3 module are reset. If Data Trace is enabled, the first Data Trace Message is a Data Write/Read w/ Sync. Message.
Data Trace Enabled	The first Data Trace Message (after Data Trace has been enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a Low Power mode or Debug mode the next Data Trace Message will be converted to a Data Write/Read with Sync. Message.
Queue Overrun	An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied. The next DTM message in the queue will be a Data Write/Read w/ Sync. Message.
Periodic Data Trace Sync.	A forced synchronization occurs periodically after 255 Data Trace Messages have been queued. A Data Write/Read w/ Sync. Message is queued. The periodic data trace message counter then resets.
Event In	If the Nexus module is enabled, a **nex_evti_b** assertion initiates a Data Trace Write/Read w/ Sync. Message upon the next data write/read (if Data Trace is enabled and the EIC bits of the DC1 Register have enabled this feature).
Collision Priority	All Messages have the following priority: Instruction 0 (WPM → DQM → PCM_{PIDMSG} → OTM → BTM → DTM) → Instruction1 (WPM → DQM → OTM → BTM → DTM), where instruction0 is the oldest instruction. A DTM Message that attempts to enter the queue at the same time as three other higher priority messages will be lost. A subsequent read/write will queue a Data Trace Read/Write w/ Sync. Message.

16.13.3 DTM Operation

16.13.3.1 Data Trace windowing

Data Write/Read Messages are enabled via the RWT field in the Data Trace Control Register (DTC) for each DTM channel. Data Trace windowing is achieved via the address range defined by the DTEA and DTSA Registers and by the RC field in the DTC register. All CPU initiated read/write accesses that fall inside or outside these address ranges, as programmed, are candidates to be traced.

16.13.3.2 Data Access / Instruction Access Data Tracing

The Nexus3 module is capable of tracing either instruction access data or data access data and can be configured for either type of data trace by setting the DI1 field within the Data Trace Control Register. This setting applies to all DTM channels.

16.13.3.3 Data Trace filtering

Data Trace filtering is available base on the settings of MSR_{PMM} and $DC4_{DTMARK}$.

16.13.3.4 Bus Cycle special cases

Table 16-37. Bus Cycle Special Cases

Special Case	Action
Bus cycle aborted	Cycle ignored
Bus cycle with data error ($\overline{TEA}$), [1]	Data Trace Message discarded
Bus cycle completed without error[1]	Cycle captured & transmitted
AHB bus cycle initiated by Nexus 3	Cycle ignored
Bus cycle is an instruction fetch	Cycle selectively ignored based on DTC_{DI} setting
Bus cycle accesses misaligned data (across 64-bit boundary) - both 1st & 2nd transactions within data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) - 1st transaction within data trace range; 2nd transaction out of data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) - 1st transaction within data trace range; 2nd transaction (regardless of within range or not) receives a bus error	Data Trace Message discarded
Bus cycle accesses misaligned data (across 64-bit boundary) - 1st transaction out of data trace range; 2nd transaction within data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) - 1st transaction out of data trace range; 2nd transaction within range, receives a bus error	Data Trace Message discarded

1. Buffering of stores in the CPU store buffer may generate a DTM prior to the actual memory access, regardless of an error termination condition from memory.

Note

For misaligned accesses (crossing 64-bit boundary), the access is broken into two accesses by the CPU. If either access is within the data trace range, a single DTM will be sent with a size encoding indicating the size of the original access (i.e. word), and the address indicating the original misaligned accesses, unless the misaligned access wraps into the

doubleword at address 0. In this case, since the two portions of the misaligned access are not contiguous, two DTMs will be sent, one for each portion. The size encodings and the addresses of the DTMs will indicate the accessed bytes of data. The data trace port handles these cases in the same manner. (See the Data Trace Port section in the Core (e200z4201n3) Core Debug Support chapter.)

Note

A store to the cache's store buffer within the data trace range may initiate a DTM message prior to completion of the actual memory access.

16.13.4 Data Trace Timing Diagrams (8 MDO / 2 MSEO configuration)

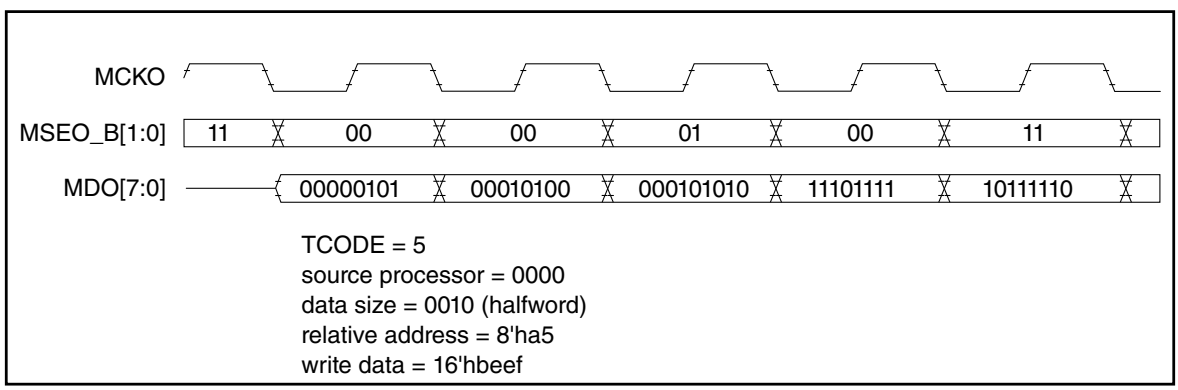

Figure 16-48. Data Trace - Data Write Message

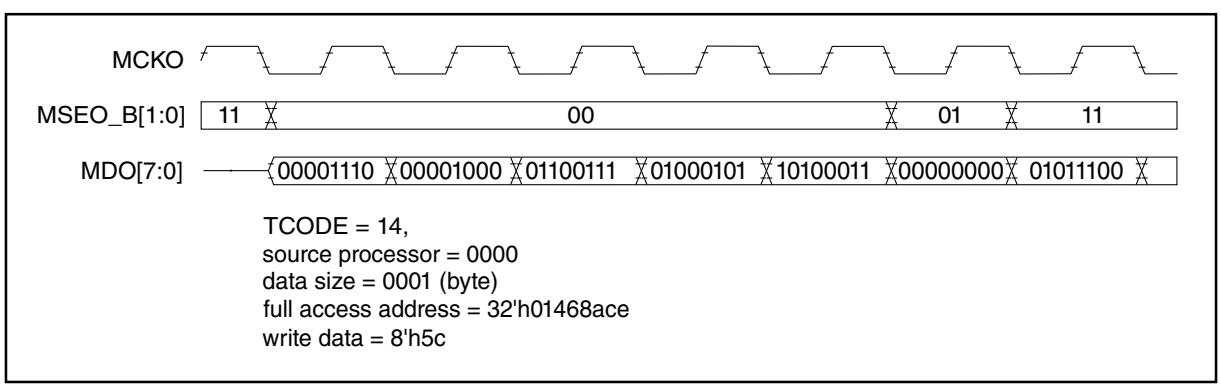

Figure 16-49. Data Trace — Data Read w/ Sync message

16.14 Data Acquisition messaging

This section details the Data Acquisition mechanisms supported by the Nexus 3 module. Data Acquisition Trace is implemented using Data Acquisition Trace Messages in accordance with IEEE-ISTO 5001 definitions. The control mechanism to export the data is different from the recommendations of the standard, however.

Data Acquisition Trace provides a convenient and flexible mechanism for the debugger to observe the architectural state of the machine through software instrumentation.

16.14.1 Data Acquisition ID Tag field

The DQTAG Tag field (DQTAG) is an 8-bit value specifying control or attribute information for the data included in the Data Acquisition message. DQTAG is sampled from $DEVENT_{DQTAG}$ when a write to DDAM is performed via **mtspr** operations. The usage of the DQTAG is left to the discretion of the development tool to be used in whatever manner is deemed appropriate for the application.

16.14.2 Data Acquisition Data field

The Data Acquisition Data field (DQDATA) is the data captured from the DDAM write operation via **mtspr** operations. Leading zeros are omitted from the message.

16.14.3 Data Acquisition Trace event

For DQM, a dedicated SPR has been allocated (DDAM). It is expected that the general use case is to instrument the software and use **mtspr** operations to generate Data Acquisition messages.

There is no explicit error response for failed accesses as a result of contention between an internal and external debugger. Software may be blocked or given ownership of DDAM and the DQTAG field of the DEVENT register via control in EDBRAC0 while in External Debug Mode. Hardware always has access to these registers. Refer to the "External Debug Resource Allocation Control Register (EDBRAC0)" section in the Core (e200z4201n3) Core Debug Support chapter for more detail on EDBRAC0.

Reads from the Data Acquisition channel do not generate a Data Acquisition event and will return zeroes for the read data.

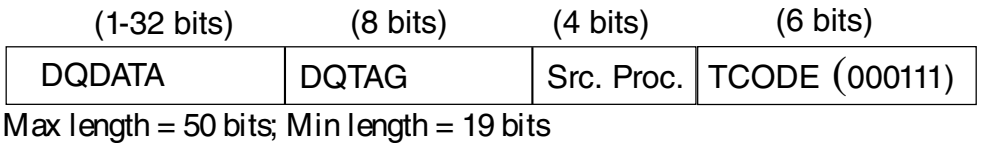

Figure 16-50. Data Acquisition message format

16.15 Watchpoint Trace messaging

Enabling Watchpoint messaging is done by setting the Watchpoint Trace Enable bit in the DC1 Register. Setting the individual Watchpoint sources is supported through the Nexus1 module and the Performance Monitor unit. The Nexus1 module is capable of setting multiple types of watchpoints. Please refer to the Core (e200z4201n3) Core Debug Support chapter for details on watchpoint initialization.

When watchpoints occur due to one or more asserted watchpoint event signals and Watchpoint Trace Messaging is enabled, a Watchpoint Trace message will be sent to the message queue to be messaged out. This message includes the watchpoint number indicating which watchpoint(s) caused the message. If more than one enabled watchpoint occurs in a single cycle, only one Watchpoint Trace message is generated and multiple bits of the watchpoint hit field will be set. The settings of the $WMSK_{WEM}$ field control which watchpoints are enabled to generate watchpoint trace messages.

The occurrence of any of the defined watchpoints can also be programmed to assert the Event Out (**evto_b**) pin for one (1) period of the output clock (**nex_mcko**) based on settings in the DC2 and DC3 registers. See Table 16-40 for details on **evto_b**.

Watchpoint information is messaged out in the following format:

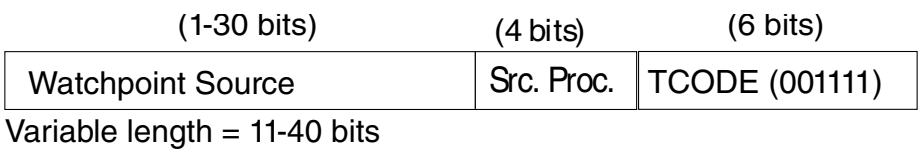

Figure 16-51. Watchpoint message format

The Watchpoint Source message field will contain a '1' for each asserted watchpoint. Leading zeros are truncated.

Table 16-38. Watchpoint Source Encoding

Watchpoint Source (1-30 bits)	Watchpoint Description
000000000000000000000000000000 - No Watchpoints enabled for Watchpoint Trace Messaging	
XXXXXXXXXXXXXXXXXXXXXXXXXXXXX1 - Watchpoint #0 enabled for WTM	
XXXXXXXXXXXXXXXXXXXXXXXXXXXX1X - Watchpoint #1 enabled for WTM	
XXXXXXXXXXXXXXXXXXXXXXXXXXX1XX - Watchpoint #2 enabled for WTM	

Table 16-38. Watchpoint Source Encoding

Watchpoint Source (1-30 bits)	Watchpoint Description
XXXXXXXXXXXXXXXXXXXXXXXXXX1XXX	Watchpoint #3 enabled for WTM
XXXXXXXXXXXXXXXXXXXXXXXXX1XXXX	Watchpoint #4 enabled for WTM
XXXXXXXXXXXXXXXXXXXXXXXX1XXXXX	Watchpoint #5 enabled for WTM
XXXXXXXXXXXXXXXXXXXXXXX1XXXXXX	Watchpoint #6 enabled for WTM
XXXXXXXXXXXXXXXXXXXXXX1XXXXXXX	Watchpoint #7 enabled for WTM
XXXXXXXXXXXXXXXXXXXXX1XXXXXXXX	Watchpoint #8 enabled for WTM

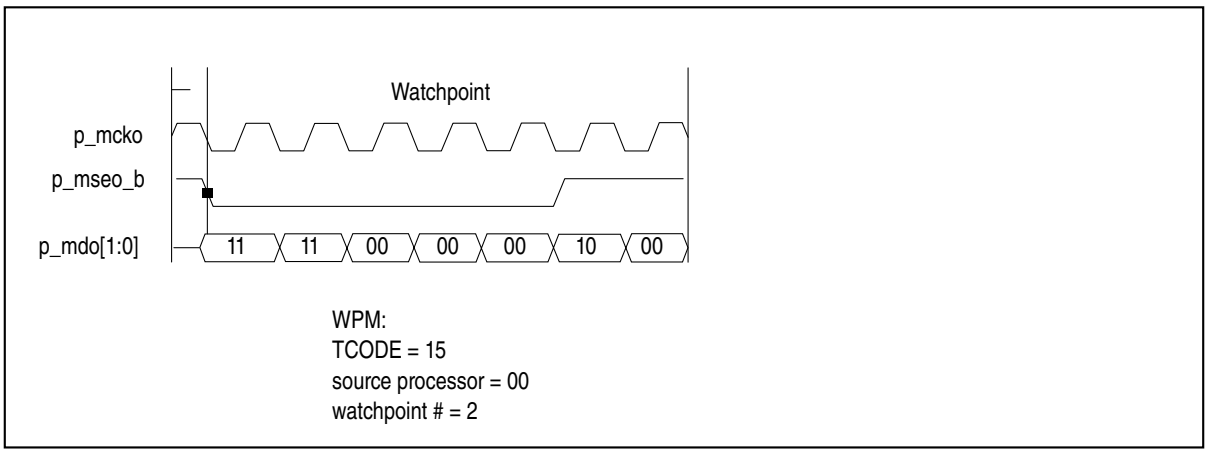

Figure 16-52. Watchpoint Message & Watchpoint Error message

16.16 Nexus 3 Read/Write access to memory-mapped resources

The Read/Write access feature allows access to memory-mapped resources via the JTAG/ OnCE port. The Read/Write mechanism supports single as well as block reads and writes to AHB resources.

The Nexus 3 module is capable of accessing resources on the system bus (AHB). Memory-mapped registers and other non-cached memory can be accessed via the standard memory map settings.

All accesses are setup and initiated by the Read/Write Access Control/Status Register (RWCS), as well as the Read/Write Access Address (RWA) and Read/Write Access Data Registers (RWD). Nexus 3 read/write accesses are run as privileged data non-cacheable accesses by default, and drive the **p_d_hprot[5:0]** bus access attributes to 6'b000011 accordingly. The $RWCS_{ATTR}$ field is provided to allow a portion of these default values to be modified when performing read or write accesses using the Nexus 3 Read/Write access mechanism.

Using the Read/Write Access Registers (RWCS/RWA/RWD), memory mapped AHB resources can be accessed through Nexus 3. The following subsections describe the steps required to access memory-mapped resources.

Note

Read/Write Access can only access memory mapped resources when system reset is de-asserted and clocks are running.

Misaligned accesses are NOT supported in the Nexus 3 module.

Uncorrectable ECC errors on Nexus 3 read access will result in the RWD register being updated with the raw data received.

16.16.1 Single write access

1. Initialize the Read/Write Access Address Register (RWA) through the access method outlined in Nexus 3 Register Access via JTAG/OnCE. Configure as follows:
   - Write Address → 32h'xxxxxxxx (write address)
2. Initialize the Read/Write Access Control/Status (RWCS) register through the access method outlined in Nexus 3 Register Access via JTAG/OnCE. Configure the bits as follows:
   - Access Control (AC) → 1b'1 (to indicate start access)
   - Map Select (MAP) → 3b'000 (primary memory map)
   - Access Priority (PR) → 2b'11 (highest priority)
   - Read/Write (RW) → 1b'1 (write access)
   - Word Size (SZ) → 3b'0xx (32-bit, 16-bit, 8-bit)
   - Access Count (CNT) → 14h'0000 or 14h'0001(single access)

Note

Access Count (CNT) of 14'h0000 or 14'h0001 will perform a single access.

3. Initialize the Read/Write Access Data (RWD) register through the access method outlined in Nexus 3 Register Access via JTAG/OnCE. Configure as follows:
   - Write Data → 32h'xxxxxxxx (write data)
4. The Nexus block will then arbitrate for the AHB system bus and transfer the data value from the data buffer RWD register to the memory mapped address in the Read/Write Access Address (RWA) register. The nex_ahb_start output will be asserted during the first clock of the address phase of the transfer. When the access has completed, Nexus clears the AC and DV bits in the RWCS register. If the access has completed without error, (ERR=1'b0), Nexus asserts the **nex_rdy_b** pin (see Table 16-40 for details) and clears the ERR bit in the RWCS register. Otherwise, if the access completes with an error, the **nex_err_b** pin will be asserted and the ERR bit

will be set to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once the DV bit has been cleared, this indicates that the device is ready for the next access, or that an error has occurred.

Note

Only the **nex_ahb_start**,**nex_err_b**, and **nex_rdy_b** pins, as well as the AC, DV, and ERR bits within the RWCS, provide Read/Write Access status to the external development tool.

16.16.2 Block write access

1. For a block write access, follow Steps 1, 2, and 3 outlined in Single write access to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS register.
2. The Nexus block then arbitrates for the AHB system bus and transfers the first data value from the RWD register to the memory-mapped address in the Read/Write Access Address (RWA) register. The nex_ahb_start output is asserted during the first clock of the address phase of the transfer. When the transfer has completed without error, the address from the RWA register is incremented to the next word size (specified in the SZ field), the number from the CNT field is decremented, and the **nex_rdy_b** pin is asserted. If the access has completed without error, Nexus clears the ERR and DV bits in the RWCS register. Otherwise, the ERR bit is set and the DV bit is cleared to indicate an error has occurred, the **nex_err_b** pin is asserted, the block transfer is aborted, and the AC bit in the RWCS register is cleared. Clearing the DV bit indicates that the device is ready for the next access in the block transfer, or that an error has occurred.
3. If the AC bit has not been cleared due to an error, repeat Step 3 in Single write access until the internal CNT value is zero (0). When this occurs, the AC bit within the RWCS register is cleared to indicate the end of the block write access.

Note

The actual RWA register value as well as the CNT field within the RWCS register are not changed when executing a block write access. The original values can be read by the external development tool at any time.

16.16.3 Single read access

1. Initialize the Read/Write Access Address (RWA)register through the access method outlined in Nexus 3 Register Access via JTAG/OnCE. Configure as follows:
   - Read Address → 32h'xxxxxxxx (read address)
2. Initialize the Read/Write Access Control/Status (RWCS) register through the access method outlined in Nexus 3 Register Access via JTAG/OnCE. Configure the bits as follows:
   - Access Control (AC) → 1b'1 (to indicate start access)
   - Map Select (MAP) → 3b'000 (primary memory map)
   - Access Priority (PR) → 2b'11 (highest priority)
   - Read/Write (RW) → 1b'0 (read access)
   - Word Size (SZ) → 3b'0xx (32-bit, 16-bit, 8-bit)
   - Access Count (CNT) → 14h'0000 or 14h'0001(single access)

Note

An Access Count (CNT) of 14'h0000 or 14'h0001 will perform a single access.

3. The Nexus block will then arbitrate for the AHB system bus and the read data will be transferred from the AHB to the RWD register. The nex_ahb_start output will be asserted during the first clock of the address phase of the transfer. When the access has completed without error, Nexus clears the ERR bit and sets the DV bit in the RWCS register and asserts the **nex_rdy_b** pin (see Table 16-40 for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set, and the DV bit will be cleared to indicate an error has occurred. The **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. The AC bit is cleared in either case.
4. The data can then be read from the Read/Write Access Data register (RWD) through the access method outlined in Nexus 3 Register Access via JTAG/OnCE.

Note

Only the **nex_ahb_start**, **nex_err_b**, and **nex_rdy_b** pins as well as the AC, DV, and ERR bits within the RWCS register provide Read/Write Access status to the external development tool.

16.16.4 Block read access

1. For a block read access, follow Steps 1 and 2 outlined in Single read access to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS register.
2. The Nexus block will then arbitrate for the AHB system bus and the read data will be transferred from the AHB to the RWD register. The nex_ahb_start output will be asserted during the first clock of the address phase of the transfer. When the access has completed without error, Nexus clears the ERR bit and sets the DV bit in the RWCS register and asserts the **nex_rdy_b** pin (see Table 16-40 for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. The AC bit will be cleared in either case.
3. When the transfer has completed without error, the address from the RWA Register is incremented to the next word size (specified in the SZ field), the number from the CNT field is decremented, Nexus clears the ERR bit and sets the DV bit in the RWCS register, and asserts the **nex_rdy_b** pin (see Table 16-40 for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, the AC bit is cleared and the block transfer is aborted, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. Once DV has been set, this indicates that the device is ready for the next access in the block transfer, or if ERR is set (AC will be cleared), the block transfer has been aborted.
4. The data can then be read from the RWD register through the access method outlined in Nexus 3 Register Access via JTAG/OnCE.

5. If AC has not been cleared due to an error, repeat Steps 3 and 4 in Single read access until the CNT value is zero (0). When this occurs, the AC bit within the RWCS register is cleared to indicate the end of the block read access.

Note

The data values must be shifted out 32 bits at a time LSB first (i.e. doubleword read = two word reads from the RWD).

Note

The actual RWA value as well as the CNT field within the RWCS register are not changed when executing a block read access. The original values can be read by the external development tool at any time.

16.16.5 Error handling

The Nexus 3 module handles various error conditions as follows:

16.16.5.1 AHB Read/Write error

All address and data errors that occur on read/write accesses to the AHB system bus will return a transfer error encoding on the **p_hresp[1:0]** signals. If this occurs:

1. The access is terminated without retrying (AC bit is cleared)
2. The ERR bit in the RWCS Register is set
3. The Error Message is sent (TCODE = 8) indicating Read/Write error

16.16.5.2 Access termination

The following cases are defined for sequences of the Read/Write protocol that differ from those described in the above sections.

1. If the AC bit in the RWCS Register is set to start Read/Write accesses and invalid values are loaded into the RWD and/or RWA, then an AHB access error may occur. This is handled as described above.
2. If a block access is in progress (all cycles not completed), and the RWCS Register is written, then the original block access is terminated at the boundary of the nearest completed access.
   a. If the RWCS is written with the AC bit set, the next Read/Write access will begin and the RWD can be written to/ read from.
   b. If the RWCS is written with the AC bit cleared, the Read/Write access is terminated at the nearest completed access. This method can be used to break (early terminate) block accesses.

16.16.6 Read/Write access error message

The Read/Write Access Error Message is sent out when an AHB system bus access error (read or write) has occurred.

Error information is messaged out in the following format:

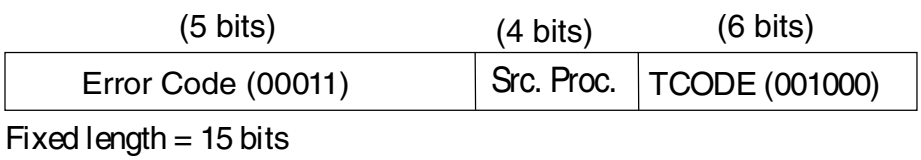

Figure 16-53. Error message format1

16.17 Nexus 3 pin interface

This section details information regarding the Nexus 3 pins and pin protocol.

The Nexus 3 pin interface provides the function of transmitting messages from the messages queues to the external tools. It is also responsible for handshaking with the message queues.

16.17.1 Pins implemented

The Nexus 3 module implements an auxiliary port consisting of one (1) **nex_evti_b** and one (1) **nex_mseo_b** or two (2) **nex_mseo_b[1:0]**. It also implements a configurable number of **nex_mdo[n:0]** pins, (1) **nex_rdy_b** pin, (1) **nex_err_b** pin, (1) **evto_b** pin, (4) **nex_wevto[3:0]** pins, and one (1) clock output pin (**nex_mcko**), as well as additional configuration pins described in Table 16-40. The output pins are synchronized to the Nexus 3 output clock (**nex_mcko**).

All Nexus 3 input functionality may be controlled through the JTAG/OnCE port in compliance with IEEE 1149.1 (see Nexus 3 Register Access via JTAG/OnCE for details). The JTAG pins are incorporated as I/O to the processor, and are further described in the "JTAG/OnCE Pins" section of the Core (e200z4201n3) Core Debug Support chapter.

Table 16-39. JTAG Pins for Nexus 3

JTAG Pins	Input/ Output	Description of JTAG Pins (included in Nexus 1)
j_tdo	O	The Test Data Output (**j_tdo**) pin is the serial output for test instructions and data. **j_tdo** is three-stateable and is actively driven in the "Shift-IR" and "Shift-DR" controller states. **j_tdo** changes on the falling edge of **j_tclk**.
j_tdi	I	The Test Data Input (**j_tdi**) pin receives serial test instruction and data. TDI is sampled on the rising edge of **j_tclk**.
j_tms	I	The Test Mode Select (**j_tms**) input pin is used to sequence the OnCE controller state machine. **j_tms** is sampled on the rising edge of **j_tclk**.
j_tclk	I	The Test Clock (**j_tclk**) input pin is used to synchronize the test logic, and control register access through the JTAG/OnCE port.
j_trst_b	I	The Test Reset (**j_trst_b**) input pin is used to asynchronously initialize the JTAG/OnCE controller.

The auxiliary pins are used to send and receive messages and are described in Table 16-40.

Table 16-40. Nexus 3 Auxiliary pins

Auxiliary pins	Input/ Output	Description of auxiliary pins
nex_mcko	O	Message Clock Out (**nex_mcko**) is a free running output clock to development tools for timing of **nex_mdo[n:0]** & **nex_mseo_b[1:0]** pin functions. **nex_mcko** is programmable through the DC1 Register.
nex_mdo[n:0]	O	Message Data Out (**nex_mdo[n:0]**) are output pins used for OTM, BTM, and DTM. External latching of **nex_mdo[n:0]** shall occur on the rising edge of the Nexus3 clock (**nex_mcko**).
nex_mseo_b[1:0]	O	Message Start/End Out (**nex_mseo_b[1:0]**) are output pins that indicate when a message on the **nex_mdo[n:0]** pins has started, when a variable length packet has ended, and when the message has ended. External latching of **nex_mseo_b[1:0]** shall occur on the rising edge of the Nexus3 clock (**nex_mcko**). One or two pin MSEO functionality is determined at integration time per SOC implementation.

Table continues on the next page...

Table 16-40. Nexus 3 Auxiliary pins (continued)

Auxiliary pins	Input/ Output	Description of auxiliary pins
nex_ahb_start	O	AHB Start (**nex_ahb_start**) is an output pin used to indicate to the external tool or SoC that the Nexus block is requesting the next Read/Write Access on the system bus. If Nexus is enabled, this signal is asserted upon an acknowledged request to start an AHB system bus transfer (Nexus read or write) and is pulsed asserted for one **nex_clk** clock period, corresponding to the first clock of the address phase of the transfer. Upon exit from system reset or if Nexus is disabled, **nex_ahb_start** remains de-asserted.
nex_rdy_b	O	Ready (**nex_rdy_b**) is an output pin used to indicate to the external tool that the Nexus block is ready for the next Read/Write Access. If Nexus is enabled, this signal is asserted upon successful (without error) completion of an AHB system bus transfer (Nexus read or write) & is held asserted until the JTAG/OnCE state machine reaches the "Capture_DR" state. Upon exit from system reset or if Nexus is disabled, **nex_rdy_b** remains deasserted.
nex_err_b	O	Error (**nex_err_b**) is an output pin used to indicate to the external tool that the Nexus block is ready for the next Read/Write Access and an error has occurred on the previous access. If Nexus is enabled, this signal is asserted upon unsuccessful (with error) completion of an AHB system bus transfer (Nexus read or write) & is held asserted until the JTAG/OnCE state machine reaches the "Capture_DR" state. Upon exit from system reset or if Nexus is disabled, **nex_err_b** remains deasserted.
evto_b	O	Event Out (**evto_b**) is an output that, when asserted, indicates one of two events has occurred based on the EOC bits in the DC1 Register. **evto_b** is held asserted for one (1) cycle of **nex_mcko**: 1. One (or more) watchpoints has occurred (from Nexus1) & EOC = 2'b00 2. Debug mode was entered (jd_debug_b asserted from Nexus1) & EOC = 2'b01
nex_evti_b	I	Event In (**nex_evti_b**) is an input that, when asserted, will initiate one of two events based on the EIC bits in the DC1 Register (if the Nexus module is enabled at reset): 1. Program Trace & Data Trace synchronization messages (provided Program Trace & Data Trace are enabled & EIC = 2'b00). 2. Debug request to Nexus1 module (provided EIC = 2'b01 and this feature is implemented).
nex_wevto[3:0]	O	Watchpoint Event Out 3:0 (**nex_wevto[3:0]**) are outputs that, when asserted, indicates one or more watchpoint events has occurred based on the settings in the DC2 and DC3 registers. **nex_wevto[3:0]** is held asserted for one (1) cycle of **nex_mcko**.
nex_ext_src_id[0:3]	I	**nex_ext_src_id[0:3]** is used to provide the SRC field value used in each message. These pins are tied to a predetermined value at SoC integration time.
nex_sfwcntl_en]	I	**nex_sfwcntl_en** is used to allow software to control the module resources via the DCR register mappings. SoC logic should drive this signal appropriately in a semi-static manner based on the presence of an external hardware debugger and appropriate security precautions.

The Nexus auxiliary port arbitration pins are used when the Nexus 3 module is implemented in a multi-Nexus SoC that shares a single auxiliary output port. The arbitration is controlled by an SoC level Nexus Aurora Router (NAR). Refer to Auxiliary port arbitration for detail on Nexus port arbitration.

Table 16-41. Nexus port arbitration signals

Nexus port arbitration pins	Input/ Output	Description of arbitration pins
nex_aux_req[1:0]	O	Nexus Auxiliary Request (**nex_aux_req[1:0]**) output signals indicate to an SoC level Nexus arbiter a request for access to the shared Nexus auxiliary port in a multi-Nexus implementation. The priority encodings are determined by how many messages are currently in the message queues (See Table 16-43.)
nex_aux_busy	O	Nexus Auxiliary Busy (**nex_aux_busy**) is an output signal to an SoC level Nexus arbiter indicating that the Nexus 3 module is currently transmitting its message after being granted the Nexus auxiliary port.
nar_aux_grant	I	Nexus Auxiliary Grant **(nar_aux_grant)** is an input from the SoC level NAR that the auxiliary port has been granted to the Nexus 3 module to transmit its message.
ext_multi_nex_sel	I	Multi-Nexus Select (**ext_multi_nex_sel**) is a static signal indicating that the Nexus 3 module is implemented within a multi-Nexus environment. If set, port control and arbitration is controlled by the SoC level arbitration module (NAR).

16.17.2 Pin protocol

The protocol for the processor transmitting messages via the auxiliary pins is accomplished with the MSEO pin function outlined in Table 16-42. Both single and dual pin cases are shown.

nex_mseo_b[1:0] is used to signal the end of variable-length packets, and not fixed length packets. **nex_mseo_b[1:0]** is sampled on the rising edge of the Nexus 3 clock (**nex_mcko**).

Single pin MSEO is not supported on the .

Table 16-42. MSEO pin(s) protocol

nex_mseo_b function	Single nex_mseo_b data (serial)	Dual nex_mseo_b[1:0] data
Start of message	1-1-0	11-00
End of message	0-1-1-(more 1's)	00 (or 01)-11-(more 1's)
End of variable length packet	0-1-0	00-01
Message transmission	0's	00's
Idle (no message)	1's	11's

Figure 16-54 illustrates the state diagram for single pin MSEO transfers.

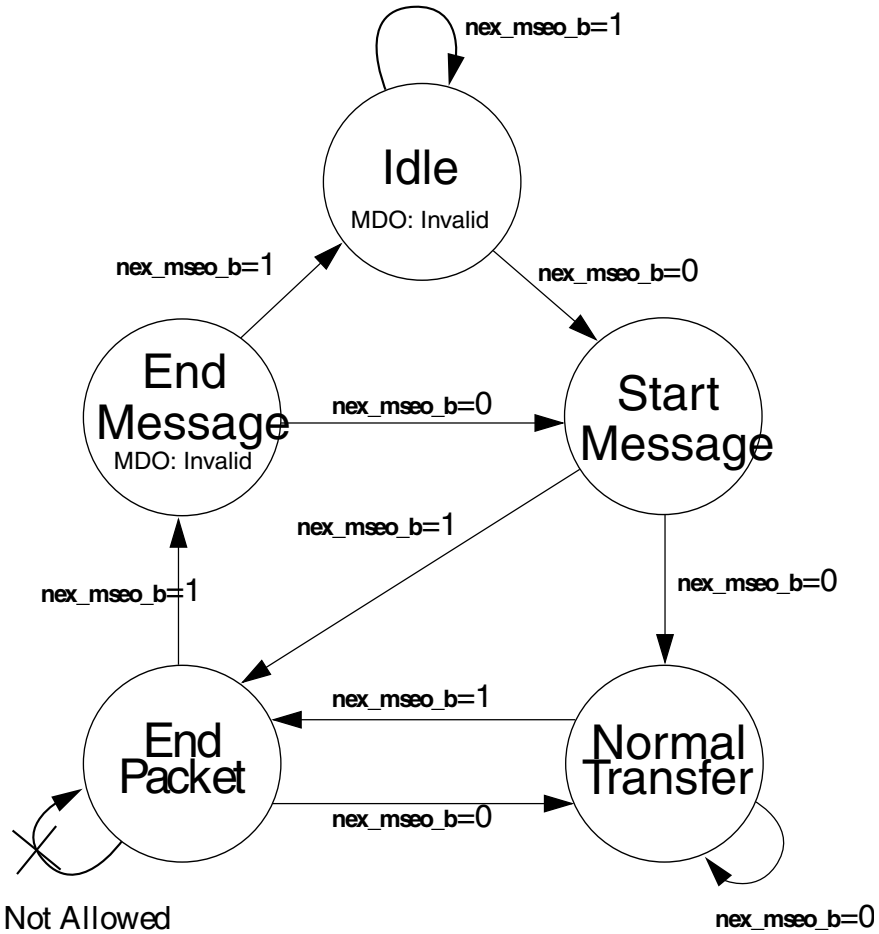

Figure 16-54. Single pin MSEO transfers

Note that the "End Message" state does not contain valid data on the **nex_mdo[n:0]** pins. Also, It is not possible to have two consecutive "End Packet" messages. This implies the minimum packet size for a variable length packet is 2x the number of **nex_mdo[n:0]** pins. This ensures that a false end of message state is not entered by emitting two consecutive '1's on the **nex_mseo_b** pin before the actual end of message.

Figure 16-55 illustrates the state diagram for dual pin MSEO transfers.

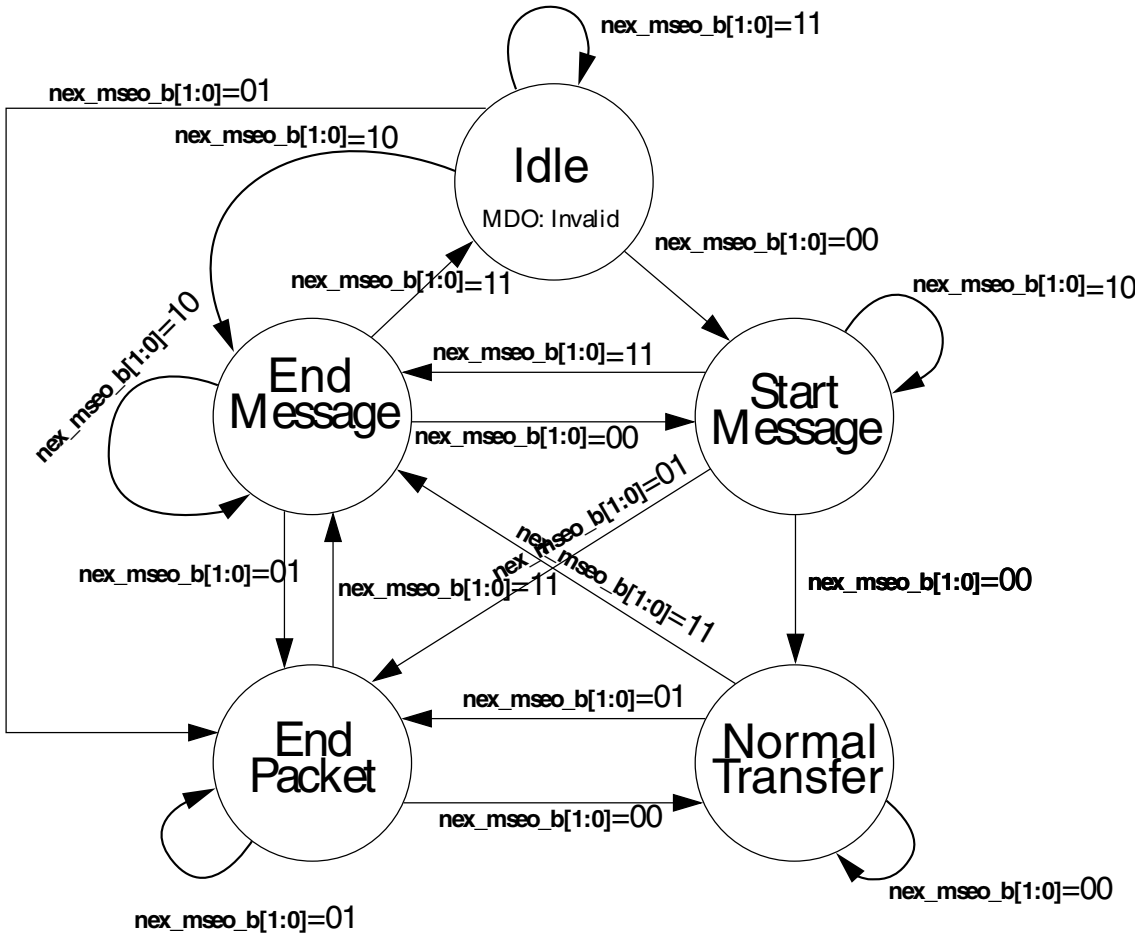

Figure 16-55. Dual pin MSEO transfers

The dual pin MSEO option is more robust that the single pin option. Termination of the current message may immediately be followed by the start of the next message on the consecutive clocks. An extra clock to end the message is not necessary as with the one MSEO pin option. The dual pin option also allows for consecutive "End Packet" states. This can be an advantage when small, variable sized packets are transferred.

Note

The "End Message" state may also indicate the end of a variable-length packet as well as the end of the message when using the dual pin option.

16.18 Rules for output messages

Class 3 compliant embedded processors must provide messages via the auxiliary port in a consistent manner as described below:

- A variable-sized packet within a message must end on a port boundary.
- A variable-sized packet may start within a port boundary only when following a fixed length packet. (If two variable-sized packets end and start on the same clock, it is impossible to know which bit is from the last packet and which bit is from the next packet.)
- Whenever a variable-length packet is sized such that it does not end on a port boundary, it is necessary to extend and zero fill the remaining bits after the highest-order bit so that it can end on a port boundary.

  For example, if the **nex_mdo[n:0]** port is 2 bits wide, and the unique portion of an indirect address TCODE is 5 bits, then the remaining 1 bit of **nex_mdo[n:0]** must be packed with a 0.

16.19 Auxiliary port arbitration

In a multi-Nexus environment, the Nexus 3 module must arbitrate for the shared Nexus port at the SoC level.The request scheme is implemented as a 2-bit request with various levels of priority. The priority levels are defined in Table 16-43 below. The Nexus 3 module will receive a 1-bit grant signal (**nar_aux_grant**) from the SoC level arbiter. When a grant is received, the Nexus 3 module will begin transmitting its message following the protocol outlined in Pin protocol. The Nexus 3 module will maintain control of the port, by asserting the **nex_aux_busy** signal, until the $\overline{\text{MSEO}}$ state machine reaches the "End Message" state.

Table 16-43. MDO Request Encodings

Request level	MDO request encoding (nex_aux_req[1:0])	Condition of queue
No Request	00	No message to send
Low Priority	01	Message queue less than 1/2 full
—	10	Reserved
High Priority	11	Message queue 1/2 full or more

16.20 Examples

The following are examples of Program Trace and Data Trace Messages.

Table 16-44 illustrates an example Indirect Branch Message with 2 MDO / 1MSEO configuration. Table 16-45 illustrates the same example with an 8 MDO / 2 MSEO configuration.

Note that T0 and S0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- MAP = (always set to 0)
- Ix = Number of instructions (variable)
- Ax = Unique portion of the address (variable)

Note that during clock 13, the **nex_mdo[n:0]** pins are ignored in the single MSEO case.

Table 16-44. Indirect Branch Message Example (2 MDO / 1 MSEO)

Clock	nex_mdo[1:0]		nex_mseo_b	State
0	X	X	1	Idle (or end of last message)
1	T1	T0	0	Start Message
2	T3	T2	0	Normal Transfer
3	T5	T4	0	Normal Transfer
4	S1	S0	0	Normal Transfer
5	S3	S2	0	Normal Transfer
6	I0	MAP	0	Normal Transfer
7	I2	I1	0	Normal Transfer
8	I4	I3	1	End Packet
9	A1	A0	0	Normal Transfer
10	A3	A2	0	Normal Transfer
11	A5	A4	0	Normal Transfer
12	A7	A6	1	End Packet
13	0	0	1	End Message
14	T1	T0	0	Start Message

Table 16-45. Indirect branch message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	I4	I3	I2	I1	I0	M A	S3	S2	0	1	End Packet

Table continues on the next page...

Table 16-45. Indirect branch message example (8 MDO / 2 MSEO) (continued)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
						P					
3	A7	A6	A5	A4	A3	A2	A1	A0	1	1	End Packet/End Message
4	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message

Table 16-46 and Table 16-47 illustrate examples of Direct Branch Messages: one with 2 MDO / 1 MSEO, and one with 8 MDO / 2 MSEO.

Note that T0 and I0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- Ix = Number of Instructions (variable)

Table 16-46. Direct branch message example (2 MDO / 1 MSEO)

Clock	nex_mdo[1:0]		nex_mseo_b	State
0	X	X	1	Idle (or end of last message)
1	T1	T0	0	Start Message
2	T3	T2	0	Normal Transfer
3	T5	T4	0	Normal Transfer
4	S1	S0	0	Normal Transfer
5	S3	S2	0	Normal Transfer
6	I1	I0	1	End Packet
7	0	0	1	End Message

Table 16-47. Direct branch message example (8 MDO / 2 MSEO)

2	0	0	0	0	I1	I0	S3	S2	1	1	End Packet/End Message
3	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message

Table 16-48 illustrates an example Data Write Message with 8 MDO / 1 MSEO configuration, and Table 16-49 illustrates the same DWM with 8 MDO / 2 MSEO configuration

Note that T0, A0, D0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- MAP = (always set to 0)
- Zx = Data size (fixed)
- Ax = Unique portion of the address (variable)
- Dx = Write data (variable 8-, 16- or 32-bit)

Table 16-48. Data write message example (8 MDO / 1 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b	State
0	X	X	X	X	X	X	X	X	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	Start Message
2	A0	Z3	Z2	Z1	Z0	0	S3	S2	1	End Packet
3	D7	D6	D5	D4	D3	D2	D1	D0	0	Normal Transfer
4	0	0	0	0	0	0	0	0	1	End Packet
5	0	0	0	0	0	0	0	0	1	End Message

Table 16-49. Data write message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	A0	Z3	Z2	Z1	Z0	0	S3	S2	0	1	End Packet
3	D7	D6	D5	D4	D3	D2	D1	D0	1	1	End Packet/ End Message

16.21 Electrical characteristics

For all electrical characteristics related to core processor and Nexus 3 operation, please refer to the Data Sheet.

16.22 IEEE 1149.1 (JTAG) RD/WR sequences

This section contains example JTAG/OnCE sequences used to access resources.

16.22.1 JTAG sequence for accessing internal Nexus registers

Table 16-50. Accessing internal Nexus 3 registers via JTAG/OnCE

Step #	TMS Pin	Description
1	1	IDLE -> SELECT-DR_SCAN
2	0	SELECT-DR_SCAN -> CAPTURE-DR (Nexus Command Register value loaded in shifter)
3	0	CAPTURE-DR -> SHIFT-DR
4	0	(7) TCK clocks issued to shift in direction (rd/wr) bit and first 6 bits of Nexus reg. addr.
5	1	SHIFT-DR -> EXIT1-DR (7th bit of Nexus reg. shifted in)
6	1	EXIT1-DR -> UPDATE-DR (Nexus shifter is transferred to Nexus Command Register)
7	1	UPDATE-DR -> SELECT-DR_SCAN
8	0	SELECT-DR_SCAN -> CAPTURE-DR (Register value is transferred to Nexus shifter)
9	0	CAPTURE-DR -> SHIFT-DR
10	0	(31) TCK clocks issued to transfer register value to TDO pin while shifting in TDI value
11	1	SHIFT-DR -> EXIT1-DR (MSB of value is shifted in/out of shifter)
12	1	EXIT1-DR -> UPDATE -DR (if access is write, shifter is transferred to register)
13	0	UPDATE-DR -> RUN-TEST/IDLE (transfer complete - Nexus controller to Reg. Select state)

16.22.2 JTAG sequence for read access of memory-mapped resources

Table 16-51. Accessing memory-mapped resources (reads)

Step #	TCLK clocks	Description
1	13	Nexus Command = write to Read/Write Access Address Register (RWA)
2	37	Write RWA (initialize starting read address — data input on TDI)
3	13	Nexus Command = write to Read/Write Control/Status Register (RWCS)
4	37	Write RWCS (initialize read access mode and CNT value — data input on TDI)
5	—	Wait for falling edge of **nex_rdy_b** or **nex_err_b** pin
6	13	Nexus Command = read Read/Write Access Data Register (RWD)
7	37	Read RWD (data output on TDO)
8	—	If CNT > 0, go back to Step #5

16.22.3 JTAG sequence for write access of memory-mapped resources

Table 16-52. Accessing memory-mapped resources (writes)

Step #	TCLK clocks	Description
1	13	Nexus Command = write to Read/Write Access Control/Status Register (RWCS)
2	37	Write RWCS (initialize write access mode and CNT value - data input on TDI)
3	13	Nexus Command = write to Read/Write Address Register (RWA)
4	37	Write RWA (initialize starting write address - data input on TDI)
5	13	Nexus Command = read Read/Write Access Data Register (RWD)
6	37	Write RWD (data output on TDO)
7	—	Wait for falling edge of **nex_rdy_b** or **nex_err_b**pin
8	—	If CNT > 0, go back to Step #5

Chapter 17
z7 Nexus Module

17.1 Introduction

The e200z7260n3Nexus 3 module provides real-time development capabilities for corresponding core processors in compliance with the IEEE-ISTO 5001 standard. This module provides development support capabilities without requiring the use of address and data pins for internal visibility.

A portion of the pin interface (the JTAG port) is also shared with the OnCE / Nexus 1 unit. The IEEE-ISTO 5001 standard defines an extensible auxiliary port which is used in conjunction with the JTAG port in these processors.

17.1.1 General Description

This chapter defines the auxiliary pin functions, transfer protocols and standard development features of a Class 3 device in compliance with the IEEE-ISTO 5001 standard. The development features supported are Program Trace, Data Trace, Watchpoint Messaging, Ownership Trace, Data Acquisition Messaging, and Read/Write Access via the JTAG interface. The Nexus 3 module also supports two Class 4 features: Watchpoint Triggering, and Processor Overrun Control.

17.1.2 Terms and Definitions

The following table contains a set of terms and definitions associated with the Nexus 3 module.

Table 17-1. Terms and Definitions

Term	Description
IEEE-ISTO 5001	Consortium & standard for real-time embedded system design. World wide Web documentation at http://www.ieee-isto.org/Nexus5001
Auxiliary Port	Refers to Nexus auxiliary port. Used as auxiliary port to the IEEE 1149.1 JTAG interface.
Branch Trace Messaging (BTM)	Visibility of addresses for taken branches and exceptions, and the number of sequential instructions executed between each taken branch.
Data Read Message (DRM)	External visibility of data reads to memory-mapped resources.
Data Write Message (DWM)	External visibility of data writes to memory-mapped resources.
Data Trace Messaging (DTM)	External visibility of how data flows through the embedded system. This may include DRM and/or DWM.
Data Acquisition Messaging (DQM)	Data Acquisition Messaging (DQM) allows code to be instrumented to export customized information to the Nexus Auxiliary Output Port.
JTAG Compliant	Device complying to IEEE 1149.1 JTAG standard
JTAG IR & DR Sequence	JTAG Instruction Register (IR) scan to load an opcode value for selecting a development register. The JTAG IR corresponds to the OnCE command register (OCMD). The selected development register is then accessed via a JTAG Data Register (DR) scan.
Nexus1	The (OnCE) debug module. This module integrated with each processor provides all static (core halted) debug functionality. This module is compliant with Class1 of the IEEE-ISTO 5001 standard.
Ownership Trace Message (OTM)	Visibility of process/function that is currently executing.
Public Messages	Messages on the auxiliary pins for accomplishing common visibility and controllability requirements
SoC	"System-on-a-Chip". SoC signifies all of the modules on a single die. This generally includes one or more processors with associated peripherals, interfaces & memory modules.
Standard	The phrase "according to the standard" is used to indicate according to the IEEE-ISTO 5001 standard.
Transfer Code (TCODE)	Message header that identifies the number and/or size of packets to be transferred, and how to interpret each of the packets.
Watchpoint	A Data or Instruction Breakpoint or other debug event that does not cause the processor to halt. Instead, a pin is used to signal that the condition occurred. A Watchpoint Message may also be generated.

17.1.3 Feature List

The Nexus 3 module is compliant with Class 3 of the IEEE-ISTO 5001 standard, with additional Class 4 features available. The following features are implemented:

- Program Trace via Branch Trace Messaging (BTM). Branch trace messaging displays program flow discontinuities (direct and indirect branches, exceptions, etc.), allowing the development tool to interpolate what transpires between the discontinuities. Thus static code may be traced.
- Data Trace via Data Write Messaging (DWM) and Data Read Messaging (DRM). This provides the capability for the development tool to trace reads and/or writes to selected internal memory resources.
- Ownership Trace via Ownership Trace Messaging (OTM). OTM facilitates ownership trace by providing visibility of which process ID or operating system task is activated. An Ownership Trace Message is transmitted when a new process/task is activated, allowing the development tool to trace ownership flow.
- Run-time access to embedded processor memory map via the JTAG port. This allows for enhanced download/upload capabilities.
- Watchpoint Messaging via the auxiliary pins
- Watchpoint Trigger enable of Program and/or Data Trace Messaging
- Auxiliary interface for higher data
  - Configurable (min/max) Message Data Out pins (**nex_mdo[n:0]**)
  - One (1) or two (2) Message Start/End Out pins (**nex_mseo_b[1:0]**)
  - One (1) Read/Write Ready pin (**nex_rdy_b**) pin
  - One (1) Read/Write Error pin (**nex_err_b**) pin
  - One (1) Watchpoint Event output pin (**evto_b**)
  - Four (4) additional Watchpoint Event output pins (**nex_wevto[3:0]**) for SoC use
  - One (1) Event In pin (**nex_evti_b**)
  - One (1) MCKO (Message Clock Out) pin
- Registers for Program Trace, Data Trace, Ownership Trace and Watchpoint Trigger.
- All features controllable and configurable via the JTAG port
- Conditional software control of the module via SoC signaling input (**nex_sfwcntl_en**)

Note

For multi-Nexus implementations, the configuration of the Message Data Out pins is controlled by the Port Control Register (at the SoC level). For single Nexus implementations (not normally implemented on an SoC), this configuration is controlled by Development Control Register 1 (DC1) within the Nexus 3 module.

In either implementation, Full Port Mode (FPM - maximum number of MDO pins) or Reduced Port Mode (RPM - minimum number of MDO pins) are supported. This setting should not be changed while the system is running.

Note

The configuration of the Message Start/End Out pins (1 or 2) is determined at the SOC integration level. This option will be hard-wired based on SOC bandwidth requirements.

17.1.4 Functional Block Diagram

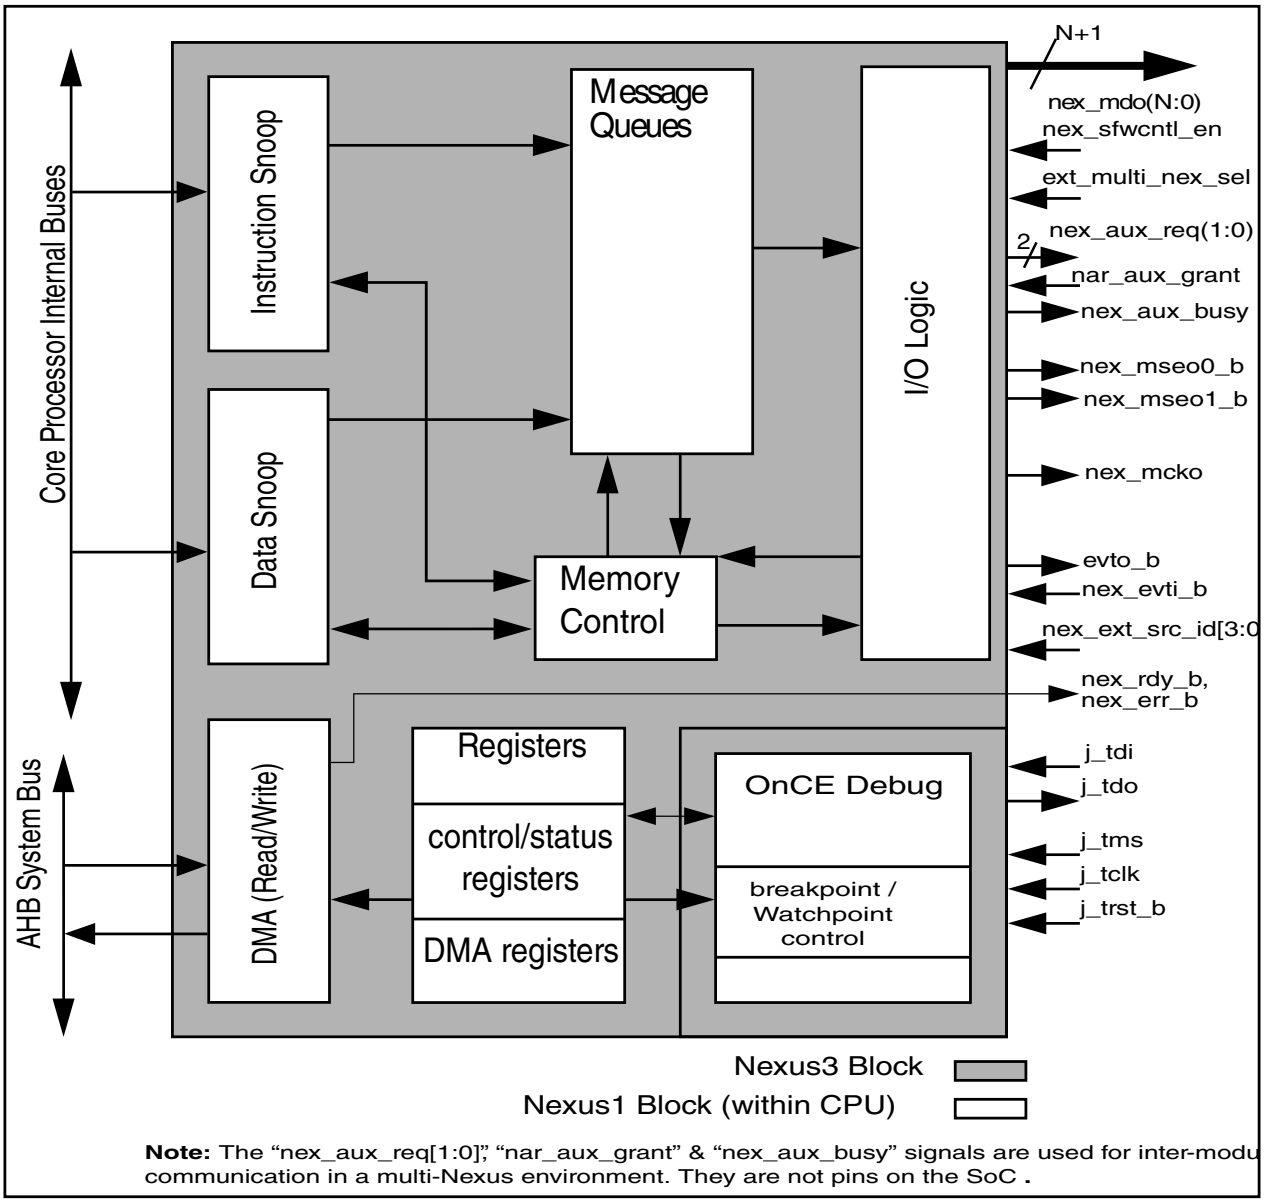

Figure 17-1. Nexus 3 Functional Block Diagram

17.2 Enabling Nexus 3 Operation

The Nexus module is enabled by loading a single instruction (*NEXUS3-ACCESS*) into the JTAG Instruction Register (IR) (OnCE OCMD register). For the Nexus3 module, the OCMD value is 0b0001111100. The Nexus 3 module may alternately be enabled if the nex_evti_b input signal is asserted at the time that j_trst_b is initially negated, or is asserted during the Test-Logic-Reset TAP state. Once enabled, the module will be ready to accept control input via the JTAG/OnCE pins.

Enabling the Nexus 3 module automatically enables the generation of Debug Status Messages.

The Nexus 3 module is disabled when the JTAG state machine initially reaches the Test-Logic-Reset state from any other state. This state can be reached by the assertion of the **j_trst_b** pin or by cycling through the state machine using the **j_tms** pin. The Nexus module will also be disabled if a Power-on-Reset (POR) event occurs. If the Nexus 3 module is disabled, no trace output will be provided, and the module will disable (drive inactive) auxiliary port output pins (**nex_mdo[n:0]**, **nex_mseo[1:0]**, **nex_mcko**). Nexus registers will not be available for reads or writes.

In order to support software control of the Nexus 3 module when no external development tool is present, the Nexus 3 module is not forced to be disabled when the JTAG state remains in the Test-Logic-Reset state. Software is allowed to control the Nexus 3 module when the input signal **nex_sfwcntl_en** is asserted by the SoC. This signal is intended to provide a mechanism for allowing software to use the Nexus 3 module to fill on-chip trace buffers or other visibility mechanisms. It is up to the SoC to determine whether a top-level Nexus 3 controller has been enabled by a hardware debugger, or whether appropriate security mechanisms have granted the capability for software to use these resources, and to drive the appropriate value to the **nex_sfwcntl_en** input. Software can enable the module by a write to any of the module's DCRs when **nex_sfwcntl_en** is asserted.

Reset of the Nexus 3 module is accomplished by a transition on **j_trst_b**, on initial entry into the Test_Logic_Reset state from another state, or if a Power-on-Reset (POR) event occurs. The module is not reset by the CPU's **p_reset_b** signal, even when software has control of the module.

17.2.1 Interaction with Low Power Modes

The Nexus 3 module will continue to operate in the Waiting and Halted states, as long as **nex_clk** remains active. In the Stopped state, **nex_clk** is gated off internally to the Nexus 3 logic, therefore watchpoint or hardware triggering recognition, message generation, and Nexus 3 read-write access to memory is suspended. The Nexus 3 logic will wait to enter the Stopped state until the message FIFOs are empty and any in-progress Nexus R/W transfer has completed. If a block transfer has been requested, the remainder of the block transfer is not completed, and the RWCS AC bit is cleared, and the ERR bit is set. Once the Stopped state has been entered, no further messages are queued and no triggering conditions are monitored. Also, Nexus R/W accesses are no longer available. Upon exiting the Stopped state, normal functions will resume assuming **nex_clk** is active.

17.3 TCODEs supported

The Nexus 3 pins allow for flexible transfer operations via Public Messages. A TCODE defines the transfer format, the number and/or size of the packets to be transferred, and the purpose of each packet. The IEEE-ISTO 5001-2003 standard defines a set of public messages and allocates additional TCODEs for vendor-specific features outside the scope of the public messages. The Nexus 3 block supports the TCODEs shown in Table 17-2.

Table 17-2. Supported TCODEs

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Debug Status	6	6	TCODE	fixed	TCODE number = 0
	4	4	SRC	fixed	source processor identifier
	8	8	STATUS	fixed	Development Status Register (DS[31:24])
Ownership Trace Message	6	6	TCODE	fixed	TCODE number = 2
	4	4	SRC	fixed	source processor identifier
	1	32	PROCESS	variable	Task/Process ID tag
Program Trace - Direct Branch Message	6	6	TCODE	fixed	TCODE number = 3
	4	4	SRC	fixed	source processor identifier
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
Program Trace - Indirect Branch Message	6	6	TCODE	fixed	TCODE number = 4
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	U-ADDR	variable	unique part of target address for taken branches/ exceptions
Data Trace - Data Write Message	6	6	TCODE	fixed	TCODE number = 5
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to Table 17-7)
	1	32	U-ADDR	variable	unique portion of the data write address
	1	64	DATA	variable	data write value(s) (see Data Trace section for details)
Data Trace - Data Read Message	6	6	TCODE	fixed	TCODE number = 6
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to Table 17-7)

Table continues on the next page...

Table 17-2. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
	1	32	U-ADDR	variable	unique portion of the data read address
	1	64	DATA	variable	data read value(s) (see Data Trace section for details)
Data Acquisition Message	6	6	TCODE	fixed	TCODE number = 7
	4	4	SRC	fixed	source processor identifier
	8	8	DQTAG	fixed	identification tag taken from $DEVENT_{DQTAG}$ register field
	1	32	DQDATA	variable	exported data taken from DDAM register
Error Message	6	6	TCODE	fixed	TCODE number = 8
	4	4	SRC	fixed	source processor identifier
	4	4	ETYPE	fixed	error type
	8	8	ECODE	fixed	error code
Program Trace - Synchronization Message	6	6	TCODE	fixed	TCODE number = 9
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow. Cleared for most sync conditions.
	1	32	F-ADDR	variable	full target address (leading zero (0) truncated)
Program Trace - Direct Branch Message w/ Sync	6	6	TCODE	fixed	TCODE number = 11
	4	4	SRC	fixed	source processor identifier
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zeros truncated)
Program Trace - Indirect Branch Message w/Sync	6	6	TCODE	fixed	TCODE number = 12
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zeros truncated)
Data Trace - Data Write Message w/ Sync	6	6	TCODE	fixed	TCODE number = 13
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to Table 17-7)
	1	32	F-ADDR	variable	full access address (leading zeros truncated)
	1	64	DATA	variable	data write value(s) (see Data Trace section for details)
Data Trace -	6	6	TCODE	fixed	TCODE number = 14
	4	4	SRC	fixed	source processor identifier

Table continues on the next page...

Table 17-2. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Data Read Message w/ Sync	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to Table 17-7)
	1	32	F-ADDR	variable	full access address (leading zeros truncated)
	1	64	DATA	variable	data read value(s) (see Data Trace section for details)
Watchpoint Message	6	6	TCODE	fixed	TCODE number = 15
	4	4	SRC	fixed	source processor identifier
	1	32	WPHIT	variable	Field indicating watchpoint source(s) (leading zeros truncated)
Resource Full Message	6	6	TCODE	fixed	TCODE number = 27
	4	4	SRC	fixed	source processor identifier
	4	4	RCODE	fixed	resource code (Refer to Table 17-5) - indicates which resource is the cause of this message
	1	32	RDATA	variable	branch / predicate instruction history (See Section Resource Full Messages.)
Program Trace - Indirect Branch History Message	6	6	TCODE	fixed	TCODE number = 28 (see Note below)
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	U-ADDR	variable	unique part of target address for taken branches/ exceptions
	1	32	HIST	variable	branch / predicate instruction history (see Branch Trace Messaging types)
Program Trace - Indirect Branch History Message w/ Sync	6	6	TCODE	fixed	TCODE number = 29 (see Note below)
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zero (0) truncated)
	1	32	HIST	variable	branch / predicate instruction history (See Branch Trace Messaging types.)
Program Trace - Program Correlation Message	6	6	TCODE	fixed	TCODE number = 33
	4	4	SRC	fixed	source processor identifier
	4	4	EVCODE	fixed	event correlated w/ program flow (Refer to Table 17-6)
	2	2	CDF	fixed	# fields of information in CDATA. 00 - reserved, 01 - one field (CDATA1) (reserved), 10 - two fields (CDATA1 + CDATA2), 11 - three fields (reserved)

Table continues on the next page...

Table 17-2. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	CDATA1	variable	correlation data field 1 - [branch / predicate instruction history] (See Program Correlation Messages.)
	0	32	CDATA2	variable	correlation data field 2- PID info (See Program Correlation Messages.)

Note

Program Trace can be implemented using either Branch History/Predicate Instruction Messages, or traditional Direct/ Indirect Branch Messages. The user can select between the two types of Program Trace. The advantages for each are discussed in Branch Trace Messaging types. If the Branch History method is selected, the shaded TCODES above will not be messaged out.

Table 17-3 shows the error code encodings used when reporting an error via the Nexus 3 Error Message.

Table 17-3. Error Code (ECODE) Encoding (TCODE = 8)

Error Code	Description
xxxxxxx1	Watchpoint Trace Message(s) Lost
xxxxxx1x	Data Trace Message(s) Lost
xxxxx1xx	Program Trace Message(s) Lost
xxxx1xxx	Ownership Trace Message(s) Lost
xxx1xxxx	Status Message(s) Lost (Debug Status messages, etc.)
xx1xxxxx	Data Acquisition Message(s) Lost
x1xxxxxx	Reserved
1xxxxxxx	Reserved

Table 17-4 shows the error type encodings used when reporting an error via the Nexus 3 Error Message.

Table 17-4. Error Type (ETYPE) Encoding (TCODE = 8)

Error Type	Description
0000	Message Queue Overrun caused one or more messages to be lost

Table continues on the next page...

Table 17-4. Error Type (ETYPE) Encoding (TCODE = 8) (continued)

Error Type	Description
0001	Contention with higher priority messages caused one or more messages to be lost
0010	Reserved
0011	Reserved
0100	Reserved
0101	Invalid access opcode (Nexus Register unimplemented)
0110 - 1111	Reserved

Table 17-5 shows the encodings used for resource codes for certain messages.

Table 17-5. Resource Code (RCODE) values (TCODE = 27)

Resource Code	Description
0000	Program Trace Instruction counter reached 255 and was reset.
0001	Program Trace, Branch / Predicate Instruction History full. This type of packet is terminated by a stop bit set to 1 after the last history bit.

Table 17-6 shows the event code encodings used for certain messages.

Table 17-6. Event Code (EVCODE) Encoding (TCODE = 33)

Event Code	Description
0000	Entry into Debug Mode
0001	Entry into Low Power Mode (CPU only)
0010-0011	Reserved for future functionality
0100	Disabling Program Trace
0101	Process ID value is established in PID0/NPIDR via **mtspr PID0/NPIDR**
0110-1000	Reserved for future functionality
1001	Begin masking of program trace messages due to MSR_{PMM}=0 and $DC4_{PTMARK}$=1
1010	Branch and link occurrence (direct branch function call)
1011-1111	Reserved for future functionality

Table 17-7 shows the data trace size encodings used for certain messages.

Table 17-7. Data Trace Size (DSZ) Encodings (TCODE = 5,6,13,14)

DTM Size Encoding	Transfer Size
0000	0 - no data
0001	Byte
0010	Halfword (2 bytes)
0011	Three bytes
0100	Word (4 bytes)

Table continues on the next page...

Table 17-7. Data Trace Size (DSZ) Encodings (TCODE = 5,6,13,14) (continued)

DTM Size Encoding	Transfer Size
0101	Five bytes
0110	Six bytes
0111	Seven bytes
1000	Doubleword (8 bytes)
1001-1111	Reserved

17.4 Nexus 3 Programmer's Model

This section describes the Nexus 3 programmers model. Nexus 3 registers are accessed using the JTAG/OnCE port in compliance with IEEE 1149.1, or by software via DCRs. See Nexus 3 Register Access via JTAG/OnCE and Nexus 3 Register Access via Software for details on Nexus 3 register access.

Note

Nexus 3 registers and output signals are numbered using bit 0 as the least significant bit. This bit ordering is consistent with the ordering defined by the IEEE-ISTO 5001 standard.

The following table details the register map for the Nexus 3 module.

Table 17-8. Nexus 3 Register Map

Nexus Register	Nexus Access Opcode	Read/ Write	Read Address	Write Address	DCR #[1]
Client Select Control (CSC)[2]	0x1	R	0x02	-	
Port Configuration Register (PCR)[3]	PCR_INDEX[2]	R/W	-	-	
Development Control 1 (DC1)	0x2	R/W	0x04	0x05	368

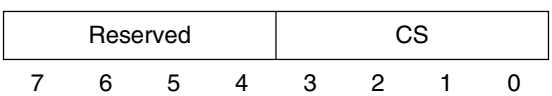
1. Software access via the **mfdcr** and **mtdcr** instructions use these values for the DCR number. Software writes to these registers via **mtdcr** when **nex_sfwcntl_en** is negated are ignored.
2. The CSC and PCR registers are shown in this table as part of the Nexus programmer's model. They are only present at the top level SoC Nexus controller in a multi-Nexus implementation, not in the Nexus 3 module. The SoC's CSC Register is readable through Nexus, but the PCR is shown for reference only here.
3. The "PCR_INDEX" is a parameter determined by the SoC.

17.4.1 Client Select Control (CSC) register

The CSC Register determines which Nexus client is under development. This register is present at the top-level SOC Nexus 3 controller to select one of multiple on-chip Nexus 3 units.



Nexus Reg# - 0x1; Read-only; Reset - 0x0

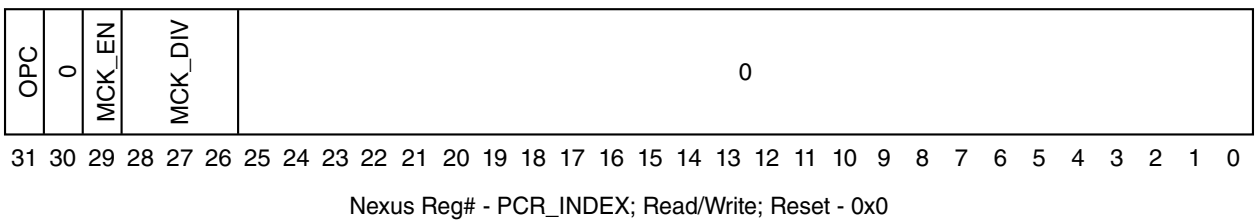
Figure 17-2. Client Select Control (CSC) register

Table 17-9. CSC field descriptions

Bits	Description
CSC[7:4]	Reserved for future Nexus Clients (read as 0)
CSC[3:0]	Client Select Control 0xx - Nexus client (SoC level)

17.4.2 Port Configuration Register (PCR) - reference only

The Port Configuration Register (PCR) controls the basic port functions for all Nexus modules in a multi-Nexus environment. This includes clock control and auxiliary port width. All bits in this register are writable only once after system reset.



Nexus Reg# - PCR_INDEX; Read/Write; Reset - 0x0

Figure 17-3. Port Configuration Register

Table 17-10. PCR field descriptions

Bit	Name	Description
31	OPC	Output Port Mode Control (SoC Level) 0 Reduced Port Mode configuration (min# **nex_mdo[n:0]** pins defined by SOC) 1 Full Port Mode configuration (max# **nex_mdo[n:0]** pins defined by SOC)

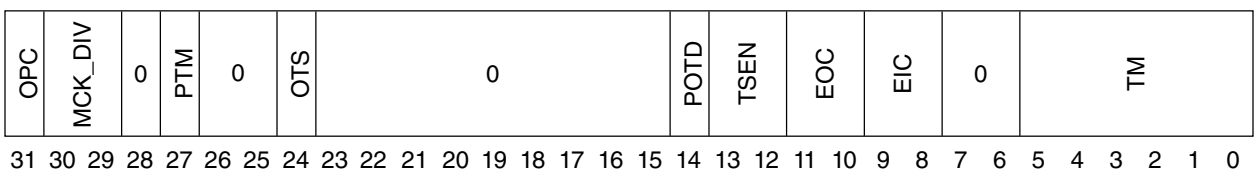
29	MCK_EN	MCKO Clock Enable (SoC Level) 0 **nex_mcko** is disabled 1 **nex_mcko** is enabled
28:26	MCK_DIV	MCKO Clock Divide Ratio (see note below) (SoC Level) 000 **nex_mcko** is 1x processor clock freq. 001 **nex_mcko** is 1/2x processor clock freq. 010 Reserved (default to 1/2x processor clock freq.) 011 **nex_mcko** is 1/4x processor clock freq. 100 Reserved (default to 1/2x processor clock freq.) 101 Reserved (default to 1/2x processor clock freq.) 110 Reserved (default to 1/2x processor clock freq.) 111 **nex_mcko** is 1/8x processor clock freq.
25:0	—	Reserved for future functionality

Note

The CSC and PCR Registers exist in a separate module at the SoC level in a multi-Nexus environment. If the core Nexus 3 module is the only Nexus module, these registers are not implemented and the Nexus 3 defined Development Control Register 1 (DC1) is used to control the SoC-level Nexus port functionality.

17.4.3 Nexus Development Control Register 1 (DC1)

Nexus Development Control Register 1 is used to control the basic development features of the Nexus 3 module. Development Control Register 1 is shown in Figure 17-4 and its fields are described in Table 17-11.



Nexus Reg# - 0x2; DCR - 368; Read/Write; Reset - 0x0

1. This field may be updated by hardware in response to watchpoint triggering if not already enable for tracing by a previous direct write to DC1. Direct writes to this field to enable one or more trace types take precedence over hardware updates. Refer to Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers for more information on watchpoint triggering.
1. This field may be updated by hardware in response to watchpoint triggering if not already enable for tracing by a previous direct write to DC1. Direct writes to this field to enable one or more trace types take precedence over hardware updates. Refer to Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers for more information on watchpoint triggering.
1. This field may be updated by hardware in response to watchpoint triggering if not already enable for tracing by a previous direct write to DC1. Direct writes to this field to enable one or more trace types take precedence over hardware updates. Refer to Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers for more information on watchpoint triggering.

Note

The Output Port Mode Control bit (OPC) and MCKO Clock Divide Ratio bits (MCK_DIV) MUST ONLY be modified during system reset or debug mode to insure correct output port and output clock functionality. It is also recommended that all other bits of the DC1 also only be modified in one of these two modes.

17.4.4 Nexus Development Control Registers 2 & 3 (DC2, DC3)

Nexus Development Control Registers 2 and 3 are used to control output signaling on the Nexus 3 module. A table of watchpoints can be found in the Core (e200z7260n3) Core Debug Support chapter.

Development Control Register 2 is shown in Figure 17-5 and its fields are described in Table 17-12.

1. Refer to Table 5 for implemented EVCODEs.

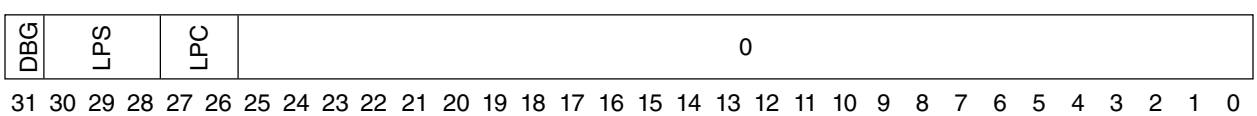
17.4.6 Development Status Register (DS)

The Development Status Register is used to report system debug status. When Debug Mode is entered or exited, or an SoC- or core-defined Low Power Mode is entered (see note below), a Debug Status Message is transmitted with DS[31:24]. The external tool can read this register at any time.



Nexus Reg# - 0x4; DCR - 409; Read-only; Reset - 0x0

25:0	—	Reserved for future functionality (read as 0)

17.4.7 Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers

The Watchpoint Trigger Registers allows the watchpoints defined within the Nexus1 logic to trigger actions. These watchpoints can control Program and/or Data Trace enable and disable. The control bits can be used to produce a related "window" for triggering Trace Messages. Watchpoint trigger register WT is used to control triggering by a single selected watchpoint. The Program Trace Start Trigger Control (PTSTC), Program Trace End Trigger Control (PTETC), Data Trace Start Trigger Control (DTSTC), and Data Trace End Trigger Control (DTETC) are used for extended trigger controls for the respective function. If multiple watchpoints are desired for triggering, or a watchpoint beyond watchpoint #13 is required, then one or more of the extended watchpoint trigger registers may be used. A field encoding of 4'b1111 in one of the WT register fields enables the corresponding extended trigger register. For all other WT field encodings, the corresponding extended trigger register is disabled and the contents are ignored. Note that direct writes to enable program trace and/or data trace in DC1 will override these controls, and trace will remain enabled until another direct write to DC1 to disable program and/or data trace occurs.

When a start trigger is detected, the designated trace features become enabled, and the corresponding enable bits of the DC1 register are set. Whenever a stop trigger is detected, the designated trace features become disabled, and the corresponding enable bits of the DC1 register are cleared. If the same trigger condition is used for both start and stop triggering, then the designated trace features will toggle between being enabled and disabled at each occurrence of the trigger condition. Similarly, if start and stop triggers

for a trace feature occur simultaneously, then the designated trace feature will toggle between enabled and disabled depending on the enable state at the time of the trigger events. For example, if tracing is enabled, and a start and stop trigger occur simultaneously, then tracing will be disabled. Direct writes of the DC1 register take precedence over any trace feature enable state that is derived from watchpoint triggering. A table of watchpoints can be found in the Core (e200z7260n3) Core Debug Support chapter.

17.4.10 Data Trace Control Register (DTC) register

The Data Trace Control Register controls whether DTM Messages are restricted to reads, writes, or both for a user programmable address range. In addition, control is provided to restrict data trace message generation to only those load or store accesses that are not stack-related, in order to minimize required data trace message bandwidth.

There are four Data Trace channels controlled by the DTC for the Nexus 3 module. Channels can be programmed to trace data accesses or instruction accesses, but not independently.

RWT1	RWT2	RWT3	RWT4	0	STDC1	STDC2	STDC3	STDC4	0	RC1	RC2	RC3	RC4	DI	0

Nexus Reg# - 0x15; DCR - 408; Read/Write; Reset - 0x0

Figure 17-25. Data Trace End Address 4 (DTEA4) register

Table 17-23 illustrates the range that will be selected for Data Trace for various cases of DTSA being less than, greater than, or equal to DTEA.

Table 17-23. Data trace - address range options

Programmed values	Range Control Bit Value	Range Selected	
DTSA < DTEA	0	DTSA ->	<- DTEA
DTSA < DTEA	1	<- DTSA	DTEA ->
DTSA > DTEA	N/A	Invalid Range - no trace	
DTSA = DTEA	N/A	Invalid Range - no trace	

Note

DTSA must be less than DTEA in order to guarantee correct Data Write/Read Traces. Data Trace ranges are *inclusive* of the DTSA and DTEA addresses for Range Control settings indicating "within range," and are *exclusive* of the DTSA and DTEA addresses for Range Control settings indicating "outside of range."

Accesses that meet the range and access type qualifiers will cause assertion of a watchpoint output for Ranges 1, 2, and 3. There are three dedicated watchpoint outputs, one for each DTSA/DTEA sets 1, 2, and 3. Range 4 does not provide a watchpoint output. Note that when DTC_{DI}=1, all instruction fetches and prefetches (including discarded prefetches) are monitored, and thus these range watchpoints differ from the IACx watchpoint outputs, which are not asserted for instructions that are not executed (i.e. when the instruction prefetch is discarded).

17.4.13 Read/Write Access Control/Status (RWCS) register

The Read Write Access Control/Status Register provides control for Read/Write Access. Read/Write access provides DMA-like access to memory-mapped resources on the AHB System bus either while the processor is halted, or during runtime. Control is provided over access type, size, count, and certain bus attributes.

Note that the internal CPU interfaces to the caches and local memory are not accessible or utilized by this mechanism. Since the external interface is used, base address port settings are used to access local memory, and not the settings of local memory control register base address values.

The RWCS Register also provides Read/Write Access Status information per Table 17-25.

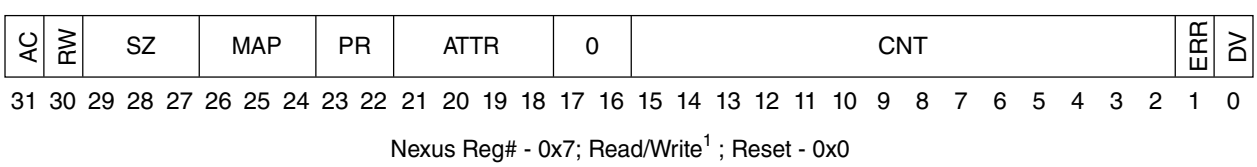

Figure 17-26. Read/Write Access Control/Status (RWCS) register

NOTES:

[1]ERR and DV are read-only

Table 17-24. RWCS field description

Bits	Name	Description
RWCS[31]	AC	Access Control 0 End access/ Access has completed 1 Start access
RWCS[30]	RW	Read/Write Select 0 Read access 1 Write access

RWCS[0]	DV[2]	Read/Write Access Data Valid (see Table 17-25)

1. The priority functionality is not currently implemented.
2. ERR and DV are read-only.

Table 17-25. Read/Write Access Status Bit Encoding

Read Action	Write Action	ERR	DV
Read Access has not completed	Write Access completed without error	0	0
Read Access error has occurred	Write Access error has occurred	1	0
Read Access completed without error	Write Access has not completed	0	1
Not Allowed	Not allowed	1	1

17.4.14 Read/Write Access Data (RWD) register

The Read/Write Access Data (RWD) register provides the data to/from system bus memory-mapped locations when initiating a read or a write access.

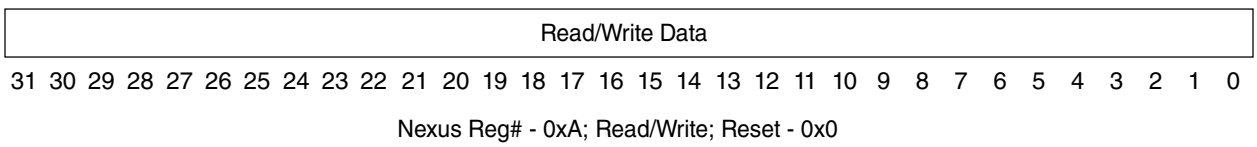

Figure 17-27. Read/Write Access Data (RWD) register

Read/Write accesses to the AHB require that the debug firmware properly retrieve/place the data in the RWD. Table 17-26 shows the proper placement of data into the RWD. Note that doubleword transfers require two passes through RWD.

Table 17-26. RWD data placement for ransfers

Transfer Size and byte offset	RWA(2:0)	RWCS[SZ]	RWD			
			31:24	23:16	15:8	7:0
Byte	x x x	0 0 0	-	-	-	X
Half	x x 0	0 0 1	-	-	X	X
Word	x 0 0	0 1 0	X	X	X	X
Doubleword	0 0 0	0 1 1				
first RWD pass (low order data)			X	X	X	X
second RWD pass (high order data)			X	X	X	X

Table Notes:

"X" indicates byte lanes with valid data

"-" indicates byte lanes that will contain unused data.

Table 17-27 shows the mapping of RWD bytes to byte lanes of the AHB read and write data buses.

Table 17-27. RWD byte lane mapping

Transfer Size and byte offset	RWA(2:0)	RWD

first RWD pass		AHB[31:24]	AHB[23:16]	AHB[15:8]	AHB[7:0]
second RWD pass		AHB[63:56]	AHB[55:48]	AHB[47:40]	AHB[39:32]

Table Notes:

"-" indicates byte lanes that will contain unused data.

17.4.15 Read/Write Access Address (RWA)

The Read/Write Access Address Register provides the system bus address to be accessed when initiating a read or a write access.

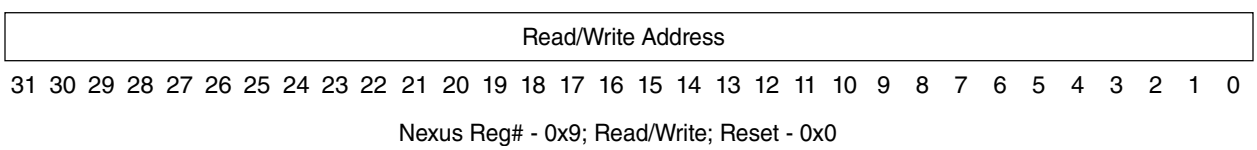

Figure 17-28. Read/Write Access Address (RWA) register

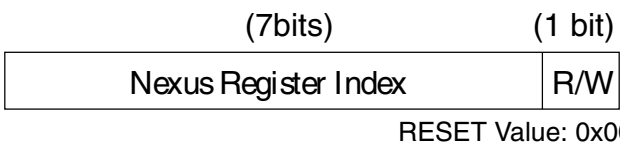
17.5 Nexus 3 Register Access via JTAG/OnCE

Access to Nexus 3 register resources is enabled by loading a single instruction ("*NEXUS3-ACCESS*") into the JTAG Instruction Register (IR) (OnCE OCMD register). For the Nexus 3 block, the OCMD value is 0b0001111100.

Once the NEXUS3-ACCESS instruction has been loaded, the JTAG/OnCE port allows tool/target communications with all Nexus 3 registers according to the register map in Table 17-8.

Reading/writing of a Nexus 3 register then requires two (2) passes through the Data-Scan (DR) path of the JTAG state machine. (See IEEE 1149.1 (JTAG) RD/WR sequences.)

1. The first pass through the DR selects the Nexus 3 register to be accessed by providing an index (see Table 17-8), and the direction (read/write). This is achieved by loading an 8-bit value into the JTAG Data Register (DR). This register has the following format:



Nexus Register Index	Selected from values in Table 17-8
Read/Write (R/W):	0 - Read 1 - Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.
   a. During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the "Capture-DR" state.
   b. During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the "Update-DR" state.

17.6 Nexus 3 Register Access via Software

Access to most Nexus 3 register resources by software is supported by mapping the Nexus 3 registers to privileged DCRs (device control registers) that are accessible via the **mfdcr** and **mtdcr** instructions. It is intended that these access only occur when no

possible conflicts with hardware-based accesses are possible. A conflict between hardware and software accesses will produce undefined results. Table 17-8 shows the mappings of Nexus 3 registers to DCR numbers. Software writes to Nexus 3 register resources are blocked when the **nex_sfwcntl_en** input signal is negated, without signaling an exception. Note that the Nexus 3 Read/Write Access functionality is not available to software, since software can use load and store instructions to access memory.

17.7 Nexus Message Fields

Nexus messages are comprised of fields. Each field contains a distinct piece of information within a message, and each message contains multiple fields. Messages are transferred in packets over the Auxiliary Output protocol. A packet is a collection of fields. A packet may contain any number of fixed length fields, but may contain at most one variable length field. The variable length field must be the last field in a packet. The following sub-sections describe a subset of the message field types.

17.7.1 TCODE Field

The TCODE field is a 6-bit fixed length field that identifies the type of message and its format. The field encodings are assigned by IEEE-ISTO 5001.

17.7.2 Source ID Field (SRC)

Each Nexus module in a device is identified by a unique Client Source Identification Number. The number assigned to each Nexus module is determined by the SoC integrator, and is provided on the **nex3_ext_src_id[0:3]** input signals. Multi-threaded processors may assign additional source ID information to indicate which thread a message is associated with. The Nexus 3 module implements a 4-bit fixed length Source ID field consisting of a Client Source ID.

17.7.3 Relative Address Field (U-ADDR)

The non-sync forms of the Program and Data Trace messages include addresses that are relative to the address that was transmitted in the previous Program or Data Trace message, respectively. The relative address format is compliant with IEEE-ISTO 5001 and is designed to reduce the number of bits transmitted for address fields.

The relative address is generated by XORing the new address with the previous, and then using only the results up to the most significant '1'. To recreate the original address, the relative address is XORed with the previously decoded address.

The relative address of a Program Trace message is calculated with respect to the previous Program Trace message, regardless of any address information that may have been sent in any other trace messages in the interim between the two Program Trace messages.

The relative address of a Data Trace message is calculated with respect to the previous Data Trace message, regardless of any address information that may have been sent in any other trace messages in the interim between the two Data Trace messages.

Program trace messages also provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

Previous Address (A1) =0x0003FC01, New Address (A2) = 0x0003F365

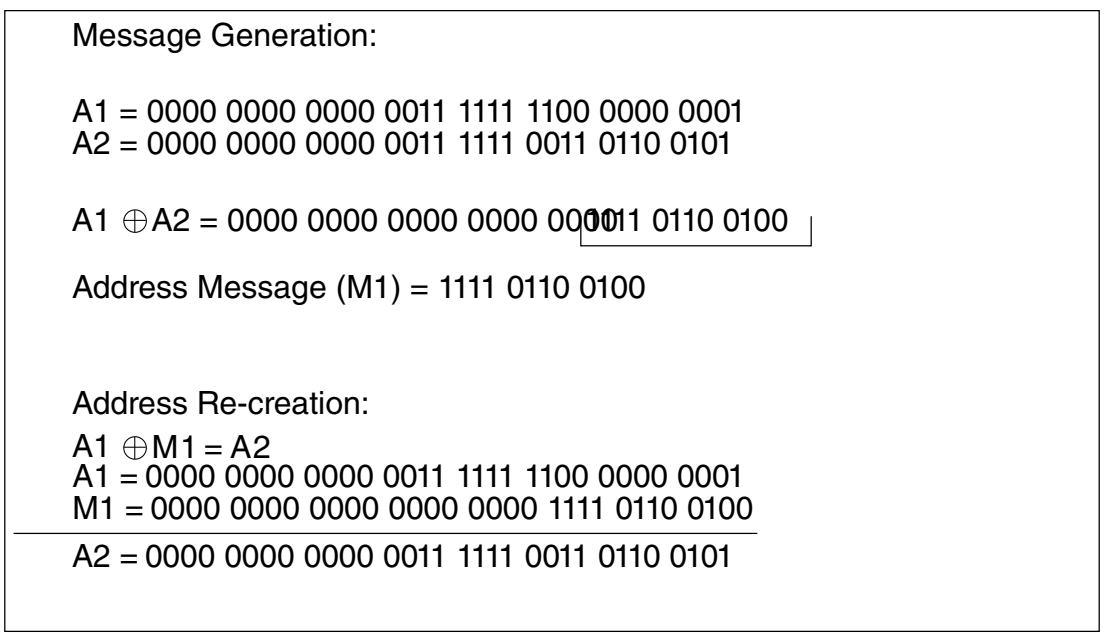


Figure 17-29. Relative address generation and recreation

17.7.4 Full Address Field (F-ADDR)

Program Trace synchronization messages provide the full address associated with the trace event (leading zeroes may be truncated) with the intent of providing a reference point for development tools to operate from when reconstructing relative addresses. Synchronization messages are generated at significant mode switches and are also generated periodically to ensure that development tools are guaranteed to have a reference address given a sufficiently large sample of trace messages. Program trace messages also provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

17.8 Nexus Message Queues

The Nexus 3 module implements internal message queues capable of storing up to three messages per cycle into a small initial queue, which then fills a larger queue at up to two messages per cycle. Messages that enter the queues are transmitted in the order in which they are received.

If more than three messages attempt to enter the queue in the same cycle, the highest priority messages are stored and the remaining message(s) will be dropped due to a collision. Collision events are expected to be rare.

The Overrun Control register (OVCR) controls the Nexus behavior as the message queue fills. The Nexus block may be programmed to:

- Allow the queue to overflow, drain the contents, queue an overrun error message and resume tracing.
- Stall the processor when the queue utilization reaches the selected threshold.
- Suppress selected message types when the queue utilization reaches the selected threshold.

17.8.1 Message Queue Overrun

In this mode, the message queue will stop accepting messages when an overrun condition is detected. The contents of the queues will be allowed to drain until empty. Incoming messages are discarded until the queue is emptied. Once empty, an overrun error message is enqueued that contains information about the types of messages that were discarded due to the overrun condition.

17.8.2 CPU Stall

In this mode, processor instruction issue is stalled when the queue utilization reaches the selected threshold. The processor is stalled long enough to drop one threshold level below the level that triggered the stall. For example, if stalling the processor is triggered at 1/4 full, the stall will stay in effect until the queue utilization drops to empty. There may be significant skid from the time that the stall request is made until the processor is able to stop completing instructions. This skid should be taken into consideration when programming the threshold. Refer to Nexus Overrun Control Register (OVCR) for complete programming options.

17.8.3 Message Suppression

In this mode, the message queue will disable selected message types when the queue utilization reaches the selected threshold. This allows lower bandwidth tracing to continue and possibly avoid an overrun condition. If an overrun condition occurs despite this message suppression, the queue will respond according to the behavior described in Message Queue Overrun. Suppressed message types are reported in the error message if they occur after overrun in addition to other discarded message types. Once triggered, message suppression will remain in effect until queue utilization drops to the threshold below the level selected to trigger suppression.

17.8.4 Nexus Message Priority

Nexus messages may be lost due to contention with other message types under the following circumstances:

- More than three messages are generated in the same cycle

Table 17-28 lists the various message types and their relative priority from highest to lowest.

Up to three message requests can be queued into the message buffer in a given cycle. If more than three message requests exist in a given cycle, the three highest priority message classes are queued into the message buffer. The remaining messages that did not successfully queue into the message buffer in that cycle will generate subsequent responses, as detailed in Table 17-28.

The CPU is capable of completing two instructions per cycle. If multiple trace messages need to be queued at the same time, they will be queued with the following priority: Instruction 0 (oldest instruction) (WPM ->DQM -> PCM_{PIDMSG} -> OTM -> BTM -> DTM)-> Instruction1 (newer instruction) (WPM -> DQM -> OTM -> BTM -> DTM). As many as three messages may be simultaneously queued. Note that for the cycle following a dropped PTM, non-periodic OTM, or DQM message, only two other messages may be queued in addition to the dropped Error Message.

Watchpoint Messages from instructions that complete at the same time or events that occur during the same cycle will be combined.

Table 17-28. Message Type Priority and Message Dropped Responses

Message Type	Message	Priority	Message Dropped Response
Error	Error	0 (highest)	N/A[1]
WP (Watchpoint Trace)	WPM (Watchpoint Message)	1	N/A[1]
DQ (Data Acquisition)	DQM (Data Acquisition Message)	2	DQM Error Message
Program Trace (PID MSG)	PCM - PID/NPIDR update (Program Correlation Message)	2	OTM Error Message
OT (Ownership)	OTM - PID/NPIDR update (Ownership Trace Message)	2	OTM Error Message[2]
Program Trace	BTM (Branch Trace Message)	2	BTM Error Message, Sync upgrade next BTM
	Sync (Program Sync Message)	3	Sync upgrade next BTM
	RFM (Resource Full for Instruction counter or history buffer)	4	BTM Error Message Sync upgrade next BTM
	DS (Debug Status Message)	5	Sync upgrade next BTM
	PCM (Program Correlation Message)	6	BTM Error Message Sync upgrade next BTM
DT (Data Trace)	DTM (Data Trace Message)	7	Sync upgrade next DTM

Table continues on the next page...

Table 17-28. Message Type Priority and Message Dropped Responses (continued)

Message Type	Message	Priority	Message Dropped Response
OT (Ownership)	OTM - Periodic update (Ownership Trace Message)	8 (lowest)	none

1. Error and Watchpoint messages are not dropped due to collisions, due to their priority.
2. Message will always be dropped if program trace is enabled, and program correlation messages for PID messages are not masked (Event Code = 0101). No error message is sent for this case since the PID value is contained in the higher priority message.

17.8.5 Data Acquisition Message Priority Loss Response

If a Data Acquisition Message (DQM) loses arbitration due to contention with higher priority messages, an error message will be generated to indicate that a DQM has been lost due to contention.

17.8.6 Ownership Trace Message Priority Loss Response

If an Ownership Trace message (OTM) due to software updates to the Process ID state loses arbitration due to contention with higher priority messages other than a program correlation message with EVCODE = 0101 (PID update), an error message will be generated to indicate that a OTM has been lost due to contention. If the pending OTM is a periodic update, the event is dropped without generating an error message.

17.8.7 Program Trace Message Priority Loss Response

If a Program Trace message (PTM) loses arbitration due to contention with higher priority messages, and the discarded PTM is a Program Correlation message, a Resource Full message for instruction count or history buffer, or a Branch Trace message, then an Error message is generated to indicate that branch trace information has been lost, and the next Branch Trace message will be upgraded to a sync-type message.

If the discarded PTM is a Program Correlation message with PID information (EVCODE=0101), the Error message will indicate a dropped OTM and a dropped Program Trace (Error code = xxxx11xx).

17.8.8 Program Trace Sync Message Priority Loss Response

If a Program Trace Sync message (SYNC) loses arbitration due to contention with higher priority messages, the Sync event is discarded, and the next Branch Trace message will be upgraded to a sync-type message.

17.8.9 Data Trace Message Priority Loss Response

If a Data Trace message (DTM) loses arbitration due to contention with higher priority messages, the DTM event is discarded, and the next DTM will be upgraded to a sync-type message.

17.9 Debug Status messages

Debug Status Messages report low power mode and debug status. Debug Status messages are enabled when Nexus 3 is enabled. Entering/exiting Debug Mode as well as entering, exiting, or changing Low Power Mode(s) will trigger a Debug Status message, indicating the value of the most significant byte in the Development Status register. Debug status information is sent out in the following format:

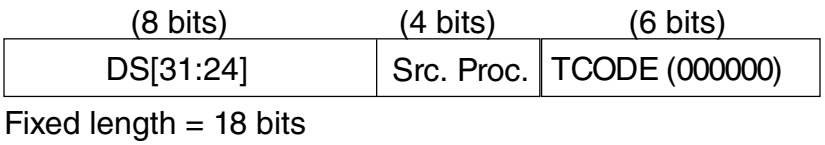

Figure 17-30. Debug Status message format

17.10 Error messages

Error messages are enabled whenever the debug logic is enabled. There are two conditions that will produce an error message, each receiving a separate error type designation:

- A message is discarded due to contention with other (higher priority) message types. These errors will have an Error Type value of 1.
- The message queue overruns. After the queue is drained, an error message is enqueued with an error code that indicates what types of messages were discarded during the interim. These errors will have an Error Type value of 0.

Note

The OVCR Register can be used in order to alleviate potential overrun situations.

Error information is messaged out in the following format (also see Table 17-3 and Table 17-4):

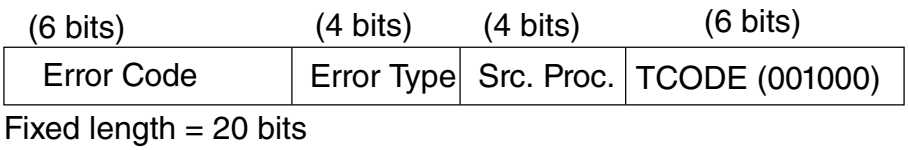

Figure 17-31. Error message format

17.11 Ownership trace

This section details the ownership trace features of the Nexus 3 module.

17.11.1 Overview

Ownership trace provides a macroscopic view, such as task flow reconstruction, when debugging software written in a high level (or object-oriented) language. It offers the highest level of abstraction for tracking operating system software execution. This is especially useful when the developer is not interested in debugging at lower levels.

17.11.2 Ownership Trace Messaging (OTM)

Ownership trace information is messaged via the auxiliary port using an Ownership Trace Message (OTM). Core (e200z7260n3) processors contain a Power ISA 2.06 defined "Process ID" register within the CPU. It is updated by the operating system software to provide task/process ID information. The contents of this register are replicated on the pins of the processor and connected to Nexus. The Process ID (PID) register value can be accessed using the **mfspr/mtspr** instructions.

Note

The CPU includes a Process ID register (PID0), thus the Nexus UBA functionality is not implemented.

In addition, to decouple trace information from the PID0 register and to provide a full independent 32-bit process ID for debug use, the Nexus PID Register (NPIDR) may be used instead of PID0 to provide OTM process ID information. It is updated by the operating system software to provide task/process ID information. The Nexus Process ID (NPIDR) register value can be accessed using the **mfspr/mtspr** instructions. This register is accessible in user or supervisor mode.

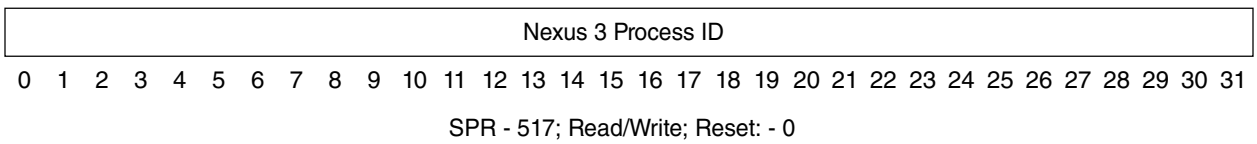

Figure 17-32. Nexus 3 Process ID Register (NPIDR)

Note

OS updates to NPIDR should be performed in addition to normal PID0 updates when a process switch occurs, in order to properly generate OTM messages with new process ID information when NPIDR is selected for OTM use.

The process ID source (PID0 or NPIDR) is selected by the setting of the $DC1_{OTS}$ control bit.

There are two conditions that will cause an Ownership Trace Message when Ownership Trace is enabled:

- When the PID0 register is written to by the processor and $DC1_{OTS}$ indicates PID0 should be used, or when the NPIDR register is written to by the processor and $DC1_{OTS}$ indicates NPIDR should be used, the data is latched within Nexus, and is messaged out via the auxiliary port, allowing development tools to trace ownership flow. However, if Program Trace is enabled, and program correlation messages for PID updates are not masked (Event Code = 0101), then an OTM will not be generated for an update to the selected process ID register, since the program correlation message will provide this process ID update information.
- Periodically, at least once every 256 messages, the most recent state of the selected process ID register is messaged out. The resulting Ownership Trace message will indicate in the PID Index sub-field that PID0/NPIDR status is being reported and the most recent value of the PID0/NPIDR register will be conveyed in the Process ID value sub-field. These periodic Ownership Trace message events can be disabled by setting $DC1_{POTD}$.

Ownership trace information is messaged out in the following format:

(1-32 bits)	(4 bits)	(4 bits)	(6 bits)
Process ID	PID Index (0000)	Src. Proc.	TCODE (000010)

Variable length = 15-46 bits

Figure 17-33. Ownership Trace Message format

17.12 Program trace

This section details the program trace mechanism supported by Nexus3 for the e200z7260n3 processor. Program trace is implemented via Branch Trace Messaging (BTM) as per the **IEEE-ISTO 5001** standard definition. Branch Trace Messaging for Core (e200z7260n3) processors is accomplished by snooping the internal address bus (between the CPU and Cache), attribute signals, and CPU Status (**p_mode[0:3]**, **p_pstat_pipe{0,1}[0:5]**).

17.12.1 Branch Trace Messaging types

Traditional Branch Trace Messaging facilitates program trace by providing the following types of information:

- Messaging for taken direct branches includes how many sequential instructions were executed since the last taken branch or exception, including the taken direct branch. Branch instructions are included in the count of sequential instructions.
- Messaging for taken indirect branches and exceptions includes how many sequential instructions were executed since the last taken branch or exception and the unique portion of the branch target address or exception vector address. Branch instructions are included in the count of sequential instructions. For taken indirect branches that trigger generation of a message, the branch is also included in the count.

Branch History Messaging facilitates program trace by providing the following information.

- Messaging for taken indirect branches and exceptions includes a) how many sequential instructions (I-CNT) were executed since the last predicate instruction, taken/not taken direct branch, taken/not-taken indirect branch, or exception, b) the unique portion of the branch target address or exception vector address, and c) a branch/predicate instruction history field. Each bit in the history field represents a direct branch or predicated instruction where a value of one (1) indicates taken, and a value of zero (0) indicates not taken. Not-taken indirect branches will generate a

history bit with a value of zero (0). Instructions that generate history bits are not included in instruction counts. For taken indirect branches that trigger generation of this message type, the branch is included in the count, but not in the history field.

17.12.1.1 Indirect Branch Message instructions

Table 17-29 shows the types of instructions and events that cause Indirect Branch Messages or Branch History Messages to be encoded.

Table 17-29. Indirect Branch Message sources

Source of Indirect Branch Message	Instructions / Detail
Taken branch relative to a register value	**bcctr, bcctrl, bclr, bclrl, se_bctr, se_bctrl, se_blr, se_blrl**
System Call / Trap exceptions taken	**se_sc, tw**
Return from interrupts / exceptions	**se_rfi, se_rfci, se_rfdi**
Exit from reset with Program Trace Enabled	**Indirect branch with Sync, target address is initial instruction, count = 1**

17.12.1.2 Direct Branch Message Instructions

Table 17-30 shows the types of instructions that will cause Direct Branch Messages or will toggle a bit in the instruction history buffer to be messaged out in a Resource Full Message or Branch History Message.

Table 17-30. Direct Branch Message sources

Source of Direct Branch Message	Instructions
Taken direct branch instructions Instruction Synchronize	**b, ba, bl, bla, bc, bca, bcl, bcla, se_b. se_bc, se_bl, e_b, e_bc, e_bl, e_bcl, se_isync**

17.12.1.3 BTM using Branch History Messages

Traditional BTM Messaging can accurately track the number of sequential instructions between branches, but cannot accurately indicate which instructions were conditionally executed, and which were not.

Branch History Messaging solves this problem by providing a predicated instruction history field in each Indirect Branch Message. Each bit in the history represents a predicated instruction or direct branch, or a not-taken indirect branch. A value of one (1)

indicates the conditional instruction was executed or the direct branch was taken. A value of zero (0) indicates the conditional instruction was not executed or the branch was not taken.

Branch History Messages solve predicated instruction tracking and save bandwidth since only indirect branches cause messages to be queued.

17.12.1.4 BTM using Traditional Program Trace Messages

Based on the PTM bit in the DC1 Register, Program Tracing can utilize either Branch History Messages (PTM = 1) or traditional Direct/Indirect Branch Messages (PTM = 0).

Branch History will save bandwidth and keep consistency between methods of Program Trace, yet may lose temporal order between BTM messages and other types of messages. Since direct branches are not messaged, but are instead included in the history field of the Indirect Branch History Message, other types of messages may enter the FIFO between Branch History Messages. The development tool cannot determine the ordering of "events" that occurred with respect to direct branches simply by the order in which messages are sent out.

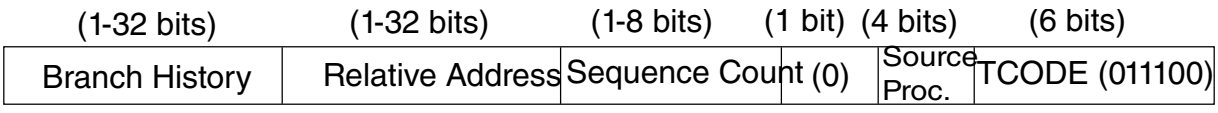
Traditional BTM messages maintain their temporal ordering because each event that can cause a message to be queued will enter the FIFO in the order it occurred and will be messaged out maintaining that order.

17.12.2 BTM Message For mats

The Nexus 3 block supports three types of traditional BTM Messages - Direct, Indirect, and Synchronization Messages. It supports two types of branch history BTM Messages - Indirect Branch History, and Indirect Branch History with Synchronization Messages.

17.12.2.1 Indirect branch messages (history)

Indirect branches include all taken branches whose destination is determined at run time, interrupts, and exceptions. If $DC1_{PTM}$ is set to '1', indirect branch information is messaged out in the following format:

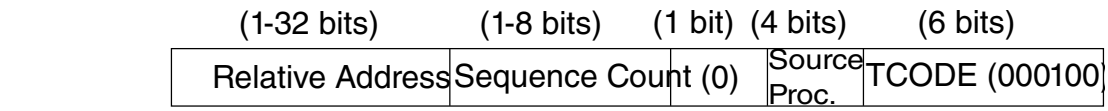


Max length = 83 bits; Min length = 14 bits

Figure 17-34. Indirect branch message (history) format

17.12.2.2 Indirect branch messages (traditional)

If $DC1_{PTM}$ is cleared to '0', indirect branch information is messaged out in the following format:

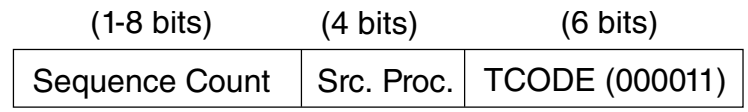


Max length = 51 bits; Min length = 13 bits

Figure 17-35. Indirect branch message format

17.12.2.3 Direct branch messages (traditional)

Direct branches (conditional or unconditional) are all taken branches whose destination is fixed in the instruction opcode. Direct branch information is messaged out in the following format:



Max length = 18 bits; Min length = 11bits

Figure 17-36. Direct Branch message format

Note

When $DC1_{PTM}$ is set, Direct Branch Messages will not be transmitted. Instead, each direct branch, not-taken indirect branch, or predicated instruction will be recorded in the history buffer.

17.12.3 Program Trace Message Fields

The following subsections describe specific fields used for Program Trace messages.

17.12.3.1 Sequential Instruction Count Field (ICNT)

Most of the program trace messages include an instruction count field. For traditional Branch messages, ICNT represents the number of sequential instructions including non-taken branches since the last Direct/Indirect Branch messages. Branch instructions that trigger message generation are included in the ICNT.

For Branch History messages, ICNT represents the number of instructions executed since the last taken/non-taken direct branch, predicate instruction, last taken/not-taken indirect branch, or exception. Branch instructions that trigger message generation are included in the ICNT. Instructions that generate history bits are not included in the ICNT.

The sequential instruction counter overflows after its value reaches 255 and is reset to 0. In addition, the next BTM Message (corresponding to the 256th or later instruction) will be converted to a w/sync type message.

The instruction counter is reset every time the instruction count is transmitted in a message or whenever there is a branch/predicate history event, as well as on exiting from debug mode.

17.12.3.2 Branch/Predicate Instruction History (HIST)

If $DC1_{PTM}$ is set, BTM messaging will use the Branch History format. The branch history (HIST) field in these messages provides a history of branch execution used for reconstructing the program flow. The branch/predicate history buffer stores information about branch and predicate instruction execution. The buffer is implemented as a left-shifting register. The buffer is preloaded with a one (1), which acts as a stop bit (the most significant 1 in the history field is a termination bit for the field). The pre-loaded bit itself is not part of the history, but is transmitted with the packet.

A value of one (1) is shifted into the history buffer for each taken direct branch (program counter relative branch) or predicate instruction whose condition evaluates to true. A value of zero (0) is shifted into the history buffer for each not-taken branch (including indirect branch instructions) or predicate instruction whose condition evaluates to false.

This history buffer information is transmitted as part of an Indirect Branch with History message, as part of a Program Correlation message, or as part of a Resource Full message if the history buffer becomes full. The history buffer is reset every time the history information is transmitted in a message, as well as on exiting from debug mode.

Table 17-31. Branch/Predicate history events

Branch/Predicate History Event	History Bit(s)	Relevant Instructions
Not taken register indirect branches	0	**bcctr, bcctrl, bclr, bclrl**

Table continues on the next page...

Table 17-31. Branch/Predicate history events (continued)

Branch/Predicate History Event	History Bit(s)	Relevant Instructions
Not taken direct branches	0	**b, ba, bc, bca, bla, bcla, bl, bcl**
Taken direct branches	1	**b, ba, bc, bca, bla, bcla, bl, bcl**[1]

1. If the EVCODE for direct branch function calls is not masked in DC4, taken **bl** and **bcl** instructions will generate Program Correlation Messages and will not be logged in the history buffer.1

17.12.3.3 Execution Mode Indication

In order for a development tool to properly interpret instruction count and history information, it must be aware of the execution mode context of that information. VLE instructions will be interpreted differently from non-VLE instructions.

Program trace messages provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

17.12.4 Resource Full Messages

The Resource Full Message is used in conjunction with Branch Trace and Branch History Messages. The Resource Full Message is generated when either the internal branch/ predicate history buffer is full, or if the BTM Instruction sequence counter (I-CNT) overflows. If synchronization is needed at the time this message is generated, the synchronization is delayed until the next Branch Trace Message that is not a Resource Full Message.

For history buffer overflow, the Resource Full Message transmits a Resource Code (RCODE) of 0b0001 and the current contents of the history buffer, including the stop bit, are transmitted in the Resource Data (RDATA) field. This history information can be concatenated by the development tool with the branch/predicate history information from subsequent messages to obtain the complete branch/predicate history between indirect changes of flow.

For instruction counter overflow, the Resource Full Message transmits an RCODE of 0b0000 and a value of 0xFF is transmitted in the RDATA field, indicating that 255 sequential instructions have been executed since the last change of flow, or, if program trace is in history mode, since the last instruction that recorded history information.

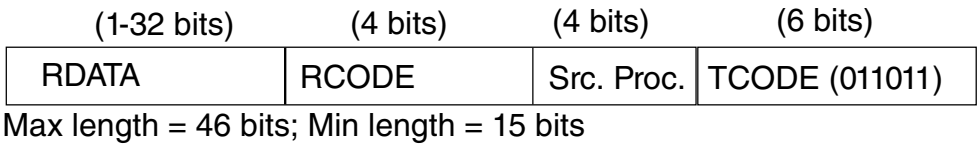


Figure 17-37. Resource Full Message format

The following table shows the RCODE encodings and RDATA information used for Resource Full Messages.

Table 17-32. RCODE encoding

RCODE	Description	RDATA field
0000	Program Trace Instruction counter reached 255 and was reset.	0xFF
0001	Program Trace, Branch / Predicate Instruction History full.	Branch HIstory. This type of packet is terminated by a stop bit set to 1 after the last history bit.

17.12.5 Program Correlation Messages

Program Correlation Messages (PCMs) are used to correlate events to the program flow that may or may not be associated with the instruction stream. The following events will result in a PCM when program trace is enabled:

- When the CPU enters debug mode, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to debug mode entry.
- When the CPU first enters a low power mode in which instructions are no longer executed, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to low power mode entry.
- Whenever program trace is disabled by any means, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to disabling program trace.
- When a "Branch and Link" instruction executes (direct branch function call — **bl/bcl/bla/bcla**-type instructions)
- When program trace becomes masked due to MSR_{PMM}='0' and $DC4_{PTMARK}$='1'.
- When a write to the process ID register selected by $DC1_{OTS}$ (PID0 or NPIDR) is made via a **mtspr** PID0 or **mtspr** NPIDR.

Refer to Table 17-6 for the event codes that are supported in this implementation. Event code masking is available via the EVCDM field of the DC4 register to allow for control over generation of Program Correlation messages for each event type.

Program Correlation is messaged out in the following formats:

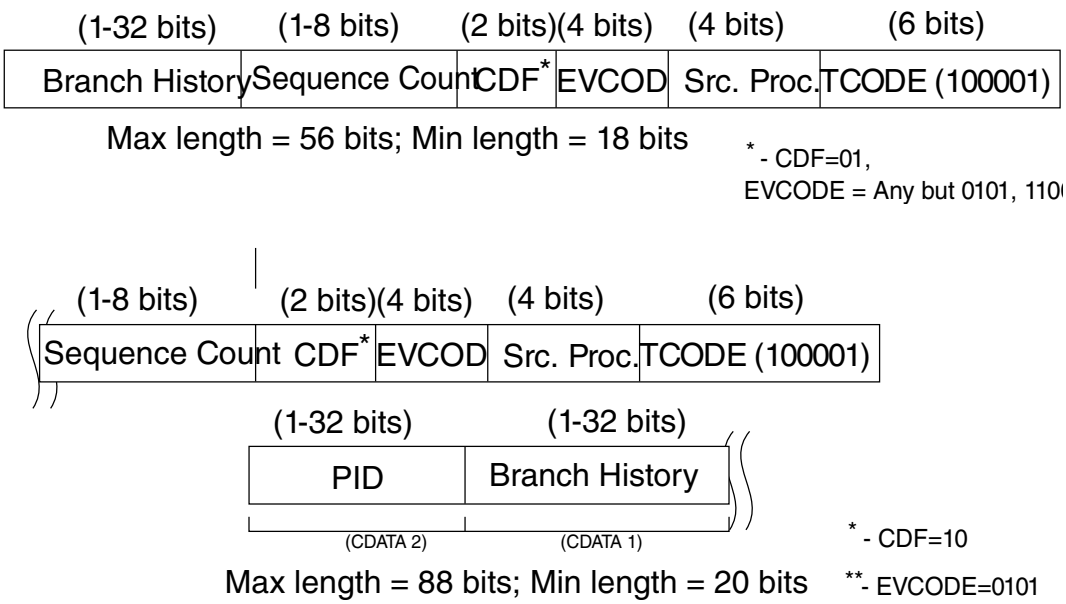

Figure 17-38. Program Correlation message formats

17.12.5.1 Program Correlation message generation for PID updates

When a (potentially) new value is established in the selected process ID register via a **mtspr** PID0/NPIDR, a Program Correlation message is generated containing the information regarding the new process ID value. This PCM also contains the current history and instruction count. The message is provided so that address translation information can be processed by the development tool in the proper program flow. The **mtspr** PID0/NPIDR is included in the instruction count information. Note that Ownership Trace Messages (other than the periodic OTM) are redundant with the information provided, and may be disabled to avoid unnecessary message bandwidth or collisions.

17.12.6 Program Trace Overflow Error messages

An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard incoming messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied.

17.12.7 Program Trace Synchronization messages

By default, program trace messages will perform XOR compression on the branch target address to produce the address field for the message. This compression is consistent with the specification in IEEE-ISTO 5001.

Under some conditions an uncompressed address is sent to provide development tools with a baseline reference address. A Program Trace Synchronization message is messaged via the auxiliary port (provided Program Trace is enabled) for the following conditions (see Table 17-33):

- Initial Program Trace message after exit from system reset or whenever program trace is enabled.
- Upon exiting from a CPU Low Power state.
- Upon exiting from Debug Mode.
- Upon occurrence of queue overrun (can be caused by any trace message), provided Program Trace is enabled.
- Upon assertion of the Event In (**nex_evti_b**) pin if the EIC bits within the DC1 Register have enabled this feature.
- When program trace becomes unmasked due to $MSR_{PMM} \rightarrow$ '1' with $DC4_{PTMARK}$='1'.

Note that the ICNT information for these messages is driven to zero, thus will not always be meaningful for some of these cases.

The format for Program Trace Synchronization messages is as follows:

(1-32 bits)	(1-8 bits)	(1 bit)	(4 bits)	(6 bits)
Full Target Address	Seq. Count (0)	(0)	Source Proc.	TCODE (001001)

Max length = 51 bits; Min length = 13 bits

Exception conditions that result in Program Trace Synchronization are summarized in Table 17-33.

Table 17-33. Program Trace exception summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (**j_trst_b**), queue pointers, counters, state machines, and registers within the Nexus 3 module are reset. Upon exiting system reset (**p_reset_b**), if Program Trace is already enabled, a Program Trace Sync Message is sent.
Program Trace Enabled	The first Program Trace Message (after Program Trace has been enabled or re-enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a Low Power mode or Debug mode, a Program Trace Sync Message is sent.
Queue Overrun	An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied. The next BTM message in the queue will be a Program Trace Sync Message.
Event In	If the Nexus module is enabled, a **nex_evti_b** assertion initiates a Program Trace Sync Message if Program Trace is enabled and the EIC bits of the DC1 Register have enabled this feature.

Note that for cases where program trace sync messages are generated due to program trace being enabled, the address contained in the sync message may either be the address of the instruction that caused program trace to be enabled, or may be the address of the first instruction of an exception handler that is executed in response to unsuccessful completion of that instruction.

17.12.8 Program Trace Direct/Indirect Branch with Sync messages

Under some conditions an uncompressed address is sent to provide development tools with a baseline reference address. A Program Trace Synchronization or a Direct/Indirect Branch with Sync message is messaged via the auxiliary port (provided Program Trace is enabled) for the following conditions (see Table 17-33):

- Upon direct/indirect branch after a Program Sync Message was lost due to a collision while attempting to enter the message queue.
- Upon direct/indirect branch after the sequential instruction counter has expired indicating 255 instructions have occurred since the last change of flow.
- When the periodic program trace counter has expired indicating 255 *without-sync* Program Trace messages have occurred since the last *with-sync* message occurred.

Note that the ICNT and History information for the first message will not always be meaningful, since the temporary masking of program trace may result in ambiguous values. Subsequent w/sync messages will not have this issue.

The format for Program Trace Direct/Indirect Branch with Sync Messages is as follows:

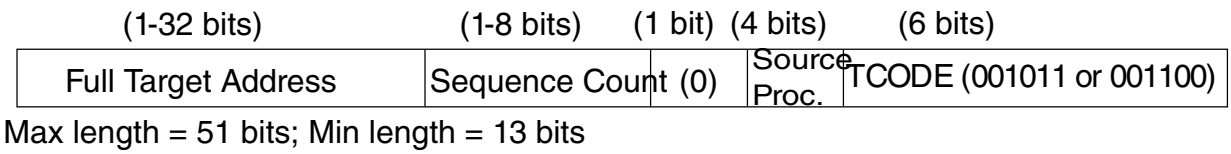

Figure 17-39. Direct/Indirect Branch with Sync message format

The format for Program Trace Indirect Branch History with Sync. messages is as follows:

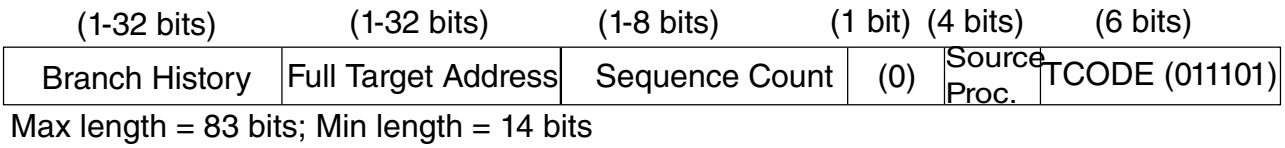

Figure 17-40. Indirect Branch History w/ Sync. message format

Exception conditions that result in Program Trace Synchronization using a w/Sync message type are summarized in Table 17-34.

Table 17-34. Program Trace Exception Summary for w/Sync BTM messages

Exception Condition	Exception Handling
Periodic Program Trace Sync.	A forced synchronization occurs periodically after 255 non-sync Program Trace Messages have been queued. A Direct/Indirect Branch w/ Sync. Message is queued. The periodic program trace message counter then resets.
Sequential Instruction Count Overflow	After the sequential instruction counter reaches its maximum count (up to 255 sequential instructions may be executed), a forced synchronization occurs. The sequential counter then resets. A Program Trace Direct/Indirect Branch w/ Sync.Message is queued upon execution of the next branch. A Resource Full Message is Queued on the overflow event. If a branch instruction is the 255th instruction to occur, and causes a Program Trace message to be queued, then no Resource Full Message is queued, and the w/Sync message will be queued for the *next* Program Trace Direct/Indirect Branch Message.
Collision Priority	All Messages have the following priority: Instruction 0 (WPM -> DQM -> PCM_{PIDMSG} → OTM → BTM → DTM) → Instruction1 (WPM → DQM → OTM → BTM → DTM), where instruction0 is the oldest instruction. A BTM Message from Instruction1 that attempts to enter the queue at the same time as three higher priority messages from either instruction will be lost. An Error Message will be sent indicating the BTM was lost. The following direct/indirect branch will queue a Direct/Indirect Branch w/ Sync. Message. The count value within this message will reflect the number of sequential instructions executed after the last successful BTM Message was generated. This count will include the branch that did not generate a message due to the collision.

17.12.9 Enabling Program Trace

Program Trace Messaging can be enabled in one of three ways:

- Setting the TM field of the DC1 Register to enable Program Trace
- Using the PTS field of the WT Register to enable Program Trace on Watchpoint hits (watchpoints are configured within the CPU)
- Filtering of Program Trace messages may be performed using the MSR_{PMM} bit and the setting of $DC4_{PTMARK}$

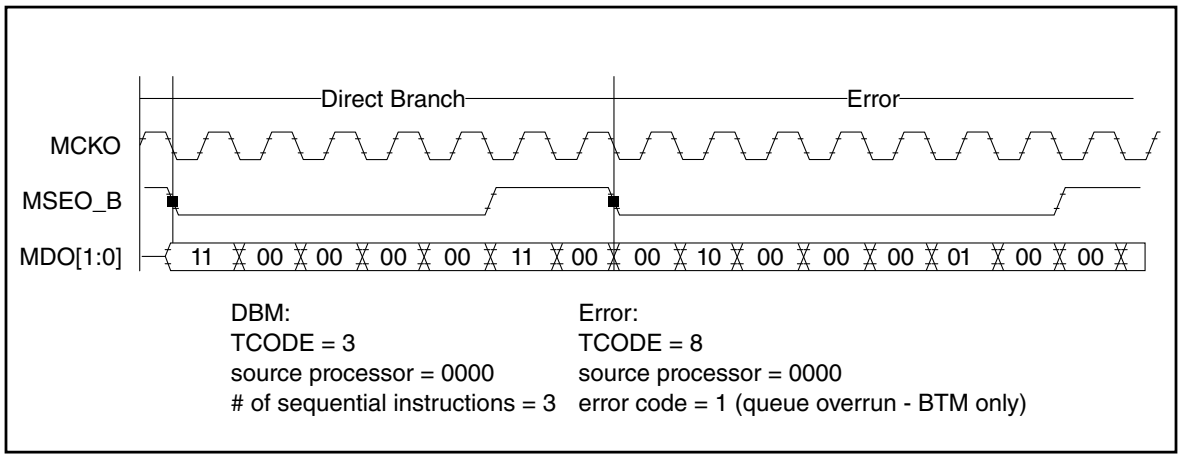

Figure 17-43. Program Trace - Direct Branch (traditional) & Error messages

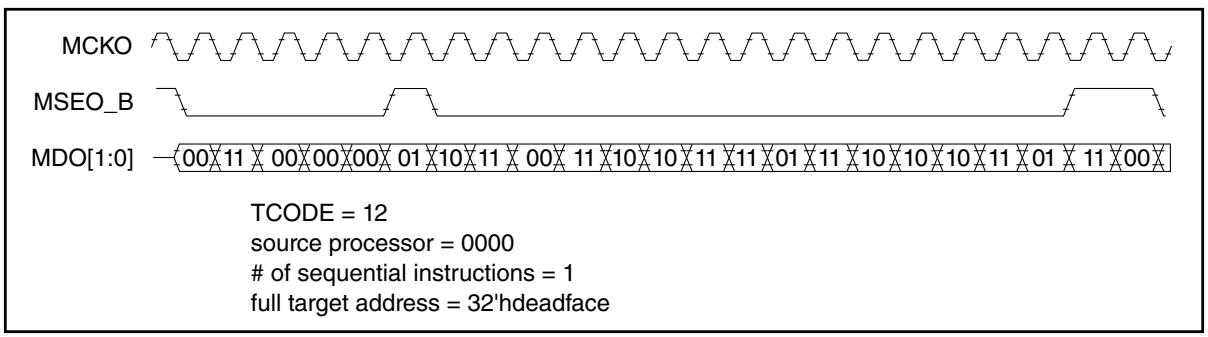

Figure 17-44. Program Trace - Indirect Branch w/ Sync. message

17.13 Data Trace

This section deals with the Data Trace mechanism supported by the Nexus 3 module. Data Trace is implemented via Data Write Messaging (DWM) and Data Read Messaging (DRM), as per the **IEEE-ISTO 5001** standard.

17.13.1 Data Trace Messaging (DTM)

Data Trace Messaging is accomplished by snooping the internal address and data buses, and storing the information for qualifying accesses (based on enabled features and matching target addresses). The Nexus 3 module traces all data access that meet the selected range and attributes.

Note

Data Trace is only performed on the internal data buses. This allows for data visibility for Core (e200z7260n3) processors that incorporate a data cache. Only CPU initiated accesses will be traced. No DMA accesses to the AHB system bus will be traced.

Data Trace Messaging can be enabled in one of three ways.

- Setting the TM field of the DC1 Register to enable Data Trace.
- Using the DTS field of the WT Register to enable Data Trace on Watchpoint hits (watchpoints are configured within the Nexus1 module).

17.13.2 DTM Message formats

The Nexus 3 block supports five types of DTM Messages — Data Write, Data Read, Data Write Synchronization, Data Read Synchronization and Error Messages.

17.13.2.1 Data Write messages

The Data Write message contains the data write value and the address of the write access, relative to the previous Data Trace Message. Data Write message information is messaged out in the following format:

(1-64 bits)	(1-32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value(s)*	Relative Address	Data Size	(0)	Src. Proc	TCODE (000101)

Max length = 111 bits; Min length = 17 bits

Figure 17-45. Data Write message format

17.13.2.2 Data Read messages

The Data Read message contains the data read value and the address of the read access, relative to the previous Data Trace message. Data Read message information is messaged out in the following format:

(1-64 bits)	(1-32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value(s)*	Relative Address	Data Size	(0)	Src. Proc	TCODE (000110)

Max length = 111 bits; Min length = 17 bits

Figure 17-46. Data Read fessage format

Note

* Core (e200z7260n3)-based CPUs are capable of generating two (2) reads or writes per clock cycle in cases where multiple registers are accessed with a single instruction (lmw/stmw). These will have a double word pair size encoding (**p_tsiz** = 0b000). In these cases, the Nexus 3 module will send one (1) Data Trace Message with the two 32-bit data values as one combined 64-bit value for each message.

For Core (e200z7260n3)-based CPUs, the doubleword encoding (**p_tsiz** = 0b000) may also indicate a doubleword access and will be sent out as a single Data Trace Message with a single 64-bit data value.

The debug/development tool will need to distinguish the two cases based on the family of processor.

17.13.2.3 Data Trace Synchronization messages

A Data Trace Write/Read with Sync. message is messaged via the auxiliary port (provided Data Trace is enabled) for the following conditions (see Table 17-35):

- Initial Data Trace Message after exit from system reset or whenever Data Trace is enabled.
- Upon returning from a CPU Low Power state.
- Upon returning from Debug Mode.
- After occurrence of queue overrun (can be caused by any trace message), provided Data Trace is enabled.
- After the periodic data trace counter has expired indicating 255 *without-sync* Data Trace messages have occurred since the last *with-sync* message occurred.
- Upon assertion of the Event In (**nex_evti_b**) pin, the first Data Trace Message will be a synchronization message if the EIC bits of the DC1 Register have enabled this feature.

- Upon Data Trace Write/Read after the previous DTM message was lost due to an attempted access to a secure memory location (for SOC's w/ security).
- Upon Data Trace Write/Read after the previous DTM message was lost due to a collision entering the FIFO between the DTM message and any two of the following: Watchpoint message, Ownership Trace message, or Program Trace message.

Data Trace Synchronization Messages provide the full address (without leading zeros) and insure that development tools fully synchronize with Data Trace regularly. Synchronization messages provide a reference address for subsequent DTMs, in which only the unique portion of the Data Trace address is transmitted. The format for Data Trace Write/Read with Sync. Messages is as follows:

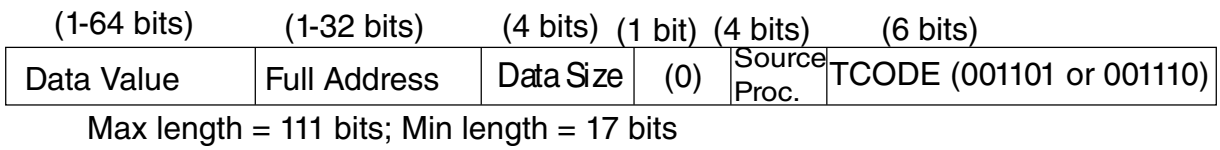

Figure 17-47. Data Write/Read with Sync. message format

Exception conditions that result in Data Trace Synchronization are summarized in Table 17-35.

Table 17-35. Data Trace Exception summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (**j_trst_b**), queue pointers, counters, state machines, and registers within the Nexus 3 module are reset. If Data Trace is enabled, the first Data Trace Message is a Data Write/Read w/ Sync. Message.
Data Trace Enabled	The first Data Trace Message (after Data Trace has been enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a Low Power mode or Debug mode the next Data Trace Message will be converted to a Data Write/Read with Sync. Message.
Queue Overrun	An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied. The next DTM message in the queue will be a Data Write/Read w/ Sync. Message.
Periodic Data Trace Sync.	A forced synchronization occurs periodically after 255 Data Trace Messages have been queued. A Data Write/Read w/ Sync. Message is queued. The periodic data trace message counter then resets.
Event In	If the Nexus module is enabled, a **nex_evti_b** assertion initiates a Data Trace Write/Read w/ Sync. Message upon the next data write/read (if Data Trace is enabled and the EIC bits of the DC1 Register have enabled this feature).
Collision Priority	All Messages have the following priority: Instruction 0 (WPM → DQM → PCM_{PIDMSG} → OTM → BTM → DTM) → Instruction1 (WPM → DQM → OTM → BTM → DTM), where instruction0 is the oldest instruction. A DTM Message that attempts to enter the queue at the same time as three other higher priority messages will be lost. A subsequent read/write will queue a Data Trace Read/Write w/ Sync. Message.

17.13.3 DTM Operation

17.13.3.1 Data Trace windowing

Data Write/Read Messages are enabled via the RWT field in the Data Trace Control Register (DTC) for each DTM channel. Data Trace windowing is achieved via the address range defined by the DTEA and DTSA Registers and by the RC field in the DTC register. All CPU initiated read/write accesses that fall inside or outside these address ranges, as programmed, are candidates to be traced.

17.13.3.2 Data Access / Instruction Access Data Tracing

The Nexus3 module is capable of tracing either instruction access data or data access data and can be configured for either type of data trace by setting the DI1 field within the Data Trace Control Register. This setting applies to all DTM channels.

17.13.3.3 Data Trace filtering

Data Trace filtering is available base on the settings of MSR_{PMM} and $DC4_{DTMARK}$.

17.13.3.4 Bus Cycle special cases

Table 17-36. Bus Cycle Special Cases

Special Case	Action
Bus cycle aborted	Cycle ignored
Bus cycle with data error ($\overline{TEA}$), [1]	Data Trace Message discarded
Bus cycle completed without error[1]	Cycle captured & transmitted
AHB bus cycle initiated by Nexus 3	Cycle ignored
Bus cycle is an instruction fetch	Cycle selectively ignored based on DTC_{DI} setting
Bus cycle accesses misaligned data (across 64-bit boundary) - both 1st & 2nd transactions within data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) - 1st transaction within data trace range; 2nd transaction out of data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) - 1st transaction within data trace range; 2nd transaction (regardless of within range or not) receives a bus error	Data Trace Message discarded
Bus cycle accesses misaligned data (across 64-bit boundary) - 1st transaction out of data trace range; 2nd transaction within data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)

Table continues on the next page...

Table 17-36. Bus Cycle Special Cases (continued)

Special Case	Action
Bus cycle accesses misaligned data (across 64-bit boundary) - 1st transaction out of data trace range; 2nd transaction within range, receives a bus error	Data Trace Message discarded

1. Buffering of stores in the CPU store buffer may generate a DTM prior to the actual memory access, regardless of an error termination condition from memory.

Note

For misaligned accesses (crossing 64-bit boundary), the access is broken into two accesses by the CPU. If either access is within the data trace range, a single DTM will be sent with a size encoding indicating the size of the original access (i.e. word), and the address indicating the original misaligned accesses, unless the misaligned access wraps into the doubleword at address 0. In this case, since the two portions of the misaligned access are not contiguous, two DTMs will be sent, one for each portion. The size encodings and the addresses of the DTMs will indicate the accessed bytes of data. The data trace port handles these cases in the same manner. (See the Data Trace Port section in the Core (e200z7260n3) Core Debug Support chapter.)

Note

A store to the cache's store buffer within the data trace range may initiate a DTM message prior to completion of the actual memory access.

17.13.4 Data Trace Timing Diagrams (8 MDO / 2 MSEO configuration)

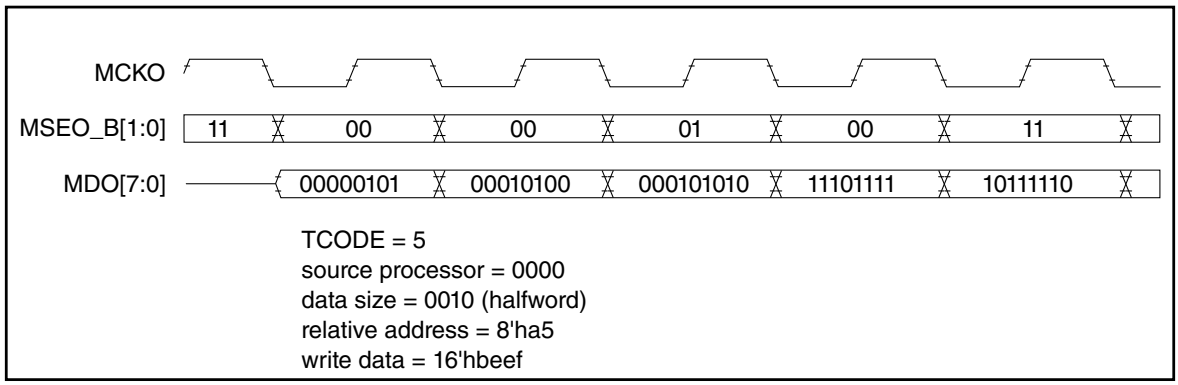

Figure 17-48. Data Trace - Data Write Message

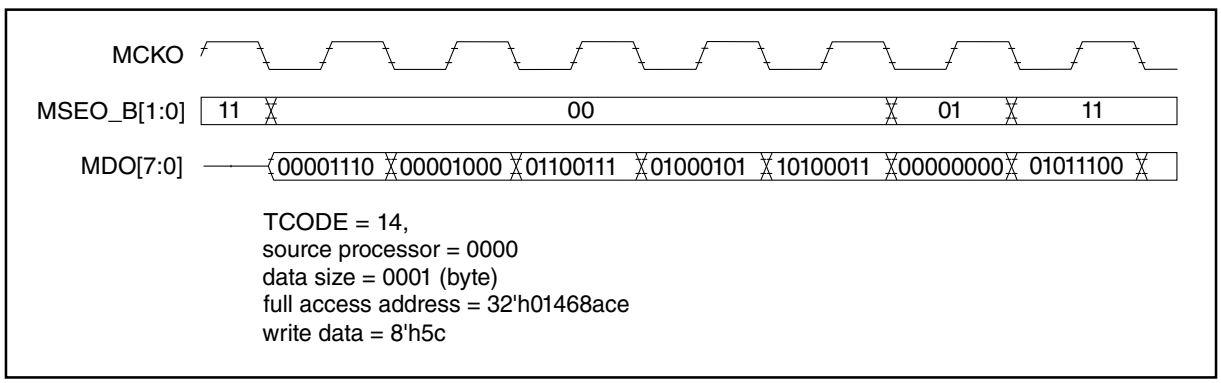

Figure 17-49. Data Trace — Data Read w/ Sync message

17.14 Data Acquisition messaging

This section details the Data Acquisition mechanisms supported by the Nexus 3 module. Data Acquisition Trace is implemented using Data Acquisition Trace Messages in accordance with IEEE-ISTO 5001 definitions. The control mechanism to export the data is different from the recommendations of the standard, however.

Data Acquisition Trace provides a convenient and flexible mechanism for the debugger to observe the architectural state of the machine through software instrumentation.

17.14.1 Data Acquisition ID Tag field

The DQTAG Tag field (DQTAG) is an 8-bit value specifying control or attribute information for the data included in the Data Acquisition message. DQTAG is sampled from $DEVENT_{DQTAG}$ when a write to DDAM is performed via **mtspr** operations. The usage of the DQTAG is left to the discretion of the development tool to be used in whatever manner is deemed appropriate for the application.

17.14.2 Data Acquisition Data field

The Data Acquisition Data field (DQDATA) is the data captured from the DDAM write operation via **mtspr** operations. Leading zeros are omitted from the message.

17.14.3 Data Acquisition Trace event

For DQM, a dedicated SPR has been allocated (DDAM). It is expected that the general use case is to instrument the software and use **mtspr** operations to generate Data Acquisition messages.

There is no explicit error response for failed accesses as a result of contention between an internal and external debugger. Software may be blocked or given ownership of DDAM and the DQTAG field of the DEVENT register via control in EDBRAC0 while in External Debug Mode. Hardware always has access to these registers. Refer to the "External Debug Resource Allocation Control Register (EDBRAC0)" section in the Core (e200z7260n3) Core Debug Support chapter for more detail on EDBRAC0.

Reads from the Data Acquisition channel do not generate a Data Acquisition event and will return zeroes for the read data.

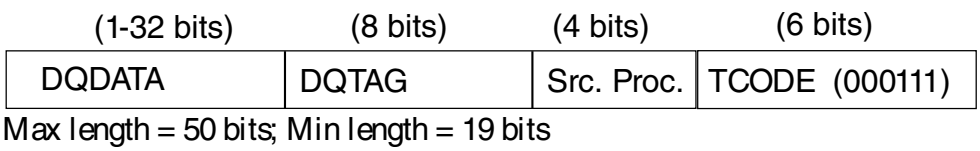

Figure 17-50. Data Acquisition message format

17.15 Watchpoint Trace messaging

Enabling Watchpoint messaging is done by setting the Watchpoint Trace Enable bit in the DC1 Register. Setting the individual Watchpoint sources is supported through the Nexus1 module and the Performance Monitor unit. The Nexus1 module is capable of setting multiple types of watchpoints. Please refer to the Core (e200z7260n3) Core Debug Support chapter for details on watchpoint initialization.

When watchpoints occur due to one or more asserted watchpoint event signals and Watchpoint Trace Messaging is enabled, a Watchpoint Trace message will be sent to the message queue to be messaged out. This message includes the watchpoint number indicating which watchpoint(s) caused the message. If more than one enabled watchpoint

occurs in a single cycle, only one Watchpoint Trace message is generated and multiple bits of the watchpoint hit field will be set. The settings of the $WMSK_{WEM}$ field control which watchpoints are enabled to generate watchpoint trace messages.

The occurrence of any of the defined watchpoints can also be programmed to assert the Event Out (**evto_b**) pin for one (1) period of the output clock (**nex_mcko**) based on settings in the DC2 and DC3 registers. See Table 17-39 for details on **evto_b**.

Watchpoint information is messaged out in the following format:

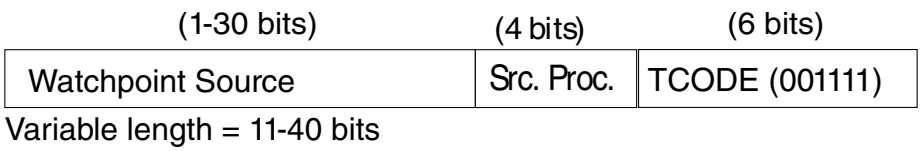

Figure 17-51. Watchpoint message format

The Watchpoint Source message field will contain a '1' for each asserted watchpoint. Leading zeros are truncated.

Table 17-37. Watchpoint Source Encoding

Watchpoint Source (1-30 bits)	Watchpoint Description
00000000000000000000000000000 - No Watchpoints enabled for Watchpoint Trace Messaging	
XXXXXXXXXXXXXXXXXXXXXXXXXXXXX1 - Watchpoint #0 enabled for WTM	
XXXXXXXXXXXXXXXXXXXXXXXXXXXX1X - Watchpoint #1 enabled for WTM	
XXXXXXXXXXXXXXXXXXXXXXXXXXX1XX - Watchpoint #2 enabled for WTM	
XXXXXXXXXXXXXXXXXXXXXXXXXX1XXX - Watchpoint #3 enabled for WTM	
XXXXXXXXXXXXXXXXXXXXXXXXX1XXXX - Watchpoint #4 enabled for WTM	
XXXXXXXXXXXXXXXXXXXXXXXX1XXXXX - Watchpoint #5 enabled for WTM	
XXXXXXXXXXXXXXXXXXXXXXX1XXXXXX - Watchpoint #6 enabled for WTM	
XXXXXXXXXXXXXXXXXXXXXX1XXXXXXX - Watchpoint #7 enabled for WTM	
XXXXXXXXXXXXXXXXXXXXX1XXXXXXXX - Watchpoint #8 enabled for WTM	
XXXXXXXXXXXXXXXXXXXX1XXXXXXXXX - Watchpoint #9 enabled for WTM	
XXXXXXXXXXXXXXXXXXX1XXXXXXXXXX - Watchpoint #10 enabled for WTM

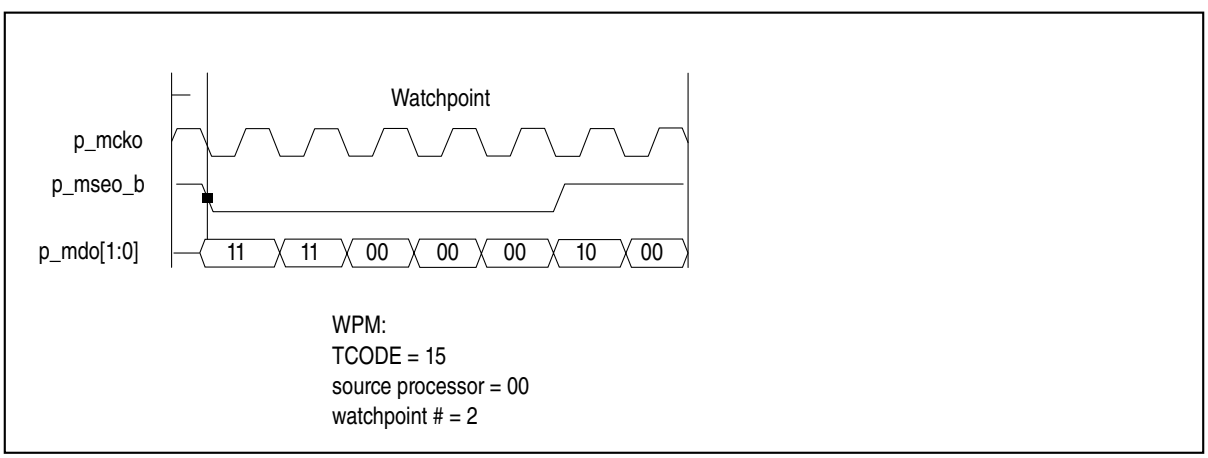

Figure 17-52. Watchpoint Message & Watchpoint Error message

17.16 Nexus 3 Read/Write access to memory-mapped resources

The Read/Write access feature allows access to memory-mapped resources via the JTAG/ OnCE port. The Read/Write mechanism supports single as well as block reads and writes to AHB resources.

The Nexus 3 module is capable of accessing resources on the system bus (AHB). Memory-mapped registers and other non-cached memory can be accessed via the standard memory map settings.

All accesses are setup and initiated by the Read/Write Access Control/Status Register (RWCS), as well as the Read/Write Access Address (RWA) and Read/Write Access Data Registers (RWD). Nexus 3 read/write accesses are run as privileged data non-cacheable accesses by default, and drive the **p_d_hprot[5:0]** bus access attributes to 6'b000011 accordingly. The $RWCS_{ATTR}$ field is provided to allow a portion of these default values to be modified when performing read or write accesses using the Nexus 3 Read/Write access mechanism.

Using the Read/Write Access Registers (RWCS/RWA/RWD), memory mapped AHB resources can be accessed through Nexus 3. The following subsections describe the steps required to access memory-mapped resources.

Note

Read/Write Access can only access memory mapped resources when system reset is de-asserted and clocks are running.

Misaligned accesses are NOT supported in the Nexus 3 module.

Uncorrectable ECC errors on Nexus 3 read access will result in the RWD register being updated with the raw data received.

17.16.1 Single write access

1. Initialize the Read/Write Access Address Register (RWA) through the access method outlined in Nexus 3 Register Access via JTAG/OnCE. Configure as follows:
   - Write Address → 32h'xxxxxxxx (write address)
2. Initialize the Read/Write Access Control/Status Register (RWCS) through the access method outlined in Nexus 3 Register Access via JTAG/OnCE. Configure the bits as follows:
   - Access Control (AC) → 1b'1 (to indicate start access)
   - Map Select (MAP) → 3b'000 (primary memory map)
   - Access Priority (PR) → 2b'11 (highest priority)
   - Read/Write (RW) → 1b'1 (write access)
   - Word Size (SZ) → 3b'0xx (32-bit, 16-bit, 8-bit)
   - Access Count (CNT) → 14h'0000 or 14h'0001(single access)

Note

Access Count (CNT) of 14'h0000 or 14'h0001 will perform a single access.

3. Initialize the Read/Write Access Data Register (RWD) through the access method outlined in Nexus 3 Register Access via JTAG/OnCE. Configure as follows:
   - Write Data → 32h'xxxxxxxx (write data)
4. The Nexus block will then arbitrate for the AHB system bus and transfer the data value from the data buffer RWD Register to the memory mapped address in the Read/Write Access Address Register (RWA). The nex_ahb_start output will be asserted during the first clock of the address phase of the transfer. When the access has completed, Nexus clears the AC and DV bits in the RWCS Register. If the access has completed without error, (ERR=1'b0), Nexus asserts the **nex_rdy_b** pin (see Table 17-39 for details) and clears the ERR bit in the RWCS Register. Otherwise, if the access completes with an error, the **nex_err_b** pin will be asserted and the ERR bit will be set to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once DV has been cleared, this indicates that the device is ready for the next access, or that an error has occurred.

Note

Only the **nex_ahb_start, nex_rdy_b,** and **nex_err_b** pins as well as the AC, DV, and ERR bits within the RWCS provide Read/Write Access status to the external development tool.

17.16.2 Block write access

1. For a block write access, follow Steps 1, 2, and 3 outlined in Single write access to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS Register.
2. The Nexus block will then arbitrate for the AHB system bus and transfer the first data value from the RWD Register to the memory mapped address in the Read/Write Access Address Register (RWA). The nex_ahb_start output will be asserted during the first clock of the address phase of the transfer. When the transfer has completed without error, the address from the RWA Register is incremented to the next word size (specified in the SZ field), the number from the CNT field is decremented, and

the **nex_rdy_b** pin is asserted. If the access has completed without error, Nexus clears the ERR and DV bits in the RWCS Register, otherwise the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, the **nex_err_b** pin is asserted, the block transfer is aborted, and the AC bit in the RWCS register is cleared. Once DV has been cleared, this indicates that the device is ready for the next access in the block transfer, or an error has occurred.

3. If AC has not been cleared due to an error, repeat Step 3 in Single write access until the internal CNT value is zero (0). When this occurs, the AC bit within the RWCS will be cleared to indicate the end of the block write access.

Note

The actual RWA value as well as the CNT field within the RWCS are not changed when executing a block write access. The original values can be read by the external development tool at any time.

17.16.3 Single read access

1. Initialize the Read/Write Access Address Register (RWA) through the access method outlined in Nexus 3 Register Access via JTAG/OnCE. Configure as follows:
   - Read Address → 32h'xxxxxxxx (read address)
2. Initialize the Read/Write Access Control/Status Register (RWCS) through the access method outlined in Nexus 3 Register Access via JTAG/OnCE. Configure the bits as follows:
   - Access Control (AC) → 1b'1 (to indicate start access)
   - Map Select (MAP) → 3b'000 (primary memory map)
   - Access Priority (PR) → 2b'11 (highest priority)
   - Read/Write (RW) → 1b'0 (read access)
   - Word Size (SZ) → 3b'0xx (32-bit, 16-bit, 8-bit)
   - Access Count (CNT) → 14h'0000 or 14h'0001(single access)

Note

Access Count (CNT) of 14'h0000 or 14'h0001 will perform a single access.

3. The Nexus block will then arbitrate for the AHB system bus and the read data will be transferred from the AHB to the RWD Register. The nex_ahb_start output will be asserted during the first clock of the address phase of the transfer. When the access has completed without error, Nexus clears the ERR bit and sets the DV bit in the RWCS Register and asserts the **nex_rdy_b** pin (see Table 17-39 for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. The AC bit will be cleared in either case.
4. The data can then be read from the Read/Write Access Data Register (RWD) through the access method outlined in Nexus 3 Register Access via JTAG/OnCE.

Note

Only the **nex_ahb_start, nex_rdy_b,** and **nex_err_b** pins as well as the AC, DV and ERR bits within the RWCS provide Read/Write Access status to the external development tool.

17.16.4 Block read access

1. For a block read access, follow Steps 1 and 2 outlined in Single read access to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS Register.
2. The Nexus block will then arbitrate for the AHB system bus and the read data will be transferred from the AHB to the RWD Register. The nex_ahb_start output will be asserted during the first clock of the address phase of the transfer. When the access has completed without error, Nexus clears the ERR bit and sets the DV bit in the RWCS Register and asserts the **nex_rdy_b** pin (see Table 17-39 for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. The AC bit will be cleared in either case.
3. When the transfer has completed without error, the address from the RWA Register is incremented to the next word size (specified in the SZ field), the number from the CNT field is decremented, Nexus clears the ERR bit and sets the DV bit in the

RWCS Register, and asserts the **nex_rdy_b** pin (see Table 17-39 for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, the AC bit is cleared and the block transfer is aborted, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. Once DV has been set, this indicates that the device is ready for the next access in the block transfer, or if ERR is set (AC will be cleared), the block transfer has been aborted.

4. The data can then be read from the Read/Write Access Data Register (RWD) through the access method outlined in Nexus 3 Register Access via JTAG/OnCE.
5. If AC has not been cleared due to an error, repeat Steps 3 and 4 in Single read access until the CNT value is zero (0). When this occurs, the AC bit within the RWCS is cleared to indicate the end of the block read access.

Note

The data values must be shifted out 32 bits at a time LSB first (i.e. doubleword read = two word reads from the RWD).

Note

The actual RWA value as well as the CNT field within the RWCS are not changed when executing a block read access. The original values can be read by the external development tool at any time.

17.16.5 Error handling

The Nexus 3 module handles various error conditions as follows:

17.16.5.1 AHB Read/Write error

All address and data errors that occur on read/write accesses to the AHB system bus will return a transfer error encoding on the **p_hresp[1:0]** signals. If this occurs:

1. The access is terminated without retrying (AC bit is cleared)
2. The ERR bit in the RWCS Register is set

3. The Error Message is sent (TCODE = 8) indicating Read/Write error

17.16.5.2 Access termination

The following cases are defined for sequences of the Read/Write protocol that differ from those described in the above sections.

1. If the AC bit in the RWCS Register is set to start Read/Write accesses and invalid values are loaded into the RWD and/or RWA, then an AHB access error may occur. This is handled as described above.
2. If a block access is in progress (all cycles not completed), and the RWCS Register is written, then the original block access is terminated at the boundary of the nearest completed access.
   a. If the RWCS is written with the AC bit set, the next Read/Write access will begin and the RWD can be written to/ read from.
   b. If the RWCS is written with the AC bit cleared, the Read/Write access is terminated at the nearest completed access. This method can be used to break (early terminate) block accesses.

17.16.6 Read/Write access error message

The Read/Write Access Error Message is sent out when an AHB system bus access error (read or write) has occurred.

Error information is messaged out in the following format:

(5 bits)	(4 bits)	(6 bits)
Error Code (00011)	Src. Proc.	TCODE (001000)

Fixed length = 15 bits

Figure 17-53. Error message format1

17.17 Nexus 3 pin interface

This section details information regarding the Nexus 3 pins and pin protocol.

The Nexus 3 pin interface provides the function of transmitting messages from the messages queues to the external tools. It is also responsible for handshaking with the message queues.

17.17.1 Pins implemented

The Nexus 3 module implements an auxiliary port consisting of one (1) **nex_evti_b** and one (1) **nex_mseo_b** or two (2) **nex_mseo_b[1:0]**. It also implements a configurable number of **nex_mdo[n:0]** pins, (1) **nex_rdy_b** pin, (1) **nex_err_b** pin, (1) **evto_b** pin, (4) **nex_wevto[3:0]** pins, and one (1) clock output pin (**nex_mcko**), as well as additional configuration pins described in Table 17-39. The output pins are synchronized to the Nexus 3 output clock (**nex_mcko**).

All Nexus 3 input functionality may be controlled through the JTAG/OnCE port in compliance with IEEE 1149.1 (see Nexus 3 Register Access via JTAG/OnCE for details). The JTAG pins are incorporated as I/O to the processor, and are further described in the "JTAG/OnCE Pins" section of the Core (e200z7260n3) Core Debug Support chapter.

Table 17-38. JTAG Pins for Nexus 3

JTAG Pins	Input/ Output	Description of JTAG Pins (included in Nexus 1)
j_tdo	O	The Test Data Output (**j_tdo**) pin is the serial output for test instructions and data. **j_tdo** is three-stateable and is actively driven in the "Shift-IR" and "Shift-DR" controller states. **j_tdo** changes on the falling edge of **j_tclk**.
j_tdi	I	The Test Data Input (**j_tdi**) pin receives serial test instruction and data. TDI is sampled on the rising edge of **j_tclk**.
j_tms	I	The Test Mode Select (**j_tms**) input pin is used to sequence the OnCE controller state machine. **j_tms** is sampled on the rising edge of **j_tclk**.
j_tclk	I	The Test Clock (**j_tclk**) input pin is used to synchronize the test logic, and control register access through the JTAG/OnCE port.
j_trst_b	I	The Test Reset (**j_trst_b**) input pin is used to asynchronously initialize the JTAG/OnCE controller.

The auxiliary pins are used to send and receive messages and are described in Table 17-39.

Table 17-39. Nexus 3 Auxiliary pins

Auxiliary pins	Input/ Output	Description of auxiliary pins
nex_mcko	O	Message Clock Out (**nex_mcko**) is a free running output clock to development tools for timing of **nex_mdo[n:0]** & **nex_mseo_b[1:0]** pin functions. **nex_mcko** is programmable through the DC1 Register.

Table continues on the next page...

Table 17-39. Nexus 3 Auxiliary pins (continued)

Auxiliary pins	Input/ Output	Description of auxiliary pins
nex_mdo[n:0]	O	Message Data Out (**nex_mdo[n:0]**) are output pins used for OTM, BTM, and DTM. External latching of **nex_mdo[n:0]** shall occur on the rising edge of the Nexus3 clock (**nex_mcko**).
nex_mseo_b[1:0]	O	Message Start/End Out (**nex_mseo_b[1:0]**) are output pins that indicate when a message on the **nex_mdo[n:0]** pins has started, when a variable length packet has ended, and when the message has ended. External latching of **nex_mseo_b[1:0]** shall occur on the rising edge of the Nexus3 clock (**nex_mcko**). One or two pin MSEO functionality is determined at integration time per SOC implementation
nex_rdy_b	O	Ready (**nex_rdy_b**) is an output pin used to indicate to the external tool that the Nexus block is ready for the next Read/Write Access. If Nexus is enabled, this signal is asserted upon successful (without error) completion of an AHB system bus transfer (Nexus read or write) & is held asserted until the JTAG/OnCE state machine reaches the "Capture_DR" state. Upon exit from system reset or if Nexus is disabled, **nex_rdy_b** remains deasserted
nex_err_b	O	Error (**nex_err_b**) is an output pin used to indicate to the external tool that the Nexus block is ready for the next Read/Write Access and an error has occurred on the previous access. If Nexus is enabled, this signal is asserted upon unsuccessful (with error) completion of an AHB system bus transfer (Nexus read or write) & is held asserted until the JTAG/OnCE state machine reaches the "Capture_DR" state. Upon exit from system reset or if Nexus is disabled, **nex_err_b** remains deasserted
evto_b	O	Event Out (**evto_b**) is an output that, when asserted, indicates one of two events has occurred based on the EOC bits in the DC1 Register. **evto_b** is held asserted for one (1) cycle of **nex_mcko**: 1. One (or more) watchpoints has occurred (from Nexus1) & EOC = 2'b00 2. Debug mode was entered (jd_debug_b asserted from Nexus1) & EOC = 2'b01
nex_evti_b	I	Event In (**nex_evti_b**) is an input that, when asserted, will initiate one of two events based on the EIC bits in the DC1 Register (if the Nexus module is enabled at reset): 1. Program Trace & Data Trace synchronization messages (provided Program Trace & Data Trace are enabled & EIC = 2'b00). 2. Debug request to Nexus1 module (provided EIC = 2'b01 and this feature is implemented).
nex_wevto[3:0]	O	Watchpoint Event Out 3:0 (**nex_wevto[3:0]**) are outputs that, when asserted, indicates one or more watchpoint events has occurred based on the settings in the DC2 and DC3 registers. **nex_wevto[3:0]** is held asserted for one (1) cycle of **nex_mcko**.
nex_ext_src_id[0:3]	I	**nex_ext_src_id[0:3]** is used to provide the SRC field value used in each message. These pins are tied to a predetermined value at SoC integration time
nex_sfwcntl_en]	I	**nex_sfwcntl_en** is used to allow software to control the module resources via the DCR register mappings. SoC logic should drive this signal appropriately in a semi-static manner based on the presence of an external hardware debugger and appropriate security precautions.

The Nexus auxiliary port arbitration pins are used when the Nexus 3 module is implemented in a multi-Nexus SoC that shares a single auxiliary output port. The arbitration is controlled by an SoC level Nexus Aurora Router (NAR). Refer to Auxiliary port arbitration for detail on Nexus port arbitration.

Table 17-40. Nexus port arbitration signals

Nexus port arbitration pins	Input/ Output	Description of arbitration pins
nex_aux_req[1:0]	O	Nexus Auxiliary Request (**nex_aux_req[1:0]**) output signals indicate to an SoC level Nexus arbiter a request for access to the shared Nexus auxiliary port in a multi-Nexus implementation. The priority encodings are determined by how many messages are currently in the message queues (See Table 17-42.)
nex_aux_busy	O	Nexus Auxiliary Busy (**nex_aux_busy**) is an output signal to an SoC level Nexus arbiter indicating that the Nexus 3 module is currently transmitting its message after being granted the Nexus auxiliary port.
nar_aux_grant	I	Nexus Auxiliary Grant **(nar_aux_grant)** is an input from the SoC level NAR that the auxiliary port has been granted to the Nexus 3 module to transmit its message.
ext_multi_nex_sel	I	Multi-Nexus Select (**ext_multi_nex_sel**) is a static signal indicating that the Nexus 3 module is implemented within a multi-Nexus environment. If set, port control and arbitration is controlled by the SoC level arbitration module (NAR).

17.17.2 Pin protocol

The protocol for the processor transmitting messages via the auxiliary pins is accomplished with the MSEO pin function outlined in Table 17-41. Both single and dual pin cases are shown.

nex_mseo_b[1:0] is used to signal the end of variable-length packets, and not fixed length packets. **nex_mseo_b[1:0]** is sampled on the rising edge of the Nexus 3 clock (**nex_mcko**).

Single pin MSEO is not supported on the .

Table 17-41. MSEO pin(s) protocol

nex_mseo_b function	Single nex_mseo_b data (serial)	Dual nex_mseo_b[1:0] data
Start of message	1-1-0	11-00
End of message	0-1-1-(more 1's)	00 (or 01)-11-(more 1's)
End of variable length packet	0-1-0	00-01
Message transmission	0's	00's
Idle (no message)	1's	11's

Figure 17-54 illustrates the state diagram for single pin MSEO transfers.

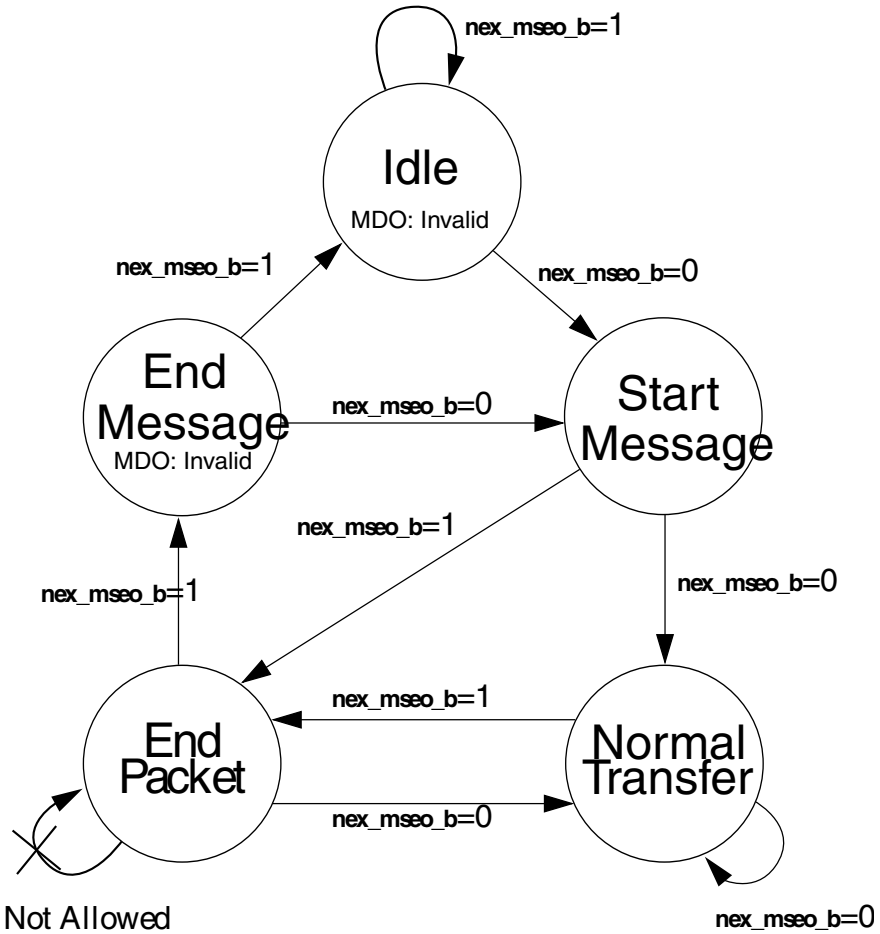

Figure 17-54. Single pin MSEO transfers

Note that the "End Message" state does not contain valid data on the **nex_mdo[n:0]** pins. Also, It is not possible to have two consecutive "End Packet" messages. This implies the minimum packet size for a variable length packet is 2x the number of **nex_mdo[n:0]** pins. This ensures that a false end of message state is not entered by emitting two consecutive '1's on the **nex_mseo_b** pin before the actual end of message.

Figure 17-55 illustrates the state diagram for dual pin MSEO transfers.

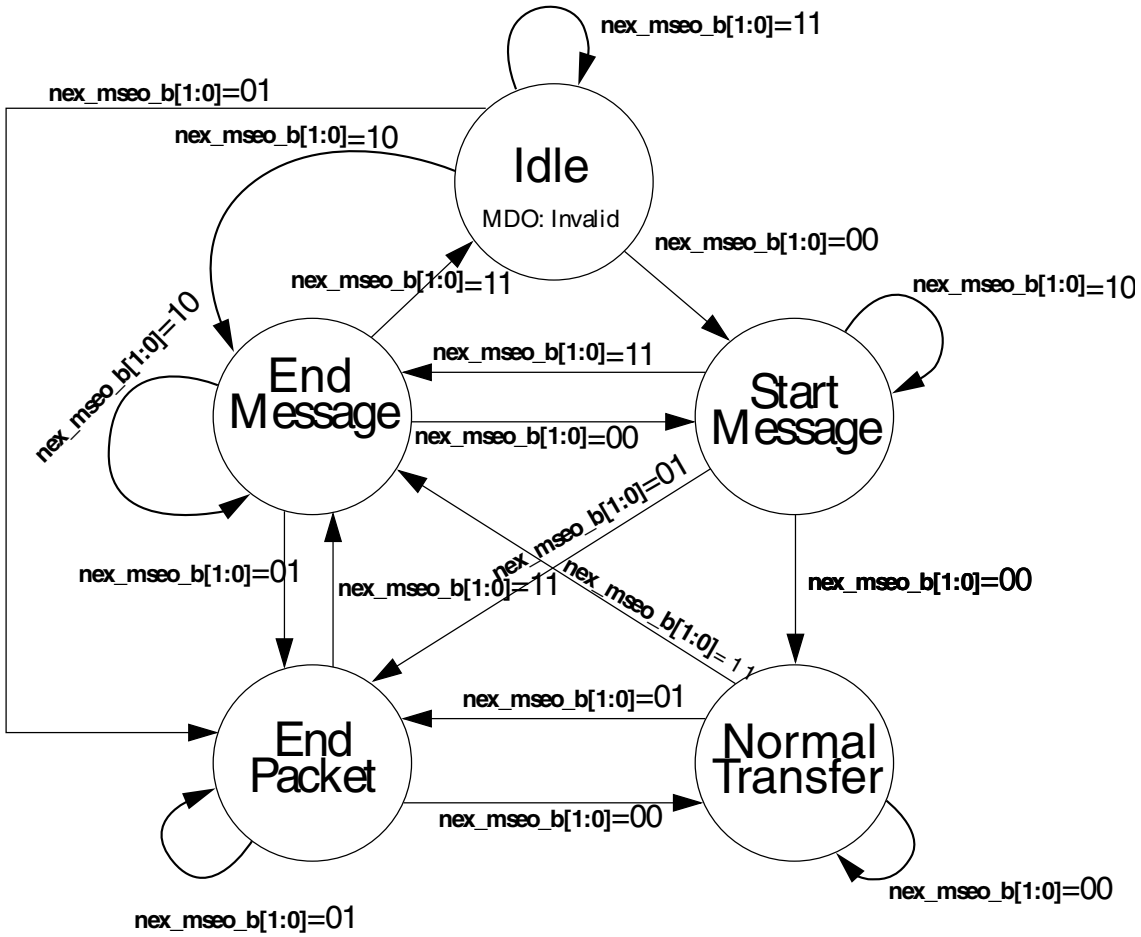

Figure 17-55. Dual pin MSEO transfers

The dual pin MSEO option is more robust that the single pin option. Termination of the current message may immediately be followed by the start of the next message on the consecutive clocks. An extra clock to end the message is not necessary as with the one MSEO pin option. The dual pin option also allows for consecutive "End Packet" states. This can be an advantage when small, variable sized packets are transferred.

Note

The "End Message" state may also indicate the end of a variable-length packet as well as the end of the message when using the dual pin option.

17.18 Rules for output messages

Class 3 compliant embedded processors must provide messages via the auxiliary port in a consistent manner as described below:

- A variable-sized packet within a message must end on a port boundary.
- A variable-sized packet may start within a port boundary only when following a fixed length packet. (If two variable-sized packets end and start on the same clock, it is impossible to know which bit is from the last packet and which bit is from the next packet.)
- Whenever a variable-length packet is sized such that it does not end on a port boundary, it is necessary to extend and zero fill the remaining bits after the highest-order bit so that it can end on a port boundary.

  For example, if the **nex_mdo[n:0]** port is 2 bits wide, and the unique portion of an indirect address TCODE is 5 bits, then the remaining 1 bit of **nex_mdo[n:0]** must be packed with a 0.

17.19 Auxiliary port arbitration

In a multi-Nexus environment, the Nexus 3 module must arbitrate for the shared Nexus port at the SoC level.The request scheme is implemented as a 2-bit request with various levels of priority. The priority levels are defined in Table 17-42 below. The Nexus 3 module will receive a 1-bit grant signal (**nar_aux_grant**) from the SoC level arbiter. When a grant is received, the Nexus 3 module will begin transmitting its message following the protocol outlined in Pin protocol. The Nexus 3 module will maintain control of the port, by asserting the **nex_aux_busy** signal, until the $\overline{\text{MSEO}}$ state machine reaches the "End Message" state.

Table 17-42. MDO Request Encodings

Request level	MDO request encoding (nex_aux_req[1:0])	Condition of queue
No Request	00	No message to send
Low Priority	01	Message queue less than 1/2 full
—	10	Reserved
High Priority	11	Message queue 1/2 full or more

17.20 Examples

The following are examples of Program Trace and Data Trace Messages.

Table 17-43 illustrates an example Indirect Branch Message with 2 MDO / 1MSEO configuration. Table 17-44 illustrates the same example with an 8 MDO / 2 MSEO configuration.

Note that T0 and S0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- MAP = (always set to 0)
- Ix = Number of instructions (variable)
- Ax = Unique portion of the address (variable)

Note that during clock 13, the **nex_mdo[n:0]** pins are ignored in the single MSEO case.

Table 17-43. Indirect Branch Message Example (2 MDO / 1 MSEO)

Clock	nex_mdo[1:0]		nex_mseo_b	State
0	X	X	1	Idle (or end of last message)
1	T1	T0	0	Start Message
2	T3	T2	0	Normal Transfer
3	T5	T4	0	Normal Transfer
4	S1	S0	0	Normal Transfer
5	S3	S2	0	Normal Transfer
6	I0	MAP	0	Normal Transfer
7	I2	I1	0	Normal Transfer
8	I4	I3	1	End Packet
9	A1	A0	0	Normal Transfer
10	A3	A2	0	Normal Transfer
11	A5	A4	0	Normal Transfer
12	A7	A6	1	End Packet
13	0	0	1	End Message
14	T1	T0	0	Start Message

Table 17-44. Indirect branch message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	I4	I3	I2	I1	I0	M A	S3	S2	0	1	End Packet

Table continues on the next page...

Table 17-44. Indirect branch message example (8 MDO / 2 MSEO) (continued)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
						P					
3	A7	A6	A5	A4	A3	A2	A1	A0	1	1	End Packet/End Message
4	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message

Table 17-45 and Table 17-46 illustrate examples of Direct Branch Messages: one with 2 MDO / 1 MSEO, and one with 8 MDO / 2 MSEO.

Note that T0 and I0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- Ix = Number of Instructions (variable)

Table 17-45. Direct branch message example (2 MDO / 1 MSEO)

Clock	nex_mdo[1:0]		nex_mseo_b	State
0	X	X	1	Idle (or end of last message)
1	T1	T0	0	Start Message
2	T3	T2	0	Normal Transfer
3	T5	T4	0	Normal Transfer
4	S1	S0	0	Normal Transfer
5	S3	S2	0	Normal Transfer
6	I1	I0	1	End Packet
7	0	0	1	End Message

Table 17-46. Direct branch message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	0	0	0	0	I1	I0	S3	S2	1	1	End Packet/End Message
3	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message

Table 17-47 illustrates an example Data Write Message with 8 MDO / 1 MSEO configuration, and Table 17-48 illustrates the same DWM with 8 MDO / 2 MSEO configuration

Note that T0, A0, D0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- MAP = (always set to 0)
- Zx = Data size (fixed)
- Ax = Unique portion of the address (variable)
- Dx = Write data (variable 8-, 16- or 32-bit)

Table 17-47. Data write message example (8 MDO / 1 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b	State
0	X	X	X	X	X	X	X	X	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	Start Message
2	A0	Z3	Z2	Z1	Z0	0	S3	S2	1	End Packet
3	D7	D6	D5	D4	D3	D2	D1	D0	0	Normal Transfer
4	0	0	0	0	0	0	0	0	1	End Packet
5	0	0	0	0	0	0	0	0	1	End Message

Table 17-48. Data write message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)

2	A0	Z3	Z2	Z1	Z0	0	S3	S2	0	1	End Packet
3	D7	D6	D5	D4	D3	D2	D1	D0	1	1	End Packet/ End Message

17.21 Electrical characteristics

For all electrical characteristics related to core processor and Nexus 3 operation, please refer to the Data Sheet.

17.22 IEEE 1149.1 (JTAG) RD/WR sequences

This section contains example JTAG/OnCE sequences used to access resources.

17.22.1 JTAG sequence for accessing internal Nexus registers

Table 17-49. Accessing internal Nexus 3 registers via JTAG/OnCE

Step #	TMS Pin	Description
1	1	IDLE -> SELECT-DR_SCAN
2	0	SELECT-DR_SCAN -> CAPTURE-DR (Nexus Command Register value loaded in shifter)
3	0	CAPTURE-DR -> SHIFT-DR
4	0	(7) TCK clocks issued to shift in direction (rd/wr) bit and first 6 bits of Nexus reg. addr.
5	1	SHIFT-DR -> EXIT1-DR (7th bit of Nexus reg. shifted in)
6	1	EXIT1-DR -> UPDATE-DR (Nexus shifter is transferred to Nexus Command Register)
7	1	UPDATE-DR -> SELECT-DR_SCAN
8	0	SELECT-DR_SCAN -> CAPTURE-DR (Register value is transferred to Nexus shifter)
9	0	CAPTURE-DR -> SHIFT-DR
10	0	(31) TCK clocks issued to transfer register value to TDO pin while shifting in TDI value
11	1	SHIFT-DR -> EXIT1-DR (MSB of value is shifted in/out of shifter)
12	1	EXIT1-DR -> UPDATE -DR (if access is write, shifter is transferred to register)
13	0	UPDATE-DR -> RUN-TEST/IDLE (transfer complete - Nexus controller to Reg. Select state)

17.22.2 JTAG sequence for read access of memory-mapped resources

Table 17-50. Accessing memory-mapped resources (reads)

Step #	TCLK clocks	Description
1	13	Nexus Command = write to Read/Write Access Address Register (RWA)
2	37	Write RWA (initialize starting read address — data input on TDI)
3	13	Nexus Command = write to Read/Write Control/Status Register (RWCS)
4	37	Write RWCS (initialize read access mode and CNT value — data input on TDI)
5	—	Wait for falling edge of **nex_rdy_b** or **nex_err_b** pin
6	13	Nexus Command = read Read/Write Access Data Register (RWD)
7	37	Read RWD (data output on TDO)
8	—	If CNT > 0, go back to Step #5

17.22.3 JTAG sequence for write access of memory-mapped resources

Table 17-51. Accessing memory-mapped resources (writes)

Step #	TCLK clocks	Description
1	13	Nexus Command = write to Read/Write Access Control/Status Register (RWCS)
2	37	Write RWCS (initialize write access mode and CNT value - data input on TDI)
3	13	Nexus Command = write to Read/Write Address Register (RWA)
4	37	Write RWA (initialize starting write address - data input on TDI)
5	13	Nexus Command = read Read/Write Access Data Register (RWD)
6	37	Write RWD (data output on TDO)
7	—	Wait for falling edge of **nex_rdy_b** or **nex_err_b** pin
8	—	If CNT > 0, go back to Step #5

Chapter 18
e200z4201n3 Core Debug Support

18.1 Chip-specific Core Debug support information

18.1.1 Debug Request During Waiting, Halted or Stopped State

When the CPU is in Waiting, Halted, or Stopped state and a debug request is asserted, the CPU asserts the p_wakeup signal to chip-level clock generator module, MC_CGM, so as to re-enable the m_clk input of the CPU. But the p_wakeup signal is not used in this device, so the CPU will not enter the debug mode via this mechanism when it is in Stopped, Halted, or Waiting State.

18.1.2 Breakpoint propagation

This device allows a watchpoint or debug request in any one core to cause a debug request to be propagated to any of the cores which have their external debug request input enabled in the Debug Control Register 0 (DBCR0[DEVT1] or DBCR0[DEVT2]).

The figure below shows the block diagram for breakpoint propagation. Here, the EVTO output from a core is connected to the DEVT1 or DEVT2 input to another core.

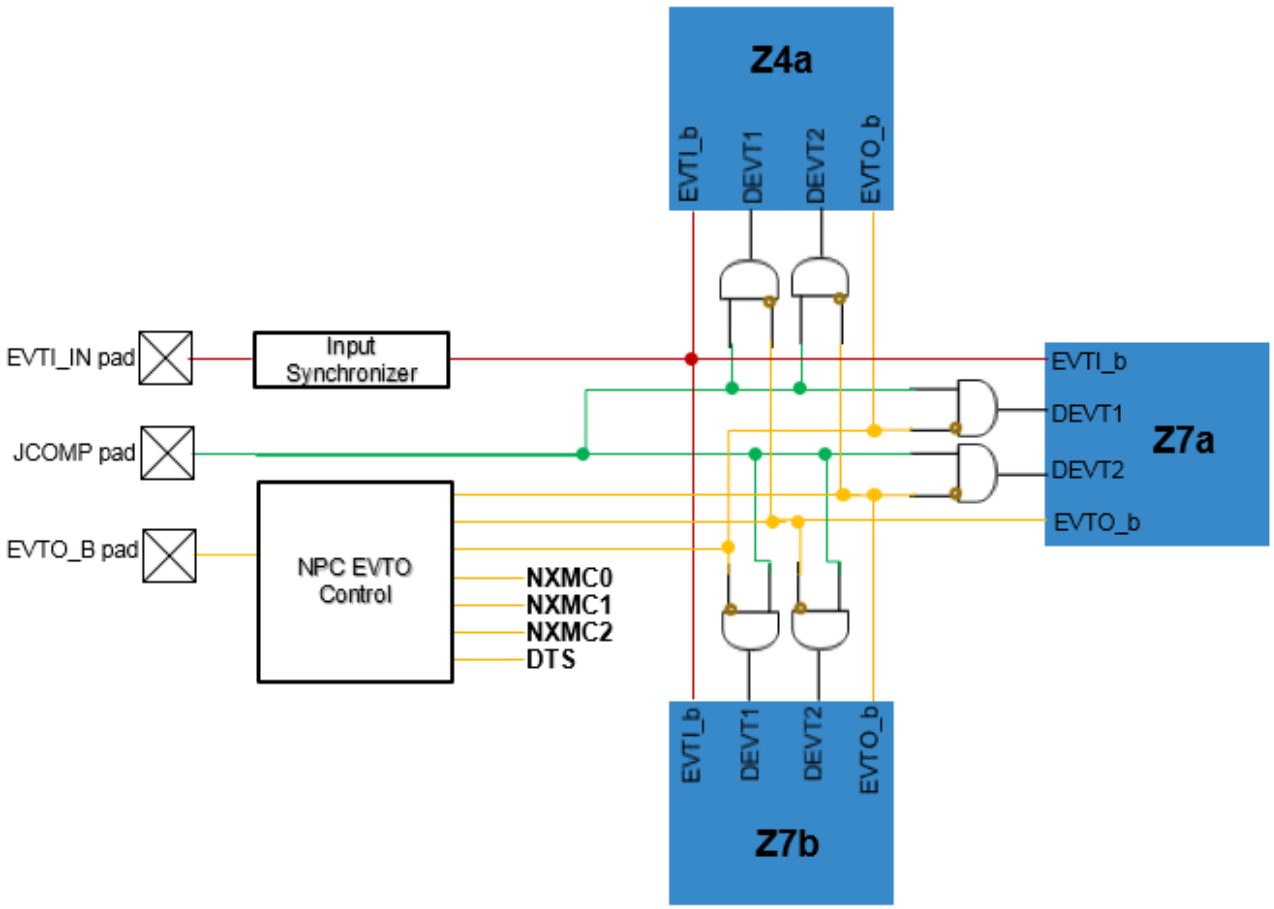

Figure 18-1. Breakpoint Propagation Connections

18.2 Overview

Internal debug support in the e200z4201n3 core allows for software and hardware debug by providing debug functions, such as instruction and data breakpoints and program trace modes. For software based debugging, debug facilities consisting of a set of software accessible debug registers and interrupt mechanisms are provided. These facilities are also available to a hardware based debugger which communicates using a modified IEEE 1149.1 Test Access Port (TAP) controller and pin interface. When hardware debug is enabled, the debug facilities controlled by hardware are protected from software modification.

Software debug facilities are defined as part of *Power ISA 2.06*. e200z4201n3 supports a subset of these defined facilities. In addition to the facilities defined in *Power ISA 2.06*, e200z4201n3 provides additional flexibility and functionality in the form of additional instruction breakpoints, linked instruction and data breakpoints, and extended range and value masking. These features are also available to a hardware-based debugger.

When not being used for debugging purposes, a portion of the debug facilities may be configured to provide a stack limit checking mechanism.

18.2.1 Software Debug Facilities

e200z4201n3 provides debug facilities to enable hardware and software debug functions, such as instruction and data breakpoints and program single stepping. The debug facilities consist of a set of debug control registers (DBCR0–2,4–8, EDBRAC0), a set of address compare registers (IAC1–8, DAC1–4), a set of 64-bit data value compare registers (DVC1, DVC2), a Debug Status Register (DBSR) for enabling and recording various kinds of debug events, a Debug Data Effective Address Register (DDEAR), and a special Debug interrupt type built into the interrupt mechanism.

The debug facilities also provide a mechanism for software-controlled processor reset, and debug mode entry. In addition, the Performance Monitor may be configured to utilize the debug interrupt type. Also, the Memory Protection Unit (MPU) may be configured to generate debug events using region descriptors which are not utilized for performing a protection function.

Software debug facilities are enabled by setting the internal debug mode bit in Debug Control register 0 ($DBCR0_{IDM}$). When internal debug mode is enabled, debug events can occur, and can be enabled to record exceptions in the Debug Status register (DBSR). If enabled by MSR_{DE}, these recorded exceptions cause Debug interrupts to occur. When $DBCR0_{IDM}$ is cleared (and $EDBCR0_{EDM}$ is cleared as well), no debug events occur, and no status flags are set in DBSR unless already set. In addition, when $DBCR0_{IDM}$ is cleared (or is overridden by $EDBCR0_{EDM}$ being set and EDBRAC0 indicating no resource is "owned" by software) no Debug interrupts will occur, regardless of the contents of DBSR. A software Debug interrupt handler may access all system resources and perform necessary functions appropriate for system debug.

18.2.1.1 *Power ISA 2.06* Compatibility

The e200z4201n3 core implements a subset of the *Power ISA 2.06* internal debug features. The following restrictions on functionality are present:

- Instruction address compares do not support compare on physical (real) addresses.
- Data address compares do not support compare on physical (real) addresses.

18.2.2 Additional Debug Facilities

In addition to the debug functionality defined in *Power ISA 2.06*, e200z4201n3 provides capability to link instruction and data breakpoints, provides additional instruction and data breakpoints, extended range and value masking, multiple watchpoint outputs, provides capability for the Performance Monitor to generate debug events, and allows for sharing of debug resources between software and a hardware debugger. (See Sharing Debug Resources by Software/Hardware.) A data trace port is also provided.

18.2.2.1 Data Trace Port

The data trace port interface is provided to assist in implementing extended debug watchpoint/breakpoint/trace capture capability with logic external to the e200z4201n3 core. This port provides information corresponding to each read or write access completed without error by the CPU. In order to report data accesses, the Nexus 3 DTC register DI control bit must be set to trace data accesses, not instruction accesses (i.e. the normal setting. See the "Data Trace Control Register (DTC)" section in the Core (e200z4201n3) Nexus 3 Module chapter. The data trace port will report aligned accesses and misaligned accesses as one access, unless the two portions of a misaligned access are non-contiguous, such as when the second portion of the misaligned access is to address 0.

18.2.3 Hardware Debug Facilities

The e200z4201n3 core contains facilities that allow for external test and debugging. A modified IEEE 1149.1 control interface is used to communicate with the core resources. This interface is implemented through a standard IEEE 1149.1 TAP (test access port) controller.

By using public instructions, the external debugger can freeze or halt the e200z4201n3 core, read and write internal state and debug facilities, single-step instructions, and resume normal execution.

Hardware Debug is enabled by setting the External Debug Mode enable bit in External Debug Control register 0 ($EDBCR0_{EDM}$), which is also aliased to $DBCR0_{EDM}$. Setting $EDBCR0_{EDM}$ overrides the Internal Debug Mode enable bit $DBCR0_{IDM}$ unless resources

are provided back to software via the settings in EDBRAC0. When the Hardware Debug facility is enabled, software is blocked from modifying the "hardware-owned" debug facilities. In addition, since resources are "owned" by the hardware debugger, inconsistent values may be present if software attempts to read "hardware-owned" debug-related resources.

When hardware debug is enabled by setting $EDBCR0_{EDM}$=1, the control registers and resources described in Debug registers are reserved for use by the external debugger. The same events described in Software Debug Events and Exceptions are also used for external debugging, but exceptions are not generated to running software. Hardware-owned debug events enabled in the respective DBCR0–8 registers are recorded in the EDBSR0 register (not the DBSR) regardless of MSR_{DE}, and no debug interrupts are generated unless a) the resource is granted back to software via EDBRAC0 settings, and b) debug mode entry is not masked by the corresponding event bit in EDBSRMSK0. Instead, the CPU will enter debug mode when an enabled event causes a EDBSR0 bit to become set. $EDBCR0_{EDM}$, EDBSR0, EDBSRMSK0, EDDEAR, and EDBRAC0 may only be written through the OnCE port.

Access to most debug resources (registers) requires that the CPU clock (**m_clk**) be running in order to perform write accesses from the external hardware debugger.

18.2.4 Sharing Debug Resources by Software/Hardware

Debug resources may be shared by a hardware debugger and software debug based on the settings of debug control register EDBRAC0. When $EDBCR0_{EDM}$ is set, EDBRAC0 settings determine which debug resources are allocated to software and which resources remain under exclusive hardware control. Software-owned resources which set DBSR bits when $DBCR0_{IDM}$=1 will cause a debug interrupt to occur when enabled with MSR_{DE}. Hardware-owned resources which set EDBSR0 bits when $EDBCR0_{EDM}$=1 will cause an entry into debug mode if the event is not masked in EDBSRMSK0. EDBRAC0 is read-only by software. When resource sharing is enabled, ($EDBCR0_{EDM}$=1 and $EDBRAC0_{IDM}$=1), only software-owned resources may be modified by software. Hardware always has full access to all registers and all register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Hardware-owned resources will set status bits in the EDBSR0 register instead of in DBSR, and will report the effective address of data breakpoints in EDDEAR instead of DDEAR. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control and status registers as appropriate when hardware modifications to the debug registers are performed.

18.2.4.1 Simultaneous Hardware and Software Debug Event Handing

Since it is possible that a "hardware-owned" resource can produce a debug event in conjunction with a software-owned resource producing a different debug event simultaneously, a priority ordering mechanism is implemented which guarantees that the hardware event is handled as soon as possible, while preserving the recognition of the software event. The CPU will give highest priority to the software event initially in order to reach a recoverable boundary, and then will give highest priority to the hardware event in order to enter debug mode as near the point of event occurrence as possible. This is implemented by allowing software exception handing to begin internal to the CPU and to reach the point where the current program counter and MSR values have been saved into DSRR0/1, and the new PC pointing to the debug interrupt handler, along with the new MSR updates. At this point, hardware priority takes over, and the CPU enters debug mode.

The following figure shows the e200z4201n3 debug resources.

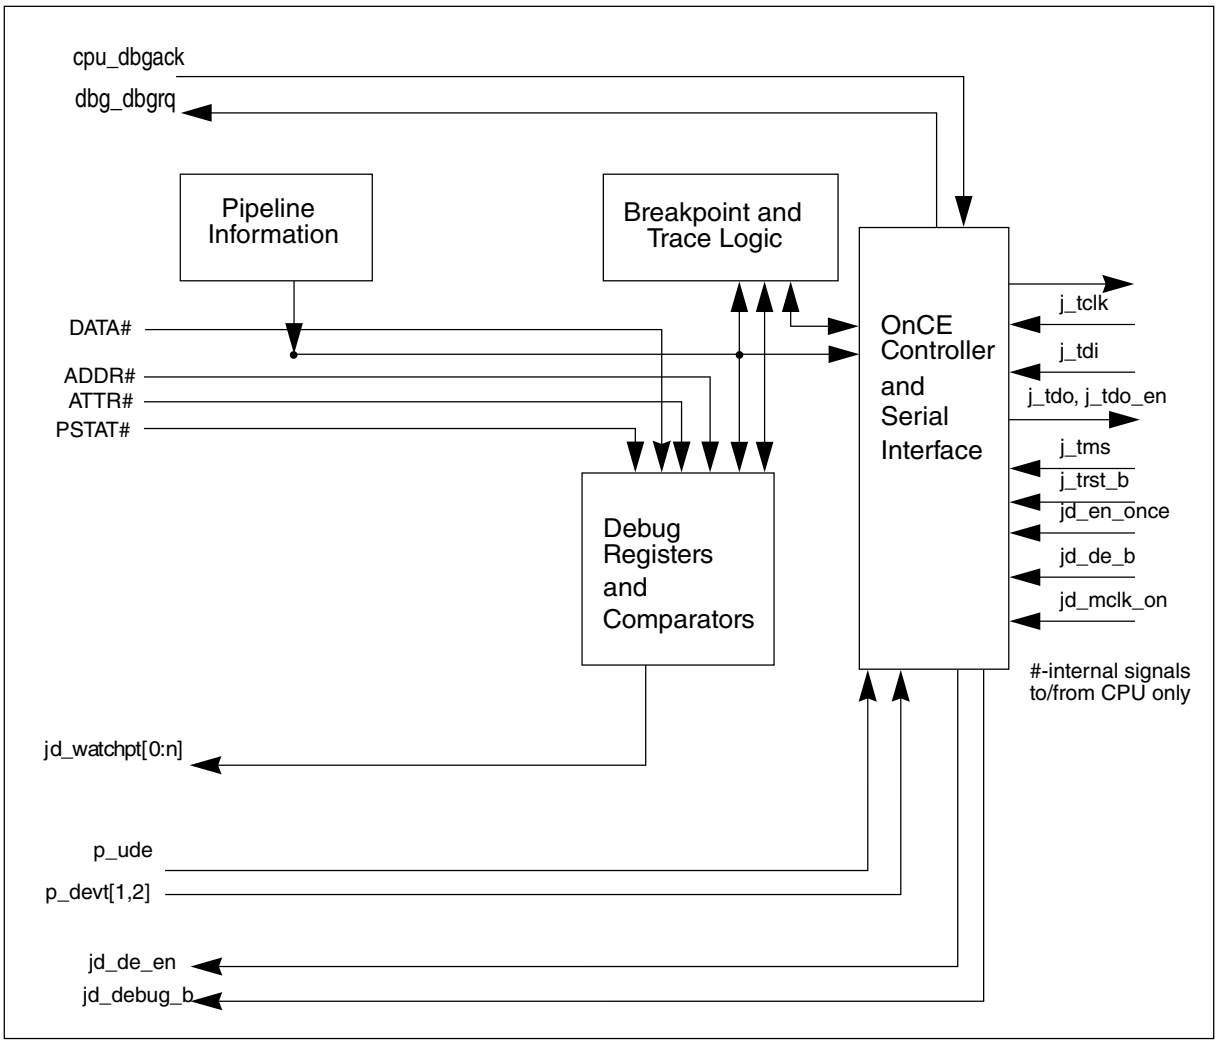

Figure 18-2. e200z4201n3 Debug Resources

18.3 Software Debug Events and Exceptions

Software debug events and exceptions are available when internal debug mode is enabled ($DBCR0_{IDM}$=1) and not overridden by external debug mode ($EDBCR0_{EDM}$ must either be cleared or corresponding resources must be allocated to software debug by the settings in EDBRAC0). When enabled, debug events cause debug exceptions to be recorded in the Debug Status Register. Specific event types are enabled by the Debug Control Registers (DBCR0–8). The Unconditional Debug Event (UDE) is an exception to this rule; it is always enabled. Once a Debug Status Register (DBSR) bit is set by a debug resource which is "owned" by software (other than MRR, DAC_OFST, or VLES), if Debug interrupts are enabled by MSR_{DE}, a Debug interrupt will be generated. The debug interrupt handler is responsible for ensuring that multiple repeated debug interrupts do not occur by clearing the DBSR as appropriate.

Certain debug events are not allowed to occur when MSR_{DE}=0 and $DBCR0_{IDM}$=1. In such situations, no debug exception occurs and thus no DBSR bit is set. Other debug events may cause debug exceptions and set DBSR bits regardless of the state of MSR_{DE}. A Debug interrupt will be delayed until MSR_{DE} is later set to '1'.

When a Debug Status Register bit is set while MSR_{DE}=0, an Imprecise Debug Event flag ($DBSR_{IDE}$) will also be set to indicate that an exception bit in the Debug Status Register was set while Debug interrupts were disabled. Debug interrupt handler software can use this bit to determine whether the address recorded in Debug Save/Restore Register 0 is an address associated with the instruction causing the debug exception, or the address of the instruction which enabled a delayed Debug interrupt by setting the MSR_{DE} bit. A **mtmsr** or **mtdbcr0** which causes both MSR_{DE} and $DBCR0_{IDM}$ to become set, enabling precise debug mode, may cause an Imprecise (Delayed) Debug exception to be generated due to an earlier recorded event in the Debug Status register.

There are eight types of debug events defined by *Power ISA 2.06*:

1. Instruction Address Compare debug events
2. Data Address Compare debug events
3. Trap debug events
4. Branch Taken debug events
5. Instruction Complete debug events
6. Interrupt/Critical Interrupt Taken debug events
7. Return/Critical Return debug events
8. Unconditional debug events

In addition, e200z4201n3 defines additional debug events:

- The External debug events DEVT1 and DEVT2 which are described in External debug event.
- The Performance Monitor Interrupt event PMI which is described in Performance Monitor Interrupt debug event.

The e200z4201n3 debug configuration supports most of these event types. Unsupported *Power ISA 2.06* defined functionality is as follows:

- Instruction Address Compare and Data Address Compare *Real address* mode is not supported

A brief description of each of the event types follows.

18.3.1 Instruction Address Compare Event

Instruction Address Compare debug events occur when enabled and execution is attempted of an instruction at an address that meets the criteria specified in the DBCR0, DBCR1, DBCR5, DBCR6, and IAC1–8 Registers. Instruction Address compares may specify user/supervisor mode, along with an effective address, masked effective address, or range of effective addresses for comparison. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. IAC events will not occur when an instruction would not have normally begun execution due to a higher priority exception at an instruction boundary.

IAC compares perform a 31-bit compare for VLE instruction storage accesses. Each halfword fetched by the instruction fetch unit will be marked with a set of bits indicating whether an Instruction Address Compare occurred on that halfword. Debug exceptions will occur if enabled and a 16-bit instruction, or the first halfword of a 32-bit instruction, is tagged with an IAC hit.

18.3.2 Data Address Compare Event

Data Address Compare debug events occur when enabled and execution of a load or store class instruction or a cache maintenance instruction results in a data access that meets the criteria specified in the DBCR0, DBCR2, DBCR4, DBCR7–8, DAC1–4, DVC1, and DVC2 Registers. Data address compares may specify user/supervisor mode, along with an effective address, masked effective address, or range of effective addresses for comparison. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. Four address compare values (DAC1–4) are provided.

The effective address of the load, store, or cache control operation is recorded in the DDEAR register when a data address compare event is recorded in DBSR if the previous values of the $DBSR_{DAC\{R,W\}}$ bits are zero. Once a DDEAR update is performed, these bits must be cleared by software prior to another DDEAR hardware update occurring. A subsequent DAC event will not update the DDEAR register if either of the $DBSR_{DAC\{R,W\}}$ bits are set.

Note

In contrast to the *Power ISA 2.06* definition, Data Address Compare events on e200z4201n3 do not prevent the load or store class instruction from completing. If a load or store class

instruction completes successfully without a Data Storage interrupt, Data Address Compare exceptions are reported at the completion of the instruction. If the exception results in a precise Debug interrupt, the address value saved in DSRR0 is the address of the instruction following the load or store class instruction. For DVC DAC events, the exception can be imprecisely reported even further past the load or store class instruction generating the event (without necessarily affecting $DBSR_{IDE}$) and the saved address value can point to a subsequent instruction past the next instruction. This occurrence is indicated in the $DBSR_{DAC\_OFST}$ field.

If a load or store class instruction does not complete successfully due to a Data Storage exception or a machine check condition for the load or store, and a Data Address Compare debug exception also occurs, the result is an imprecise Debug interrupt, the address value saved in DSRR0 is the address of the load or store class instruction, and the $DBSR_{IDE}$ bit will be set. In addition to occurring when $DBCR0_{IDM}$=1, this circumstance can also occur when $EDBCR0_{EDM}$=1 and the event is hardware-owned, in which case $EDBSR0_{IDE}$ will be set.

Note

DAC events will not be recorded if a load multiple word or store multiple word instruction is interrupted prior to completion by a critical input or external input interrupt.

Note

DAC events will occur for cache control instructions without performing data compares, regardless of the settings of the DBCRx registers and DVC registers for data value comparison qualifications, i.e. no data comparisons are performed since these instructions do not have associated data values.

Note

DAC events are not signaled on the second portion of a misaligned load or store that is broken up into two separate accesses.

Note

DAC events are not signaled on the **mpure** or **mpuwe** MPU instructions.

Note

DAC[1,2] events are not signaled if DVC[1,2]M is non-zero and a DSI exception occurs on the load or store, since the load or store access is not performed. For a **lmw** or **stmw** transfer however, if a DVC successfully occurs on a transfer and a later transfer encounters a DSI exception, the DAC event will be reported, since a successful data value compare took place.

Note

Due to internal pipeline status, for a reported DAC event on a **lmw** or **stmw** transfer, the value stored in the DDEAR/ EDDEAR will be the effective address of the first transfer of the sequence, and not necessarily the precise transfer that caused the DAC event.

18.3.2.1 Data Address Compare Event Status Updates

Data Address Compare debug events with Data Value compares can be reported ambiguously in several circumstances involving issuing a sequence of load or store class instructions. Due to the CPU pipeline and the delay in performing the data value compare following completion of the access, if the first load or store class instruction generates a DVC DAC, a second and possibly third load or store class instruction may also generate a DAC or DVC DAC event, or may generate a DSI exception with or without a simultaneous DAC event.

Also, since non-load/store instructions may be dual-issued in combination with a load/ store instruction, the actual number of additional instructions that are completed following a recognized DVC DAC on a load/store instruction may vary from 0 to 5. This value will be reported in the $DBSR_{DAC\_OFST}$ field when the DVC DAC status is recorded.

Table 18-1 outlines the settings of the DBSR, DSRR0 saved value, and potential updating of the ESR register for various exception cases on sequences of load/store class instructions. Not all exception combinations are covered in the table, such as IAC, ISI, or Alignment exceptions on subsequent instructions. In general these exceptions will cause further instruction issue to be halted, execution of the excepting instruction to be aborted, and reporting of these exceptions will be masked. The saved DSRR0 value will point to

this excepting instruction, and the exception(s) may be regenerated after returning from the debug interrupt handler and attempting to re-execute the instruction pointed to by DSRR0. In addition, in the examples in Table 18-1, the DAC_OFST and DSRR0 values assume no dual issue occurs. If dual-issue occurs with the first, second, or third column, then the DAC_OFST and DSRR0 values will point beyond the values shown.

Table 18-1. DAC events and Resultant Updates

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
DSI, no DAC	—	—	Take DSI exception, no DBSR update. Update ESR.
DSI, with DACx	—	—	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST not set. DSRR0 points to 1st load/store class instruction. No ESR update.
DACx	—	—	Take Debug exception, DBSR update setting DACx, DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update.
DVC DACx	No exceptions, any instruction	No exceptions, Non-ldst instruction	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b001. DSRR0 points to 3rd instruction. No ESR update.
DVC DACx	No exceptions	No exceptions, Ldst instruction	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b010. DSRR0 points to instruction after 3rd instruction. No ESR update.
DVC DACx	DSI, no DAC	—	Take Debug exception, DBSR update setting DACx, DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update. **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	DSI, with DACy	—	Take Debug exception, DBSR update setting DACx. DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update. **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	DACy	—	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy,Normal Ldst	Non-Ldst instruction	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy,Normal Ldst	Ldst instruction,no exception	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd load/store class instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

Table continues on the next page...

Table 18-1. DAC events and Resultant Updates (continued)

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
DVC DACx	DVC DACy,Normal Ldst	DSI Error, with or without DAC	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. No ESR update. DSRR0 points to 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case. **Note:** in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	DVC DACy,Normal Ldst	DACy, or DVC DAC_y Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd load/store class instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy,Ldst multiple (lmw, stmw)	Any instruction including ld/st	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	Any instruction(no exception)	DSI, with or without DAC,Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. No ESR update. **Note:** in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	Any instruction(no exception)	DACy, or DVC DAC_y Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd class instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

Table 18-2 through Table 18-5 show some example updates for specific code sequences of dual issuing of load/store class instructions with non-load/store class instructions and the results of DAC and DVC events on selected ones of the load/store instructions.

Table 18-2. DAC events and Resultant Updates, Dual-issue case 1

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) load/store (6) alu	Event(s)	Result
	Instruction (1): DSI, no DAC	Take DSI exception, no DBSR update, Update ESR.
	Instruction (1): DSI, with DACx	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST set to 3'b000. DSRR0 points to instruction (1). No ESR update.
	Instruction (1): DACx	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b000. DSRR0 points to instruction (2). No ESR update.
	Instruction (1): DVC DACx No other exceptions	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No ESR update. No debug event updates for instruction (6)
	Instruction (1): DVC DACx Instruction (3): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b001. DSRR0 points to instruction (3). No ESR update. No debug event updates for instructions (3)–(6). **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
	Instruction (1): DVC DACx Instruction (3): DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction (4). No debug event updates for instructions (4)–(6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
	Instruction (1): DVC DACx Instruction (3): DVC DACy	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No ESR update. No debug event updates for instruction (6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
	Instruction (1): DVC DACx Instruction (3): DVC DACy Instruction (5): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. No ESR update. DSRR0 points to instruction (4). No debug event updates for instructions (4)–(6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case. **Note:** in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.

No debug event updates for instructions (4)–(6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
	Instruction (1): DVC DACx Instruction (3): DVC DACy	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b011. DSRR0 points to instruction (5). No ESR update. No debug event updates for instructions (5)–(6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

18.3.3 Linked Instruction Address Compare and Data Address Compare Events

Data Address Compare 1, 2, 3, and 4 debug events may be 'linked' with an Instruction Address Compare event by setting the DAC[1–4]LNK control bits in DBCR2 and DBCR8 to further refine when a Data Address Compare debug event is generated. DAC1

may be linked with IAC1, DAC2 (when not used as a mask or range bounds register) may be linked with IAC3. DAC3 may be linked with IAC5, DAC4 (when not used as a mask or range bounds register) may be linked with IAC7. When linked, a DAC debug event occurs when the same instruction that generates the DAC 'hit' also generates a corresponding linked IAC 'hit'. When linked, the IAC event is not recorded in the Debug Status register, regardless of whether a corresponding linked DAC event occurs, or whether the IAC event enable is set.

When enabled and execution of a load or store class instruction results in a data access with an address that meets the criteria specified in the DBCRx, DACx, and DVCx Registers, and the instruction also meets the criteria for generating an Instruction Address Compare event, a Linked Data Address Compare debug event occurs. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. The normal DAC1 status bit in the DBSR is used for recording these events. The IAC status bit is not set if the corresponding Instruction Address Compare register is linked.

Linking is enabled using control bits in DBCR2 and DBCR8. Note that linking is only available in EDM or IDM. Attempts to use linking otherwise are ignored.

Note

Linked DAC events will not be recorded if a load multiple word or store multiple word type instruction is interrupted prior to completion by a critical input or external input interrupt.

18.3.4 Trap Debug Event

A Trap debug event (TRAP) occurs if Trap debug events are enabled ($DBCR0_{TRAP}$=1), a Trap instruction (**tw**) is executed, and the conditions specified by the instruction for the trap are met. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Trap debug event occurs, the $DBSR_{TRAP}$ bit is set to 1 to record the debug exception.

18.3.5 Branch Taken Debug Event

A Branch Taken debug event (BRT) occurs if Branch Taken debug events are enabled ($DBCR0_{BRT}$=1) and execution is attempted of a branch instruction that will be taken (either an unconditional branch, or a conditional branch whose branch condition is true), and MSR_{DE}=1. Branch Taken debug events are not recognized if MSR_{DE}=0 at the time of execution of the branch instruction and thus $DBSR_{IDE}$ can not be set by a Branch Taken

debug event. When a Branch Taken debug event is recognized, the $DBSR_{BRT}$ bit is set to 1 to record the debug exception, and the address of the branch instruction will be recorded in DSRR0.

18.3.6 Instruction Complete Debug Event

An Instruction Complete debug event (ICMP) occurs if Instruction Complete debug events are enabled ($DBCR0_{ICMP}$=1), execution of any instruction is completed, and MSR_{DE}=1. If execution of an instruction is suppressed due to the instruction causing some other exception that is enabled to generate an interrupt, then the attempted execution of that instruction does not cause an Instruction Complete debug event. The ***se_sc*** instruction does not fall into the category of an instruction whose execution is suppressed, since the instruction actually executes and then generates a System Call interrupt. In this case, the Instruction Complete debug exception will also be set. When an Instruction Complete debug event is recognized, $DBSR_{ICMP}$ is set to 1 to record the debug exception and the address of the next instruction to be executed will be recorded in DSRR0.

Instruction Complete debug events are not recognized if MSR_{DE}=0 at the time of execution of the instruction, thus $DBSR_{IDE}$ is not generally set by an ICMP debug event.

One circumstance may cause the $DBSR_{ICMP}$ and $DBSR_{IDE}$ bits to be set. This occurs when a EFPU Round exception occurs. Since the instruction is by definition completed (SRR0 points to the following instruction), this interrupt takes higher priority than the Debug interrupt so as not to be lost, and $DBSR_{IDE}$ is set to indicate the imprecise recognition of a Debug interrupt. In this case, the Debug interrupt will be taken with SRR0 pointing to the instruction following the instruction that generated the EFPU Round exception, and DSRR0 will point to the Round exception handler. In addition to occurring when $DBCR0_{IDM}$=1, this circumstance can also occur when $EDBCR0_{EDM}$=1 and the event is hardware-owned, in which case $EDBSR0_{IDE}$ will be set.

Note

Instruction complete debug events are not generated by the execution of an instruction that sets MSR_{DE} to '1' while $DBCR0_{ICMP}$=1, nor by the execution of an instruction that sets $DBCR0_{ICMP}$ to '1' while MSR_{DE}=1.

18.3.7 Interrupt Taken Debug Event

An Interrupt Taken debug event (IRPT) occurs if Interrupt Taken debug events are enabled ($DBCR0_{IRPT}$=1) and a base-class interrupt occurs. Only base-class interrupts (an interrupt using SRR0/1) cause an Interrupt Taken debug event. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an Interrupt Taken debug event occurs, the $DBSR_{IRPT}$ bit is set to 1 to record the debug exception. The value saved in DSRR0 will be the address of the non-critical interrupt handler.

18.3.8 Critical Interrupt Taken Debug Event

A Critical Interrupt Taken debug event (CIRPT) occurs if Critical Interrupt Taken debug events are enabled ($DBCR0_{CIRPT}$=1) and a critical interrupt occurs. Only critical class interrupts (an interrupt using CSRR0/1) cause a Critical Interrupt Taken debug event. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Critical Interrupt Taken debug event occurs, the $DBSR_{CIRPT}$ bit is set to 1 to record the debug exception. The value saved in DSRR0 will be the address of the critical interrupt handler.

18.3.9 Return Debug Event

A Return debug event (RET) occurs if Return debug events are enabled ($DBCR0_{RET}$=1) and an attempt is made to execute an **se_rfi** instruction. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Return debug event occurs, the $DBSR_{RET}$ bit is set to 1 to record the debug exception.

If MSR_{DE}=0 at the time of the execution of the **se_rfi** (i.e. before the MSR is updated by the **se_rfi**), then $DBSR_{IDE}$ is also set to 1 to record the imprecise debug event.

If MSR_{DE}=1 at the time of the execution of the **se_rfi**, a Debug interrupt will occur provided there exists no higher priority exception that is enabled to cause an interrupt. Debug Save/Restore Register 0 will be set to the address of the **se_rfi** instruction.

18.3.10 Critical Return Debug Event

A Critical Return debug event (CRET) occurs if Critical Return debug events are enabled ($DBCR0_{CRET}$=1) and an attempt is made to execute an **se_rfci** instruction. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Critical Return debug event occurs, the $DBSR_{CRET}$ bit is set to 1 to record the debug exception.

If MSR_{DE}=0 at the time of the execution of the **se_rfci** (i.e. before the MSR is updated by the **se_rfci**), then $DBSR_{IDE}$ is also set to 1 to record the imprecise debug event.

If MSR_{DE}=1 at the time of the execution of the **se_rfci**, a Debug interrupt will occur provided there exists no higher priority exception that is enabled to cause an interrupt. Debug Save/Restore Register 0 will be set to the address of the **se_rfci** instruction.

18.3.11 External debug event

An External debug event (DEVT1, DEVT2) occurs if External debug events are enabled ($DBCR0_{DEVT1}$=1 or $DBCR0_{DEVT2}$=1), and the respective **p_devt1** or **p_devt2** input signal transitions to the asserted state while the CPU is not in the Stopped state. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an External debug event occurs, $DBSR_{DEVT\{1,2\}}$ is set to '1' to record the debug exception. This debug event is an asynchronous event, but is only sampled when the CPU **m_clk** is active.

18.3.12 Unconditional debug event

An Unconditional debug event (UDE) occurs when the Unconditional Debug Event (**p_ude**) input transitions to the asserted state. The Unconditional debug event is the only debug event that does not have a corresponding enable bit for the event in DBCR0. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an Unconditional debug event occurs, the $DBSR_{UDE}$ bit is set to '1' to record the debug exception. This debug event is an asynchronous event.

18.3.13 Performance Monitor Interrupt debug event

A Performance Monitor Interrupt debug event (PMI) occurs if Performance Monitor Interrupt debug events are enabled ($PMGC0_{UDI}$=1), and a performance monitor interrupt event occurs. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Performance Monitor Interrupt debug event occurs, $DBSR_{PMI}$ is set to '1' to record the debug exception. This debug event is an asynchronous event.

18.4 Debug registers

This section describes debug-related registers that are software accessible. These registers are intended for use by special debug tools and debug software, not by general application code.

Access to these registers (other than DBSR) by software is conditioned by the External Debug mode control bit ($EDBCR0_{EDM}$) and the settings of debug control register EDBRAC0, which can be set by the hardware debug port. If $EDBCR0_{EDM}$ is set and if the bit in EDBRAC0 corresponding to the resource is cleared, software is prevented from modifying debug register values other than in DBSR, since the resource is not "owned" by software. Software always has ownership of DBSR. Execution of a **mtspr** instruction targeting a debug register or register field not "owned" by software will not cause modifications to occur, and no exception will be signaled. In addition, since the external debugger hardware may be manipulating debug register values, the state of these registers or register fields not "owned" by software is not guaranteed to be consistent if accessed (read) by software with a **mfspr** instruction, other than the $DBCR0_{EDM}$ bit itself and the EDBRAC0 register. Hardware always has full access to all registers and all register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control registers as appropriate when hardware modifications to the debug registers is performed.

18.4.1 Debug Address and Value Registers

Instruction Address Compare registers IAC1–8 are used to hold instruction addresses for address comparison purposes. In addition, IAC2 and IAC4 may hold mask information for IAC1 and IAC3 respectively and IAC6 and IAC8 may hold mask information for IAC5 and IAC7 respectively, when *Address Bit Match* compare modes are selected. Note that when performing instruction address compares, the low order bit of the instruction address and the corresponding IAC register is ignored for VLE instructions.

Data Address Compare registers DAC1–4 are used to hold data access addresses for address comparison purposes. In addition, DAC2 and DAC4 may hold mask information for DAC1 and DAC3 respectively when *Address Bit Match* compare modes are selected.

Data Value Compare registers DVC1 and DVC2 are used to hold data values for data comparison purposes. DVC1 and DVC2 are 64-bit registers. Data value comparisons are used to qualify Data Address compare 1 and 2 debug events. Data value comparisons are

not available for Data address compare 3–4 events. DVC1 is associated with DAC1, and DVC2 is associated with DAC2. The most significant byte of the DVC1(2) register (labeled B0 in the following figure) corresponds to the byte data value transferred to/from memory byte offset 0, 8, …, and the least significant byte of the register (labeled B7 in the following figure) corresponds to byte offset 7, F, … . When enabled for performing data value comparisons, each enabled byte in DVC1(2) is compared with the memory value transferred on the corresponding active byte lane of the data memory interface to determine if a match occurs. Inactive byte lanes do not participate in the comparison, they are implicitly masked. The Byte Strobe Assertion for Transfers table in the Core (e200z4201n3) Core Complex Overview chapter shows active byte lanes for data transfers. Software must also program the DVC1(2) register byte positions based on the alignment of the access. Misaligned accesses are not fully supported, since the data address and data value comparisons are only performed on the initial access in the case of a misaligned access; thus, accesses that cross a 64-bit boundary cannot be fully matched. For address and size combinations that involve two transfers, only the initial transfer is used for data address and value matching.

DVC1 and DVC2 may be read or written using **mtspr** and **mfspr** instructions. The DVC1U and DVC2U SPR numbers (601,602) are used for accessing the upper 32-bit portion of the DVC register. The DVC1 and DVC2 SPR numbers (318,319) are used for accessing the lower 32-bit portion of the DVC register.

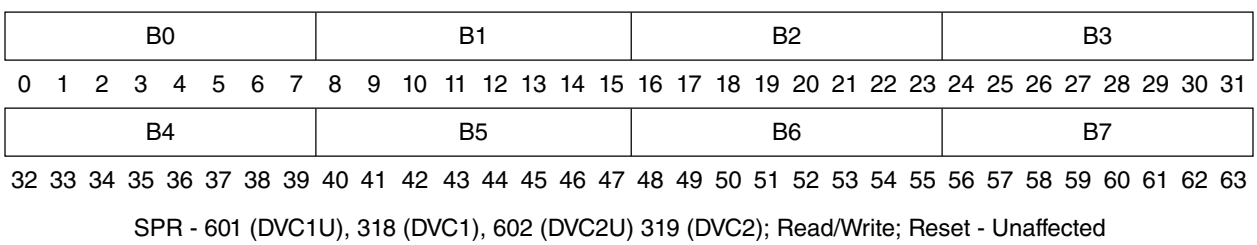

Figure 18-3. DVC1, DVC2 registers

18.4.2 Debug Control and Status registers

Debug Control Registers (DBCR0–8 and EDBRAC0) are used to enable debug events, reset the processor, and set the debug mode of the processor. The Debug Status register (DBSR) records debug exceptions while Internal Debug mode is enabled. The Debug Data Effective Address register (DDEAR) records the effective address of a Data Address Compare event while Internal Debug mode is enabled.

e200z4201n3 requires that a context synchronizing instruction follow a **mtspr** DBCR0–8 or DBSR to ensure that any alterations enabling/disabling debug events are effective. The context synchronizing instruction may or may not be affected by the alteration. Typically, an **se_isync** instruction is used to create a synchronization boundary beyond which it can be guaranteed that the newly written control values are in effect.

For watchpoint generation, configuration settings contained in DBCR1–8 are used, even though the corresponding event(s) may be disabled (via DBCR0) from setting DBSR flags.

18.4.2.1 Debug Control Register 0 (DBCR0)

Debug Control Register 0 is used to enable debug modes and controls which debug events are allowed to set DBSR or EDBSR0 flags. e200z4201n3 adds some implementation specific bits to this register, as seen in the following figure.

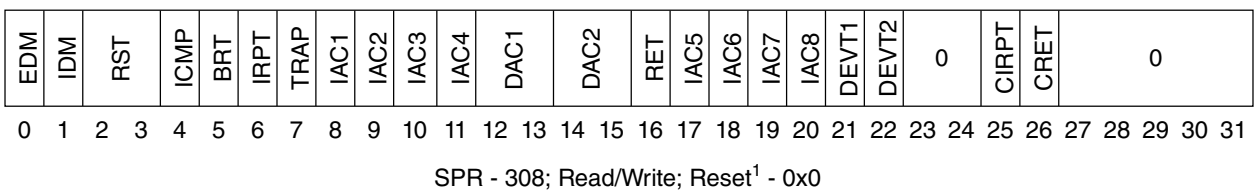

Figure 18-4. Debug Control Register 0 (DBCR0) register

Note

[1] $DBCR0_{EDM}$ is affected by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state, but is not affected by **p_reset_b**. All other bits are reset by processor reset **p_reset_b** if $DBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $DBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources (other than RST) from reset by **p_reset_b**, and only software-owned resources indicated by EDBRAC0 and the $DBCR0_{RST}$ field will be reset by **p_reset_b**. The $DBCR0_{RST}$ field will always be reset by **p_reset_b** regardless of the value of $DBCR0_{EDM}$.

The following provides bit definitions for Debug Control Register 0.

Table 18-6. DBCR0 field descriptions

Bit	Name	Description
0	EDM	External Debug mode. This bit is read-only by software. When external debug mode is enabled, hardware-owned resources in debug registers are not affected by processor reset p_reset_b. This allows the debugger to set up hardware debug events that remain active across a processor reset. 0 External debug mode disabled. Internal debug events not mapped into external debug events. 1 External debug mode enabled. Hardware-owned debug events will not cause the CPU to vector to interrupt code. Software is not permitted to write to debug registers {DBCR0–8, IAC1–8, DAC1–4, DVC1–2[U]} unless permitted by settings in EDBRAC0. Hardware-owned events will set status bits in EDBSR0. Programming Notes: It is recommended that debug status bits in the Debug Status Registers be cleared before disabling external debug mode to avoid any internal imprecise debug interrupts. Software may use this bit to determine if external debug has control over the debug registers. The hardware debugger must set the EDM bit to '1' before other bits in this register (and other debug registers) may be altered. On the initial setting of this bit to '1', all other bits are unchanged. This bit is only writable through the OnCE port.
1	IDM	Internal Debug mode 0 Debug exceptions are disabled. Debug events do not affect DBSR. 1 Debug exceptions are enabled. Enabled debug events owned by software will update the DBSR. If MSR_{DE}=1, the occurrence of a debug event, or the recording of an earlier debug event in the Debug Status Register when MSR_{DE} was cleared, will cause a Debug interrupt.
2:3	RST	Reset Control 00 No function 01 **p_dbrstc[1]** pin asserted by Debug Reset Control. Allows external device to initiate processor or system reset 10 **p_dbrstc[0]** pin asserted by Debug Reset Control. Allows external device to initiate processor or system reset. 11 Reserved
4	ICMP	Instruction Complete Debug Event Enable 0 ICMP debug events are disabled 1 ICMP debug events are enabled
5	BRT	Branch Taken Debug Event Enable 0 BRT debug events are disabled 1 BRT debug events are enabled
6	IRPT	Interrupt Taken Debug Event Enable 0 IRPT debug events are disabled 1 IRPT debug events are enabled
7	TRAP	Trap Taken Debug Event Enable 0 TRAP debug events are disabled 1 TRAP debug events are enabled
8	IAC1	Instruction Address Compare 1 Debug Event Enable 0 IAC1 debug events are disabled

18.4.2.2 Debug Control Register 1 (DBCR1)

Debug Control Register 1 is used to configure Instruction Address Compare operation. The DBCR1 register is shown in the following figure.

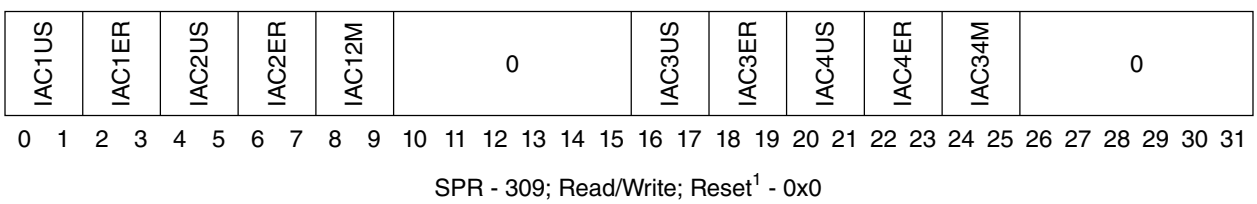

Figure 18-5. DBCR1 Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 1.

Table 18-7. DBCR1 field descriptions

Bit	Name	Description
0:1	IAC1US	Instruction Address Compare 1 User/Supervisor Mode

Table continues on the next page...

Table 18-7. DBCR1 field descriptions (continued)

Bit	Name	Description
		00 IAC1 debug events not affected by MSR_{PR}
		01 Reserved
		10 IAC1 debug events can only occur if MSR_{PR}=0 (Supervisor mode)
		11 IAC1 debug events can only occur if MSR_{PR}=1. (User mode)
2:3	IAC1ER	Instruction Address Compare 1 Effective/Real Mode
		00 IAC1 debug events are based on effective address
		01 Unimplemented (Book E real address compare), no match can occur
		10 IAC1 debug events are based on effective address and can only occur if MSR_{IS}=0
		11 IAC1 debug events are based on effective address and can only occur if MSR_{IS}=1
4:5	IAC2US	Instruction Address Compare 2 User/Supervisor Mode
		00 IAC2 debug events not affected by MSR_{PR}
		01 Reserved
		10 IAC2 debug events can only occur if MSR_{PR}=0 (Supervisor mode)

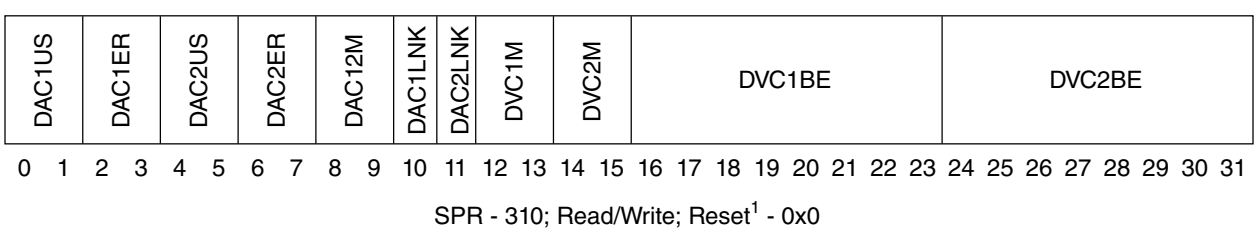
22:23	IAC4ER	Instruction Address Compare 4 Effective/Real Mode 00 IAC4 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 IAC4 debug events are based on effective address and can only occur if MSR_{IS}=0 11 IAC4 debug events are based on effective address and can only occur if MSR_{IS}=1
24:25	IAC34M	Instruction Address Compare 3/4 Mode 00 Exact address compare. IAC3 debug events can only occur if the address of the instruction fetch is equal to the value specified in IAC3. IAC4 debug events can only occur if the address of the instruction fetch is equal to the value specified in IAC4. 01 Address bit match. IAC3 debug events can occur only if the address of the instruction fetch, ANDed with the contents of IAC4 are equal to the contents of IAC3, also ANDed with the contents of IAC4. IAC4 debug events do not occur. IAC3US and IAC3ER settings are used. 10 Inclusive address range compare. IAC3 debug events can occur only if the address of the instruction fetch is greater than or equal to the value specified in IAC3 and less than the value specified in IAC4. IAC4 debug events do not occur. IAC3US and IAC3ER settings are used. 11 Exclusive address range compare. IAC3 debug events can occur only if the address of the instruction fetch is less than the value specified in IAC3 or is greater than or equal to the value specified in IAC4. IAC4 debug events do not occur. IAC3US and IAC3ER settings are used.
26:31	—	Reserved

18.4.2.3 Debug Control Register 2 (DBCR2)

Debug Control Register 2 is used to configure Data Address Compare and Data Value Compare operation.The DBCR2 register is shown in the following figure.



SPR - 310; Read/Write; Reset[1] - 0x0

Figure 18-6. DBCR2 Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 2.

Table 18-8. DBCR2 Bit Definitions

Bit	Name	Description
0:1	DAC1US	Data Address Compare 1 User/Supervisor Mode 00 DAC1 debug events not affected by MSR_{PR} 01 Reserved 10 DAC1 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 DAC1 debug events can only occur if MSR_{PR}=1 (User mode)
2:3	DAC1ER	Data Address Compare 1 Effective/Real Mode 00 DAC1 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 DAC1 debug events are based on effective address and can only occur if MSR_{DS}=0 11 DAC1 debug events are based on effective address and can only occur if MSR_{DS}=1
4:5	DAC2US	Data Address Compare 2 User/Supervisor Mode 00 DAC2 debug events not affected by MSR_{PR} 01 Reserved 10 DAC2 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 DAC2 debug events can only occur if MSR_{PR}=1. (User mode)
6:7	DAC2ER	Data Address Compare 2 Effective/Real Mode 00 DAC2 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 DAC2 debug events are based on effective address and can only occur if MSR_{DS}=0 11 DAC2 debug events are based on effective address and can only occur if MSR_{DS}=1
8:9	DAC12M	Data Address Compare 1/2 Mode 00 Exact address compare. DAC1 debug events can only occur if the address of the data access is equal to the value specified in DAC1. DAC2 debug events can only occur if the address of the data access is equal to the value specified in DAC2. 01 Address bit match. DAC1 debug events can occur only if the address of the data access ANDed with the contents of DAC2, are equal to the contents of DAC1 also ANDed with the contents of DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used. 10 Inclusive address range compare. DAC1 debug events can occur only if the address of the data access is greater than or equal to the value specified in DAC1 and less than the value specified in DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used.

Table continues on the next page...

Table 18-8. DBCR2 Bit Definitions (continued)

Bit	Name	Description
		11 Exclusive address range compare. DAC1 debug events can occur only if the address of the data access is less than the value specified in DAC1 or is greater than or equal to the value specified in DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used.
10	DAC1LNK	Data Address Compare 1 Linked. When linked to IAC1, DAC1 debug events are conditioned based on whether the instruction also generated an IAC1 debug event. Note that linking is only available in EDM or IDM. 0 No effect 1 DAC1 debug events are linked to IAC1 debug events. IAC1 debug events do not affect DBSR When linked to IAC1, DAC1 debug events are conditioned based on whether the instruction also generated an IAC1 debug event. Note that linking is only available in EDM or IDM.
11	DAC2LNK	Data Address Compare 2 Linked. When linked to IAC3, DAC2 debug events are conditioned based on whether the instruction also generated an IAC3 debug event. DAC2 can only be linked if DAC12M specifies Exact Address Compare since DAC2 debug events are not generated in the other compare modes. Note that linking is only available in EDM or IDM. 0 No effect 1 DAC 2 debug events are linked to IAC3 debug events. IAC3 debug events do not affect DBSR
12:13	DVC1M	Data Value Compare 1 Mode When $DBCR4_{DVC1C}$=0: 00 DAC1 debug events not affected by data value compares. 01 DAC1 debug events can only occur when all bytes specified in the DVC1BE field match the corresponding data byte values for active byte lanes of the memory access. 10 DAC1 debug events can only occur when any byte specified in the DVC1BE field matches the corresponding data byte value for active byte lanes of the memory access. 11 DAC1 debug events can only occur when all bytes specified in the DVC1BE field within at least one of the halfwords of the data value of the memory access matches the corresponding DVC1 value. **NOTE:** Inactive byte lanes of the memory access are automatically masked. When $DBCR4_{DVC1C}$=1: 00 Reserved 01 DAC1 debug events can only occur when any byte specified in the DVC1BE field does not match the corresponding data byte value for active byte lanes of the memory access. If all active bytes match, then no event will be generated. 10 DAC1 debug events can only occur when all bytes specified in the DVC1BE field do not match the corresponding data byte values for active byte lanes of the memory access. If any active byte match occurs, no event will be generated. 11 Reserved **NOTE:** Note: Inactive byte lanes of the memory access are automatically masked.
14:15	DVC2M	Data Value Compare 2 Mode When $DBCR4_{DVC2C}$=0: 00 DAC2 debug events not affected by data value compares. 01 DAC2 debug events can only occur when all bytes specified in the DVC2BE field match the corresponding data byte values for active byte lanes of the memory access.

Table continues on the next page...

Table 18-8. DBCR2 Bit Definitions (continued)

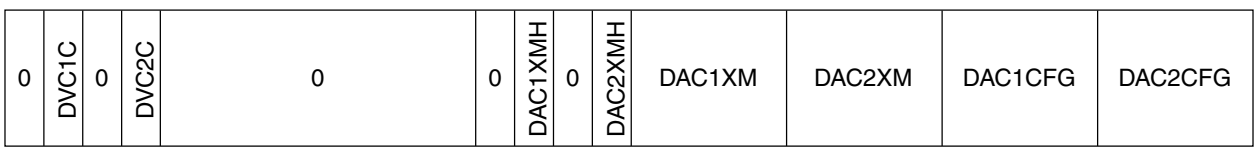
Bit	Name	Description
		10 DAC2 debug events can only occur when any byte specified in the DVC2BE field matches the corresponding data byte value for active byte lanes of the memory access. 11 DAC2 debug events can only occur when all bytes specified in the DVC2BE field within at least one of the halfwords of the data value of the memory access matches the corresponding DVC2 value. **NOTE:** Inactive byte lanes of the memory access are automatically masked. When $DBCR4_{DVC2C}$=1: 00 Reserved 01 DAC2 debug events can only occur when any byte specified in the DVC2BE field does not match the corresponding data byte value for active byte lanes of the memory access. If all active bytes match, then no event will be generated. 10 DAC2 debug events can only occur when all bytes specified in the DVC2BE field do not match the corresponding data byte values for active byte lanes of the memory access. If any active byte match occurs, no event will be generated. 11 Reserved **NOTE:** Inactive byte lanes of the memory access are automatically masked.
16:23	DVC1BE	Data Value Compare 1 Byte Enables Specifies which bytes in the aligned doubleword value associated with the memory access are compared to the corresponding bytes in DVC1. Inactive byte lanes of a memory access smaller than 64 bits are automatically masked by hardware. If all bits in the DVC1BE field are clear, then a match will occur regardless of the data. Misaligned accesses that cross a doubleword boundary are not fully supported. 1xxxxxxx Byte lane 0 is enabled for comparison with the value in bits 0:7 of DVC1. x1xxxxxx Byte lane 1 is enabled for comparison with the value in bits 8:15 of DVC1. xx1xxxxx Byte lane 2 is enabled for comparison with the value in bits 16:23 of DVC1. xxx1xxxx Byte lane 3 is enabled for comparison with the value in bits 24:31 of DVC1. xxxx1xxx Byte lane 4 is enabled for comparison with the value in bits 32:39 of DVC1. xxxxx1xx Byte lane 5 is enabled for comparison with the value in bits 40:47 of DVC1. xxxxxx1x Byte lane 6 is enabled for comparison with the value in bits 48:55 of DVC1. xxxxxxx1 Byte lane 7 is enabled for comparison with the value in bits 56:63 of DVC1.
24:31	DVC2BE	Data Value Compare2 Byte Enables Specifies which bytes in the aligned doubleword value associated with the memory access are compared to the corresponding bytes in DVC2. Inactive byte lanes of a memory access smaller than 64 bits are automatically masked by hardware. If all bits in the DVC1BE field are clear, then a match will occur regardless of the data. Misaligned accesses that cross a doubleword boundary are not fully supported. 1xxxxxxx Byte lane 0 is enabled for comparison with the value in bits 0:7 of DVC2. x1xxxxxx Byte lane 1 is enabled for comparison with the value in bits 8:15 of DVC2. xx1xxxxx Byte lane 2 is enabled for comparison with the value in bits 16:23 of DVC2. xxx1xxxx Byte lane 3 is enabled for comparison with the value in bits 24:31 of DVC2. xxxx1xxx Byte lane 4 is enabled for comparison with the value in bits 32:39 of DVC2. xxxxx1xx Byte lane 5 is enabled for comparison with the value in bits 40:47 of DVC2.

Table 18-8. DBCR2 Bit Definitions

Bit	Name	Description
		xxxxxx1x Byte lane 6 is enabled for comparison with the value in bits 48:55 of DVC2. xxxxxxx1 Byte lane 7 is enabled for comparison with the value in bits 56:63 of DVC2.

18.4.2.4 Debug Control Register 4 (DBCR4)

Debug Control Register 4 is used to extend data address and value compare matching functionality. DBCR4 is shown in the following figure.



SPR - 563; Read/Write; Reset[1] - 0x0

Figure 18-7. DBCR4 Register

Note

[1] DBCR4 is reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 4.

Table 18-9. DBCR4 field description

Bit	Name	Description
0	—	Reserved
1	DVC1C	Data Value Compare 1 Control. DVC1C controls whether DVC1 data value comparisons utilize the normal compare operation, or an alternate “inverted compare” operation. In inverted polarity mode, data value compares perform a not-equal comparison. See details in the DBCR2 register definition. 0 Normal DVC1 operation. 1 Inverted polarity DVC1 operation
2	—	Reserved
3	DVC2C	Data Value Compare 2 Control. DVC2C controls whether DVC2 data value comparisons utilize the normal compare operation, or an alternate “inverted compare” operation. In inverted polarity mode, data value compares perform a not-equal comparison. See details in the DBCR2 register definition 0 Normal DVC2 operation.

Table continues on the next page...

Table 18-9. DBCR4 field description (continued)

Bit	Name	Description
		1 Inverted polarity DVC2 operation
4:12	—	Reserved
13	DAC1XMH	Data Address Compare 1 Extended Mask Control High. DAC1XMH extends the range of the DAC1XM field. 0 DAC1XM masks 0–15 low-order address bits 1 DAC1XM masks 16–31 low-order address bits
14	—	Reserved
15	DAC2XMH	Data Address Compare 2 Extended Mask Control High. . DAC2XMH extends the range of the DAC2XM field. 0 DAC2XM masks 0–15 low-order address bits 1 DAC2XM masks 16–31 low-order address bits
16:19	DAC1XM	Data Address Compare 1 Extended Mask Control. DAC1XM allows for binary power of 2 address range compares for DAC1 without requiring the use of DAC2. Value of DAC1XMH || DAC1XM: 00000 No additional masking when DBCR2[DAC12M] = 00 00001 - 11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC1 when comparing the storage address with the value in DAC1 for exact address compare (DBCR2[DAC12M] = 00). Address ranges of 2 bytes to 2GB are supported.
20:23	DAC2XM	Data Address Compare 2 Extended Mask Control Value of DAC2XMH || DAC2XM: 00000 No additional masking when DBCR2[DAC12M] = 00 00001 - 11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC2 when comparing the storage address with the value in DAC2 for exact address compare (DBCR2[DAC12M] = 00). Address ranges of 2 bytes to 2GB are supported. DAC2XM allows for binary power of 2 address range compares for DAC2.
24:27	DAC1CFG	Data Address Compare 1 Configuration 0000 DAC1 debug watchpoints are enabled for load-type or store-type data storage accesses when $DBCR0_{DAC1}$=00 0001 DAC1 debug watchpoints are enabled only for store-type data storage accesses when $DBCR0_{DAC1}$=00 0010 DAC1 debug watchpoints are enabled only for load-type data storage accesses when $DBCR0_{DAC1}$=00 0011 Reserved 01xx Reserved 1000 DAC1 address comparisons are used for stack limit checking. DAC1 address comparisons are qualified with use of GPR R1 in <EA> calculation for most load or store instructions. No debug events occur for DAC1. When a qualified DAC1 match occurs, a machine check exception is generated for supervisor-mode accesses or a DSI is generated for user-mode accesses, and a DAC1 watchpoint is generated. $DBCR0_{DAC1}$ and $DBCR2_{DVC1M}$ settings are ignored. 1001 – 1111 Reserved DAC1CFG controls whether DAC1 data address comparisons utilize the normal PowerISA operation for generating both debug events and watchpoints, a watchpoint-only function, or a stack limit checking function (with watchpoint).

Table continues on the next page...

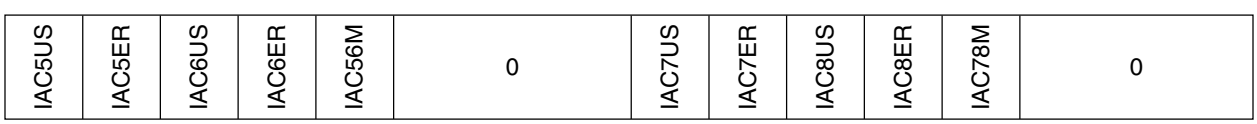
Table 18-9. DBCR4 field description (continued)

Bit	Name	Description
		NOTE: unlike the DAC3–4CFG fields, debug event enabling for DAC1 is controlled by the DAC1 field in DBCR0. The DAC1CFG encodings 0000–0010 are used to control watchpoint generation when $DBCR0_{DAC1}$=0; when $DBCR0_{DAC1}$!=00, DAC1 watchpoints will fire whenever a DAC1 debug event occurs.
28:31	DAC2CFG	Data Address Compare 2 Configuration 0000 DAC2 debug watchpoints are enabled for load-type or store-type data storage accesses when $DBCR0_{DAC2}$=00 0001 DAC2 debug watchpoints are enabled only for store-type data storage accesses when $DBCR0_{DAC2}$=00 0010 DAC2 debug watchpoints are enabled only for load-type data storage accesses when $DBCR0_{DAC2}$=00 0011 Reserved 01xx Reserved 1xxx Reserved DAC2CFG controls whether DAC2 data address comparisons utilize the normal compare operation for generating both debug events and watchpoints, or a watchpoint-only function. **NOTE:** Unlike the DAC3–4CFG fields, debug event enabling for DAC2 is controlled by the DAC2 field in DBCR0. The DAC2CFG encodings 0000–0010 are used to control watchpoint generation when $DBCR0_{DAC2}$=00. When $DBCR0_{DAC2}$!=00, DAC2 watchpoints will fire whenever a DAC2 debug event occurs.

18.4.2.5 Debug Control Register 5 (DBCR5)

Debug Control Register 5 is used to configure Instruction Address Compare operation for IAC5–8. The DBCR5 register is shown in the following figure.

.



SPR - 564; Read/Write; Reset[1] - 0x0

Figure 18-8. DBCR5 Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 5.

Table 18-10. DBCR5 field descriptions

Bit(s)	Name	Description
0:1	IAC5US	Instruction Address Compare 5 User/Supervisor Mode 00 IAC5 debug events not affected by MSR_{PR} 01 Reserved 10 IAC5 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 IAC5 debug events can only occur if MSR_{PR}=1. (User mode)
2:3	IAC5ER	Instruction Address Compare 5 Effective/Real Mode 00 IAC5 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 IAC5 debug events are based on effective address and can only occur if MSR_{IS}=0 11 IAC5 debug events are based on effective address and can only occur if MSR_{IS}=1
4:5	IAC6US	Instruction Address Compare 6 User/Supervisor Mode 00 IAC6 debug events not affected by MSR_{PR} 01 Reserved 10 IAC6 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 IAC6 debug events can only occur if MSR_{PR}=1. (User mode)
6:7	IAC6ER	Instruction Address Compare 6 Effective/Real Mode 00 IAC6 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 IAC6 debug events are based on effective address and can only occur if MSR_{IS}=0 11 IAC6 debug events are based on effective address and can only occur if MSR_{IS}=1
8:9	IAC56M	Instruction Address Compare 5/6 Mode 00 Exact address compare. IAC5 debug events can only occur if the address of the instruction fetch is equal to the value specified in IAC5. IAC6 debug events can only occur if the address of the instruction fetch is equal to the value specified in IAC6. 01 Address bit match. IAC5 debug events can occur only if the address of the instruction fetch, ANDed with the contents of IAC6 are equal to the contents of IAC5, also ANDed with the contents of IAC6. IAC6 debug events do not occur. IAC5US and IAC5ER settings are used. 10 Inclusive address range compare. IAC5 debug events can occur only if the address of the instruction fetch is greater than or equal to the value specified in IAC5 and less than the value specified in IAC6. IAC6 debug events do not occur. IAC5US and IAC5ER settings are used. 11 Exclusive address range compare. IAC5 debug events can occur only if the address of the instruction fetch is less than the value specified in IAC5 or is greater than or equal to the value specified in IAC6. IAC6 debug events do not occur. IAC5US and IAC5ER settings are used.
10:15	—	Reserved

Number of low order bits masked in IAC8 when comparing the storage address with the value in IAC8 for exact address compare (DBCR5[IAC78M]=00). Ranges up to 4 KB are supported. 1101 - 1111 Reserved

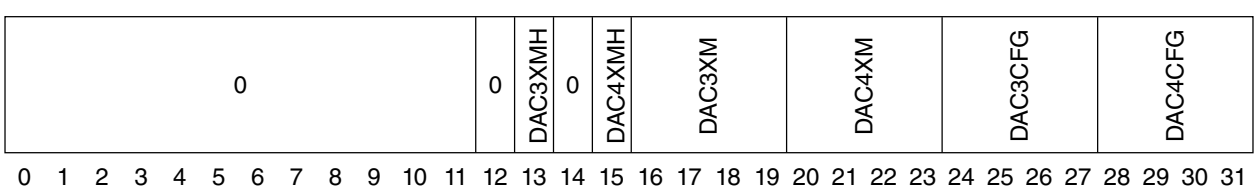
18.4.2.7 Debug Control Register 7 (DBCR7)

Debug Control Register 7 is used to enable and configure Data Address Compare 3 and 4 functionality. DBCR7 is shown in the following figure.



SPR - 596; Read/Write; Reset[1] - 0x0

Figure 18-10. DBCR7 Register

Note

[1] DBCR7 is reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 7.

Table 18-12. DBCR7 Field Descriptions

Bit	Name	Description
0:12	—	Reserved
13	DAC3XMH	Data Address Compare 3 Extended Mask Control High .DAC3XMH extends the range of the DAC3XM field 0 DAC3XM masks 0–15 low-order address bits 1 DAC3XM masks 16–31 low-order address bits
14	—	Reserved
15	DAC4XMH	Data Address Compare 4 Extended Mask Control High. . DAC4XMH extends the range of the DAC4XM field. 0 DAC4XM masks 0–15 low-order address bits 1 DAC4XM masks 16–31 low-order address bits
16:19	DAC3XM	Data Address Compare 3 Extended Mask Control. DAC3XM allows for binary power of 2 address range compares for DAC3 without requiring the use of DAC4. Value of DAC3XMH || DAC3XM: 00000 No additional masking when DBCR8[DAC34M] = 00 00001 - 11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC3 when comparing the storage address with the value in DAC3 for exact address compare (DBCR8[DAC34M] = 00). Address ranges of 2 bytes to 2GB are supported.
20:23	DAC4XM	Data Address Compare 4 Extended Mask Control. DAC4XM allows for binary power of 2 address range compares for DAC4 without requiring the use of DAC3. Value of DAC4XMH || DAC4XM: 00000 No additional masking when DBCR8[DAC34M] = 00 00001 - 11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC4 when comparing the storage address with the value in DAC4 for exact address compare (DBCR8[DAC34M] = 00). Address ranges of 2 bytes to 2GB are supported.
24:27	DAC3CFG	Data Address Compare 3 Configuration. DAC3CFG controls whether DAC3 data address comparisons utilize the normal compare operation for generating both debug events and watchpoints, a watchpoint-only function, or a stack limit checking function (with watchpoint). 0000 DAC3 debug watchpoints are enabled for load-type or store-type data storage accesses 0001 DAC3 debug watchpoints are enabled only for store-type data storage accesses

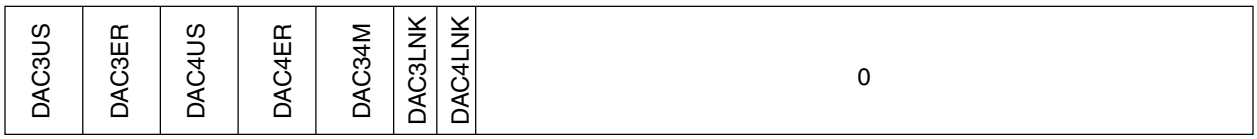
Table continues on the next page...

Table 18-12. DBCR7 Field Descriptions (continued)

Bit	Name	Description
		0010 DAC3 debug watchpoints are enabled only for load-type data storage accesses 0011 Reserved 0100Reserved 0101 DAC3 debug events and watchpoints are enabled only for store-type data storage accesses 0110 DAC3 debug events and watchpoints are enabled only for load-type data storage accesses 0111 DAC3 debug events and watchpoints are enabled for load-type or store-type data storage accesses 1000 DAC3 address comparisons are used for stack limit checking. DAC3 address comparisons are qualified with use of GPR R1 in <EA> calculation for most load or store instructions. No debug events occur for DAC3. When a qualified match occurs, a machine check exception is generated for supervisor-mode accesses or a DSI is generated for user-mode accesses, and a DAC3 watchpoints is generated. 1001 - 1111 Reserved
28:31	DAC4CFG	Data Address Compare 4 Configuration. DAC4CFG controls whether DAC4 data address comparisons utilize the normal compare operation for generating both debug events and watchpoints, or a watchpoint-only function. 0000 DAC4 debug watchpoints are enabled for load-type or store-type data storage accesses 0001 DAC4 debug watchpoints are enabled only for store-type data storage accesses 0010 DAC4 debug watchpoints are enabled only for load-type data storage accesses 0011 Reserved 0100 Reserved 0101 DAC4 debug events and watchpoints are enabled only for store-type data storage accesses 0110 DAC4 debug events and watchpoints are enabled only for load-type data storage accesses 0111 DAC4 debug events and watchpoints are enabled for load-type or store-type data storage accesses 1xxx Reserved

18.4.2.8 Debug Control Register 8 (DBCR8)

Debug Control Register 8 is used to configure Data Address Compare 3 and 4 operation. The DBCR8 register is shown in the following figure.



SPR - 597; Read/Write; Reset[1] - 0x0

Figure 18-11. DBCR8 Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 8.

Table 18-13. DBCR8 Bit Definitions

Bit(s)	Name	Description
0:1	DAC3US	Data Address Compare 3 User/Supervisor Mode 00 - DAC3 debug events not affected by MSR_{PR} 01 - Reserved 10 - DAC3 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 - DAC3 debug events can only occur if MSR_{PR}=1. (User mode)
2:3	DAC3ER	Data Address Compare 3 Effective/Real Mode 00 - DAC3 debug events are based on effective address 01 - Unimplemented (Book E real address compare), no match can occur 10 - DAC3 debug events are based on effective address and can only occur if MSR_{DS}=0 11 - DAC3 debug events are based on effective address and can only occur if MSR_{DS}=1
4:5	DAC4US	Data Address Compare 4 User/Supervisor Mode. 00 - DAC4 debug events not affected by MSR_{PR} 01 - Reserved 10 - DAC4 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 - DAC4 debug events can only occur if MSR_{PR}=1. (User mode)
6:7	DAC4ER	Data Address Compare 4 Effective/Real Mode 00 - DAC4 debug events are based on effective address 01 - Unimplemented (Book E real address compare), no match can occur 10 - DAC4 debug events are based on effective address and can only occur if MSR_{DS}=0

Table continues on the next page...

Table 18-13. DBCR8 Bit Definitions (continued)

Bit(s)	Name	Description
		11 - DAC4 debug events are based on effective address and can only occur if MSR_{DS}=1
8:9	DAC34M	Data Address Compare 3/4 Mode 00 - Exact address compare. DAC3 debug events can only occur if the address of the data access is equal to the value specified in DAC3. DAC4 debug events can only occur if the address of the data access is equal to the value specified in DAC4. 01 - Address bit match. DAC3 debug events can occur only if the address of the data access ANDed with the contents of DAC4, are equal to the contents of DAC3 also ANDed with the contents of DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used. 10 - Inclusive address range compare. DAC3 debug events can occur only if the address of the data access is greater than or equal to the value specified in DAC3 and less than the value specified in DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used. 11 - Exclusive address range compare. DAC3 debug events can occur only if the address of the data access is less than the value specified in DAC3 or is greater than or equal to the value specified in DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used.
10	DAC3LNK	Data Address Compare 3 Linked 0 - No effect 1 - DAC3 debug events are linked to IAC5 debug events. IAC5 debug events do not affect DBSR When linked to IAC5, DAC3 debug events are conditioned based on whether the instruction also generated an IAC5 debug event. Note that linking is only available in EDM or IDM.
11	DAC4LNK	Data Address Compare 4 Linked 0 - No effect 1 - DAC4 debug events are linked to IAC7 debug events. IAC7 debug events do not affect DBSR When linked to IAC7, DAC4 debug events are conditioned based on whether the instruction also generated an IAC7 debug event. Note that linking is only available in EDM or IDM.
12:31	—	Reserved

18.4.2.9 Debug Status Register (DBSR)

The Debug Status Register (DBSR) contains status on debug events and the most recent processor reset. The Debug Status Register is set via hardware, and read and cleared via software. Bits in the Debug Status Register can be cleared using **mtspr***DBSR,RS*. Clearing is done by writing to the Debug Status Register with a 1 in any bit position that is to be cleared and 0 in all other bit positions. The write data to the Debug Status Register is not direct data, but a mask. A '1' causes the bit to be cleared, and a '0' has no

effect. Debug Status bits are set by Debug events only while Internal Debug Mode is enabled ($DBCR0_{IDM}$=1). When debug interrupts are enabled (MSR_{DE}=1 $DBCR0_{IDM}$=1 and $EDBCR0_{EDM}$=0, or MSR_{DE}=1, $DBCR0_{IDM}$=1, $EDBCR0_{EDM}$=1 and software is allocated resource(s) via EDBRAC0), a set bit in DBSR other than MRR, DAC_OFST, or VLES will cause a debug interrupt to be generated. The debug interrupt handler is responsible for clearing DBSR bits prior to returning to normal execution. When resource sharing is enabled, ($EDBCR0_{EDM}$=1 and $EDBRAC0_{IDM}$=1), only software-owned resources may be modified by software, and status bits associated with hardware-owned resources will not be set by hardware in DBSR. The DBSR register is shown in the following figure.

SPR - 304; Read/Clear; Reset - 0x1000_0000

Figure 18-12. DBSR Register

The following table provides bit definitions for the Debug Status Register.

Table 18-14. DBSR Bit Definitions

Bit(s)	Name	Description
0	IDE	Imprecise Debug Event Set to 1 if MSR_{DE}=0 and $DBCR0_{IDM}$=1 and a debug event causes its respective Debug Status Register bit to be set to 1. It may also be set to '1' if an imprecise debug event occurs due to a DAC event on a load or store which is terminated with error, or if an ICMP event occurs in conjunction with a EFPU FP round exception.
1	UDE	Unconditional Debug Event Set to 1 if an Unconditional debug event occurred.
2:3	MRR	Most Recent Reset. 00 - No reset occurred since these bits were last cleared by software 01 - A hard reset occurred since these bits were last cleared by software 10 - Reserved 11 - Reserved
4	ICMP	Instruction Complete Debug Event Set to 1 if an Instruction Complete debug event occurred.
5	BRT	Branch Taken Debug Event Set to 1 if an Branch Taken debug event occurred.
6	IRPT	Interrupt Taken Debug Event Set to 1 if an Interrupt Taken debug event occurred.
7	TRAP	Trap Taken Debug Event

Table continues on the next page...

Table 18-14. DBSR Bit Definitions (continued)

Bit(s)	Name	Description
		Set to 1 if a Trap Taken debug event occurred.
8	IAC	Instruction Address Compare Debug Event Set to 1 if an IAC debug event occurred.
9:11	—	Reserved
12	DACR	Data Address Compare Read Debug Event Set to 1 if a read-type DAC debug event occurred
13	DACW	Data Address Compare Write Debug Event Set to 1 if a write-type DAC debug event occurred
14	—	Reserved
15	DNI	DNI Debug Event Set to 1 if a DNI debug event occurred
16	RET	Return Debug Event Set to 1 if a Return debug event occurred
17:20	—	Reserved
21	DEVT1	External Debug Event 1 Debug Event Set to 1 if a DEVT1 debug event occurred
22	DEVT2	External Debug Event 2 Debug Event Set to 1 if a DEVT2 debug event occurred
23	PMI	Performance Monitor Interrupt Debug Event Set to 1 if a Performance Monitor Interrupt event occurred with $PMGC0_{UDI}$=1
24	MPU	Memory Protection Unit Debug Event Set to 1 if a MPU debug event occurred. For MPU debug events, the IAC, DACR, or DACW status bit will also be set, depending on the type of access which matched a region descriptor enabled to generate debug events, in order to further define the type of MPU debug event. Note that software MPU debug events on data accesses normally occur after the data access is performed and the instruction completes, thus act like a normal DAC debug event. The instruction may not complete if a DSI occurs. In this case, IDE will be set to indicate this occurrence.
25	CIRPT	Critical Interrupt Taken Debug Event Set to 1 if a Critical Interrupt Taken debug event occurred.
26	CRET	Critical Return Debug Event Set to 1 if a Critical Return debug event occurred
27	VLES	VLE Status Set to 1 if an ICMP, BRT, TRAP, RET, CRET, IAC, or DAC debug event occurred on a Power ISA VLE Instruction. Undefined for IRPT, CIRPT, DEVT[1,2], and UDE events
28:30	DAC_OFST	Data Address Compare Offset Indicates offset-1 of saved DSRR0 value from the address of the load or store instruction which took a DAC Debug exception, unless a simultaneous DSI error occurs, in which case this field is set to 3'b000 and $DBSR_{IDE}$ is set to 1. Normally set to 3'b000 by a non-DVC DAC. A DVC DAC may set this field to any value.
31	—	Reserved

18.4.2.10 Debug Data Effective Address Register (DDEAR)

The Debug Data Effective Address Register (DDEAR) contains address information for data address compare debug events (DAC or MPU DAC). DDEAR is update by hardware with the effective address of the load, store, or cache control operation when a data address compare event is recorded in DBSR if the previous values of the $DBSR_{DAC\{R,W\}}$ bits are zero. Once a DDEAR update is performed, these bits must be cleared by software prior to another DDEAR hardware update occurring. A subsequent DAC or MPU DAC event will not update the DDEAR register if either of the $DBSR_{DAC\{R,W\}}$ bits are set, in order to capture the first event address.

The DDEAR register is shown in the following table.

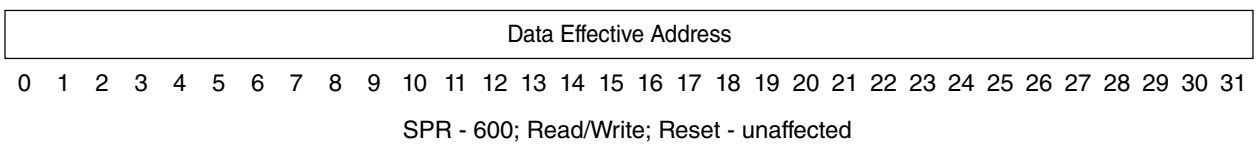


Figure 18-13. DDEAR Register

18.4.3 External Debug Resource Allocation Control Register (EDBRAC0)

The External Debug Resource Allocation Control Register (EDBRAC0) controls resource allocation when $EDBCR0_{EDM}$ is set to '1'. EDBRAC0 provides a mechanism for the hardware debugger to share certain debug resources with software. Individual resources are allocated based on the settings of EDBRAC0 when $EDBCR0_{EDM}$=1. EDBRAC0 settings are ignored when $EDBCR0_{EDM}$=0.

Hardware-owned resources which generate debug events update EDBSR0 instead of DBSR and cause entry into debug mode if the event is not masked in EDBSRMSK0, while software-owned resources which generate debug events if $DBCR0_{IDM}$=1 update DBSR, causing debug interrupts to occur if MSR_{DE}=1. EDBRAC0 is controlled via the OnCE port hardware, and is read-only to software.

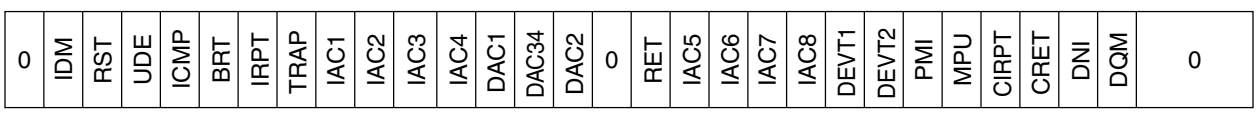
The DBSR status register is always owned by software. Debug status bits in DBSR are set by software-owned debug events only while Internal Debug Mode is enabled. When debug interrupts are enabled (MSR_{DE}=1 $DBCR0_{IDM}$=1 and $EDBCR0_{EDM}$=0, or MSR_{DE}=1, $DBCR0_{IDM}$=1 and $EDBCR0_{EDM}$=1 and software is allocated resource(s) via EDBRAC0), a set bit in DBSR by an event which is software-owned (other than MRR, DAC_OFST, or VLES) will cause a debug interrupt to be generated.

Debug status bits in EDBSR0 are set by hardware-owned debug events only while External Debug Mode is enabled ($EDBCR0_{EDM}$=1). When $EDBCR0_{EDM}$=1, a set bit in EDBSR0 by an event which is hardware-owned (other than IDE, DAC_OFST, or VLES) will cause entry into debug mode unless entry is masked via EDBSRMSK0.

If $EDBCR0_{EDM}$=1, DBSR status bits corresponding to hardware-owned debug events are masked from being set by hardware.

Software-owned resources may be modified by software, but only the corresponding control bits in DBCR0–8 or MPU0CSR0 are affected by execution of a **mtspr**, thus only a portion of these registers may be affected, depending on the allocation settings in EDBRAC0. The debug interrupt handler is still responsible for clearing DBSR bits for software-owned resources prior to returning to normal execution. Hardware always has full access to all registers and register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control and status registers as appropriate when hardware modifications to the debug registers is performed.

The EDBRAC0 register is shown in the following figure.



SPR - 638; Read-only by Software; Reset - Unaffected by **p_reset_b,** reset to 0x00000180 by **m_por** or while in the test-logic-reset OnCE controller state

Figure 18-14. EDBRAC0 Register

Table 18-14 provides bit definitions for the Debug External Resource Control Register. Note that EDBRAC0 controls are disabled when EDBCR0EDM=0.

Table 18-15. EDBRAC0 Bit Definitions

Bit(s)	Name	Description
0	—	Reserved
1	IDM	Internal Debug Mode control 0 - Internal Debug mode may not be enabled by software. $DBCR0_{IDM}$ is owned exclusively by hardware. **mtspr** DBCR0–8 and other debug registers is always ignored. No resource sharing occurs, regardless of the settings of other fields in EDBRAC0. Hardware exclusively owns all resources. 1 - Internal Debug mode may be enabled by software. $DBCR0_{IDM}$ is owned by software. $DBCR0_{IDM}$ is software readable/writable. When $EDBRAC0_{IDM}$=1, software writes to hardware-owned bits in DBCR0–8 via **mtspr** are ignored.

Table continues on the next page...

Table 18-15. EDBRAC0 Bit Definitions (continued)

Bit(s)	Name	Description
2	RST	Reset Field Control 0 - $DBCR0_{RST}$ owned exclusively by hardware debug. No **mtspr** access by software to $DBCR0_{RST}$ field. 1 - $DBCR0_{RST}$ accessible by software debug. $DBCR0_{RST}$ is software readable/writable.
3	UDE	Unconditional Debug Event 0 - Event owned by hardware debug. 1 - Event owned by software debug.
4	ICMP	Instruction Complete Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{ICMP}$ field. 1 - Event owned by software debug. $DBCR0_{ICMP}$ is software readable/writable.
5	BRT	Branch Taken Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{BRT}$ field. 1 - Event owned by software debug. $DBCR0_{BRT}$ is software readable/writable.
6	IRPT	Interrupt Taken Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{IRPT}$ field. 1 - Event owned by software debug. $DBCR0_{IRPT}$ is software readable/writable.
7	TRAP	Trap Taken Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{TRAP}$ field. 1 - Event owned by software debug. $DBCR0_{TRA}$P is software readable/writable.
8	IAC1	Instruction Address Compare 1 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC1 control and status fields. 1 - Event owned by software debug. IAC1 control fields are software readable/writable.
9	IAC2	Instruction Address Compare 2 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC2 control and status fields. 1 - Event owned by software debug. IAC2 control fields are software readable/writable.
10	IAC3	Instruction Address Compare 3 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC3 control and status fields. 1 - Event owned by software debug. IAC3 control fields are software readable/writable.
11	IAC4	Instruction Address Compare 4 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC4 control and status fields. 1 - Event owned by software debug. IAC4 control fields are software readable/writable.
12	DAC1	Data Address Compare 1 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to DAC1 control and status fields.

Table continues on the next page...

Table 18-15. EDBRAC0 Bit Definitions (continued)

Bit(s)	Name	Description
		1 - Event owned by software debug. DAC1 control fields are software readable/ writable.
13	DAC34	Data Address Compare 3 and 4 Debug Events 0 - Events owned by hardware debug. No **mtspr** access by software to DAC3 and DAC4 control and status fields. 1 - Event owned by software debug. DAC3 and DAC4 control fields are software readable/writable.
14	DAC2	Data Address Compare 2 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to DAC2 control and status fields. 1 - Event owned by software debug. DAC2 control fields are software readable/ writable.
15	—	Reserved
16	RET	Return Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{RET}$ field. 1 - Event owned by software debug. $DBCR0_{RET}$ is software readable/writable.
17	IAC5	Instruction Address Compare 5 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC5 control and status fields. 1 - Event owned by software debug. IAC5 control fields are software readable/writable.
18	IAC6	Instruction Address Compare 6 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC6 control and status fields. 1 - Event owned by software debug. IAC6 control fields are software readable/writable.
19	IAC7	Instruction Address Compare 7 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC7 control and status fields. 1 - Event owned by software debug. IAC7 control fields are software readable/writable.
20	IAC8	Instruction Address Compare 8 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC8 control and status fields. 1 - Event owned by software debug. IAC8 control are software readable/writable.
21	DEVT1	External Debug Event Input 1 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{DEVT1}$ field. 1 - Event owned by software debug. $DBCR0_{DEVT1}$ is software readable/writable.
22	DEVT2	External Debug Event Input 2 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{DEVT2}$ field. 1 - Event owned by software debug. $DBCR0_{DEVT2}$ is software readable/writable.
23	PMI	Performance Monitor Interrupt Debug Event

Table continues on the next page...

Table 18-15. EDBRAC0 Bit Definitions (continued)

Bit(s)	Name	Description
		0 - Event owned by hardware debug. No **mtspr** access by software to the PMRs. Performance monitor interrupts set $EDBSR0_{PMI}$ regardless of the setting of $PMGC0_{UDI}$ 1 - Event owned by software debug. PMRs are software readable/writable. **Note:** this bit is reset to '1'.
24	MPU	Memory Protection Unit Debug Event 0 - Event owned by hardware debug. No **mpuwe** access by software to region descriptors which have the DEBUG control bit set to '1' or to the $MPU0CSR0_{DRDEN,DWDEN,IDEN}$ control bits, unless the CPU is in a debug session (**jd_debug_b** is asserted). MPU debug events set $EDBSR0_{MPU}$, and if not masked by $EDBSRMSK0_{MPU}$, one of $EDBSR0_{IAC}$, $EDBSR0_{DACR}$, or $EDBSR0_{DACW}$. MPU flash invalidates do not affect DEBUG=1 entries unless the CPU is in a debug session (**jd_debug_b** is asserted). 1 - Event owned by software debug. All region descriptors and the $MPU0CSR0_{DRDEN,DWDEN,IDEN}$ control bits are software readable/writable. **Note:** this bit is reset to '1'.
25	CIRPT	Critical Interrupt Taken Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{CIRPT}$ field. 1 - Event owned by software debug. $DBCR0_{CIRPT}$ is software readable/writable.
26	CRET	Critical Return Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{CRET}$ field. 1 - Event owned by software debug. $DBCR0_{CRET}$ is software readable/writable.
27	DNI	DNI Instruction Debug Control 0 - DNI resource owned by hardware debug. Execution of an **e_dni** or **se_dni** instruction results in entry into debug mode. 1 - DNI resource owned by software debug. Execution of an **e_dni** or **se_dni** instruction results in either a debug interrupt ($DBCR0_{IDM}$=1 and MSR_{DE}=1) or a nop ($DBCR0_{IDM}$=0 or MSR_{DE}=0). **Note:** DNI events are not blocked during a debug session
28	DQM	Data Acquisition Messaging Registers 0 - $DEVENT_{DQTAG}$ and DDAM register are exclusively owned by hardware debug. No **mtspr** access by software to $DEVENTD_{QTAG}$ field or DDAM register. Attempted access by software is ignored. 1 - $DEVENT_{DQTAG}$ and DDAM register are owned by software. Software has read/write access to $DEVENT_{DQTAG}$ field and DDAM register.
29:31	—	Reserved

Table 18-16 shows which resources are controlled by EDBRAC0 settings.

1. Note: IDM not required to be set to enable software access.

EDBRAC0 also controls which bits or fields in DBCR0–8, MPU0CSR0, and the PMRs are reset by assertion of **p_reset_b** when $EDBCR0_{EDM}$=1. Only software-owned bits or fields as shown in Table 18-16 are affected in this case, except that $DBCR0_{RST}$ and $DBSR_{MRR}$ are updated by assertion of **p_reset_b** regardless of the value of $EDBCR0_{EDM}$ or EDBRAC0.

18.4.4 Debug Event Select Register (DEVENT)

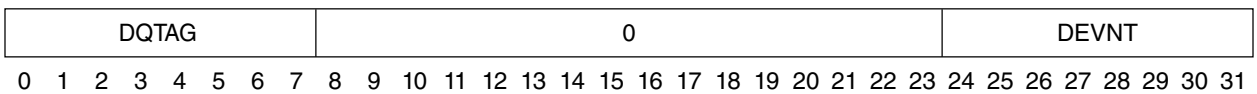
The Debug Event Select Register allows instrumented software to internally generate signals when a **mtspr** instruction is executed and this register is accessed. The values written to this register determine which of the **p_devnt_out[0:7]** processor output signals are asserted upon access. Writing a '1' to any of these bit positions will cause a one clock pulse to be generated on the corresponding output. For **p_devnt_out[0:3]**, a corresponding **jd_watchpt[x]** output is asserted as well to indicate a watchpoint has

occurred. These signals may be used for internal core debug resources as well as for SoC level cross-triggering. See the SoC User's Manual for more information on SoC use cases.

The $DEVENT_{DEVNT}$ register field value is undefined on a read; it may or may not remain set to the last value written. Since it is unconditionally shared by hardware debug and software, software should not rely on any value remaining.

The upper 8 bits of the DEVENT register also provide the DQTAG used to identify channels within Data Acquisition Messages. See the "Data Acquisition ID Tag Field" section in the Core (e200z4201n3) Nexus 3 Module chapter for more detail on the DQTAG.

The DEVENT register is shown in the following figure.



SPR - 975; Reset[1] - 0x0

Figure 18-15. DEVENT Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**. Note that DEVNT field is shared by hardware and software but is always reset by **p_reset_b**.

The following table provides bit definitions for the Debug Event Register.

Table 18-17. DEVENT Bit Definitions

Bit(s)	Name	Description
0:7	DQTAG	Data Acquisition Message IDTAG channel identifier (supplied to Nexus 3)
8:23	—	Reserved, should be cleared.
24:31	DEVNT	Debug Event Signals 00000000 - No signal is asserted xxxxxxx1 - **p_devnt_out[0]** and **jd_watchpt[12]** are asserted for one clock xxxxxx1x - **p_devnt_out[1]** and **jd_watchpt[13]** are asserted for one clock xxxxx1xx - **p_devnt_out[2]** and **jd_watchpt[20]** are asserted for one clock xxxx1xxx - **p_devnt_out[3]** and **jd_watchpt[21]** are asserted for one clock xxx1xxxx - **p_devnt_out[4]** is asserted for one clock xx1xxxxx - **p_devnt_out[5]** is asserted for one clock

Table 18-17. DEVENT Bit Definitions

Bit(s)	Name	Description
		x1xxxxxx - **p_devnt_out[6]** is asserted for one clock 1xxxxxxx - **p_devnt_out[7]** is asserted for one clock

18.4.5 Debug Data Acquisition Message Register (DDAM)

The Debug Data Acquisition Message Register allows instrumented software to generate real-time Data Acquisition Messages (as defined by Nexus 3) via a **mtspr** instruction to this register. See the "Data Acquisition Messaging" section in the Core (e200z4201n3) Nexus 3 Module chapter for details.

The DDAM register is shown in the following figure.

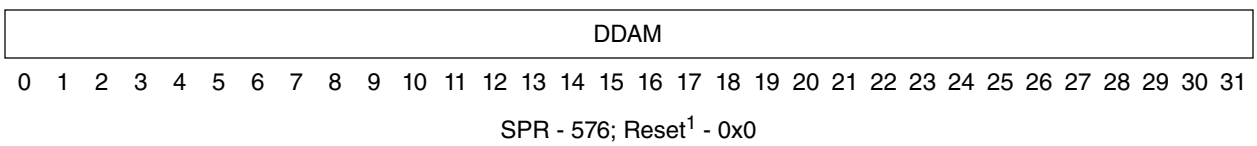


Figure 18-16. DDAM Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for the Debug Data Acquisition Message Register.

Table 18-18. DDAM Bit Definitions

Bit(s)	Name	Description
0:31	DDAM	Value to be transmitted in a Data Acquisition Message (DQM) (supplied to Nexus 3 with strobe)

18.5 Using Debug Resources for Stack Limit Checking

The DAC1,2 and DAC3,4 resources can be used for stack overflow/underflow detection when not being used as a hardware or software debug resource. Stack limit checking is available regardless of EDM or IDM mode, and when resources used for stack limit checking are owned by software, will utilize a DSI or machine check exception. Software-owned stack limit checking does not require IDM to be set. Hardware owned stack limit checking requires EDM to be set.

When stack limit checking is enabled, and DAC resources used for stack limit checking are owned by software, DAC events are not generated for resources configured to perform stack limit checking, and no DBSR DAC status flag will be set due to a detected stack limit violation. Instead, depending on the processor mode, a data storage interrupt or a machine check exception is signaled. When stack limit checking is enabled, and DAC resources used for stack limit checking are owned by hardware, DAC events will be generated for resources configured to perform stack limit checking, and the EDBSR0 DAC status flag will be set due to a detected stack limit violation, causing entry into debug halted mode in the same way as a DAC exception normally does. The only difference is that qualification of the access address is performed as discussed in the next paragraph.

Stack limit checking is implemented in the same way as range compares using DAC1,2 or 3,4, or extended masking using DAC1 or DAC3, but qualify a load or store access address with the use of GPR R1 as the base or index register used to compute an effective address when a load or store instruction is executed. No stack limit checking is performed for other instructions which may calculate an EA using GPR R1 such as cache, MMU/MPU management instructions, or instructions which indicate GPR R1 is used to hold a decoration value (for decorated load/store type instructions). When DAC resources configured to perform stack limit checking are not owned by hardware, if a stack limit violation occurs when performing the load or store, the access is aborted, and an error report machine check is generated, with MCSRR0 pointing to the address of the load or store access which generated the stack overflow/underflow. If DAC resources configured to perform stack limit checking are owned by hardware, then a normal DAC event is generated (but qualified with use of GPR R1), and debug mode entry will occur in the same manner as for a non-stack limit DAC event.

Enabling of this functionality is described in more detail in Table 18-9. Note that IDM is not required to be set for software-owned stack limit checking.

In contrast to the normal case of DAC address matching resulting in a debug event, the stack limit check address compare logic operates differently for stack limit checking. When using resources for stack limit checking, a DACn hit to a resource enabled for performing stack limit checking on a stack access indicates a stack limit violation.

When stack limit checking is enabled by the setting of the $DBCR4_{DAC1CFG}$ field to '1000' or the $DBCR8_{DAC3CFG}$ field to '1000' (or both), and the corresponding DACn resources are owned by software, DACn events are not generated and the DBSR DAC status flag will not be set due to a detected stack limit hit. Instead, if stack limit checking is enabled for supervisor mode stack accesses in DAC1 or DAC3, and a compare hit occurs for a supervisor mode stack access (A load or store using GPR R1 in the <EA> calculation), a machine check exception is signaled. If stack limit checking is enabled for user mode accesses, a DSI exception is signaled when a stack limit checking enabled DAC1 or DAC3 compare hit occurs for a user mode access. A watchpoint for DAC1 or DAC3 will be generated when the stack limit violation is detected, even though the instruction does not complete. Stack limit checking for supervisor mode stack accesses is considered enabled when either the $DBCR4_{DAC1CFG}$ field is set to '1000' with $DBCR2_{DAC1US}$ set to '00' or '10', or the $DBCR7_{DAC3CFG}$ field is set to '1000' with $DBCR8_{DAC3US}$ set to '00' or '10', or both. Stack limit checking for user mode stack accesses is considered enabled when either the $DBCR4_{DAC1CFG}$ field is set to '1000' with $DBCR2_{DAC1US}$ set to '00' or '01', or the $DBCR7_{DAC3CFG}$ field is set to '1000' with $DBCR8_{DAC3US}$ set to '00' or '01', or both. Note that unlike regular debug DAC events, both halves of a misaligned access are checked for limit violations.

When stack limit checking is enabled for a stack access, and DACn resources are owned by hardware, the EDBSR0 DAC status flag will be set due to a detected stack limit violation, to cause entry into debug halted mode or to generate a watchpoint, or both, in the same way as a DAC event normally does, i.e. after the access has completed. The only difference is that qualification of the access address is performed as discussed in the next paragraph. If the access is aborted due to a DSI or other exception such as machine check condition, the $EDBSR0_{IDE}$ status bit will also be set to indicate that the data access instruction was not completed.

Stack limit checking is implemented in the same way as address compares using DACn, but qualify a load or store access address with the use of GPR R1 as the base or index register used to compute an effective address when a load or store instruction is executed. No stack limit checking is performed for other instructions which may calculate an EA using GPR R1 such as cache, MMU/MPU management instructions, or instructions which indicate GPR R1 is used to hold a decoration value (for decorated load/store type instructions). When DACn resources are not owned by hardware, if a stack limit violation occurs (a hit to a stack limit enabled DAC is detected) when performing the load or store, the access request is aborted and the access is not performed. Instead, for supervisor mode accesses, an error report machine check exception is generated, with MCSRR0

pointing to the address of the load or store instruction which generated the stack overflow/underflow, and for user mode accesses, a DSI exception is generated, with SRR0 pointing to the address of the load or store instruction which generated the stack overflow/underflow. If all stack limit check enabled DACn resources are owned by hardware, then a DAC event is generated (but qualified with use of GPR R1), and debug mode entry will occur in the same manner as for a non-stack limit DAC event. In this case, the instruction and access will normally have completed, in the same manner as a normal DAC event.

Independent limit checks for supervisor and user accesses may be implemented by allocating independent DACn resources to each, or a single limit may be applied using a single DACn resource. Typically, a DAC1,2 pair operating in exclusive address range mode is utilized for stack limit checking for a single shared limit. For separate limits, DAC3,4 may also be utilized. If more than one DACn resource is utilized, a DAC hit on any resource utilized for stack limit checking will cause the corresponding stack limit exception action to occur. If both a hardware-owned and a software-owned resource generate a stack limit exception for a given load or store, the software resource will have priority, since it is detected prior to completion of the access, and the access is aborted, thus the hardware event will not occur.

Enabling of this functionality is described in more detail in the description of the DACnCFG fields in Table 18-9 and Table 18-12 in Debug Control and Status registers. Note that for DAC1 and DAC2, access type (read, write) control is part of DBCR0.

18.6 External Debug Support

External debug support is supplied through the OnCE controller serial interface which allows access to internal CPU registers and other system state while the CPU is halted in debug mode. All debug resources including DBCR0–8, DBSR, IAC1–8, DAC1–4, and DVC1–2 are accessible through the serial OnCE interface in external debug mode. Setting the $EDBCR0_{EDM}$/$DBCR0_{EDM}$ bit to '1' through the OnCE interface enables external debug mode, and unless otherwise permitted by the settings in EDBRAC0, disables software updates to the debug control registers. When $EDBCR0_{EDM}$ is set, debug events enabled to set respective status bits will also cause the CPU to enter Debug Mode if the event is not masked in EDBSRMSK0, as opposed to generating Debug Interrupts, unless the specific events are allocated to software via the settings in EDBRAC0. In Debug Mode, the CPU is halted at a recoverable boundary, and an external Debug Control Module may control CPU operation through the On-Chip Emulation logic (OnCE).

Note that the descriptions of events in the subsections of Software Debug Events and Exceptions refer to setting DBSR status bits, however, when resources are owned by hardware, the events for those resources set the respective status bits in EDBSR0 instead of DBSR.

Note

On the initial setting of $EDBCR0_{EDM}$ to '1', other bits in DBCR0 will remain unchanged. After $EDBCR0_{EDM}$ has been set, all debug register resources may be subsequently controlled through the OnCE interface. The CPU should be placed into debug mode via the OCR_{DR} control bit prior to writing EDM to '1'. This gives the debugger the opportunity to cleanly write to the DBCRx registers and the DBSR to clear out any residual state / control information which could cause unintended operation.

Note

It is intended for the CPU to remain in external debug mode ($EDBCR0_{EDM}$=1) in order to single step or perform other debug mode entry/ reentry via the OCR_{DR}, by performing go+noexit commands, or by assertion of the **jd_de_b** signal.

Note

$EDBCR0_{EDM}$ operation will be blocked if OnCE operation is disabled (**jd_en_once** negated) regardless of whether it is set or cleared. This means that if $EDBCR0_{EDM}$ was previously set, and then **jd_en_once** is negated (this should not occur), entry into debug mode will be blocked, and all *hardware* debug events are blocked. Watchpoints are not blocked.

Due to clock domain design, the CPU clock (**m_clk**) must be active in order to perform writes to debug registers other than the OnCE Command register (OCMD), the OnCE Control register (OCR), External Debug Control Register 0 (EDBCR0), External Debug Status register 0 (EDBSR0), External Debug Status Register Mask 0 (EDBSRMSK0), or the $EDBCR0_{EDM}$ bit. Register read data is synchronized back to the **j_tclk** clock domain. The OnCE Control register provides the capability of signaling the system level clock controller that the CPU clock should be activated if not already active.

Updates to the DBCRx, DBSR, and most other debug registers via the OnCE interface should be performed with the CPU in debug mode to guarantee proper operation. Due to the various points in the CPU pipeline where control is sampled and event handshaking is

performed, it is possible that modifications to these registers while the CPU is running may result in early or late entry into debug mode, and may have incorrect status posted in the DBSR register.

If resource sharing is enabled via EDBRAC0, updates to the EDBRAC0, DBCRx, and DBSR registers must be performed with the CPU in debug mode, since simultaneous updates of register portions could otherwise be attempted, and such updates are not guaranteed to properly occur. The results of such an attempt are undefined.

18.6.1 External Debug Registers

The external debug registers are used for controlling several debug aspects of the core and reporting status while in External Debug Mode.

18.6.1.1 External Debug Control Register 0 (EDBCR0)

EDBCR0 is a control register accessible to an external debugger through the OnCE/Jtag port. An external development tool can write to this register in order to enable external debug mode or to enable Debugger Notify Halt instructions (**e_dnh**, **se_dnh**), as well as to control aspects of Debugger Notify Interrupt instructions (**e_dni**, **se_dni**).

EDBCR0 is not accessible by software, However, the state of $EDBCR0_{EDM}$ is reflected as a read-only bit in $DBCR0_{EDM}$ to software. There is only one physical EDM bit implemented; it is reflected in both the DBCR0 and EDBCR0 registers, and may be written and read using either register by the hardware debugger. For future compatibility, EDBCR0 updates are preferred.

EDBCR0 is shown in the following figure.

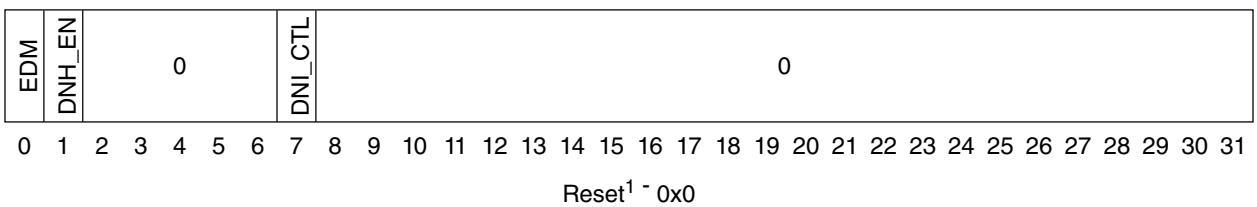

Figure 18-17. EDBCR0 Register

Note

[1] EDBCRO is affected (reset) by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state, but is not affected by **p_reset_b.**

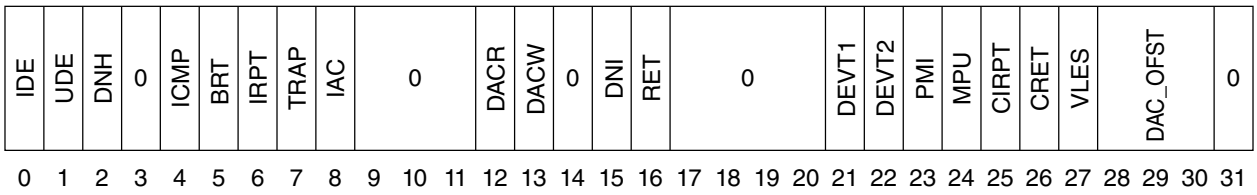
The following table provides bit definitions for External Debug Control Register 0.

Table 18-19. EDBCR0 Bit Definitions

Bit(s)	Name	Description
0	EDM	External Debug Mode. This bit is also reflected in DBCR0 0 - External debug mode disabled. Internal debug events not mapped into external debug events. 1 - External debug mode enabled. Hardware-owned events will not cause the CPU to vector to interrupt code. Software is not permitted to write to debug registers {DBCRx, IAC1-8, DAC1-4, DVC1-2[U]} unless permitted by settings in EDBRAC0. When external debug mode is enabled, hardware-owned resources in debug registers are not affected by processor reset **p_reset_b**. This allows the debugger to set up hardware debug events which remain active across a processor reset.
1	DNH_EN	**dnh** Instruction Enable 0 - execution of **e_dnh** and **se_dnh** instructions cause illegal instruction exceptions to occur. 1 - execution of **e_dnh** and **se_dnh** instructions cause entry into debug mode and a debug halt occurs, regardless of the value of EDM.
2:6	---	Reserved
7	DNI_CTL	**dni** Instruction Control 0 - When the **dni** resource is owned by hardware, the MSR_{DE} bit is cared, and when MSRDE=0, execution of **e_dni** and **se_dni** instructions are nop'ed and no entry into debug mode occurs. 1 - When the **dni** resource is owned by hardware, the MSR_{DE} bit is don't-cared, and execution of **e_dni** and **se_dni** instructions cause entry into debug mode and a debug halt occurs, regardless of the value of MSR_{DE}. Note that this control bit is only used when the dni resource is owned by hardware via control in $EDBRAC0_{DNI}$, and thus also only when EDM=1
8:31	---	Reserved

18.6.1.2 External Debug Status Register 0 (EDBSR0)

The External Debug Status Register 0 (EDBSR0) contains status on debug events owned by hardware. The External Debug Status Register 0 is set via hardware, and read and cleared via OnCE access by the debugger. Clearing is done by writing to the External Debug Status Register via the OnCE port, with a '1' in any bit position that is to be cleared and '0' in all other bit positions. The write data to EDBSR0 is not direct data, but a mask. A '1' causes the bit to be cleared, and a '0' has no effect. The EDBSR0 register is shown in the following figure.



Read/Write; Reset[1] - 0x0000_0000

Figure 18-18. EDBSR0 Register

Note

[1] Reset by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state or while $EDBCRO_{EDM}$=O.

The following table provides bit definitions for External Debug Status Register 0.

Table 18-20. EDBSR0 Bit Definitions

Bit(s)	Name	Description
0	IDE	Imprecise Debug Event Set to 1 if $EDBCR0_{EDM}$=1 and an imprecise debug event occurs for a hardware-owned DAC event due to a load or store which is terminated with error, or if a hardware-owned ICMP event occurs in conjunction with a EFPU round exception. This bit will not be set for imprecise debug events which are masked via settings in EDBSRMSK0.
1	UDE	Unconditional Debug Event Set to 1 if a hardware-owned Unconditional debug event occurred.
2	DNH	Debugger Notify Halt Event Set to 1 if a debugger notify halt instruction was executed and caused a debug halt.
3	—	Reserved
4	ICMP	Instruction Complete Debug Event Set to 1 if a hardware-owned Instruction Complete debug event occurred.
5	BRT	Branch Taken Debug Event Set to 1 if a hardware-owned Branch Taken debug event occurred.
6	IRPT	Interrupt Taken Debug Event Set to 1 if a hardware-owned Interrupt Taken debug event occurred.
7	TRAP	Trap Taken Debug Event Set to 1 if a hardware-owned Trap Taken debug event occurred.
8	IAC	Instruction Address Compare 1 Debug Event Set to 1 if a hardware-owned IAC debug event occurred.
9:11	—	Reserved
12	DACR	Data Address Compare Read Debug Event Set to 1 if a hardware-owned read-type DAC debug event occurred
13	DACW	Data Address Compare Write Debug Event Set to 1 if a hardware-owned write-type DAC1 debug event occurred
14	—	Reserved

Table continues on the next page...

Table 18-20. EDBSR0 Bit Definitions (continued)

Bit(s)	Name	Description
15	DNI	DNI Debug Event Set to 1 if a hardware-owned DNI debug event occurred
16	RET	Return Debug Event Set to 1 if a hardware-owned Return debug event occurred
17:20	—	Reserved
21	DEVT1	External Debug Event 1 Debug Event Set to 1 if a hardware-owned DEVT1 debug event occurred
22	DEVT2	External Debug Event 2 Debug Event Set to 1 if a hardware-owned DEVT2 debug event occurred
23	PMI	Performance Monitor Interrupt Debug Event Set to 1 if a Performance Monitor Interrupt event occurred with $EDBRAC0_{PMI}$=0 regardless of the setting of $PMGC0_{UDI}$
24	MPU	Memory Protection Unit Debug Event Set to 1 if a hardware-owned MPU debug event occurred. For MPU debug events, if $EDBSRMSK0_{MPU}$ is cleared, the IAC, DACR, or DACW status bit will also be set, depending on the type of access which matched a region descriptor enabled to generate debug events, in order to further define the type of MPU debug event. If $EDBSRMSK0_{MPU}$ is set at the time a MPU debug event occurs, the IAC, DACR, and DACW status bits will not be set by MPU debug events, in order to properly mask the MPU debug event. Note that hardware MPU debug events on data accesses normally occur after the data access is performed and the instruction completes, thus act like a normal DAC debug event. The instruction may not complete if a DSI occurs. In this case, IDE will be set to indicate this occurrence.
25	CIRPT	Critical Interrupt Taken Debug Event Set to 1 if a hardware-owned Critical Interrupt Taken debug event occurred.
26	CRET	Critical Return Debug Event Set to 1 if a hardware-owned Critical Return debug event occurred
27	VLES	VLE Status Set to 1 if a hardware-owned ICMP, BRT, TRAP, RET, CRET, IAC, or DAC debug event occurred on a Power ISA VLE Instruction. Also set for execution of an e_dnh or se_dnh instruction when enabled by $EDBCR0_{DNH\_EN}$. Undefined for IRPT, CIRPT, DEVT[1,2], and UDE events
28:30	DAC_OFST	Data Address Compare Offset Indicates offset-1 of saved DSRR0 value from the address of the load or store instruction which took a hardware-owned DAC Debug exception, unless a simultaneous DSI error occurs, in which case this field is set to 3'b000 and $EDBSR0_{IDE}$ is set to 1. Normally set to 3'b000 by a non-DVC DAC. A DVC DAC may set this field to any value.
31	—	Reserved

18.6.1.3 External Debug Status Register Mask 0 (EDBSRMSK0)

The External Debug Status Register Mask 0 (EDBSRMSK0) is used to mask debug events set in EDBSR0 from causing entry into debug halted mode. A '1' stored in any mask bit prevents debug mode entry caused by the corresponding bit being set in EDBSR0. The mask has no effect on DBSR actions or on the setting of EDBSR0 status bits by hardware-owned events, except that the IDE bit will not be set by imprecise hardware-owned debug events which are masked. EDBSRMSK0 may be used to allow debug events owned by hardware to be configured for watchpoint generation purposes without causing debug mode entry when the watchpoint occurs. EDBSRMSK0 is read and written via OnCE access by the debugger. No software access is provided. The EDBSRMSK0 register is shown in the following figure.

Read/Write; Reset[1] - 0x0000_0000

Figure 18-19. EDBSRMSK0 Register

Note

[1] Reset by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state or while $EDBCRO_{EDM}$=O.

The following table provides bit definitions for External Debug Status Register Mask 0.

Table 18-21. EDBSRMSK0 Bit Definitions

Bit(s)	Name	Description
0	—	Reserved
1	UDE	Unconditional Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{UDE}$
2	DNH	Debugger Notify Halt Event Set to 1 to mask debug mode entry by $EDBSR0_{DNH}$
3	—	Reserved
4	ICMP	Instruction Complete Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{ICMP}$
5	BRT	Branch Taken Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{BRT}$
6	IRPT	Interrupt Taken Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{IRPT}$
7	TRAP	Trap Taken Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{TRAP}$

Table continues on the next page...

Table 18-21. EDBSRMSK0 Bit Definitions (continued)

Bit(s)	Name	Description
8	IAC	Instruction Address Compare Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{IAC}$
9:11	—	Reserved
12	DACR	Data Address Compare 1 Read Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{DACR}$
13	DACW	Data Address Compare 1 Write Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{DACW}$
14	—	Reserved
15	DNI	DNI Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{DNI}$
16	RET	Return Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{RET}$
17:20	—	Reserved
21	DEVT1	External Debug Event 1 Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{DEVT1}$
22	DEVT2	External Debug Event 2 Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{DEVT2}$
23	PMI	Performance Monitor Interrupt Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{PMI}$
24	MPU	Memory Protection Unit Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{MPU}$
25	CIRPT	Critical Interrupt Taken Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{CIRPT}$
26	CRET	Critical Return Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{CRET}$
22:31	—	Reserved

18.6.1.4 External Debug Data Effective Address Register (EDDEAR)

The External Debug Data Effective Address Register (EDDEAR) contains address information for hardware-owned data address compare debug events, including MPU DAC events. EDDEAR is update by hardware with the effective address of the load, store, or cache control operation when an unmasked data address compare event is recorded in EDBSR0 if the previous values of $EDBSR0_{DAC\{R,W\}}$ bits which are unmasked in EDBSRMSK0 are zero. Once an EDDEAR update is performed, these unmasked bits must be cleared by the hardware debugger prior to another EDDEAR

hardware update occurring. A subsequent hardware-owned unmasked DAC event will not update the EDDEAR register if either of the $EDBSR0_{DAC\{R,W\}}$ bits are set and are not masked by EDBSRMSK0, in order to capture the first unmasked event address. EDDEAR is read and written via OnCE access by the debugger. No software access is provided.

The EDDEAR register is shown in the following figure.

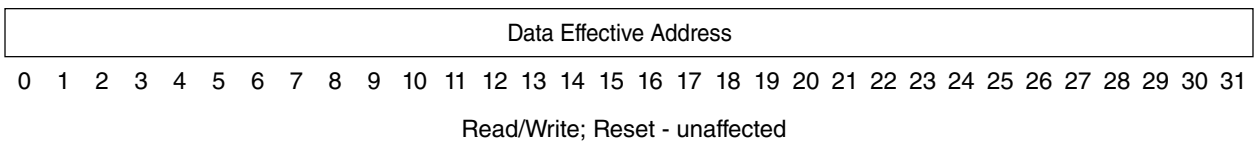


Figure 18-20. EDDEAR Register

18.6.2 OnCE Introduction

The e200z4201n3 on-chip emulation circuitry (OnCE™/Nexus Class 1 interface) provides a means of interacting with the e200z4201n3 core and integrated system so that a user may examine registers, memory, or on-chip peripherals facilitating hardware/ software development. OnCE operation is controlled via an industry standard IEEE 1149.1 TAP controller. By using public instructions, the external hardware debugger can freeze or halt the CPU, read and write internal state, and resume normal execution. The core does not contain IEEE 1149.1 standard boundary cells on its interface, as it is a building block for further integration. It does not support the JTAG related boundary scan instruction functionality, although JTAG public instructions may be decoded and signaled to external logic.

The OnCE logic provides for Nexus Class 1 static debug capability (utilizing the same set of resources available to software while in internal debug mode).

In order to enable full OnCE operation, the **jd_enable_once** input signal must be asserted. In some system integrations, this is automatic, since the input will be tied asserted. Other integrations may require the execution of the Enable OnCE command via the TAP and appropriate entry of serial data. Exact requirements will be documented by the integrated product specification. The **jd_enable_once** input signal should not change state during a debug session, or undefined activity may occur.

The following figures show the TAP controller state model and the TAP registers implemented by the OnCE logic.

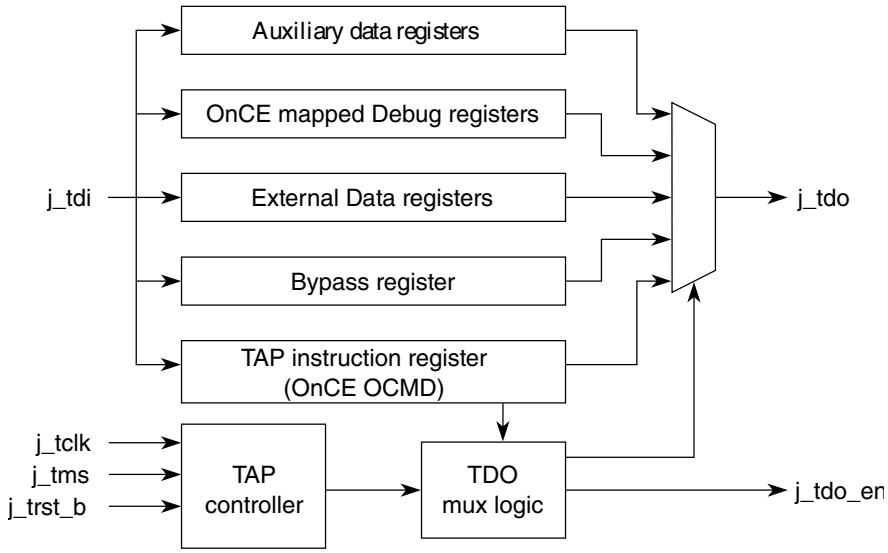

Figure 18-21. OnCE TAP Controller and Registers

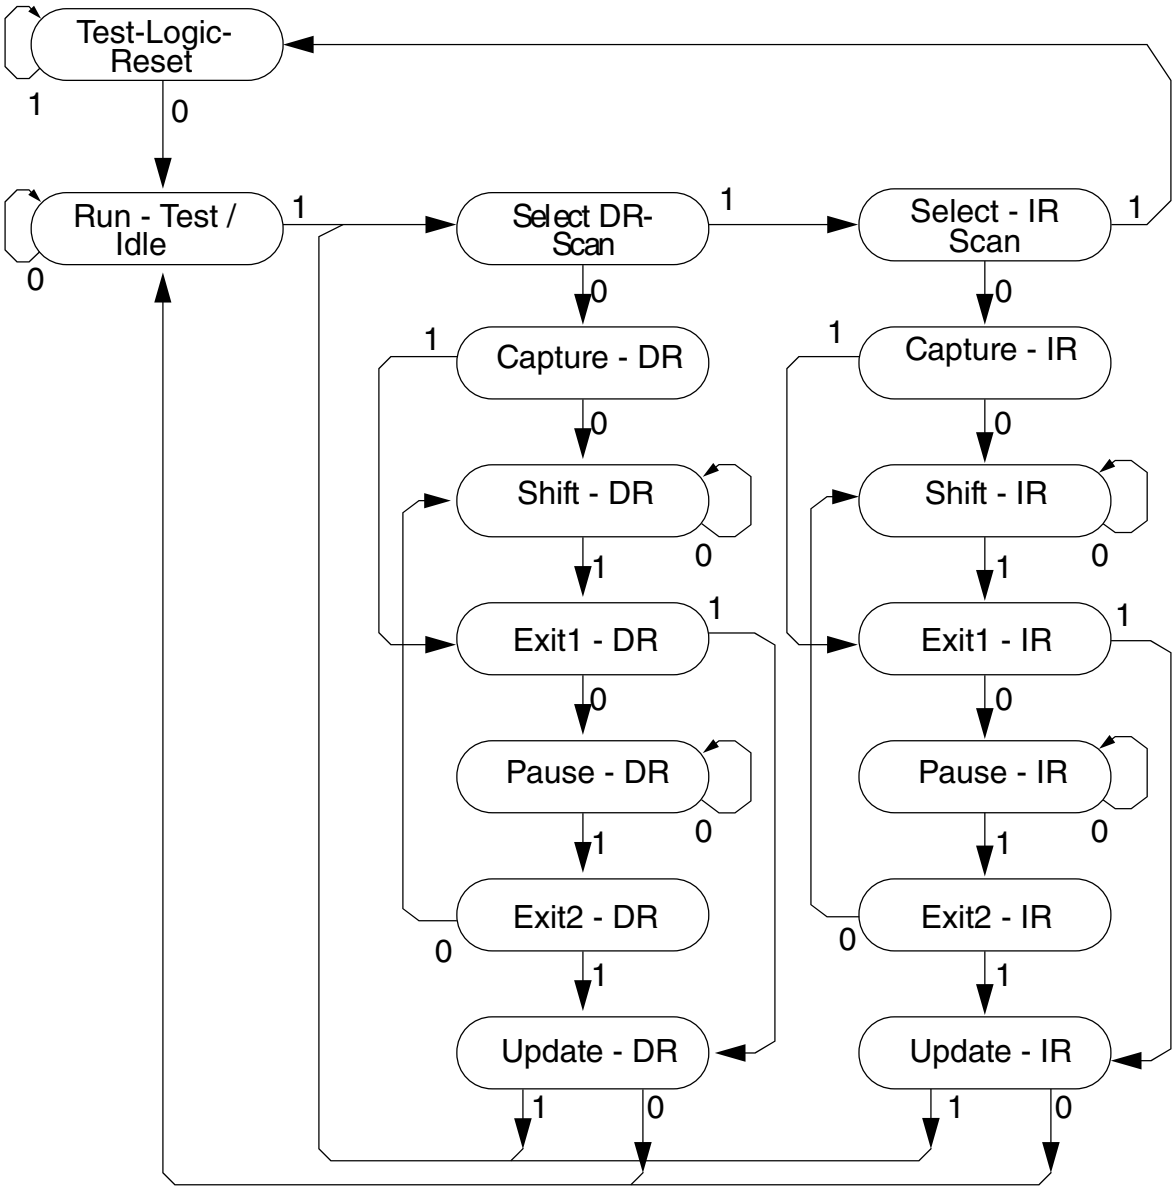
The OnCE controller is implemented as a 16-state FSM, with a one-to-one correspondence to the states defined for the JTAG TAP controller.



Access to processor registers and the contents of memory locations are performed by enabling external debug mode (setting $EDBCR0_{EDM}$ to '1'), placing the processor into debug mode, followed by scanning instructions and data into and out of the CPU Scan Chain (CPUSCR); execution of scanned instructions by the CPU is used as the method to access required data. Memory locations may be read by scanning a load instruction into the CPU core which will reference the desired memory location, executing the load instruction, and then scanning out the result of the load. Other resources are accessed in a similar manner.

The initial entry by the CPU into the debug state (or mode) from normal, Waiting, Stopped, or Halted states (all indicated via the OnCE Status Register (OSR), OnCE Status Register) by assertion of one or more debug requests, begins a *debug session*. The **jd_debug_b** output signal indicates that a debug session is in progress, and the OSR will

indicate the CPU is in the debug state. Instructions may the be single-stepped by scanning new values into the CPUSCR, and performing a OnCE go+noexit command (See OnCE Command Register (OCMD)). The CPU will then temporarily exit the debug state (but not the debug session) to execute the instruction, and will then return to the debug state (again indicated via the OnCE Status Register (OSR)). The debug session remains in force until the final OnCE go+exit command is executed, at which time the CPU will return to the previous state it was in (unless a new debug request is pending). A scan into the CPUSCR is required prior to executing each go+exit or go+noexit OnCE command.

18.6.3 JTAG/OnCE Pins

The JTAG/OnCE pin interface is used to transfer OnCE instructions and data to the OnCE control block. Depending on the particular resource being accessed, the CPU may need to be placed in the Debug mode. For resources outside of the CPU block and contained in the OnCE block, the processor is not disturbed, and may continue execution. If a processor resource is required, an internal debug request (**dbg_dbgrq**) may be asserted to the CPU by the OnCE controller, and causes the CPU to finish the current instruction being executed, save the instruction pipeline information, enter Debug Mode, and wait for further commands. Asserting **dbg_dbgrq** will cause the chip to temporarily exit the Waiting, Stopped or Halted power management states.

The following table details the primary JTAG/OnCE interface signals.

Table 18-22. JTAG/OnCE Primary Interface Signals

Signal name	Type	Description
j_trst_b	I	JTAG test reset
j_tclk	I	JTAG test clock
j_tms	I	JTAG test mode select
j_tdi	I	JTAG test data input
j_tdo	O	Test data out to master controller or pad
j_tdo_en[1]	O	Enables TDO output buffer

1. j_tdo_en is asserted when the TAP controller is in the shift_DR or shift_IR state.

A full description of JTAG pins is provided in the JTAG Support Signals section of the Core (e200z4201n3) Core Complex Overview.

18.6.4 OnCE Internal Interface Signals

The following paragraphs describe the OnCE interface signals to other internal blocks associated with the OnCE controller.

18.6.4.1 CPU Debug Request (dbg_dbgrq)

The **dbg_dbgrq** signal is asserted by the OnCE control logic to request the CPU to enter the debug state. It may be asserted for a number of different conditions, and causes the CPU to finish the current instruction being executed, save the instruction pipeline information, enter the debug mode, and wait for further commands.

18.6.4.2 CPU Debug Acknowledge (cpu_dbgack)

The **cpu_dbgack** signal is asserted by the CPU upon entering the debug state. This signal is used as part of the handshake mechanism between the OnCE control logic and the rest of the CPU. The CPU core may enter debug mode either through a software or hardware event.

18.6.4.3 CPU Address, Attributes

The CPU address and attribute information are used by the Nexus3 unit with information for real-time address trace information.

18.6.4.4 CPU Data

The CPU data buses are used to supply the Nexus3 debug unit with information for real-time data trace capability.

18.6.5 OnCE Interface Signals

The following paragraphs describe additional OnCE interface signals to other external blocks such as a Nexus controller and external blocks which may need information pertaining to debug operation.

18.6.5.1 OnCE Enable (jd_en_once)

The OnCE enable signal **jd_en_once** is used to enable the OnCE controller to allow certain instructions and operations to be executed. Assertion of this signal will enable the full OnCE command set, as well as operation of control signals and OnCE Control register functions. When this signal is disabled, only the Bypass, ID and Enable_OnCE

commands are executed by the OnCE unit, and all other commands default to a "Bypass" command. The OnCE Status register (OSR) is not visible when OnCE operation is disabled. In addition, OnCE Control register (OCR) functions are disabled, as is the operation of the **jd_de_b** input. Secure systems may choose to leave the **jd_en_once** signal negated until a security check has been performed. Other systems should tie this signal asserted to enable full OnCE operation. The **j_en_once_regsel** output signal is provided to assist external logic performing security checks.

The **jd_en_once** input must only change state during the Test-Logic-Reset, Run-Test/ Idle, or Update_DR TAP states. A new value will take affect after one additional **j_tclk** cycle of synchronization. In addition, **jd_enable_once** input signal must not change state during a debug session, or undefined activity may occur.

18.6.5.2 OnCE Debug Request/Event (jd_de_b, jd_de_en)

If implemented at the SoC level, a system level bidirectional open drain debug event pin **DE_b** (not part of the e200z4201n3 interface) provides a fast means of entering the Debug Mode of operation from an external command controller (when input) as well as a fast means of acknowledging the entering of the Debug Mode of operation to an external command controller (when output). The assertion of this pin by a command controller causes the CPU core to finish the current instruction being executed, save the instruction pipeline information, enter Debug Mode, and wait for commands to be entered. If **DE_b** was used to enter the Debug Mode then **DE_b** must be negated after the OnCE controller responds with an acknowledge and before sending the first OnCE command. The assertion of this pin by the CPU Core acknowledges that it has entered the Debug Mode and is waiting for commands to be entered.

To support operation of this system pin, the OnCE logic supplies the **jd_de_en** output and samples the **jd_de_b** input when OnCE is enabled (**jd_en_once** asserted). Assertion of **jd_de_b** will cause the OnCE logic to place the CPU into Debug Mode. Once Debug Mode has been entered, the **jd_de_en** output will be asserted for three **j_tclk** periods to signal an acknowledge. **jd_de_en** can be used to enable the open-drain pulldown of the system level **DE_b** pin.

For systems which do not implement a system level bidirectional open drain debug event pin **DE_b**, the **jd_de_en** and **jd_de_b** signals may still be used to handshake debug entry.

18.6.5.3 OnCE Debug Output (jd_debug_b)

The OnCE Debug output **jd_debug_b** is used to indicate to on-chip resources that a debug session is in progress. Peripherals and other units may use this signal to modify normal operation for the duration of a debug session, which may involve the CPU executing a sequence of instructions solely for the purpose of visibility/system control which are not part of the normal instruction stream the CPU would have executed had it not been placed in debug mode. This signal is asserted the first time the CPU enters the debug state, and remains asserted until the CPU is released by a write to the OnCE Command Register with the GO and EX bits set, and a register specified as either "No Register Selected" or the CPUSCR. This signal will remain asserted even though the CPU may enter and exit the debug state for each instruction executed under control of the OnCE controller. See OnCE Command Register (OCMD) for more information on the function of the GO and EX bits. This signal is not normally used by the CPU.

18.6.5.4 CPU Clock On Input (jd_mclk_on)

The CPU Clock On input **jd_mclk_on** is used to indicate that the CPU's **m_clk** input is active. This input signal is expected to be driven by system logic external to the e200z4201n3 core, is synchronized to the **j_tclk** (scan clock) clock domain, and is presented as a status flag on the **j_tdo** output during the Shift_IR state. External firmware may use this signal to ensure proper scan sequences will occur to access debug resources in the **m_clk** clock domain.

18.6.5.5 Watchpoint Events (jd_watchpt[0:31])

The **jd_watchpt[0:31]** signals may be asserted by the OnCE control logic to signal that a watchpoint condition has occurred. Watchpoints do not directly cause the CPU to be affected. They are provided to allow external visibility only or for triggering purposes. Watchpoint events are conditioned by the settings in the DBCRxx registers, as well as by the DEVENT register, the DTC/DTSA/DTEA registers, the Performance Monitor control register settings, and generation of MPU debug events. Refer to for details of the signal assignments. Note that assertion of most watchpoint outputs is conditioned on being in EDM or IDM. The Performance monitor, DEVENT, and DTC watchpoints are not conditioned however, and may assert regardless of the state of EDM or IDM. In addition, DAC1 or DAC3 watchpoints may be generated for stack limit violation occurrences when those resources are configured to perform stack limit checking, regardless of the state of EDM or IDM.

18.6.5.6 Update DR w/go+exit (j_ocmd_go_exit)

This signal indicates the TAP controller is in the Update_DR state and that the go and exit bits in the OnCE Command register are high, and RS indicates "no register selected". This signal will assert regardless of whether the CPU is currently in debug mode. It may be monitored by external logic to cause a synchronous exit from debug mode of other modules (but not other CPUs) in the system. A debugger can place all of the CPU tap controllers in parallel, scan in a go+exit command with "no register selected", and sequence through the Update_DR state to cause any CPU currently in debug mode to exit. CPUs which are not it debug mode will ignore the command.

18.6.6 OnCE Controller and serial interface

The OnCE Controller contains the OnCE command register, the OnCE decoder, and the status/control register. The following figure is a block diagram of the OnCE controller. In operation, the OnCE Command register acts as the IR for the TAP controller, and all other OnCE resources are treated as data registers (DR) by the TAP controller. The Command register is loaded by serially shifting in commands during the TAP controller Shift-IR state, and is loaded during the Update-IR state. The Command register selects a resource to be accessed as a data register (DR) during the TAP controller Capture-DR, Shift-DR and Update-DR states.

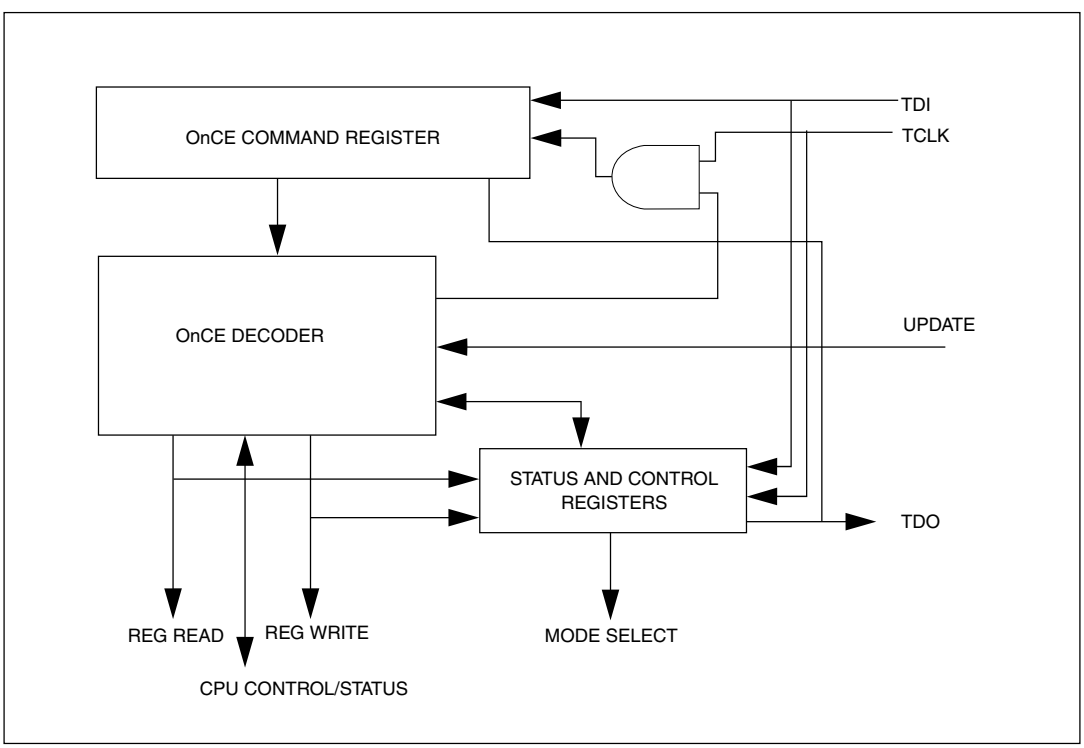


Figure 18-22. OnCE Controller and Serial Interface

18.6.6.1 OnCE Status Register

Status information regarding the state of the CPU is latched into the OnCE Status register when the OnCE controller state machine enters the Capture-IR state. When OnCE operation is enabled, this information is provided on the **j_tdo** output in serial fashion when the Shift_IR state is entered following a Capture-IR. Information is shifted out least significant bit first.

MCLK	ERR	0	RESET	HALT	STOP	DEBUG	WAIT	0	1
0	1	2	3	4	5	6	7	8	9

Figure 18-23. OnCE Status Register

The following table provides bit definitions for the Once Status Register.

Table 18-23. OnCE Status Register Bit Definitions

Bit(s)	Name	Description
0	MCLK	MCLK **m_clk** Status Bit 0 - Inactive state 1 - Active state This status bit reflects the logic level on the **jd_mclk_on** input signal after capture by **j_tclk**.
1	ERR	ERROR This bit is used to indicate that an error condition occurred during attempted execution of the last single-stepped instruction (GO+NoExit with CPUSCR or No Register Selected in OCMD), and that the instruction may not have been properly executed. This could occur if an Interrupt (all classes including External, Critical, machine check, Storage, Alignment, Program, etc.) occurred while attempting to perform the instruction single step. In this case, the CPUSCR will contain information related to the first instruction of the Interrupt handler, and no portion of the handler will have been executed.
3	RESET	RESET Mode This bit reflects the inverted logic level on the CPU **p_reset_b** input after capture by **j_tclk**.
4	HALT	HALT Mode This bit reflects the logic level on the CPU **p_halted** output after capture by **j_tclk**.
5	STOP	STOP Mode This bit reflects the logic level on the CPU **p_stopped** output after capture by **j_tclk**.
6	DEBUG	Debug Mode This bit is asserted once the CPU is in debug mode. It is negated once the CPU exits debug mode (even during a debug session)
7	WAIT	Waiting Mode This bit reflects the logic level on the CPU **p_waiting** output after capture by **j_tclk**.

Table continues on the next page...

Table 18-23. OnCE Status Register Bit Definitions (continued)

Bit(s)	Name	Description
8	0	Reserved, set to 0 for 1149.1 compliance
9	1	Reserved, set to 1 for 1149.1 compliance

18.6.6.2 OnCE Command Register (OCMD)

The OnCE Command Register (OCMD) is a 10-bit shift register that receives its serial data from the TDI pin and serves as the instruction register (IR). It holds the 10-bit commands to be used as input for the OnCE Decoder. The Command Register is shown in Figure 18-24. The OCMD is updated when the TAP controller enters the Update-IR state. It contains fields for controlling access to a resource, as well as controlling single-step operation and exit from OnCE mode.

Although the OCMD is updated during the Update-IR TAP controller state, the corresponding resource is accessed in the DR scan sequence of the TAP controller, and as such, the Update-DR state must be transitioned through in order for an access to occur. In addition, the Update-DR state must also be transitioned through in order for the single-step and/or exit functionality to be performed, even though the command appears to have no data resource requirement associated with it.

Reset - 10'b1000000010 on assertion of **j_trst_b** or **m_por** , or while in the Test_Logic_Reset state

Figure 18-24. OnCE Command Register

Table 18-24 provides bit definitions for the Once Command Register.

Table 18-24. OnCE Command Register Bit Definitions

Bit(s)	Name	Description
0	R/W	Read/Write Command Bit The R/W bit specifies the direction of data transfer. The table below describes the options defined by the R/W bit. **Note:** The R/W bit generally ignored for read-only or write-only registers, although the PC FIFO pointer is only guaranteed to be update when R/W=1. In addition, it is ignored for all bypass operations. When performing writes, most registers are sampled in the Capture-DR state into a 32-bit shift register, and subsequently shifted out on **j_tdo** during the first 32 clocks of Shift-DR. 0 - Write the data associated with the command into the register specified by RS[0:6]

Table continues on the next page...

Table 18-24. OnCE Command Register Bit Definitions (continued)

Bit(s)	Name	Description
		1 - Read the data contained in the register specified by RS[0:6]
1	GO	Go Go Command Bit If the GO bit is set, and the CPU is currently in debug mode, the CPU will execute the instruction which resides in the IR register in the CPUSCR. To execute the instruction, the processor leaves the debug mode, executes the instruction, and if the EX bit is cleared, returns to the debug mode immediately after executing the instruction. The processor goes on to normal operation if the EX bit is set, and no other debug request source is asserted. The GO command is executed only if the operation is a read/write to CPUSCR or a read/write to "No Register Selected". Otherwise the GO bit is ignored.The processor will leave the debug mode after the TAP controller Update-DR state is entered. On a GO+NoExit operation, returning to debug mode is treated as a debug event, thus exceptions such as machine checks and interrupts may take priority and prevent execution of the intended instruction. Debug firmware should mask these exceptions as appropriate. The OSR_{ERR} bit indicates such an occurrence. If the CPU is not currently in debug mode, then the GO command will be ignored. Note that asynchronous interrupts are blocked on a GO+Exit operation until the first instruction to be executed begins execution. See Exiting Debug Mode and Interrupt Blocking. 0 - Inactive (no action taken) 1 - Execute instruction in IR
2	EX	Exit Command Bit 0 - Remain in debug mode 1 - Leave debug mode If the EX bit is set, the processor will leave the debug mode and resume normal operation until another debug request is generated. The Exit command is executed only if the Go command is issued, and the operation is a read/write to CPUSCR or a read/write to "No Register Selected". Otherwise the EX bit is ignored. The processor will leave the debug mode after the TAP controller Update-DR state is entered. Note that if the DR bit in the OnCE control register is set or remains set, or if a bit in EDBSR0 is set and $EDBCR0_{EDM}$=1 (external debug mode is enabled), or if another debug request source is asserted, then the processor may return to the debug mode *without* execution of an instruction, even though the EX bit was set. Note that asynchronous interrupts are blocked on a GO+Exit operation until the first instruction to be executed begins execution. See Exiting Debug Mode and Interrupt Blocking.
3:9	RS	Register Select The Register Select bits define which register is source (destination) for the read (write) operation. Table 18-25 indicates the OnCE register addresses. Attempted writes to read-only registers are ignored.

Table 18-25 indicates the OnCE register addresses.

111 1110	Enable_OnCE[1]
111 1111	Bypass

1. Causes assertion of the j_en_once_regsel output.

The Once Decoder receives as input the 10-bit command from the OCMD, and status signals from the processor, and generates all the strobes required for reading and writing the selected OnCE registers.

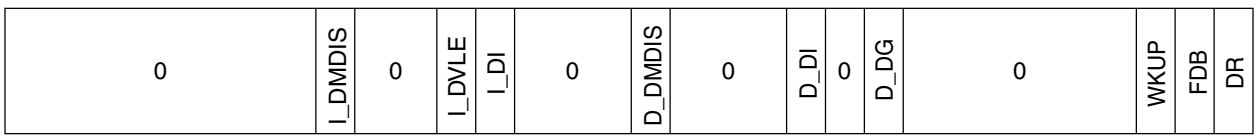
Single stepping of instructions is performed by placing the CPU in debug mode, scanning in appropriate information into the CPUSCR, and setting the Go bit (with the EX bit cleared) with the RS field indicating either the CPUSCR or No Register Selected. After executing a single instruction, the CPU will re-enter debug mode and await further commands. During single-stepping, exception conditions may occur if not properly masked by debug firmware (interrupts, machine checks, bus error conditions, etc.) and may prevent the desired instruction from being successfully executed. The OSR_{ERR} bit is set to indicate this condition. In these cases, values in the CPUSCR will correspond to the first instruction of the exception handler.

Additionally, the $EDBCR0_{EDM}$ bit is forced to '1' internally while single-stepping to prevent Debug events from generating Debug interrupts. Also, during a debug session, the DBSR register is frozen from updates due to debug events other than execution of a DNI-type instruction, regardless of EDBCR0EDM. DBSR may still be modified during a debug session via a single-stepped **mtspr** instruction, or via OnCE access.

If the CPU is not currently in debug mode, go+exit and go+noexit commands are ignored, although for a go+exit command with "No Register Selected", the j_ocmd_go_exit output will be asserted.

18.6.6.3 OnCE Control Register (OCR)

The OnCE Control Register is a 32-bit register used to force the e200z4201n3 core into debug mode and to enable / disable sections of the OnCE control logic. It also provides control over the MPU during a debug session (see MPU Operation During Debug). The control bits are read/write. These bits are only effective while OnCE is enabled (**jd_en_once** asserted). The OCR is shown in the following figure.



Reset - 0xo000_0000 on **m_por, j_trst_b,** or entering Test_logic_Reset state

Figure 18-25. OnCE Control Register

The following table provides bit definitions for the OnCE Control Register.

Table 18-26. OnCE Control Register Bit Definitions

Bit(s)	Name	Description
0:7	—	Reserved
8	I_DMDIS	Instruction Side Debug MPU Disable Control Bit (I_DMDIS) 0 - MPU not disabled for debug sessions 1 - MPU disabled for debug sessions This bit may be used to control whether the MPU is enabled normally, or whether the MPU is disabled during a debug session for Instruction Accesses. When enabled, the MPU functions normally. When disabled, for Instruction Accesses, the I bit is taken from the OCR bit I_DI. The SX and UX access permission control bits are set to'1' to allow full access. When disabled, no MPU exceptions are generated for Instruction accesses. External access errors can still occur. MPU entries with DEBUG=1 are not affected by this control bit.
9:10	—	Reserved
11	I_DVLE	Instruction Side Debug 'VLE' Attribute Bit (I_DVLE) This bit is used to provide the 'VLE' attribute bit to be used during a debug session. Note: this bit is ignored, since VLE is always enabled.
12	I_DI	Instruction Side Debug 'I' Attribute Bit (I_DI) This bit is used to provide the 'I' attribute bit to be used for Instruction accesses for Instruction accesses during a debug session.
13:15	—	Reserved
16	D_DMDIS	Data Side Debug MPU Disable Control Bit (D_DMDIS) 0 - MPU not disabled for debug sessions 1 - MPU disabled for debug sessions

Table continues on the next page...

Table 18-26. OnCE Control Register Bit Definitions (continued)

Bit(s)	Name	Description
		This bit may be used to control whether the MPU is enabled normally, or whether the MPU is disabled during a debug session for Data Accesses. When enabled, the MPU functions normally. When disabled, for Data Accesses, the MPU I and G bits are taken from the OCR bits D_DI and D_DG. The SR, SW, UR, and UW access permission control bits are set to'1' to allow full access. When disabled, no MPU exceptions are generated for Data accesses. External access errors can still occur. MPU entries with DEBUG=1 are not affected by this control bit.
17:19	—	Reserved
20	D_DI	Data Side Debug 'I' Attribute Bit (D_DI) This bit is used to provide the 'I' attribute bit to be used for Data accesses during a debug session.
21	—	Reserved
22	D_DG	Data Side Debug 'G' Attribute Bit (D_DG) This bit is used to provide the 'G' attribute bit to be used for Data accesses during a debug session.
23:28	—	Reserved
29	WKUP	Wakeup Request Bit (WKUP) This control bit may be used to force the **p_wakeup** output signal to be asserted. This control function may be used by debug firmware to request that the chip-level clock controller restore the **m_clk** input to normal operation regardless of whether the CPU is in a low power state to ensure that debug resources may be properly accessed by external hardware through scan sequences.
30	FDB	Force Breakpoint Debug Mode Bit (FDB) This control bit is used to determine whether the processor is operating in breakpoint debug enable mode or not. The processor may be placed in breakpoint debug enable mode by setting this bit. In breakpoint debug enable mode, execution of the '**bkpt**' pseudo- instruction will cause the processor to enter debug mode, as if the **jd_de_b** input had been asserted. This bit is qualified with $EDBCR0_{EDM}$, which must be set for FDB to take effect. Note that this bit has no effect on **e_dnh** or **se_dnh** instruction operation.
31	DR	CPU Debug Request Control Bit This control bit is used to unconditionally request the CPU to enter the Debug Mode. The CPU will indicate that Debug Mode has been entered via the data scanned out in the shift-IR state. 0 - No Debug Mode request 1 - Unconditional Debug Mode request When the DR bit is set the processor will enter Debug mode at the next instruction boundary.

18.6.7 Access to Debug Resources

Resources contained in the OnCE Module which do not require the processor core to be halted for access may be accessed while the e200z4201n3 core is running, and will not interfere with processor execution. Accesses to other resources such as the CPUSCR require the e200z4201n3 core to be placed in debug mode to avoid synchronization hazards. Debug firmware may ensure that it is safe to access these resources by determining the state of the e200z4201n3 core prior to access. Note that a scan operation to update the CPUSCR is required prior to exiting debug mode if debug mode has been entered.

Some cases of write accesses other than accesses to the OnCE Command and Control registers, or the EDM bit of DBCR0 require **m_clk** to be running for proper operation. The OnCE control register provides a means of signaling this need to a system level clock control module via the OCR_{WKUP} control bit.

In addition, since the CPU may cause multiple bits of certain registers to change state, reads of certain registers while the CPU is running (DBSR, etc.) may not have consistent bit settings unless read twice with the same value indicated. In order to guarantee that the contents are consistent, the CPU should be placed into debug mode, or multiple reads should be performed until consistent values have been obtained on consecutive reads.

The following table provides a list of access requirements for OnCE registers.

Table 18-27. OnCE Register Access Requirements

Register name	Access requirements					Notes
	Requires jd_en_once to be asserted	Requires EDBCR0 $_{EDM}$ = 1 for write access	Requires m_clk active for Write Access	Requires CPU to be halted for Read Access	Requires CPU to be halted for Write Access	
Enable_OnCE	N	N	N	N	—	
Bypass	N	N	N	N	N	
CPUSCR	Y	Y	Y	Y	Y	
DAC1–4	Y	Y	Y	N	*[1]	
DBCR0	Y	Y	Y	N	*[1]	*$EDBCR0_{EDM}$ access only requires **jd_en_once** asserted
DBCR1–8	Y	Y	Y	N	*[1]	
DEVENT	Y	Y	Y	N	*[1]	
EDBRAC0 (DBERC0)	Y	N	Y	N	*[1]	
DBSR	Y	Y	Y	N[2]	*[1]	
EDBCR0	Y	N	N	N	N	
EDBSR0	Y	N	Y	N	N	

Table continues on the next page...

Table 18-27. OnCE Register Access Requirements (continued)

Register name	Access requirements					Notes
	Requires jd_en_once to be asserted	Requires EDBCR0 EDM = 1 for write access	Requires m_clk active for Write Access	Requires CPU to be halted for Read Access	Requires CPU to be halted for Write Access	
EDBSRMSK0	Y	N	N	N	N	
IAC1–8	Y	Y	Y	N	*[1]	
JTAG ID	N	N	—	N	—	Read-only
MPU0CSR0	Y	N	Y	N	N	
OCR	Y	N	N	N	N	
OSR	Y	N	—	N	—	Read-only, accessed by scanning out IR while **jd_en_once** is asserted
Cache Debug Access Control (CDACNTL)	Y	N	Y	N	N	CPU gives lowest priority to a Cache access request when it is not debug halted
Cache Debug Access Data (CDADATA)	Y	N	Y	N	N	CPU gives lowest priority to a Cache access request when it is not debug halted
Nexus3-Access	Y	N	N	N	N	
PMR-Access	Y	N	N	N	N	
PMR Registers	Y	Y	Y	N	N	
External GPRs	Y	N	N	N	N	
LSRL Select	Y	N	?	?	?	System Test logic implementation determines LSRL functionality

1. Writes to these registers while the CPU is running may have unpredictable results due to the pipelined nature of operation, and the fact that updates are not synchronized to a particular clock, instruction, or bus cycle boundary, therefore it is strongly recommended to ensure the processor is first placed into debug mode before updates to these registers are performed.
2. Reads of these registers while the CPU is running may not give data that is self-consistent due to synchronization across clock domains.

18.6.8 Methods of Entering Debug Mode

The OnCE Status Register indicates that the CPU has entered the debug mode via the DEBUG status bit. The following sections describe how Debug Mode is entered assuming the OnCE circuitry has been enabled. OnCE operation is enabled by the assertion of the **jd_en_once** input See OnCE Enable (jd_en_once).

18.6.8.1 External Debug Request During RESET

Holding the **jd_de_b** signal asserted during the assertion of **p_reset_b,** and continuing to hold it asserted following the negation of **p_reset_b** causes the e200z4201n3 core to enter Debug Mode. After receiving an acknowledge via the OnCE Status Register DEBUG bit, the external command controller should negate the **jd_de_b** signal before sending the first command. Note that in this case the e200z4201n3 core does not execute an instruction before entering Debug Mode, although the first instruction to be executed will be fetched prior to entering Debug Mode in order to properly initialize the CPUSCR.

18.6.8.2 Debug Request During RESET

Asserting a debug request by setting the DR bit in the OCR during the assertion of **p_reset_b** and then negating **p_reset_b** causes the chip to enter debug mode. In this case the CPU will fetch the first instruction of the reset exception handler in order to properly initialize the CPUSCR, but does not execute an instruction before entering debug mode.

18.6.8.3 Debug Request During Normal Activity

Asserting a debug request by setting the DR bit in the OCR during normal chip activity causes the chip to finish the execution of the current instruction and then enter the debug mode. Note that in this case the chip completes the execution of the current instruction and stops after the newly fetched instruction enters the CPU instruction register. This process is the same for any newly fetched instruction including instructions fetched by the interrupt processing, or those that will be aborted by the interrupt processing.

18.6.8.4 Debug Request During Waiting, Halted or Stopped State

Asserting a debug request by setting the DR bit in the OCR when the chip is in the Waiting state (**p_waiting** asserted), Halted state (**p_halted** asserted) or Stopped state (**p_stopped** asserted) causes the CPU to exit the state and enter the debug mode once the CPU clock **m_clk** has been restored. Note that in this case, the CPU will negate the **p_waiting, p_halted** and **p_stopped** outputs. Once the debug session has ended, the CPU will return to the state it was in prior to entering debug mode.

To signal the chip-level clock generator to re-enable **m_clk**, the **p_wakeup** output will be asserted whenever the debug block is asserting a debug request to the CPU due to OCR_{DR} being set, or **jd_de_b** assertion, and will remain set from then until the debug session ends (**jd_debug_b** goes from asserted to negated). In addition, the status of the **jd_mclk_on** input (after synchronization to the **j_tclk** clock domain) may be sampled

along with other status bits from the **j_tdo** outputs during the Shift_IR TAP controller state. This status may be used if necessary by external debug firmware to ensure proper scan sequences occur to registers in the **m_clk** clock domain.

18.6.8.5 Software Request During Normal Activity

Upon executing a '**bkpt**' pseudo-instruction (for e200z4201n3, defined to be an all 0's instruction opcode) when the OCR register's (FDB) bit is set (debug mode enable control bit is true), and $EDBCR0_{EDM}$=1, the CPU enters the debug mode after the instruction following the '**bkpt**' pseudo-instruction has entered the instruction register.

18.6.8.6 Debug Notify Halt Instructions

The **e_dnh** and **se_dnh** instructions allow software to transition the core from a running state to a debug halted state if enabled by $EDBCR0_{DNH\_EN}$, and provide the external debugger with bits reserved in the instruction itself to pass additional information. Entry into debug mode is ***not*** conditioned on $EDBCR0_{EDM}$, allowing for debug of software debug handlers as well as other software. For e200z4201n3, when the CPU enters a debug halted state due to a **e_dnh** or **se_dnh** instruction, the instruction will be stored in the CPUSCR[IR] portion, and the CPUSCR[PC] value will point to the instruction. The external debugger should update the CPUSCR prior to exiting the debug halted state to point past the **e_dnh** or **se_dnh** instruction.

18.6.9 CPU Status and Control Scan Chain Register (CPUSCR)

A number of on-chip registers store the CPU pipeline status and are configured in a single scan chain for access by the OnCE controller. The CPUSCR register contains these processor resources, which are used to restore the pipeline and resume normal chip activity upon return from the debug mode, as well as a mechanism for the emulator software to access processor and memory contents. The following figure shows the block diagram of the pipeline information registers contained in the CPUSCR. Once debug mode has been entered, it is required to scan in and update this register prior to exiting debug mode.

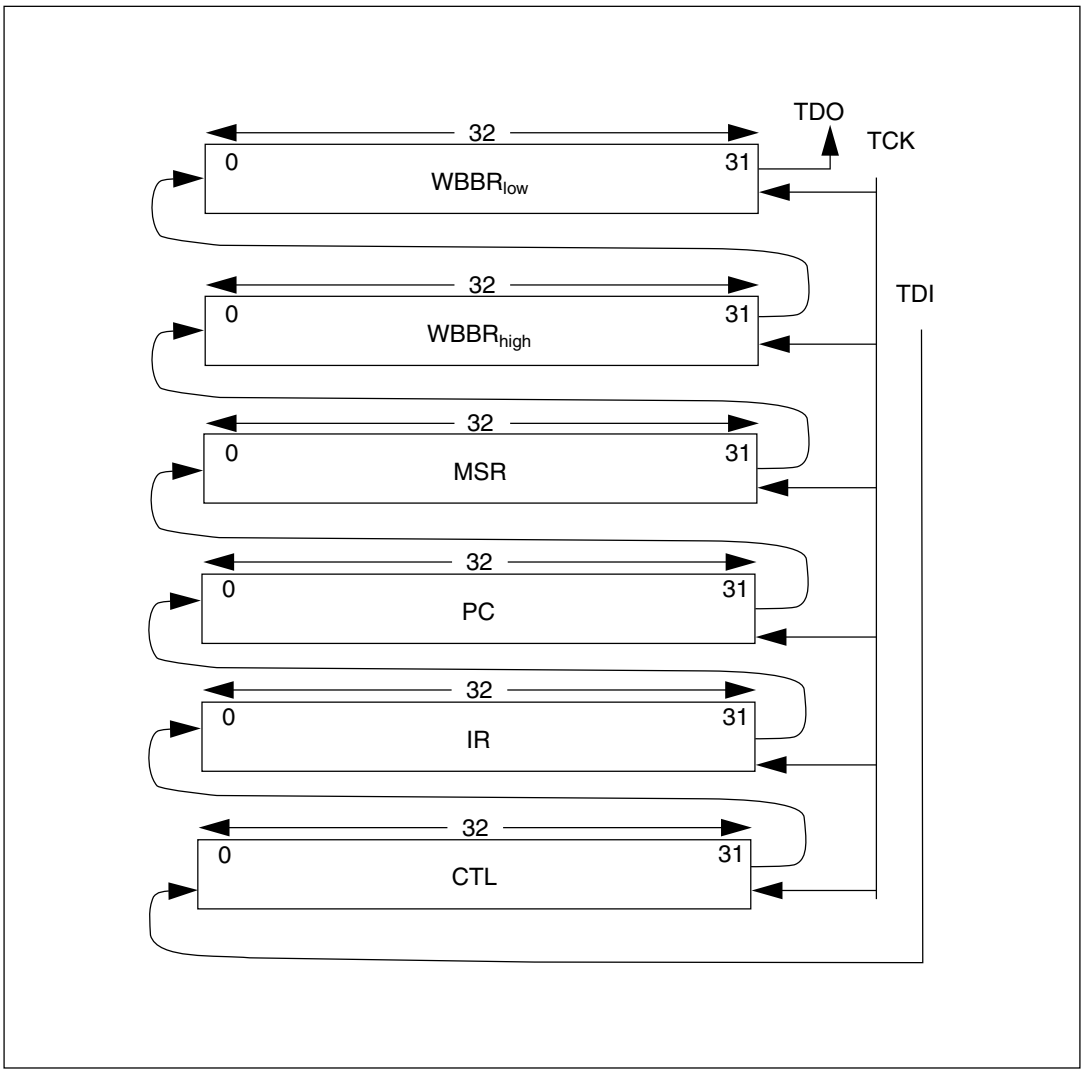


Figure 18-26. CPU Scan Chain Register (CPUSCR)

18.6.9.1 Instruction Register (IR)

The Instruction Register (IR) provides a mechanism for controlling the debug session by serving as a means for forcing in selected instructions, and then causing them to be executed in a controlled manner by the debug control block. The opcode of the next instruction to be executed when entering debug mode is contained in this register when the scan-out of this chain begins. This value should be saved for later restoration if continuation of the normal instruction stream is desired.

On scan-in, in preparation for exiting debug mode, this register is filled with an instruction opcode selected by debug control software. By selecting appropriate instructions and controlling the execution of those instructions, the results of execution may be used to examine or change memory locations and processor registers. The debug

control module external to the processor core will control execution by providing a single-step capability. Once the debug session is complete and normal processing is to be resumed, this register may be loaded with the value originally scanned out.

18.6.9.2 Control State Register (CTL)

The Control State Register (CTL) is a 32-bit register that stores the value of certain internal CPU state variables before the debug mode is entered. This register is affected by the operations performed during the debug session and should normally be restored by the external command controller when returning to normal mode. In addition to saved internal state variables, two of the bits are used by emulation firmware to control the debug process. In certain circumstances, emulation firmware must modify the content of this register as well as the PC and IR values in the CPUSCR before exiting debug mode. These cases are described below.

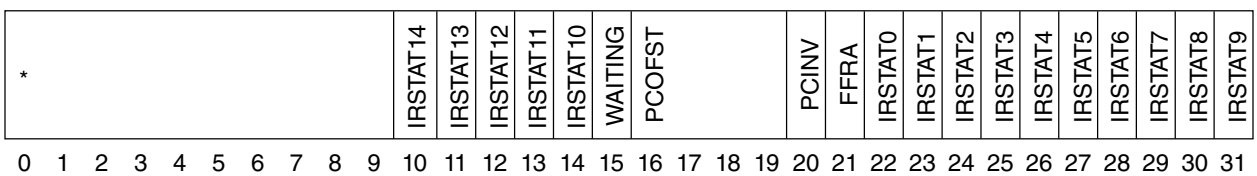

Figure 18-27. Control State Register (CTL)

WAITING — WAITING State Status

This bit indicates whether the CPU was in the waiting state prior to entering debug mode. If set, the CPU was in the waiting state. Upon exiting a debug session, the value of this bit in the restored CPUSCR will determine whether the CPU re-enters the waiting state on a go+exit.

0- CPU was not in the waiting state when debug mode was entered

1- CPU was in the waiting state when debug mode was entered

PCOFST — PC Offset Field

This field indicates whether the value in the PC portion of the CPUSCR must be adjusted prior to exiting debug mode. Due to the pipelined nature of the CPU, the PC value must be backed-up by emulation software in certain circumstances. The PCOFST field specifies the value to be subtracted from the original value of the PC. This adjusted PC value should be restored into the PC portion of the CPUSCR just prior to exiting debug mode with a go+exit. In the event the PCOFST is non-zero, the IR should be loaded with a nop instruction instead of the original IR value, other wise the original value of IR should be restored. (But see PCINV which overrides this field)

0000 - No correction required.

0001 - Subtract 0x04 from PC.

0010 - Subtract 0x08 from PC.

0011 - Subtract 0x0C from PC.

0100 - Subtract 0x10 from PC.

0101 - Subtract 0x14 from PC.

all other encodings are reserved

* — Internal State Bits

Table continues on the next page...

These control bits represent internal processor state and should be restored to their original value after a debug session is completed, i.e when a OnCE command is issued with the GO and EX bits set and not ignored. When performing instruction execution during a debug session. See OnCE Debug Output (jd_debug_b), which is not part of the normal program execution flow, these bits should be set to a 0.

PCINV — PC and IR Invalid Status Bit

This status bit indicates that the values in the IR and PC portions of the CPUSCR are invalid. Exiting debug mode with the saved values in the PC and IR will have unpredictable results. Debug firmware should initialize the PC and IR values in the CPUSCR with desired values prior to exiting debug mode if this bit was set when debug mode was initially entered.

0= No error condition exists.

1= Error condition exists. PC and IR are corrupted.

FFRA— Feed Forward RA Operand Bit

This control bit causes the content of the $WBBR_{lo}$ to be used as the RA operand value (RS for logical, mtspr, mtdcr, cntlzw, and shift operations, RX for VLE se_ instructions, RT for e_{logical_op}2i type instructions, RB for evaddiw, evsubifw, and the value to use as the PC for calculating the LR update value for branch with link type instructions) of the first instruction to be executed following an update of the CPUSCR.

This allows the debug firmware to update processor registers — initialize the $WBBR_{lo}$ with the desired value, set the FFRA bit, and execute a ori Rx,Rx,0 instruction to the desired register.

Note: not all instructions support using the FFRA control. FFRA is mainly intended for use with the ori instruction to allow the debugger to write to a GPR. Support for other instructions is implementation-dependent.

0= No action.

1= Content of $WBBR_{lo}$ used as operand value

IRStat0 — IR Status Bit 0

This control bit indicates a TEA status for the IR.

0= No TEA occurred on the fetch of this instruction.

1= TEA occurred on the fetch of this instruction.

IRStat1 — IR Status Bit 1

This control bit is reserved.

IRStat2 — IR Status Bit 2

This control bit indicates an Instruction Address Compare 1 event status for the IR.

0= No Instruction Address Compare event 1 occurred on the fetch of this instruction.

1= An Instruction Address Compare event 1 occurred on the fetch of this instruction.

IRStat3 — IR Status Bit 3

This control bit indicates an Instruction Address Compare 2 event status for the IR.

0= No Instruction Address Compare 2 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 2 event occurred on the fetch of this instruction.

IRStat4 — IR Status Bit 4

This control bit indicates an Instruction Address Compare 3 event status for the IR.

0= No Instruction Address Compare event 3 occurred on the fetch of this instruction.

1= An Instruction Address Compare event 3 occurred on the fetch of this instruction.

IRStat5 — IR Status Bit 5

This control bit indicates an Instruction Address Compare 4 event status for the IR.

Table continues on the next page...

0= No Instruction Address Compare 4 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 4 event occurred on the fetch of this instruction.

IRStat6 — IR Status Bit 6

This control bit indicates a Parity Error status for the IR.

0= No Parity Error occurred on the fetch of this instruction.

1= Parity Error occurred on the fetch of this instruction from the I-Cache .

IRStat7 — IR Status Bit 7

This control bit indicates a Precise External Termination Error status for the IR.

0= No Precise External Termination Error occurred on the fetch of this instruction.

1= A Precise External Termination Error occurred on the fetch of this instruction.

IRStat8 — IR Status Bit 8

This control bit indicates the Power ISA VLE status for the IR.

0= IR contains a BookE instruction. (unused encoding)

1= IR contains a Power ISA VLE instruction, aligned in the Most Significant Portion of IR if 16-bit.

- this bit should not be modified by the debugger, otherwise the resulting operation is boundedly undefined. It should always indicate VLE (=1).

IRStat9 — IR Status Bit 9

This control bit is reserved.

IRStat10 — IR Status Bit 10

This control bit indicates an Instruction Address Compare 5 event status for the IR.

0= No Instruction Address Compare 5 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 5 event occurred on the fetch of this instruction.

IRStat11 — IR Status Bit 11

This control bit indicates an Instruction Address Compare 6 event status for the IR.

0= No Instruction Address Compare 6 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 6 event occurred on the fetch of this instruction.

IRStat12 — IR Status Bit 12

This control bit indicates an Instruction Address Compare 7 event status for the IR.

0= No Instruction Address Compare 7 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 7 event occurred on the fetch of this instruction.

IRStat13 — IR Status Bit 13

This control bit indicates an Instruction Address Compare 8 event status for the IR.

0= No Instruction Address Compare 8 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 8 event occurred on the fetch of this instruction.

IRStat14 — IR Status Bit 14

This control bit indicates an MPU Instruction Address Compare event status for the IR.

0= No MPU Instruction Address Compare event occurred on the fetch of this instruction.

1= An MPU Instruction Address Compare event occurred on the fetch of this instruction.

Emulation firmware should modify the content of the CTL, PC, and IR values in the CPUSCR during execution of debug related instructions as well as just prior to exiting debug with a go+exit command. During the debug session, the CTL register should be

written with the FFRA bit set as appropriate, and all other bit set to '0', and the IR set to the value of the desired instruction to be executed. IRStat8 will be used to determine the type of instruction present in the IR.

Just prior to exiting debug mode with a go+exit, the PCINV status bit which was originally present when debug mode was first entered should be tested, and if set, the PC and IR initialized for performing whatever recovery sequence is appropriate for a faulted exception vector fetch. If the PCINV bit is cleared, then the PCOFST bits should be examined to determine whether the PC value must be adjusted. Due to the pipelined nature of the CPU, the PC value must be backed-up by emulation software in certain circumstances. The PCOFST field specifies the value to be subtracted from the original value of the PC. This adjusted PC value should be restored in to the PC portion of the CPUSCR just prior to exiting debug mode with a go+exit. In the event the PCOFST is non-zero, the IR should be loaded with a nop instruction (such as **ori r0,r0,0**) instead of the original IR value, otherwise the original value of IR should be restored. Note that when a correction is made to the PC value, it will generally point to the last completed instruction, although that instruction will not be re-executed. The nop instruction is executed instead, and instruction fetch and execution will resume at location PC+4. IRStat8 will be used to determine the type of instruction present in the IR, thus should be cleared in this case. Note that debug events which may occur on the nop (ICMP) will be generated if enabled.

For the CTL register, the internal state bits should be restored to their original value. The IRStatus bits should be set to '0's if the PC was adjusted. If no PC adjustment was performed, emulation firmware should determine whether other IRStat flags should be set to '0' to avoid re-entry into debug mode for an instruction breakpoint request. Upon exiting debug mode with go+exit, if one of these bits is set, debug mode will be re-entered prior to any further instruction execution.

18.6.9.3 Program Counter Register (PC)

The PC is a 32-bit register that stores the value of the program counter which was present when the chip entered the debug mode. It is affected by the operations performed during the debug mode and must be restored by the external command controller when the CPU returns to normal mode. PC normally points to the instruction contained in the IR portion of CPUSCR. If debug firmware wishes to redirect program flow to an arbitrary location, the PC and IR should be initialized to correspond to the first instruction to be executed upon resumption of normal processing. Alternatively, the IR may be set to a nop and the PC set to point to the location prior to the location at which it is desired to redirect flow to. On exiting debug mode, the nop will be executed, and instruction fetch and execution will resume at PC+4.

18.6.9.4 Write-Back Bus Register ($WBBR_{low}$, $WBBR_{high}$)

WBBR is used as a means of passing operand information between the CPU and the external command controller. Whenever the external command controller needs to read the contents of a register or memory location, it will force the chip to execute an instruction that brings that information to WBBR. $WBBR_{low}$ holds the 32-bit result of most instructions including load data returned for a load or load with update instruction. $WBBR_{high}$ holds the updated effective address calculated by a load with update instruction. It is undefined for other instructions.

As an example, to read the 32 bits of processor register **r1**, an **ori r1,r1,0** instruction is executed, and the result value of the instruction will be latched into $WBBR_{low}$. The contents of $WBBR_{low}$ can then be delivered serially to the external command controller. To update a processor resource, this register is initialized with a data value to be written, and an **ori** instruction is executed which uses this value as a substitute data value. The Control State register FFRA bit forces the value of the $WBBR_{low}$ to be substituted for the normal RS source value of the **ori** instruction, thus allowing updates to processor registers to be performed. (Refer to Control State Register (CTL) for more detail on the CTL_{FFRA} bit.)

$WBBR_{low}$ and $WBBR_{high}$ are generally undefined on instructions which do not writeback a result, and due to control issues are not defined on **lmw** or branch instructions as well.

18.6.9.5 Machine State Register (MSR)

The MSR is a 32-bit register used to read/write the Machine State Register. Whenever the external command controller needs to save or modify the contents of the Machine State Register, this register is used.This register is affected by the operations performed during the debug mode and must be restored by the external command controller when returning to normal mode.

18.6.9.6 Exiting Debug Mode and Interrupt Blocking

When exiting debug mode with a Go+Exit, "asynchronous" interrupts are blocked until the first instruction to be executed begins execution. This includes External and Critical input, NMI, and machine check interrupts. Asynchronous debug interrupts are not blocked however, and the CPU will re-enter debug mode without executing an instruction

following Go+Exit, although it may fetch an instruction and discard it. Exceptions due to an illegal instruction or error flags set within the CPUSCR CTL register are not blocked, since they apply to the instruction in the CPUSCR IR.

18.6.10 Reserved Registers (Reserved)

The Reserved Registers are used to control various test control logic. These registers are not intended for customer use. To preclude device and/or system damage, these registers should not be accessed.

18.7 MPU Operation During Debug

A debug session begins when the CPU initially enters debug mode, and ends when a OnCE command with GO+EXIT is executed, releasing the CPU for normal operation. If desired during a debug session, the debug firmware may substitute default values obtained from the OnCE Control Register for Access Attribute (I, G) bits. Refer to the bit definitions in the OCR (OnCE Control Register (OCR) for more detail.

Normal operation of the MPU may be modified during a 'debug session' via the OnCE Control Register (OCR). A debug session begins when the CPU initially enters debug mode, and ends when a OnCE command with GO+EXIT is executed, releasing the CPU for normal operation. If desired during a debug session, the debug firmware may disable the MPU protection mechanism and may substitute default values for the Access Protection (UX, UR, UW, SX, SR, SW) bits, and values obtained from the OnCE Control Register for Memory Attributes (I, G) bits normally provided by a matching MPU entry.

When disabled during a debug session, no MPU-related storage interrupt conditions will occur. If the debugger desires to use the normal protection mechanism, the MPU may be left enabled in the OnCE OCR, and normal protections provided by the MPU (including the possibility of a storage interrupt) will remain in effect.

The OCR control bits are used when debug mode is entered. Refer to the bit definitions in the OCR (OnCE Control Register (OCR) for more detail. When the MPU is disabled for instruction accesses (OCR_{I_DMDIS}) or for data accesses (OCR_{D_DMDIS}), substituted access attribute bits will control operation on respective accesses initiated during debug.

18.8 Cache Array Access During Debug

The cache arrays may be read and written during debug mode via the CDACNTL and CDADATA debug registers.

18.9 Basic Steps for Enabling, Using, and Exiting External Debug Mode

The following steps show one possible scenario for a debugger wishing to use the external debug facilities. *This simplified flow is intended to illustrate basic operations, but does not cover all potential methods in depth.*

Enabling External Debug Mode and initializing Debug registers

- The debugger should ensure that the **jd_en_once** control signal is asserted in order to enable OnCE operation.
- Select the OCR and write a value to it in which OCR_{DR}, OCR_{WKUP}, are set to '1'. The tap controller must step through the proper states as outlined earlier. This step will place the CPU in a debug state in which it is halted and awaiting single-step commands or a release to normal mode.
- Scan out the value of the OSR to determine that the CPU clock is running and the CPU has entered the Debug state. This can be done in conjunction with a Read of the CPUSCR. The OSR is shifted out during the Shift_IR state. The CPUSCR will be shifted out during the Shift_DR state. The debugger should save the scanned-out value of CPUSCR for later restoration.
- Select the DBCR0 register and update it with the $EDBCR0_{EDM}$ bit set.
- Clear the DBSR status bits.
- Write appropriate values to the DBCR0–8, IAC, and DAC registers. Note that the initial write to DBCR0 will only affect the EDM bit, so the remaining portion of the register must now be initialized, keeping the EDM bit set

At this point the system is ready to commence debug operations. Depending on the desired operation, different steps must occur.

- Optionally, ensure that the values entered into the MSR portion of the CPUSCR during the following steps cause interrupt to be disabled (clearing MSR_{EE} and MSR_{CE}). This will ensure that external interrupt sources do not cause single-step errors.

To single-step the CPU:

- debugger scans in either a new or a previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in Control State Register (CTL)), with a Go+Noexit OnCE Command value.
- The debugger scans out the OSR with "no-register selected", Go cleared, and determines that the CPU has re-entered the Debug state and that no ERR condition occurred.

To return the CPU to normal operation (without disabling external debug mode)

- The OCR_{DR} control bit should be cleared, leaving the OCR_{WKUP} bit set.
- The debugger restores the CPUSCR with a previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in Control State Register (CTL)), with a Go+Exit OnCE Command value.
- The OCR_{WKUP} bit may then be cleared.

To exit External Debug Mode

- The debugger should place the CPU in the debug state via the OCR_{DR} with OCR_{WKUP} asserted, scanning out and saving the CPUSCR.
- The debugger should write the DBCR0–8 registers as needed, likely clearing every enable except the $EDBCR0_{EDM}$ bit.
- The debugger should write the DBSR to a cleared state.
- The debugger should re-write the DBCR0 with all bits including EDM cleared.
- The debugger should clear the OCR_{DR} bit.
- The debugger restores the CPUSCR with the previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in Control State Register (CTL)), with a Go+Exit OnCE Command value.
- The OCR_{WKUP} bit may then be cleared.

Note

These steps are meant by way of examples, and are not meant to be an exact template for debugger operation.

Chapter 19
z7 Core Debug Support

19.1 Overview

Internal debug support in the e200z7260n3 core allows for software and hardware debug by providing debug functions, such as instruction and data breakpoints and program trace modes. For software based debugging, debug facilities consisting of a set of software accessible debug registers and interrupt mechanisms are provided. These facilities are also available to a hardware based debugger which communicates using a modified IEEE 1149.1 Test Access Port (TAP) controller and pin interface. When hardware debug is enabled, the debug facilities controlled by hardware are protected from software modification.

Software debug facilities are defined as part of Power ISA 2.06. e200z7260n3 supports a subset of these defined facilities. In addition to the facilities defined in Power ISA 2.06, e200z7260n3 provides additional flexibility and functionality in the form of additional instruction breakpoints, linked instruction and data breakpoints, and extended range and value masking. These features are also available to a hardware-based debugger.

When not being used for debugging purposes, a portion of the debug facilities may be configured to provide a stack limit checking mechanism.

19.1.1 Software Debug Facilities

e200z7260n3 provides debug facilities to enable hardware and software debug functions, such as instruction and data breakpoints and program single stepping. The debug facilities consist of a set of debug control registers (DBCR0–2,4–8, EDBRAC0), a set of address compare registers (IAC1–8, DAC1–4), a set of 64-bit data value compare registers (DVC1, DVC2), a Debug Status Register (DBSR) for enabling and recording various kinds of debug events, a Debug Data Effective Address Register (DDEAR), and a special Debug interrupt type built into the interrupt mechanism.

The debug facilities also provide a mechanism for software-controlled processor reset, and debug mode entry. In addition, the Performance Monitor may be configured to utilize the debug interrupt type. Also, the Memory Protection Unit (MPU) may be configured to generate debug events using region descriptors which are not utilized for performing a protection function.

Software debug facilities are enabled by setting the internal debug mode bit in Debug Control register 0 ($DBCR0_{IDM}$). When internal debug mode is enabled, debug events can occur, and can be enabled to record exceptions in the Debug Status register (DBSR). If enabled by MSR_{DE}, these recorded exceptions cause Debug interrupts to occur. When $DBCR0_{IDM}$ is cleared (and $EDBCR0_{EDM}$ is cleared as well), no debug events occur, and no status flags are set in DBSR unless already set. In addition, when $DBCR0_{IDM}$ is cleared (or is overridden by $EDBCR0_{EDM}$ being set and EDBRAC0 indicating no resource is "owned" by software) no Debug interrupts will occur, regardless of the contents of DBSR. A software Debug interrupt handler may access all system resources and perform necessary functions appropriate for system debug.

19.1.1.1 Power ISA 2.06 Compatibility

The e200z7260n3 core implements a subset of the Power ISA 2.06 internal debug features. The following restrictions on functionality are present:

- Instruction address compares do not support compare on physical (real) addresses.
- Data address compares do not support compare on physical (real) addresses.

19.1.2 Additional Debug Facilities

In addition to the debug functionality defined in Power ISA 2.06, e200z7260n3 provides capability to link instruction and data breakpoints, provides additional instruction and data breakpoints, extended range and value masking, multiple watchpoint outputs, provides capability for the Performance Monitor to generate debug events, and allows for sharing of debug resources between software and a hardware debugger. (See Sharing Debug Resources by Software/Hardware.) A data trace port is also provided.

19.1.2.1 Data Trace Port

The data trace port interface is provided to assist in implementing extended debug watchpoint/breakpoint/trace capture capability with logic external to the e200z7260n3 core. This port provides information corresponding to each read or write access

completed without error by the CPU. In order to report data accesses, the Nexus 3 DTC register DI control bit must be set to trace data accesses, not instruction accesses (i.e. the normal setting. See the "Data Trace Control Register (DTC)" section in the Core (e200z7260n3) Nexus 3 Module chapter. The data trace port will report aligned accesses and misaligned accesses as one access, unless the two portions of a misaligned access are non-contiguous, such as when the second portion of the misaligned access is to address 0.

19.1.3 Hardware Debug Facilities

The e200z7260n3 core contains facilities that allow for external test and debugging. A modified IEEE 1149.1 control interface is used to communicate with the core resources. This interface is implemented through a standard 1149.1 TAP (test access port) controller.

By using public instructions, the external debugger can freeze or halt the e200z7260n3 core, read and write internal state and debug facilities, single-step instructions, and resume normal execution.

Hardware Debug is enabled by setting the External Debug Mode enable bit in External Debug Control register 0 ($EDBCR0_{EDM}$), which is also aliased to $DBCR0_{EDM}$. Setting $EDBCR0_{EDM}$ overrides the Internal Debug Mode enable bit $DBCR0_{IDM}$ unless resources are provided back to software via the settings in EDBRAC0. When the Hardware Debug facility is enabled, software is blocked from modifying the "hardware-owned" debug facilities. In addition, since resources are "owned" by the hardware debugger, inconsistent values may be present if software attempts to read "hardware-owned" debug-related resources.

When hardware debug is enabled by setting $EDBCR0_{EDM}$=1, the control registers and resources described in Debug registers are reserved for use by the external debugger. The same events described in Software Debug Events and Exceptions are also used for external debugging, but exceptions are not generated to running software. Hardware-owned debug events enabled in the respective DBCR0–8 registers are recorded in the EDBSR0 register (not the DBSR) regardless of MSR_{DE}, and no debug interrupts are generated unless a) the resource is granted back to software via EDBRAC0 settings, and b) debug mode entry is not masked by the corresponding event bit in EDBSRMSK0. Instead, the CPU will enter debug mode when an enabled event causes a EDBSR0 bit to become set. $EDBCR0_{EDM}$, EDBSR0, EDBSRMSK0, EDDEAR, and EDBRAC0 may only be written through the OnCE port.

Access to most debug resources (registers) requires that the CPU clock (**m_clk**) be running in order to perform write accesses from the external hardware debugger.

19.1.4 Sharing Debug Resources by Software/Hardware

Debug resources may be shared by a hardware debugger and software debug based on the settings of debug control register EDBRAC0. When $EDBCR0_{EDM}$ is set, EDBRAC0 settings determine which debug resources are allocated to software and which resources remain under exclusive hardware control. Software-owned resources which set DBSR bits when $DBCR0_{IDM}$=1 will cause a debug interrupt to occur when enabled with MSR_{DE}. Hardware-owned resources which set EDBSR0 bits when $EDBCR0_{EDM}$=1 will cause an entry into debug mode if the event is not masked in EDBSRMSK0. EDBRAC0 is read-only by software. When resource sharing is enabled, ($EDBCR0_{EDM}$=1 and $EDBRAC0_{IDM}$=1), only software-owned resources may be modified by software. Hardware always has full access to all registers and all register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Hardware-owned resources will set status bits in the EDBSR0 register instead of in DBSR, and will report the effective address of data breakpoints in EDDEAR instead of DDEAR. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control and status registers as appropriate when hardware modifications to the debug registers are performed.

19.1.4.1 Simultaneous Hardware and Software Debug Event Handing

Since it is possible that a "hardware-owned" resource can produce a debug event in conjunction with a software-owned resource producing a different debug event simultaneously, a priority ordering mechanism is implemented which guarantees that the hardware event is handled as soon as possible, while preserving the recognition of the software event. The CPU will give highest priority to the software event initially in order to reach a recoverable boundary, and then will give highest priority to the hardware event in order to enter debug mode as near the point of event occurrence as possible. This is implemented by allowing software exception handing to begin internal to the CPU and to reach the point where the current program counter and MSR values have been saved into DSRR0/1, and the new PC pointing to the debug interrupt handler, along with the new MSR updates. At this point, hardware priority takes over, and the CPU enters debug mode.

The following figure shows the e200z7260n3 debug resources.

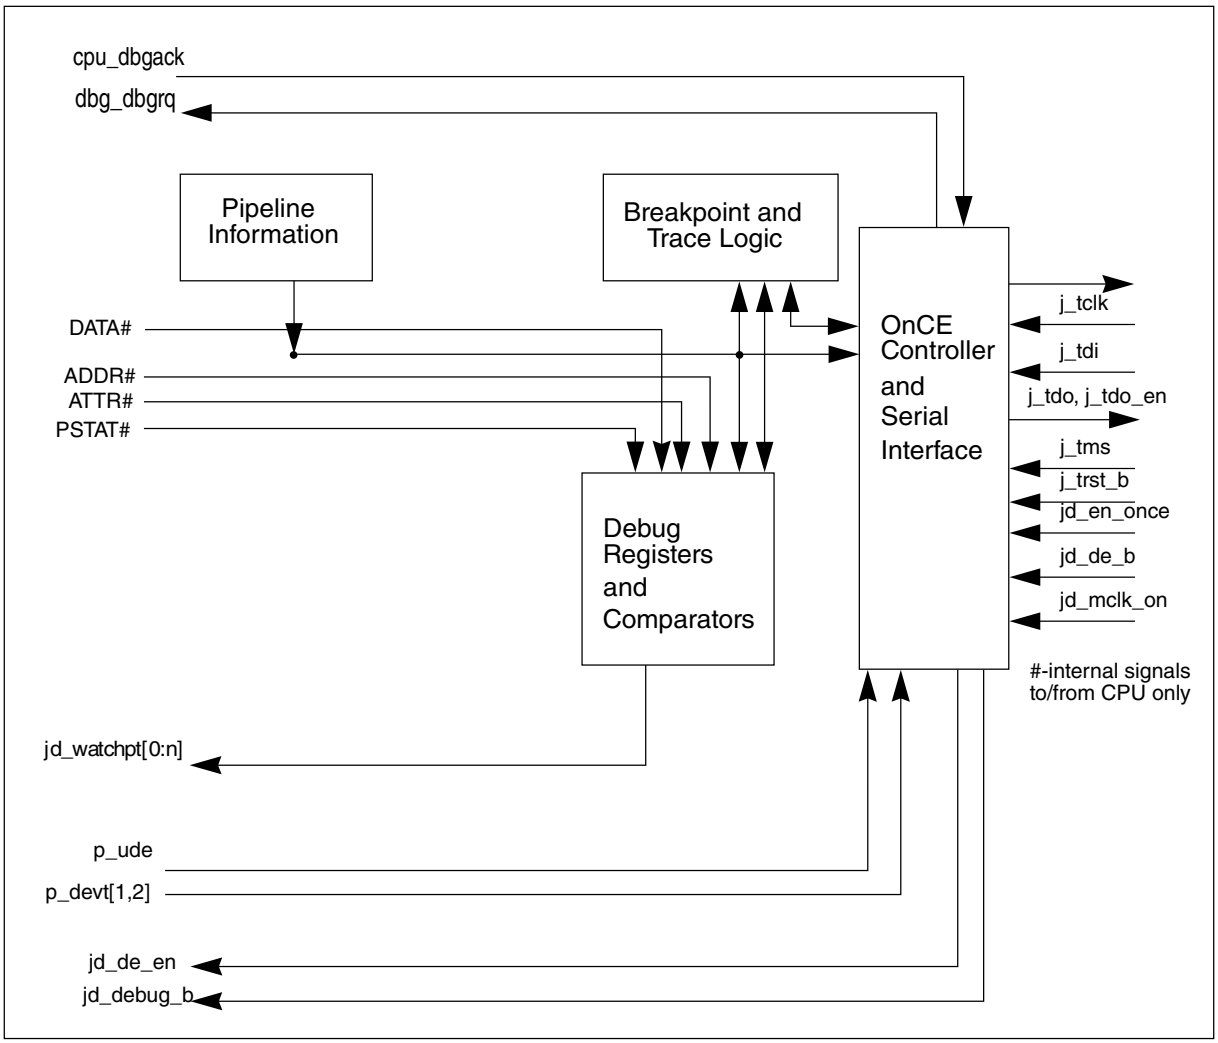

Figure 19-1. e200z7260n3 Debug Resources

19.2 Software Debug Events and Exceptions

Software debug events and exceptions are available when internal debug mode is enabled ($DBCR0_{IDM}$=1) and not overridden by external debug mode ($EDBCR0_{EDM}$ must either be cleared or corresponding resources must be allocated to software debug by the settings in EDBRAC0). When enabled, debug events cause debug exceptions to be recorded in the Debug Status Register. Specific event types are enabled by the Debug Control Registers (DBCR0–8). The Unconditional Debug Event (UDE) is an exception to this rule; it is always enabled. Once a Debug Status Register (DBSR) bit is set by a debug resource which is "owned" by software (other than MRR, DAC_OFST, or VLES), if Debug interrupts are enabled by MSR_{DE}, a Debug interrupt will be generated. The debug interrupt handler is responsible for ensuring that multiple repeated debug interrupts do not occur by clearing the DBSR as appropriate.

Certain debug events are not allowed to occur when MSR_{DE}=0 and $DBCR0_{IDM}$=1. In such situations, no debug exception occurs and thus no DBSR bit is set. Other debug events may cause debug exceptions and set DBSR bits regardless of the state of MSR_{DE}. A Debug interrupt will be delayed until MSR_{DE} is later set to '1'.

When a Debug Status Register bit is set while MSR_{DE}=0, an Imprecise Debug Event flag ($DBSR_{IDE}$) will also be set to indicate that an exception bit in the Debug Status Register was set while Debug interrupts were disabled. Debug interrupt handler software can use this bit to determine whether the address recorded in Debug Save/Restore Register 0 is an address associated with the instruction causing the debug exception, or the address of the instruction which enabled a delayed Debug interrupt by setting the MSR_{DE} bit. A **mtmsr** or **mtdbcr0** which causes both MSR_{DE} and $DBCR0_{IDM}$ to become set, enabling precise debug mode, may cause an Imprecise (Delayed) Debug exception to be generated due to an earlier recorded event in the Debug Status register.

There are eight types of debug events defined by Power ISA 2.06:

- Instruction Address Compare debug events
- Data Address Compare debug events
- Trap debug events
- Branch Taken debug events
- Instruction Complete debug events
- Interrupt/Critical Interrupt Taken debug events
- Return/Critical Return debug events
- Unconditional debug events

In addition, e200z7260n3 defines additional debug events:

- The External debug events DEVT1 and DEVT2 which are described in External debug event.
- The Performance Monitor Interrupt event PMI which is described in Performance Monitor Interrupt debug event.

The e200z7260n3 debug configuration supports most of these event types. Unsupported Power ISA 2.06 defined functionality is as follows:

- Instruction Address Compare and Data Address Compare *Real address* mode is not supported

A brief description of each of the event types follows.

19.2.1 Instruction Address Compare Event

Instruction Address Compare debug events occur when enabled and execution is attempted of an instruction at an address that meets the criteria specified in the DBCR0, DBCR1, DBCR5, DBCR6, and IAC1–8 Registers. Instruction Address compares may specify user/supervisor mode, along with an effective address, masked effective address, or range of effective addresses for comparison. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. IAC events will not occur when an instruction would not have normally begun execution due to a higher priority exception at an instruction boundary.

IAC compares perform a 31-bit compare for VLE instruction storage accesses. Each halfword fetched by the instruction fetch unit will be marked with a set of bits indicating whether an Instruction Address Compare occurred on that halfword. Debug exceptions will occur if enabled and a 16-bit instruction, or the first halfword of a 32-bit instruction, is tagged with an IAC hit.

19.2.2 Data Address Compare Event

Data Address Compare debug events occur when enabled and execution of a load or store class instruction or a cache maintenance instruction results in a data access that meets the criteria specified in the DBCR0, DBCR2, DBCR4, DBCR7–8, DAC1–4, DVC1, and DVC2 Registers. Data address compares may specify user/supervisor mode, along with an effective address, masked effective address, or range of effective addresses for comparison. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. Four address compare values (DAC1–4) are provided.

The effective address of the load, store, or cache control operation is recorded in the DDEAR register when a data address compare event is recorded in DBSR if the previous values of the $DBSR_{DAC\{R,W\}}$ bits are zero. Once a DDEAR update is performed, these bits must be cleared by software prior to another DDEAR hardware update occurring. A subsequent DAC event will not update the DDEAR register if either of the $DBSR_{DAC\{R,W\}}$ bits are set.

Note

In contrast to the Power ISA 2.06 definition, Data Address Compare events on e200z7260n3 do not prevent the load or store class instruction from completing. If a load or store class

instruction completes successfully without a Data Storage interrupt, Data Address Compare exceptions are reported at the completion of the instruction. If the exception results in a precise Debug interrupt, the address value saved in DSRR0 is the address of the instruction following the load or store class instruction. For DVC DAC events, the exception can be imprecisely reported even further past the load or store class instruction generating the event (without necessarily affecting $DBSR_{IDE}$) and the saved address value can point to a subsequent instruction past the next instruction. This occurrence is indicated in the $DBSR_{DAC\_OFST}$ field.

If a load or store class instruction does not complete successfully due to a Data Storage exception or a machine check condition for the load or store, and a Data Address Compare debug exception also occurs, the result is an imprecise Debug interrupt, the address value saved in DSRR0 is the address of the load or store class instruction, and the $DBSR_{IDE}$ bit will be set. In addition to occurring when $DBCR0_{IDM}$=1, this circumstance can also occur when $EDBCR0_{EDM}$=1 and the event is hardware-owned, in which case $EDBSR0_{IDE}$ will be set.

Note

DAC events will not be recorded if a load multiple word or store multiple word instruction is interrupted prior to completion by a critical input or external input interrupt.

Note

DAC events will occur for cache control instructions without performing data compares, regardless of the settings of the DBCRx registers and DVC registers for data value comparison qualifications, i.e. no data comparisons are performed since these instructions do not have associated data values.

Note

DAC events are not signaled on the second portion of a misaligned load or store that is broken up into two separate accesses.

Note

DAC events are not signaled on the **mpure** or **mpuwe** MPU instructions.

Note

DAC[1,2] events are not signaled if DVC[1,2]M is non-zero and a DSI exception occurs on the load or store, since the load or store access is not performed. For a **lmw** or **stmw** transfer however, if a DVC successfully occurs on a transfer and a later transfer encounters a DSI exception, the DAC event will be reported, since a successful data value compare took place.

Note

Due to internal pipeline status, for a reported DAC event on a **lmw** or **stmw** transfer, the value stored in the DDEAR/ EDDEAR will be the effective address of the first transfer of the sequence, and not necessarily the precise transfer that caused the DAC event.

19.2.2.1 Data Address Compare Event Status Updates

Data Address Compare debug events with Data Value compares can be reported ambiguously in several circumstances involving issuing a sequence of load or store class instructions. Due to the CPU pipeline and the delay in performing the data value compare following completion of the access, if the first load or store class instruction generates a DVC DAC, a second and possibly third load or store class instruction may also generate a DAC or DVC DAC event, or may generate a DSI exception with or without a simultaneous DAC event.

Also, since non-load/store instructions may be dual-issued in combination with a load/ store instruction, the actual number of additional instructions that are completed following a recognized DVC DAC on a load/store instruction may vary from 0 to 5. This value will be reported in the $DBSR_{DAC\_OFST}$ field when the DVC DAC status is recorded.

Table 19-1 outlines the settings of the DBSR, DSRR0 saved value, and potential updating of the ESR register for various exception cases on sequences of load/store class instructions. Not all exception combinations are covered in the table, such as IAC, ISI, or Alignment exceptions on subsequent instructions. In general these exceptions will cause further instruction issue to be halted, execution of the excepting instruction to be aborted, and reporting of these exceptions will be masked. The saved DSRR0 value will point to

this excepting instruction, and the exception(s) may be regenerated after returning from the debug interrupt handler and attempting to re-execute the instruction pointed to by DSRR0. In addition, in the examples in Table 19-1, the DAC_OFST and DSRR0 values assume no dual issue occurs. If dual-issue occurs with the first, second, or third column, then the DAC_OFST and DSRR0 values will point beyond the values shown.

Table 19-1. DAC events and Resultant Updates

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
DSI, no DAC	—	—	Take DSI exception, no DBSR update. Update ESR.
DSI, with DACx	—	—	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST not set. DSRR0 points to 1st load/store class instruction. No ESR update.
DACx	—	—	Take Debug exception, DBSR update setting DACx, DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update.
DVC DACx	No exceptions, any instruction	No exceptions, Non-ldst instruction	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b001. DSRR0 points to 3rd instruction. No ESR update.
DVC DACx	No exceptions	No exceptions, Ldst instruction	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b010. DSRR0 points to instruction after 3rd instruction. No ESR update.
DVC DACx	DSI, no DAC	—	Take Debug exception, DBSR update setting DACx, DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update. **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	DSI, with DACy	—	Take Debug exception, DBSR update setting DACx. DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update. **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	DACy	—	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy,Normal Ldst	Non-Ldst instruction	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy,Normal Ldst	Ldst instruction,no exception	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd load/store class instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

Table continues on the next page...

Table 19-1. DAC events and Resultant Updates (continued)

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
DVC DACx	DVC DACy,Normal Ldst	DSI Error, with or without DAC	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. No ESR update. DSRR0 points to 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case. **Note:** in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	DVC DACy,Normal Ldst	DACy, or DVC DAC_y Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd load/store class instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy,Ldst multiple (lmw, stmw)	Any instruction including ld/st	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	Any instruction(no exception)	DSI, with or without DAC,Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. No ESR update. **Note:** in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	Any instruction(no exception)	DACy, or DVC DAC_y Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd class instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

Table 19-2 through Table 19-5 show some example updates for specific code sequences of dual issuing of load/store class instructions with non-load/store class instructions and the results of DAC and DVC events on selected ones of the load/store instructions.

Table 19-2. DAC events and Resultant Updates, dual-issue case 1

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) load/store (6) alu	Event(s)	Result
	Instruction (1): DSI, no DAC	Take DSI exception, no DBSR update, Update ESR.
	Instruction (1): DSI, with DACx	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST set to 3'b000. DSRR0 points to instruction (1). No ESR update.
	Instruction (1): DACx	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b000. DSRR0 points to instruction (2). No ESR update.
	Instruction (1): DVC DACx No other exceptions	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No ESR update. No debug event updates for instruction (6)
	Instruction (1): DVC DACx Instruction (3): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b001. DSRR0 points to instruction (3). No ESR update. No debug event updates for instructions (3)–(6). **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
	Instruction (1): DVC DACx Instruction (3): DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction (4). No debug event updates for instructions (4)–(6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
	Instruction (1): DVC DACx Instruction (3): DVC DACy	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No ESR update. No debug event updates for instruction (6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
	Instruction (1): DVC DACx Instruction (3): DVC DACy Instruction (5): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. No ESR update. DSRR0 points to instruction (4). No debug event updates for instructions (4)–(6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case. **Note:** in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.

No debug event updates for instructions (4)–(6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
	Instruction (1): DVC DACx Instruction (3): DVC DACy	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b011. DSRR0 points to instruction (5). No ESR update. No debug event updates for instructions (5)–(6). **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

19.2.3 Linked Instruction Address Compare and Data Address Compare Events

Data Address Compare 1, 2, 3, and 4 debug events may be 'linked' with an Instruction Address Compare event by setting the DAC[1–4]LNK control bits in DBCR2 and DBCR8 to further refine when a Data Address Compare debug event is generated. DAC1

may be linked with IAC1, DAC2 (when not used as a mask or range bounds register) may be linked with IAC3. DAC3 may be linked with IAC5, DAC4 (when not used as a mask or range bounds register) may be linked with IAC7. When linked, a DAC debug event occurs when the same instruction that generates the DAC 'hit' also generates a corresponding linked IAC 'hit'. When linked, the IAC event is not recorded in the Debug Status register, regardless of whether a corresponding linked DAC event occurs, or whether the IAC event enable is set.

When enabled and execution of a load or store class instruction results in a data access with an address that meets the criteria specified in the DBCRx, DACx, and DVCx Registers, and the instruction also meets the criteria for generating an Instruction Address Compare event, a Linked Data Address Compare debug event occurs. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. The normal DAC1 status bit in the DBSR is used for recording these events. The IAC status bit is not set if the corresponding Instruction Address Compare register is linked.

Linking is enabled using control bits in DBCR2 and DBCR8. Note that linking is only available in EDM or IDM. Attempts to use linking otherwise are ignored.

Note

Linked DAC events will not be recorded if a load multiple word or store multiple word type instruction is interrupted prior to completion by a critical input or external input interrupt.

19.2.4 Trap Debug Event

A Trap debug event (TRAP) occurs if Trap debug events are enabled ($DBCR0_{TRAP}$=1), a Trap instruction (**tw**) is executed, and the conditions specified by the instruction for the trap are met. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Trap debug event occurs, the $DBSR_{TRAP}$ bit is set to 1 to record the debug exception.

19.2.5 Branch Taken Debug Event

A Branch Taken debug event (BRT) occurs if Branch Taken debug events are enabled ($DBCR0_{BRT}$=1) and execution is attempted of a branch instruction that will be taken (either an unconditional branch, or a conditional branch whose branch condition is true), and MSR_{DE}=1. Branch Taken debug events are not recognized if MSR_{DE}=0 at the time of execution of the branch instruction and thus $DBSR_{IDE}$ can not be set by a Branch Taken

debug event. When a Branch Taken debug event is recognized, the $DBSR_{BRT}$ bit is set to 1 to record the debug exception, and the address of the branch instruction will be recorded in DSRR0.

19.2.6 Instruction Complete Debug Event

An Instruction Complete debug event (ICMP) occurs if Instruction Complete debug events are enabled ($DBCR0_{ICMP}$=1), execution of any instruction is completed, and MSR_{DE}=1. If execution of an instruction is suppressed due to the instruction causing some other exception that is enabled to generate an interrupt, then the attempted execution of that instruction does not cause an Instruction Complete debug event. The ***se_sc*** instruction does not fall into the category of an instruction whose execution is suppressed, since the instruction actually executes and then generates a System Call interrupt. In this case, the Instruction Complete debug exception will also be set. When an Instruction Complete debug event is recognized, $DBSR_{ICMP}$ is set to 1 to record the debug exception and the address of the next instruction to be executed will be recorded in DSRR0.

Instruction Complete debug events are not recognized if MSR_{DE}=0 at the time of execution of the instruction, thus $DBSR_{IDE}$ is not generally set by an ICMP debug event.

One circumstance may cause the $DBSR_{ICMP}$ and $DBSR_{IDE}$ bits to be set. This occurs when a EFPU Round exception occurs. Since the instruction is by definition completed (SRR0 points to the following instruction), this interrupt takes higher priority than the Debug interrupt so as not to be lost, and $DBSR_{IDE}$ is set to indicate the imprecise recognition of a Debug interrupt. In this case, the Debug interrupt will be taken with SRR0 pointing to the instruction following the instruction that generated the EFPU Round exception, and DSRR0 will point to the Round exception handler. In addition to occurring when $DBCR0_{IDM}$=1, this circumstance can also occur when $EDBCR0_{EDM}$=1 and the event is hardware-owned, in which case $EDBSR0_{IDE}$ will be set.

Note

Instruction complete debug events are not generated by the execution of an instruction that sets MSR_{DE} to '1' while $DBCR0_{ICMP}$=1, nor by the execution of an instruction that sets $DBCR0_{ICMP}$ to '1' while MSR_{DE}=1.

19.2.7 Interrupt Taken Debug Event

An Interrupt Taken debug event (IRPT) occurs if Interrupt Taken debug events are enabled ($DBCR0_{IRPT}$=1) and a base-class interrupt occurs. Only base-class interrupts (an interrupt using SRR0/1) cause an Interrupt Taken debug event. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an Interrupt Taken debug event occurs, the $DBSR_{IRPT}$ bit is set to 1 to record the debug exception. The value saved in DSRR0 will be the address of the non-critical interrupt handler.

19.2.8 Critical Interrupt Taken Debug Event

A Critical Interrupt Taken debug event (CIRPT) occurs if Critical Interrupt Taken debug events are enabled ($DBCR0_{CIRPT}$=1) and a critical interrupt occurs. Only critical class interrupts (an interrupt using CSRR0/1) cause a Critical Interrupt Taken debug event. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Critical Interrupt Taken debug event occurs, the $DBSR_{CIRPT}$ bit is set to 1 to record the debug exception. The value saved in DSRR0 will be the address of the critical interrupt handler.

19.2.9 Return Debug Event

A Return debug event (RET) occurs if Return debug events are enabled ($DBCR0_{RET}$=1) and an attempt is made to execute an **se_rfi** instruction. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Return debug event occurs, the $DBSR_{RET}$ bit is set to 1 to record the debug exception.

If MSR_{DE}=0 at the time of the execution of the **se_rfi** (i.e. before the MSR is updated by the **se_rfi**), then $DBSR_{IDE}$ is also set to 1 to record the imprecise debug event.

If MSR_{DE}=1 at the time of the execution of the **se_rfi**, a Debug interrupt will occur provided there exists no higher priority exception that is enabled to cause an interrupt. Debug Save/Restore Register 0 will be set to the address of the **se_rfi** instruction.

19.2.10 Critical Return Debug Event

A Critical Return debug event (CRET) occurs if Critical Return debug events are enabled ($DBCR0_{CRET}$=1) and an attempt is made to execute an **se_rfci** instruction. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Critical Return debug event occurs, the $DBSR_{CRET}$ bit is set to 1 to record the debug exception.

If MSR_{DE}=0 at the time of the execution of the **se_rfci** (i.e. before the MSR is updated by the **se_rfci**), then $DBSR_{IDE}$ is also set to 1 to record the imprecise debug event.

If MSR_{DE}=1 at the time of the execution of the **se_rfci**, a Debug interrupt will occur provided there exists no higher priority exception that is enabled to cause an interrupt. Debug Save/Restore Register 0 will be set to the address of the **se_rfci** instruction.

19.2.11 External debug event

An External debug event (DEVT1, DEVT2) occurs if External debug events are enabled ($DBCR0_{DEVT1}$=1 or $DBCR0_{DEVT2}$=1), and the respective **p_devt1** or **p_devt2** input signal transitions to the asserted state while the CPU is not in the Stopped state. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an External debug event occurs, $DBSR_{DEVT\{1,2\}}$ is set to '1' to record the debug exception. This debug event is an asynchronous event, but is only sampled when the CPU **m_clk** is active.

19.2.12 Unconditional debug event

An Unconditional debug event (UDE) occurs when the Unconditional Debug Event (**p_ude**) input transitions to the asserted state. The Unconditional debug event is the only debug event that does not have a corresponding enable bit for the event in DBCR0. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an Unconditional debug event occurs, the $DBSR_{UDE}$ bit is set to '1' to record the debug exception. This debug event is an asynchronous event.

19.2.13 Performance Monitor Interrupt debug event

A Performance Monitor Interrupt debug event (PMI) occurs if Performance Monitor Interrupt debug events are enabled ($PMGC0_{UDI}$=1), and a performance monitor interrupt event occurs. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Performance Monitor Interrupt debug event occurs, $DBSR_{PMI}$ is set to '1' to record the debug exception. This debug event is an asynchronous event.

19.3 Debug registers

This section describes debug-related registers that are software accessible. These registers are intended for use by special debug tools and debug software, not by general application code.

Access to these registers (other than DBSR) by software is conditioned by the External Debug mode control bit ($EDBCR0_{EDM}$) and the settings of debug control register EDBRAC0, which can be set by the hardware debug port. If $EDBCR0_{EDM}$ is set and if the bit in EDBRAC0 corresponding to the resource is cleared, software is prevented from modifying debug register values other than in DBSR, since the resource is not "owned" by software. Software always has ownership of DBSR. Execution of a **mtspr** instruction targeting a debug register or register field not "owned" by software will not cause modifications to occur, and no exception will be signaled. In addition, since the external debugger hardware may be manipulating debug register values, the state of these registers or register fields not "owned" by software is not guaranteed to be consistent if accessed (read) by software with a **mfspr** instruction, other than the $DBCR0_{EDM}$ bit itself and the EDBRAC0 register. Hardware always has full access to all registers and all register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control registers as appropriate when hardware modifications to the debug registers is performed.

19.3.1 Debug Address and Value Registers

Instruction Address Compare registers IAC1–8 are used to hold instruction addresses for address comparison purposes. In addition, IAC2 and IAC4 may hold mask information for IAC1 and IAC3 respectively and IAC6 and IAC8 may hold mask information for IAC5 and IAC7 respectively, when *Address Bit Match* compare modes are selected. Note that when performing instruction address compares, the low order bit of the instruction address and the corresponding IAC register is ignored for VLE instructions.

Data Address Compare registers DAC1–4 are used to hold data access addresses for address comparison purposes. In addition, DAC2 and DAC4 may hold mask information for DAC1 and DAC3 respectively when *Address Bit Match* compare modes are selected.

Data Value Compare registers DVC1 and DVC2 are used to hold data values for data comparison purposes. DVC1 and DVC2 are 64-bit registers. Data value comparisons are used to qualify Data Address compare 1 and 2 debug events. Data value comparisons are

not available for Data address compare 3–4 events. DVC1 is associated with DAC1, and DVC2 is associated with DAC2. The most significant byte of the DVC1(2) register (labeled B0 in the following figure) corresponds to the byte data value transferred to/from memory byte offset 0, 8, …, and the least significant byte of the register (labeled B7 in the following figure) corresponds to byte offset 7, F, … . When enabled for performing data value comparisons, each enabled byte in DVC1(2) is compared with the memory value transferred on the corresponding active byte lane of the data memory interface to determine if a match occurs. Inactive byte lanes do not participate in the comparison, they are implicitly masked. The Byte Strobe Assertion for Transfers table in the Core (e200z7260n3) Core Complex Overview chapter shows active byte lanes for data transfers. Software must also program the DVC1(2) register byte positions based on the alignment of the access. Misaligned accesses are not fully supported, since the data address and data value comparisons are only performed on the initial access in the case of a misaligned access; thus, accesses that cross a 64-bit boundary cannot be fully matched. For address and size combinations that involve two transfers, only the initial transfer is used for data address and value matching.

DVC1 and DVC2 may be read or written using **mtspr** and **mfspr** instructions. The DVC1U and DVC2U SPR numbers (601,602) are used for accessing the upper 32-bit portion of the DVC register. The DVC1 and DVC2 SPR numbers (318,319) are used for accessing the lower 32-bit portion of the DVC register.

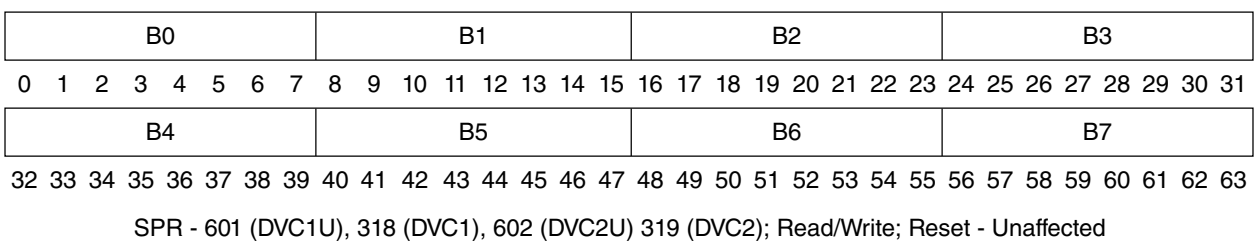

Figure 19-2. DVC1, DVC2 registers

19.3.2 Debug Control and Status registers

Debug Control Registers (DBCR0–8 and EDBRAC0) are used to enable debug events, reset the processor, and set the debug mode of the processor. The Debug Status register (DBSR) records debug exceptions while Internal Debug mode is enabled. The Debug Data Effective Address register (DDEAR) records the effective address of a Data Address Compare event while Internal Debug mode is enabled.

e200z7260n3 requires that a context synchronizing instruction follow a **mtspr** DBCR0–8 or DBSR to ensure that any alterations enabling/disabling debug events are effective. The context synchronizing instruction may or may not be affected by the alteration. Typically, an **se_isync** instruction is used to create a synchronization boundary beyond which it can be guaranteed that the newly written control values are in effect.

For watchpoint generation, configuration settings contained in DBCR1–8 are used, even though the corresponding event(s) may be disabled (via DBCR0) from setting DBSR flags.

19.3.2.1 Debug Control Register 0 (DBCR0)

Debug Control Register 0 is used to enable debug modes and controls which debug events are allowed to set DBSR or EDBSR0 flags. e200z7260n3 adds some implementation specific bits to this register, as seen in the following figure.

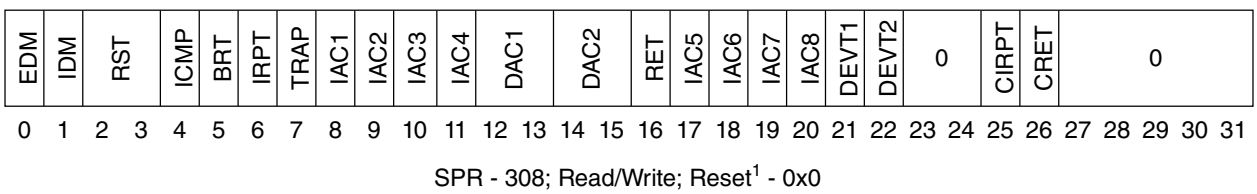

Figure 19-3. Debug Control Register 0 (DBCR0) register

Note

[1] $DBCR0_{EDM}$ is affected by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state, but is not affected by **p_reset_b**. All other bits are reset by processor reset **p_reset_b** if $DBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $DBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources (other than RST) from reset by **p_reset_b**, and only software-owned resources indicated by EDBRAC0 and the $DBCR0_{RST}$ field will be reset by **p_reset_b**. The $DBCR0_{RST}$ field will always be reset by **p_reset_b** regardless of the value of $DBCR0_{EDM}$.

The following provides bit definitions for Debug Control Register 0.

Table 19-6. DBCR0 field descriptions

Bit	Name	Description
0	EDM	External Debug mode. This bit is read-only by software. When external debug mode is enabled, hardware-owned resources in debug registers are not affected by processor reset p_reset_b. This allows the debugger to set up hardware debug events that remain active across a processor reset. 0 External debug mode disabled. Internal debug events not mapped into external debug events. 1 External debug mode enabled. Hardware-owned debug events will not cause the CPU to vector to interrupt code. Software is not permitted to write to debug registers {DBCR0–8, IAC1–8, DAC1–4, DVC1–2[U]} unless permitted by settings in EDBRAC0. Hardware-owned events will set status bits in EDBSR0. Programming Notes: It is recommended that debug status bits in the Debug Status Registers be cleared before disabling external debug mode to avoid any internal imprecise debug interrupts. Software may use this bit to determine if external debug has control over the debug registers. The hardware debugger must set the EDM bit to '1' before other bits in this register (and other debug registers) may be altered. On the initial setting of this bit to '1', all other bits are unchanged. This bit is only writable through the OnCE port.
1	IDM	Internal Debug mode 0 Debug exceptions are disabled. Debug events do not affect DBSR. 1 Debug exceptions are enabled. Enabled debug events owned by software will update the DBSR. If MSR_{DE}=1, the occurrence of a debug event, or the recording of an earlier debug event in the Debug Status Register when MSR_{DE} was cleared, will cause a Debug interrupt.
2:3	RST	Reset Control 00 No function 01 **p_dbrstc[1]** pin asserted by Debug Reset Control. Allows external device to initiate processor or system reset 10 **p_dbrstc[0]** pin asserted by Debug Reset Control. Allows external device to initiate processor or system reset. 11 Reserved
4	ICMP	Instruction Complete Debug Event Enable 0 ICMP debug events are disabled 1 ICMP debug events are enabled
5	BRT	Branch Taken Debug Event Enable 0 BRT debug events are disabled 1 BRT debug events are enabled
6	IRPT	Interrupt Taken Debug Event Enable 0 IRPT debug events are disabled 1 IRPT debug events are enabled
7	TRAP	Trap Taken Debug Event Enable 0 TRAP debug events are disabled 1 TRAP debug events are enabled
8	IAC1	Instruction Address Compare 1 Debug Event Enable 0 IAC1 debug events are disabled

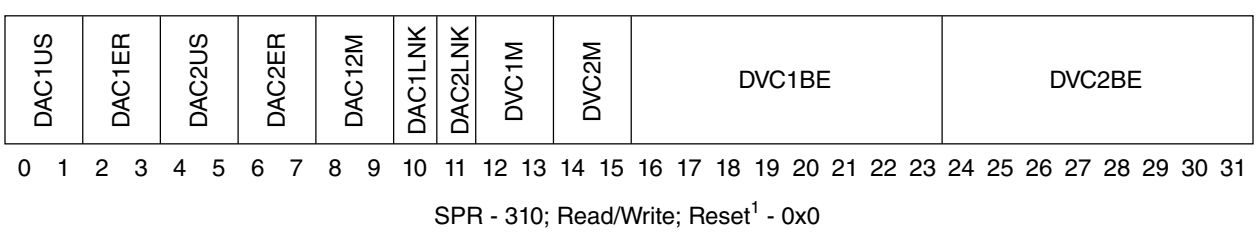
19.3.2.3 Debug Control Register 2 (DBCR2)

Debug Control Register 2 is used to configure Data Address Compare and Data Value Compare operation.The DBCR2 register is shown in the following figure.



SPR - 310; Read/Write; Reset[1] - 0x0

Figure 19-5. DBCR2 Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 2.

Table 19-8. DBCR2 Bit Definitions

Bit	Name	Description
0:1	DAC1US	Data Address Compare 1 User/Supervisor Mode 00 DAC1 debug events not affected by MSR_{PR} 01 Reserved 10 DAC1 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 DAC1 debug events can only occur if MSR_{PR}=1 (User mode)
2:3	DAC1ER	Data Address Compare 1 Effective/Real Mode 00 DAC1 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 DAC1 debug events are based on effective address and can only occur if MSR_{DS}=0 11 DAC1 debug events are based on effective address and can only occur if MSR_{DS}=1
4:5	DAC2US	Data Address Compare 2 User/Supervisor Mode 00 DAC2 debug events not affected by MSR_{PR} 01 Reserved 10 DAC2 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 DAC2 debug events can only occur if MSR_{PR}=1. (User mode)
6:7	DAC2ER	Data Address Compare 2 Effective/Real Mode 00 DAC2 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 DAC2 debug events are based on effective address and can only occur if MSR_{DS}=0 11 DAC2 debug events are based on effective address and can only occur if MSR_{DS}=1
8:9	DAC12M	Data Address Compare 1/2 Mode 00 Exact address compare. DAC1 debug events can only occur if the address of the data access is equal to the value specified in DAC1. DAC2 debug events can only occur if the address of the data access is equal to the value specified in DAC2. 01 Address bit match. DAC1 debug events can occur only if the address of the data access ANDed with the contents of DAC2, are equal to the contents of DAC1 also ANDed with the contents of DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used. 10 Inclusive address range compare. DAC1 debug events can occur only if the address of the data access is greater than or equal to the value specified in DAC1 and less than the value specified in DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used.

Table continues on the next page...

Table 19-8. DBCR2 Bit Definitions (continued)

Bit	Name	Description
		11 Exclusive address range compare. DAC1 debug events can occur only if the address of the data access is less than the value specified in DAC1 or is greater than or equal to the value specified in DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used.
10	DAC1LNK	Data Address Compare 1 Linked. When linked to IAC1, DAC1 debug events are conditioned based on whether the instruction also generated an IAC1 debug event. Note that linking is only available in EDM or IDM. 0 No effect 1 DAC1 debug events are linked to IAC1 debug events. IAC1 debug events do not affect DBSR When linked to IAC1, DAC1 debug events are conditioned based on whether the instruction also generated an IAC1 debug event. Note that linking is only available in EDM or IDM.
11	DAC2LNK	Data Address Compare 2 Linked. When linked to IAC3, DAC2 debug events are conditioned based on whether the instruction also generated an IAC3 debug event. DAC2 can only be linked if DAC12M specifies Exact Address Compare since DAC2 debug events are not generated in the other compare modes. Note that linking is only available in EDM or IDM. 0 No effect 1 DAC 2 debug events are linked to IAC3 debug events. IAC3 debug events do not affect DBSR
12:13	DVC1M	Data Value Compare 1 Mode When $DBCR4_{DVC1C}$=0: 00 DAC1 debug events not affected by data value compares. 01 DAC1 debug events can only occur when all bytes specified in the DVC1BE field match the corresponding data byte values for active byte lanes of the memory access. 10 DAC1 debug events can only occur when any byte specified in the DVC1BE field matches the corresponding data byte value for active byte lanes of the memory access. 11 DAC1 debug events can only occur when all bytes specified in the DVC1BE field within at least one of the halfwords of the data value of the memory access matches the corresponding DVC1 value. **NOTE:** Inactive byte lanes of the memory access are automatically masked. When $DBCR4_{DVC1C}$=1: 00 Reserved 01 DAC1 debug events can only occur when any byte specified in the DVC1BE field does not match the corresponding data byte value for active byte lanes of the memory access. If all active bytes match, then no event will be generated. 10 DAC1 debug events can only occur when all bytes specified in the DVC1BE field do not match the corresponding data byte values for active byte lanes of the memory access. If any active byte match occurs, no event will be generated. 11 Reserved **NOTE:** Note: Inactive byte lanes of the memory access are automatically masked.
14:15	DVC2M	Data Value Compare 2 Mode When $DBCR4_{DVC2C}$=0: 00 DAC2 debug events not affected by data value compares. 01 DAC2 debug events can only occur when all bytes specified in the DVC2BE field match the corresponding data byte values for active byte lanes of the memory access.

Table continues on the next page...

Table 19-8. DBCR2 Bit Definitions (continued)

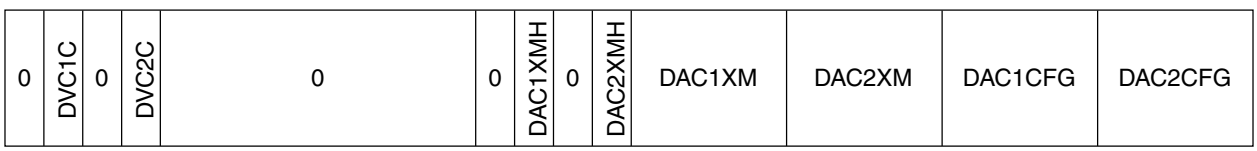
Bit	Name	Description
		10 DAC2 debug events can only occur when any byte specified in the DVC2BE field matches the corresponding data byte value for active byte lanes of the memory access. 11 DAC2 debug events can only occur when all bytes specified in the DVC2BE field within at least one of the halfwords of the data value of the memory access matches the corresponding DVC2 value. **NOTE:** Inactive byte lanes of the memory access are automatically masked. When $DBCR4_{DVC2C}$=1: 00 Reserved 01 DAC2 debug events can only occur when any byte specified in the DVC2BE field does not match the corresponding data byte value for active byte lanes of the memory access. If all active bytes match, then no event will be generated. 10 DAC2 debug events can only occur when all bytes specified in the DVC2BE field do not match the corresponding data byte values for active byte lanes of the memory access. If any active byte match occurs, no event will be generated. 11 Reserved **NOTE:** Inactive byte lanes of the memory access are automatically masked.
16:23	DVC1BE	Data Value Compare 1 Byte Enables Specifies which bytes in the aligned doubleword value associated with the memory access are compared to the corresponding bytes in DVC1. Inactive byte lanes of a memory access smaller than 64 bits are automatically masked by hardware. If all bits in the DVC1BE field are clear, then a match will occur regardless of the data. Misaligned accesses that cross a doubleword boundary are not fully supported. 1xxxxxxx Byte lane 0 is enabled for comparison with the value in bits 0:7 of DVC1. x1xxxxxx Byte lane 1 is enabled for comparison with the value in bits 8:15 of DVC1. xx1xxxxx Byte lane 2 is enabled for comparison with the value in bits 16:23 of DVC1. xxx1xxxx Byte lane 3 is enabled for comparison with the value in bits 24:31 of DVC1. xxxx1xxx Byte lane 4 is enabled for comparison with the value in bits 32:39 of DVC1. xxxxx1xx Byte lane 5 is enabled for comparison with the value in bits 40:47 of DVC1. xxxxxx1x Byte lane 6 is enabled for comparison with the value in bits 48:55 of DVC1. xxxxxxx1 Byte lane 7 is enabled for comparison with the value in bits 56:63 of DVC1.
24:31	DVC2BE	Data Value Compare2 Byte Enables Specifies which bytes in the aligned doubleword value associated with the memory access are compared to the corresponding bytes in DVC2. Inactive byte lanes of a memory access smaller than 64 bits are automatically masked by hardware. If all bits in the DVC1BE field are clear, then a match will occur regardless of the data. Misaligned accesses that cross a doubleword boundary are not fully supported. 1xxxxxxx Byte lane 0 is enabled for comparison with the value in bits 0:7 of DVC2. x1xxxxxx Byte lane 1 is enabled for comparison with the value in bits 8:15 of DVC2. xx1xxxxx Byte lane 2 is enabled for comparison with the value in bits 16:23 of DVC2. xxx1xxxx Byte lane 3 is enabled for comparison with the value in bits 24:31 of DVC2. xxxx1xxx Byte lane 4 is enabled for comparison with the value in bits 32:39 of DVC2. xxxxx1xx Byte lane 5 is enabled for comparison with the value in bits 40:47 of DVC2.

Table 19-8. DBCR2 Bit Definitions

Bit	Name	Description
		xxxxxx1x Byte lane 6 is enabled for comparison with the value in bits 48:55 of DVC2. xxxxxxx1 Byte lane 7 is enabled for comparison with the value in bits 56:63 of DVC2.

19.3.2.4 Debug Control Register 4 (DBCR4)

Debug Control Register 4 is used to extend data address and value compare matching functionality. DBCR4 is shown in the following figure.



SPR - 563; Read/Write; Reset[1] - 0x0

Figure 19-6. DBCR4 Register

Note

[1] DBCR4 is reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 4.

Table 19-9. DBCR4 field description

Bit	Name	Description
0	—	Reserved
1	DVC1C	Data Value Compare 1 Control. DVC1C controls whether DVC1 data value comparisons utilize the normal compare operation, or an alternate “inverted compare” operation. In inverted polarity mode, data value compares perform a not-equal comparison. See details in the DBCR2 register definition. 0 Normal DVC1 operation. Inverted polarity DVC1 operation
2	—	Reserved
3	DVC2C	Data Value Compare 2 Control. DVC2C controls whether DVC2 data value comparisons utilize the normal compare operation, or an alternate “inverted compare” operation. In inverted polarity mode, data value compares perform a not-equal comparison. See details in the DBCR2 register definition 0 Normal DVC2 operation.

Table continues on the next page...

Table 19-9. DBCR4 field description (continued)

Bit	Name	Description
		1 Inverted polarity DVC2 operation
4:12	—	Reserved
13	DAC1XMH	Data Address Compare 1 Extended Mask Control High. DAC1XMH extends the range of the DAC1XM field. 0 - DAC1XM masks 0–15 low-order address bits 1 - DAC1XM masks 16–31 low-order address bits
14	—	Reserved
15	DAC2XMH	Data Address Compare 2 Extended Mask Control High. . DAC2XMH extends the range of the DAC2XM field. 0 DAC2XM masks 0–15 low-order address bits 1 DAC2XM masks 16–31 low-order address bits
16:19	DAC1XM	Data Address Compare 1 Extended Mask Control. DAC1XM allows for binary power of 2 address range compares for DAC1 without requiring the use of DAC2. Value of DAC1XMH || DAC1XM: 00000 No additional masking when DBCR2[DAC12M] = 00 00001 - 11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC1 when comparing the storage address with the value in DAC1 for exact address compare (DBCR2[DAC12M] = 00). Address ranges of 2 bytes to 2GB are supported.
20:23	DAC2XM	Data Address Compare 2 Extended Mask Control Value of DAC2XMH || DAC2XM: 00000 No additional masking when DBCR2[DAC12M] = 00 00001 - 11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC2 when comparing the storage address with the value in DAC2 for exact address compare (DBCR2[DAC12M] = 00). Address ranges of 2 bytes to 2GB are supported. DAC2XM allows for binary power of 2 address range compares for DAC2.
24:27	DAC1CFG	Data Address Compare 1 Configuration 0000 DAC1 debug watchpoints are enabled for load-type or store-type data storage accesses when $DBCR0_{DAC1}$=00 0001 DAC1 debug watchpoints are enabled only for store-type data storage accesses when $DBCR0_{DAC1}$=00 0010 DAC1 debug watchpoints are enabled only for load-type data storage accesses when $DBCR0_{DAC1}$=00 0011 Reserved 01xx Reserved 1000 DAC1 address comparisons are used for stack limit checking. DAC1 address comparisons are qualified with use of GPR R1 in <EA> calculation for most load or store instructions. No debug events occur for DAC1. When a qualified DAC1 match occurs, a machine check exception is generated for supervisor-mode accesses or a DSI is generated for user-mode accesses, and a DAC1 watchpoint is generated. $DBCR0_{DAC1}$ and $DBCR2_{DVC1M}$ settings are ignored. 1001 – 1111 Reserved DAC1CFG controls whether DAC1 data address comparisons utilize the normal PowerISA operation for generating both debug events and watchpoints, a watchpoint-only function, or a stack limit checking function (with watchpoint).

Table continues on the next page...

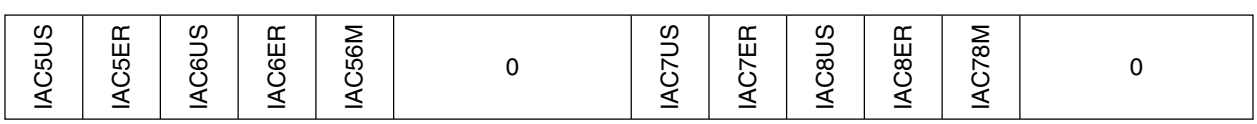
Table 19-9. DBCR4 field description (continued)

Bit	Name	Description
		NOTE: unlike the DAC3–4CFG fields, debug event enabling for DAC1 is controlled by the DAC1 field in DBCR0. The DAC1CFG encodings 0000–0010 are used to control watchpoint generation when $DBCR0_{DAC1}$=0; when $DBCR0_{DAC1}$!=00, DAC1 watchpoints will fire whenever a DAC1 debug event occurs.
28:31	DAC2CFG	Data Address Compare 2 Configuration 0000 DAC2 debug watchpoints are enabled for load-type or store-type data storage accesses when $DBCR0_{DAC2}$=00 0001 DAC2 debug watchpoints are enabled only for store-type data storage accesses when $DBCR0_{DAC2}$=00 0010 DAC2 debug watchpoints are enabled only for load-type data storage accesses when $DBCR0_{DAC2}$=00 0011 Reserved 01xx Reserved 1xxx Reserved DAC2CFG controls whether DAC2 data address comparisons utilize the normal compare operation for generating both debug events and watchpoints, or a watchpoint-only function. **NOTE:** Unlike the DAC3–4CFG fields, debug event enabling for DAC2 is controlled by the DAC2 field in DBCR0. The DAC2CFG encodings 0000–0010 are used to control watchpoint generation when $DBCR0_{DAC2}$=00. When $DBCR0_{DAC2}$!=00, DAC2 watchpoints will fire whenever a DAC2 debug event occurs.

19.3.2.5 Debug Control Register 5 (DBCR5)

Debug Control Register 5 is used to configure Instruction Address Compare operation for IAC5–8. The DBCR5 register is shown in the following figure.

.



SPR - 564; Read/Write; Reset[1] - 0x0

Figure 19-7. DBCR5 Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 5.

Table 19-10. DBCR5 field descriptions

Bit(s)	Name	Description
0:1	IAC5US	Instruction Address Compare 5 User/Supervisor Mode 00 IAC5 debug events not affected by MSR_{PR} 01 Reserved 10 IAC5 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 IAC5 debug events can only occur if MSR_{PR}=1. (User mode)
2:3	IAC5ER	Instruction Address Compare 5 Effective/Real Mode 00 IAC5 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 IAC5 debug events are based on effective address and can only occur if MSR_{IS}=0 11 IAC5 debug events are based on effective address and can only occur if MSR_{IS}=1
4:5	IAC6US	Instruction Address Compare 6 User/Supervisor Mode 00 IAC6 debug events not affected by MSR_{PR} 01 Reserved 10 IAC6 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 IAC6 debug events can only occur if MSR_{PR}=1. (User mode)
6:7	IAC6ER	Instruction Address Compare 6 Effective/Real Mode 00 IAC6 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 IAC6 debug events are based on effective address and can only occur if MSR_{IS}=0 11 IAC6 debug events are based on effective address and can only occur if MSR_{IS}=1
8:9	IAC56M	Instruction Address Compare 5/6 Mode 00 Exact address compare. IAC5 debug events can only occur if the address of the instruction fetch is equal to the value specified in IAC5. IAC6 debug events can only occur if the address of the instruction fetch is equal to the value specified in IAC6. 01 Address bit match. IAC5 debug events can occur only if the address of the instruction fetch, ANDed with the contents of IAC6 are equal to the contents of IAC5, also ANDed with the contents of IAC6. IAC6 debug events do not occur. IAC5US and IAC5ER settings are used. 10 Inclusive address range compare. IAC5 debug events can occur only if the address of the instruction fetch is greater than or equal to the value specified in IAC5 and less than the value specified in IAC6. IAC6 debug events do not occur. IAC5US and IAC5ER settings are used. 11 Exclusive address range compare. IAC5 debug events can occur only if the address of the instruction fetch is less than the value specified in IAC5 or is greater than or equal to the value specified in IAC6. IAC6 debug events do not occur. IAC5US and IAC5ER settings are used.
10:15	—	Reserved

Number of low order bits masked in IAC8 when comparing the storage address with the value in IAC8 for exact address compare (DBCR5[IAC78M]=00). Ranges up to 4 KB are supported. 1101 - 1111 Reserved

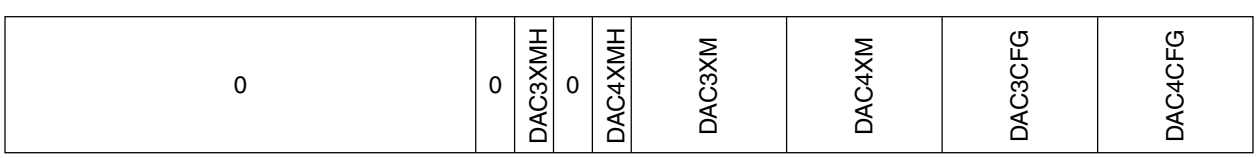
19.3.2.7 Debug Control Register 7 (DBCR7)

Debug Control Register 7 is used to enable and configure Data Address Compare 3 and 4 functionality. DBCR7 is shown in the following figure.



SPR - 596; Read/Write; Reset[1] - 0x0

Figure 19-9. DBCR7 Register

Note

[1] DBCR7 is reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 7.

Table 19-12. DBCR7 Field Descriptions

Bit	Name	Description
0:12	—	Reserved
13	DAC3XMH	Data Address Compare 3 Extended Mask Control High .DAC3XMH extends the range of the DAC3XM field 0 DAC3XM masks 0–15 low-order address bits 1 DAC3XM masks 16–31 low-order address bits
14	—	Reserved
15	DAC4XMH	Data Address Compare 4 Extended Mask Control High. . DAC4XMH extends the range of the DAC4XM field. 0 DAC4XM masks 0–15 low-order address bits 1 DAC4XM masks 16–31 low-order address bits
16:19	DAC3XM	Data Address Compare 3 Extended Mask Control. DAC3XM allows for binary power of 2 address range compares for DAC3 without requiring the use of DAC4. Value of DAC3XMH || DAC3XM: 00000 No additional masking when DBCR8[DAC34M] = 00 00001 - 11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC3 when comparing the storage address with the value in DAC3 for exact address compare (DBCR8[DAC34M] = 00). Address ranges of 2 bytes to 2GB are supported.
20:23	DAC4XM	Data Address Compare 4 Extended Mask Control. DAC4XM allows for binary power of 2 address range compares for DAC4 without requiring the use of DAC3. Value of DAC4XMH || DAC4XM: 00000 No additional masking when DBCR8[DAC34M] = 00 00001 - 11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC4 when comparing the storage address with the value in DAC4 for exact address compare (DBCR8[DAC34M] = 00). Address ranges of 2 bytes to 2GB are supported.
24:27	DAC3CFG	Data Address Compare 3 Configuration. DAC3CFG controls whether DAC3 data address comparisons utilize the normal compare operation for generating both debug events and watchpoints, a watchpoint-only function, or a stack limit checking function (with watchpoint). 0000 DAC3 debug watchpoints are enabled for load-type or store-type data storage accesses 0001 DAC3 debug watchpoints are enabled only for store-type data storage accesses

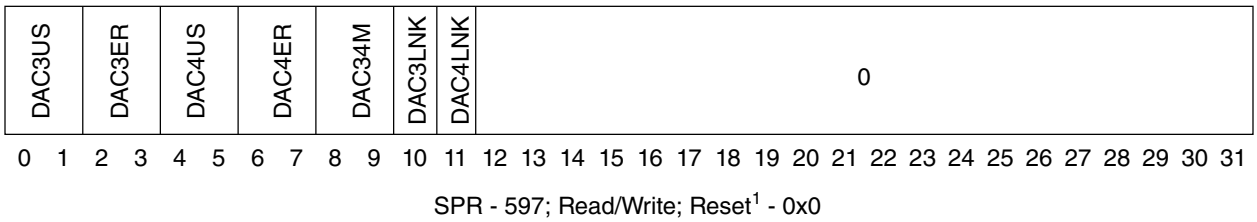
Table continues on the next page...

Table 19-12. DBCR7 Field Descriptions (continued)

Bit	Name	Description
		0010 DAC3 debug watchpoints are enabled only for load-type data storage accesses 0011 Reserved 0100Reserved 0101 DAC3 debug events and watchpoints are enabled only for store-type data storage accesses 0110 DAC3 debug events and watchpoints are enabled only for load-type data storage accesses 0111 DAC3 debug events and watchpoints are enabled for load-type or store-type data storage accesses 1000 DAC3 address comparisons are used for stack limit checking. DAC3 address comparisons are qualified with use of GPR R1 in <EA> calculation for most load or store instructions. No debug events occur for DAC3. When a qualified match occurs, a machine check exception is generated for supervisor-mode accesses or a DSI is generated for user-mode accesses, and a DAC3 watchpoints is generated. 1001 - 1111 Reserved
28:31	DAC4CFG	Data Address Compare 4 Configuration. DAC4CFG controls whether DAC4 data address comparisons utilize the normal compare operation for generating both debug events and watchpoints, or a watchpoint-only function. 0000 DAC4 debug watchpoints are enabled for load-type or store-type data storage accesses 0001 DAC4 debug watchpoints are enabled only for store-type data storage accesses 0010 DAC4 debug watchpoints are enabled only for load-type data storage accesses 0011 Reserved 0100 Reserved 0101 DAC4 debug events and watchpoints are enabled only for store-type data storage accesses 0110 DAC4 debug events and watchpoints are enabled only for load-type data storage accesses 0111 DAC4 debug events and watchpoints are enabled for load-type or store-type data storage accesses 1xxx Reserved

19.3.2.8 Debug Control Register 8 (DBCR8)

Debug Control Register 8 is used to configure Data Address Compare 3 and 4 operation. The DBCR8 register is shown in the following figure.



SPR - 597; Read/Write; Reset[1] - 0x0

Figure 19-10. DBCR8 Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for Debug Control Register 8.

Table 19-13. DBCR8 Bit Definitions

Bit(s)	Name	Description
0:1	DAC3US	Data Address Compare 3 User/Supervisor Mode 00 - DAC3 debug events not affected by MSR_{PR} 01 - Reserved 10 - DAC3 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 - DAC3 debug events can only occur if MSR_{PR}=1. (User mode)
2:3	DAC3ER	Data Address Compare 3 Effective/Real Mode 00 - DAC3 debug events are based on effective address 01 - Unimplemented (Book E real address compare), no match can occur 10 - DAC3 debug events are based on effective address and can only occur if MSR_{DS}=0 11 - DAC3 debug events are based on effective address and can only occur if MSR_{DS}=1
4:5	DAC4US	Data Address Compare 4 User/Supervisor Mode. 00 - DAC4 debug events not affected by MSR_{PR} 01 - Reserved 10 - DAC4 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 - DAC4 debug events can only occur if MSR_{PR}=1. (User mode)
6:7	DAC4ER	Data Address Compare 4 Effective/Real Mode 00 - DAC4 debug events are based on effective address 01 - Unimplemented (Book E real address compare), no match can occur 10 - DAC4 debug events are based on effective address and can only occur if MSR_{DS}=0

Table continues on the next page...

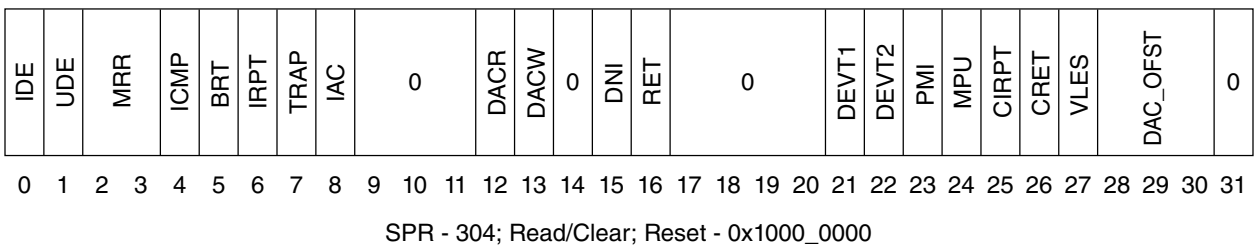
Table 19-13. DBCR8 Bit Definitions (continued)

Bit(s)	Name	Description
		11 - DAC4 debug events are based on effective address and can only occur if MSR_{DS}=1
8:9	DAC34M	Data Address Compare 3/4 Mode 00 - Exact address compare. DAC3 debug events can only occur if the address of the data access is equal to the value specified in DAC3. DAC4 debug events can only occur if the address of the data access is equal to the value specified in DAC4. 01 - Address bit match. DAC3 debug events can occur only if the address of the data access ANDed with the contents of DAC4, are equal to the contents of DAC3 also ANDed with the contents of DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used. 10 - Inclusive address range compare. DAC3 debug events can occur only if the address of the data access is greater than or equal to the value specified in DAC3 and less than the value specified in DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used. 11 - Exclusive address range compare. DAC3 debug events can occur only if the address of the data access is less than the value specified in DAC3 or is greater than or equal to the value specified in DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used.
10	DAC3LNK	Data Address Compare 3 Linked 0 - No effect 1 - DAC3 debug events are linked to IAC5 debug events. IAC5 debug events do not affect DBSR When linked to IAC5, DAC3 debug events are conditioned based on whether the instruction also generated an IAC5 debug event. Note that linking is only available in EDM or IDM.
11	DAC4LNK	Data Address Compare 4 Linked 0 - No effect 1 - DAC4 debug events are linked to IAC7 debug events. IAC7 debug events do not affect DBSR When linked to IAC7, DAC4 debug events are conditioned based on whether the instruction also generated an IAC7 debug event. Note that linking is only available in EDM or IDM.
12:31	—	Reserved

19.3.2.9 Debug Status Register (DBSR)

The Debug Status Register (DBSR) contains status on debug events and the most recent processor reset. The Debug Status Register is set via hardware, and read and cleared via software. Bits in the Debug Status Register can be cleared using **mtspr***DBSR,RS*. Clearing is done by writing to the Debug Status Register with a 1 in any bit position that is to be cleared and 0 in all other bit positions. The write data to the Debug Status Register is not direct data, but a mask. A '1' causes the bit to be cleared, and a '0' has no

effect. Debug Status bits are set by Debug events only while Internal Debug Mode is enabled ($DBCR0_{IDM}$=1). When debug interrupts are enabled (MSR_{DE}=1 $DBCR0_{IDM}$=1 and $EDBCR0_{EDM}$=0, or MSR_{DE}=1, $DBCR0_{IDM}$=1, $EDBCR0_{EDM}$=1 and software is allocated resource(s) via EDBRAC0), a set bit in DBSR other than MRR, DAC_OFST, or VLES will cause a debug interrupt to be generated. The debug interrupt handler is responsible for clearing DBSR bits prior to returning to normal execution. When resource sharing is enabled, ($EDBCR0_{EDM}$=1 and $EDBRAC0_{IDM}$=1), only software-owned resources may be modified by software, and status bits associated with hardware-owned resources will not be set by hardware in DBSR. The DBSR register is shown in the following figure.



SPR - 304; Read/Clear; Reset - 0x1000_0000

Figure 19-11. DBSR Register

The following table provides bit definitions for the Debug Status Register.

Table 19-14. DBSR Bit Definitions

Bit(s)	Name	Description
0	IDE	Imprecise Debug Event Set to 1 if MSR_{DE}=0 and $DBCR0_{IDM}$=1 and a debug event causes its respective Debug Status Register bit to be set to 1. It may also be set to '1' if an imprecise debug event occurs due to a DAC event on a load or store which is terminated with error, or if an ICMP event occurs in conjunction with a EFPU FP round exception.
1	UDE	Unconditional Debug Event Set to 1 if an Unconditional debug event occurred.
2:3	MRR	Most Recent Reset. 00 - No reset occurred since these bits were last cleared by software 01 - A hard reset occurred since these bits were last cleared by software 10 - Reserved 11 - Reserved
4	ICMP	Instruction Complete Debug Event Set to 1 if an Instruction Complete debug event occurred.
5	BRT	Branch Taken Debug Event Set to 1 if an Branch Taken debug event occurred.
6	IRPT	Interrupt Taken Debug Event Set to 1 if an Interrupt Taken debug event occurred.
7	TRAP	Trap Taken Debug Event

Table continues on the next page...

Table 19-14. DBSR Bit Definitions (continued)

Bit(s)	Name	Description
		Set to 1 if a Trap Taken debug event occurred.
8	IAC	Instruction Address Compare Debug Event Set to 1 if an IAC debug event occurred.
9:11	—	Reserved
12	DACR	Data Address Compare Read Debug Event Set to 1 if a read-type DAC debug event occurred
13	DACW	Data Address Compare Write Debug Event Set to 1 if a write-type DAC debug event occurred
14	—	Reserved
15	DNI	DNI Debug Event Set to 1 if a DNI debug event occurred
16	RET	Return Debug Event Set to 1 if a Return debug event occurred
17:20	—	Reserved
21	DEVT1	External Debug Event 1 Debug Event Set to 1 if a DEVT1 debug event occurred
22	DEVT2	External Debug Event 2 Debug Event Set to 1 if a DEVT2 debug event occurred
23	PMI	Performance Monitor Interrupt Debug Event Set to 1 if a Performance Monitor Interrupt event occurred with $PMGC0_{UDI}$=1
24	MPU	Memory Protection Unit Debug Event Set to 1 if a MPU debug event occurred. For MPU debug events, the IAC, DACR, or DACW status bit will also be set, depending on the type of access which matched a region descriptor enabled to generate debug events, in order to further define the type of MPU debug event. Note that software MPU debug events on data accesses normally occur after the data access is performed and the instruction completes, thus act like a normal DAC debug event. The instruction may not complete if a DSI occurs. In this case, IDE will be set to indicate this occurrence.
25	CIRPT	Critical Interrupt Taken Debug Event Set to 1 if a Critical Interrupt Taken debug event occurred.
26	CRET	Critical Return Debug Event Set to 1 if a Critical Return debug event occurred
27	VLES	VLE Status Set to 1 if an ICMP, BRT, TRAP, RET, CRET, IAC, or DAC debug event occurred on a PowerISA VLE Instruction. Undefined for IRPT, CIRPT, DEVT[1,2], and UDE events
28:30	DAC_OFST	Data Address Compare Offset Indicates offset-1 of saved DSRR0 value from the address of the load or store instruction which took a DAC Debug exception, unless a simultaneous DSI error occurs, in which case this field is set to 3'b000 and $DBSR_{IDE}$ is set to 1. Normally set to 3'b000 by a non-DVC DAC. A DVC DAC may set this field to any value.
31	—	Reserved

19.3.2.10 Debug Data Effective Address Register (DDEAR)

The Debug Data Effective Address Register (DDEAR) contains address information for data address compare debug events (DAC or MPU DAC). DDEAR is update by hardware with the effective address of the load, store, or cache control operation when a data address compare event is recorded in DBSR if the previous values of the $DBSR_{DAC\{R,W\}}$ bits are zero. Once a DDEAR update is performed, these bits must be cleared by software prior to another DDEAR hardware update occurring. A subsequent DAC or MPU DAC event will not update the DDEAR register if either of the $DBSR_{DAC\{R,W\}}$ bits are set, in order to capture the first event address.

The DDEAR register is shown in the following table.

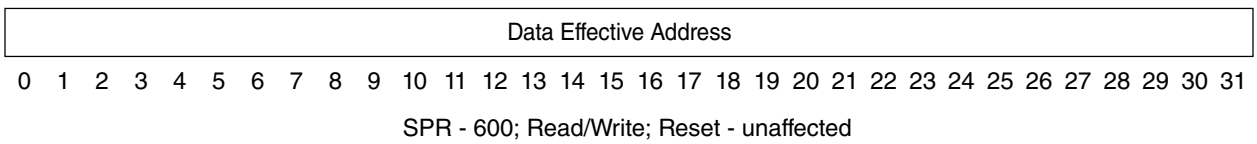


Figure 19-12. DDEAR Register

19.3.3 External Debug Resource Allocation Control Register (EDBRAC0)

The External Debug Resource Allocation Control Register (EDBRAC0) controls resource allocation when $EDBCR0_{EDM}$ is set to '1'. EDBRAC0 provides a mechanism for the hardware debugger to share certain debug resources with software. Individual resources are allocated based on the settings of EDBRAC0 when $EDBCR0_{EDM}$=1. EDBRAC0 settings are ignored when $EDBCR0_{EDM}$=0.

Hardware-owned resources which generate debug events update EDBSR0 instead of DBSR and cause entry into debug mode if the event is not masked in EDBSRMSK0, while software-owned resources which generate debug events if $DBCR0_{IDM}$=1 update DBSR, causing debug interrupts to occur if MSR_{DE}=1. EDBRAC0 is controlled via the OnCE port hardware, and is read-only to software.

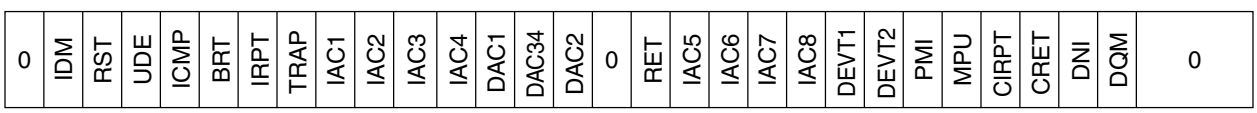
The DBSR status register is always owned by software. Debug status bits in DBSR are set by software-owned debug events only while Internal Debug Mode is enabled. When debug interrupts are enabled (MSR_{DE}=1 $DBCR0_{IDM}$=1 and $EDBCR0_{EDM}$=0, or MSR_{DE}=1, $DBCR0_{IDM}$=1 and $EDBCR0_{EDM}$=1 and software is allocated resource(s) via EDBRAC0), a set bit in DBSR by an event which is software-owned (other than MRR, DAC_OFST, or VLES) will cause a debug interrupt to be generated.

Debug status bits in EDBSR0 are set by hardware-owned debug events only while External Debug Mode is enabled ($EDBCR0_{EDM}$=1). When $EDBCR0_{EDM}$=1, a set bit in EDBSR0 by an event which is hardware-owned (other than IDE, DAC_OFST, or VLES) will cause entry into debug mode unless entry is masked via EDBSRMSK0.

If $EDBCR0_{EDM}$=1, DBSR status bits corresponding to hardware-owned debug events are masked from being set by hardware.

Software-owned resources may be modified by software, but only the corresponding control bits in DBCR0–8 or MPU0CSR0 are affected by execution of a **mtspr**, thus only a portion of these registers may be affected, depending on the allocation settings in EDBRAC0. The debug interrupt handler is still responsible for clearing DBSR bits for software-owned resources prior to returning to normal execution. Hardware always has full access to all registers and register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control and status registers as appropriate when hardware modifications to the debug registers is performed.

The EDBRAC0 register is shown in the following figure.



SPR - 638; Read-only by Software; Reset - Unaffected by **p_reset_b,** reset to 0x00000180 by **m_por** or while in the test-logic-reset OnCE controller state

Figure 19-13. EDBRAC0 Register

Table 19-14 provides bit definitions for the Debug External Resource Control Register. Note that EDBRAC0 controls are disabled when EDBCR0EDM=0.

Table 19-15. EDBRAC0 Bit Definitions

Bit(s)	Name	Description
0	—	Reserved
1	IDM	Internal Debug Mode control 0 - Internal Debug mode may not be enabled by software. $DBCR0_{IDM}$ is owned exclusively by hardware. **mtspr** DBCR0–8 and other debug registers is always ignored. No resource sharing occurs, regardless of the settings of other fields in EDBRAC0. Hardware exclusively owns all resources. 1 - Internal Debug mode may be enabled by software. $DBCR0_{IDM}$ is owned by software. $DBCR0_{IDM}$ is software readable/writable. When $EDBRAC0_{IDM}$=1, software writes to hardware-owned bits in DBCR0–8 via **mtspr** are ignored.

Table continues on the next page...

Table 19-15. EDBRAC0 Bit Definitions (continued)

Bit(s)	Name	Description
2	RST	Reset Field Control 0 - $DBCR0_{RST}$ owned exclusively by hardware debug. No **mtspr** access by software to $DBCR0_{RST}$ field. 1 - $DBCR0_{RST}$ accessible by software debug. $DBCR0_{RST}$ is software readable/writable.
3	UDE	Unconditional Debug Event 0 - Event owned by hardware debug. 1 - Event owned by software debug.
4	ICMP	Instruction Complete Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{ICMP}$ field. 1 - Event owned by software debug. $DBCR0_{ICMP}$ is software readable/writable.
5	BRT	Branch Taken Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{BRT}$ field. 1 - Event owned by software debug. $DBCR0_{BRT}$ is software readable/writable.
6	IRPT	Interrupt Taken Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{IRPT}$ field. 1 - Event owned by software debug. $DBCR0_{IRPT}$ is software readable/writable.
7	TRAP	Trap Taken Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{TRAP}$ field. 1 - Event owned by software debug. $DBCR0_{TRA}$P is software readable/writable.
8	IAC1	Instruction Address Compare 1 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC1 control and status fields. 1 - Event owned by software debug. IAC1 control fields are software readable/writable.
9	IAC2	Instruction Address Compare 2 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC2 control and status fields. 1 - Event owned by software debug. IAC2 control fields are software readable/writable.
10	IAC3	Instruction Address Compare 3 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC3 control and status fields. 1 - Event owned by software debug. IAC3 control fields are software readable/writable.
11	IAC4	Instruction Address Compare 4 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC4 control and status fields. 1 - Event owned by software debug. IAC4 control fields are software readable/writable.
12	DAC1	Data Address Compare 1 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to DAC1 control and status fields.

Table continues on the next page...

Table 19-15. EDBRAC0 Bit Definitions (continued)

Bit(s)	Name	Description
		1 - Event owned by software debug. DAC1 control fields are software readable/ writable.
13	DAC34	Data Address Compare 3 and 4 Debug Events 0 - Events owned by hardware debug. No **mtspr** access by software to DAC3 and DAC4 control and status fields. 1 - Event owned by software debug. DAC3 and DAC4 control fields are software readable/writable.
14	DAC2	Data Address Compare 2 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to DAC2 control and status fields. 1 - Event owned by software debug. DAC2 control fields are software readable/ writable.
15	—	Reserved
16	RET	Return Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{RET}$ field. 1 - Event owned by software debug. $DBCR0_{RET}$ is software readable/writable.
17	IAC5	Instruction Address Compare 5 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC5 control and status fields. 1 - Event owned by software debug. IAC5 control fields are software readable/writable.
18	IAC6	Instruction Address Compare 6 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC6 control and status fields. 1 - Event owned by software debug. IAC6 control fields are software readable/writable.
19	IAC7	Instruction Address Compare 7 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC7 control and status fields. 1 - Event owned by software debug. IAC7 control fields are software readable/writable.
20	IAC8	Instruction Address Compare 8 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to IAC8 control and status fields. 1 - Event owned by software debug. IAC8 control are software readable/writable.
21	DEVT1	External Debug Event Input 1 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{DEVT1}$ field. 1 - Event owned by software debug. $DBCR0_{DEVT1}$ is software readable/writable.
22	DEVT2	External Debug Event Input 2 Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{DEVT2}$ field. 1 - Event owned by software debug. $DBCR0_{DEVT2}$ is software readable/writable.
23	PMI	Performance Monitor Interrupt Debug Event

Table continues on the next page...

Table 19-15. EDBRAC0 Bit Definitions (continued)

Bit(s)	Name	Description
		0 - Event owned by hardware debug. No **mtspr** access by software to the PMRs. Performance monitor interrupts set $EDBSR0_{PMI}$ regardless of the setting of $PMGC0_{UDI}$ 1 - Event owned by software debug. PMRs are software readable/writable. **Note:** this bit is reset to '1'.
24	MPU	Memory Protection Unit Debug Event 0 - Event owned by hardware debug. No **mpuwe** access by software to region descriptors which have the DEBUG control bit set to '1' or to the $MPU0CSR0_{DRDEN,DWDEN,IDEN}$ control bits, unless the CPU is in a debug session (**jd_debug_b** is asserted). MPU debug events set $EDBSR0_{MPU}$, and if not masked by $EDBSRMSK0_{MPU}$, one of $EDBSR0_{IAC}$, $EDBSR0_{DACR}$, or $EDBSR0_{DACW}$. MPU flash invalidates do not affect DEBUG=1 entries unless the CPU is in a debug session (**jd_debug_b** is asserted). 1 - Event owned by software debug. All region descriptors and the $MPU0CSR0_{DRDEN,DWDEN,IDEN}$ control bits are software readable/writable. **Note:** this bit is reset to '1'.
25	CIRPT	Critical Interrupt Taken Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{CIRPT}$ field. 1 - Event owned by software debug. $DBCR0_{CIRPT}$ is software readable/writable.
26	CRET	Critical Return Debug Event 0 - Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{CRET}$ field. 1 - Event owned by software debug. $DBCR0_{CRET}$ is software readable/writable.
27	DNI	DNI Instruction Debug Control 0 - DNI resource owned by hardware debug. Execution of an **e_dni** or **se_dni** instruction results in entry into debug mode. 1 - DNI resource owned by software debug. Execution of an **e_dni** or **se_dni** instruction results in either a debug interrupt ($DBCR0_{IDM}$=1 and MSR_{DE}=1) or a nop ($DBCR0_{IDM}$=0 or MSR_{DE}=0). **Note:** DNI events are not blocked during a debug session
28	DQM	Data Acquisition Messaging Registers 0 - $DEVENT_{DQTAG}$ and DDAM register are exclusively owned by hardware debug. No **mtspr** access by software to $DEVENTD_{QTAG}$ field or DDAM register. Attempted access by software is ignored. 1 - $DEVENT_{DQTAG}$ and DDAM register are owned by software. Software has read/write access to $DEVENT_{DQTAG}$ field and DDAM register.
29:31	—	Reserved

Table 19-16 shows which resources are controlled by EDBRAC0 settings.

1. Note: IDM not required to be set to enable software access.

EDBRAC0 also controls which bits or fields in DBCR0–8, MPU0CSR0, and the PMRs are reset by assertion of **p_reset_b** when $EDBCR0_{EDM}$=1. Only software-owned bits or fields as shown in Table 19-16 are affected in this case, except that $DBCR0_{RST}$ and $DBSR_{MRR}$ are updated by assertion of **p_reset_b** regardless of the value of $EDBCR0_{EDM}$ or EDBRAC0.

19.3.4 Debug Event Select Register (DEVENT)

The Debug Event Select Register allows instrumented software to internally generate signals when a **mtspr** instruction is executed and this register is accessed. The values written to this register determine which of the **p_devnt_out[0:7]** processor output signals are asserted upon access. Writing a '1' to any of these bit positions will cause a one clock pulse to be generated on the corresponding output. For **p_devnt_out[0:3]**, a corresponding **jd_watchpt[x]** output is asserted as well to indicate a watchpoint has

occurred. These signals may be used for internal core debug resources as well as for SoC level cross-triggering. See the SoC User's Manual for more information on SoC use cases.

The $DEVENT_{DEVNT}$ register field value is undefined on a read; it may or may not remain set to the last value written. Since it is unconditionally shared by hardware debug and software, software should not rely on any value remaining.

The upper 8 bits of the DEVENT register also provide the DQTAG used to identify channels within Data Acquisition Messages. See the "Data Acquisition ID Tag Field" section in the Core (e200z7260n3) Nexus 3 Module chapter for more detail on the DQTAG.

The DEVENT register is shown in the following figure.

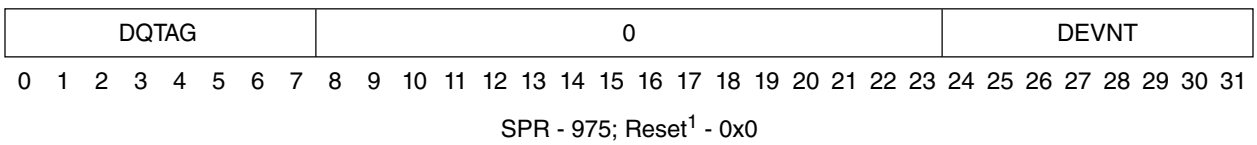

Figure 19-14. DEVENT Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**. Note that DEVNT field is shared by hardware and software but is always reset by **p_reset_b**.

The following table provides bit definitions for the Debug Event Register.

Table 19-17. DEVENT Bit Definitions

Bit(s)	Name	Description
0:7	DQTAG	Data Acquisition Message IDTAG channel identifier (supplied to Nexus 3)
8:23	—	Reserved, should be cleared.

19.3.5 Debug Data Acquisition Message Register (DDAM)

The Debug Data Acquisition Message Register allows instrumented software to generate real-time Data Acquisition Messages (as defined by Nexus 3) via a **mtspr** instruction to this register. See the "Data Acquisition Messaging" section in the Core (e200z7260n3) Nexus 3 Module chapter for details.

The DDAM register is shown in the following figure.

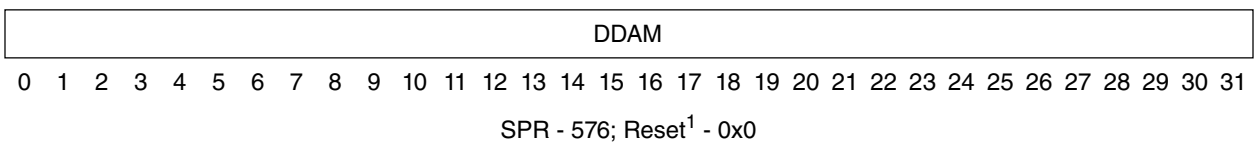

Figure 19-15. DDAM Register

Note

[1] Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

The following table provides bit definitions for the Debug Data Acquisition Message Register.

Table 19-18. DDAM Bit Definitions

Bit(s)	Name	Description
0:31	DDAM	Value to be transmitted in a Data Acquisition Message (DQM) (supplied to Nexus 3 with strobe)

19.4 Using Debug Resources for Stack Limit Checking

The DAC1,2 and DAC3,4 resources can be used for stack overflow/underflow detection when not being used as a hardware or software debug resource. Stack limit checking is available regardless of EDM or IDM mode, and when resources used for stack limit checking are owned by software, will utilize a DSI or machine check exception. Software-owned stack limit checking does not require IDM to be set. Hardware owned stack limit checking requires EDM to be set.

When stack limit checking is enabled, and DAC resources used for stack limit checking are owned by software, DAC events are not generated for resources configured to perform stack limit checking, and no DBSR DAC status flag will be set due to a detected stack limit violation. Instead, depending on the processor mode, a data storage interrupt or a machine check exception is signaled. When stack limit checking is enabled, and DAC resources used for stack limit checking are owned by hardware, DAC events will be generated for resources configured to perform stack limit checking, and the EDBSR0 DAC status flag will be set due to a detected stack limit violation, causing entry into debug halted mode in the same way as a DAC exception normally does. The only difference is that qualification of the access address is performed as discussed in the next paragraph.

Stack limit checking is implemented in the same way as range compares using DAC1,2 or 3,4, or extended masking using DAC1 or DAC3, but qualify a load or store access address with the use of GPR R1 as the base or index register used to compute an effective address when a load or store instruction is executed. No stack limit checking is performed for other instructions which may calculate an EA using GPR R1 such as cache, MMU/MPU management instructions, or instructions which indicate GPR R1 is used to hold a decoration value (for decorated load/store type instructions). When DAC resources configured to perform stack limit checking are not owned by hardware, if a stack limit violation occurs when performing the load or store, the access is aborted, and an error report machine check is generated, with MCSRR0 pointing to the address of the load or store access which generated the stack overflow/underflow. If DAC resources configured to perform stack limit checking are owned by hardware, then a normal DAC event is generated (but qualified with use of GPR R1), and debug mode entry will occur in the same manner as for a non-stack limit DAC event.

Enabling of this functionality is described in more detail in Table 19-9. Note that IDM is not required to be set for software-owned stack limit checking.

In contrast to the normal case of DAC address matching resulting in a debug event, the stack limit check address compare logic operates differently for stack limit checking. When using resources for stack limit checking, a DACn hit to a resource enabled for performing stack limit checking on a stack access indicates a stack limit violation.

When stack limit checking is enabled by the setting of the $DBCR4_{DAC1CFG}$ field to '1000' or the $DBCR8_{DAC3CFG}$ field to '1000' (or both), and the corresponding DACn resources are owned by software, DACn events are not generated and the DBSR DAC status flag will not be set due to a detected stack limit hit. Instead, if stack limit checking is enabled for supervisor mode stack accesses in DAC1 or DAC3, and a compare hit occurs for a supervisor mode stack access (A load or store using GPR R1 in the <EA> calculation), a machine check exception is signaled. If stack limit checking is enabled for user mode accesses, a DSI exception is signaled when a stack limit checking enabled DAC1 or DAC3 compare hit occurs for a user mode access. A watchpoint for DAC1 or DAC3 will be generated when the stack limit violation is detected, even though the instruction does not complete. Stack limit checking for supervisor mode stack accesses is considered enabled when either the $DBCR4_{DAC1CFG}$ field is set to '1000' with $DBCR2_{DAC1US}$ set to '00' or '10', or the $DBCR7_{DAC3CFG}$ field is set to '1000' with $DBCR8_{DAC3US}$ set to '00' or '10', or both. Stack limit checking for user mode stack accesses is considered enabled when either the $DBCR4_{DAC1CFG}$ field is set to '1000' with $DBCR2_{DAC1US}$ set to '00' or '01', or the $DBCR7_{DAC3CFG}$ field is set to '1000' with $DBCR8_{DAC3US}$ set to '00' or '01', or both. Note that unlike regular debug DAC events, both halves of a misaligned access are checked for limit violations.

When stack limit checking is enabled for a stack access, and DACn resources are owned by hardware, the EDBSR0 DAC status flag will be set due to a detected stack limit violation, to cause entry into debug halted mode or to generate a watchpoint, or both, in the same way as a DAC event normally does, i.e. after the access has completed. The only difference is that qualification of the access address is performed as discussed in the next paragraph. If the access is aborted due to a DSI or other exception such as machine check condition, the $EDBSR0_{IDE}$ status bit will also be set to indicate that the data access instruction was not completed.

Stack limit checking is implemented in the same way as address compares using DACn, but qualify a load or store access address with the use of GPR R1 as the base or index register used to compute an effective address when a load or store instruction is executed. No stack limit checking is performed for other instructions which may calculate an EA using GPR R1 such as cache, MMU/MPU management instructions, or instructions which indicate GPR R1 is used to hold a decoration value (for decorated load/store type instructions). When DACn resources are not owned by hardware, if a stack limit violation occurs (a hit to a stack limit enabled DAC is detected) when performing the load or store, the access request is aborted and the access is not performed. Instead, for supervisor mode accesses, an error report machine check exception is generated, with MCSRR0

pointing to the address of the load or store instruction which generated the stack overflow/underflow, and for user mode accesses, a DSI exception is generated, with SRR0 pointing to the address of the load or store instruction which generated the stack overflow/underflow. If all stack limit check enabled DACn resources are owned by hardware, then a DAC event is generated (but qualified with use of GPR R1), and debug mode entry will occur in the same manner as for a non-stack limit DAC event. In this case, the instruction and access will normally have completed, in the same manner as a normal DAC event.

Independent limit checks for supervisor and user accesses may be implemented by allocating independent DACn resources to each, or a single limit may be applied using a single DACn resource. Typically, a DAC1,2 pair operating in exclusive address range mode is utilized for stack limit checking for a single shared limit. For separate limits, DAC3,4 may also be utilized. If more than one DACn resource is utilized, a DAC hit on any resource utilized for stack limit checking will cause the corresponding stack limit exception action to occur. If both a hardware-owned and a software-owned resource generate a stack limit exception for a given load or store, the software resource will have priority, since it is detected prior to completion of the access, and the access is aborted, thus the hardware event will not occur.

Enabling of this functionality is described in more detail in the description of the DACnCFG fields in Table 19-9 and Table 19-12 in Debug Control and Status registers. Note that for DAC1 and DAC2, access type (read, write) control is part of DBCR0.

19.5 External Debug Support

External debug support is supplied through the OnCE controller serial interface which allows access to internal CPU registers and other system state while the CPU is halted in debug mode. All debug resources including DBCR0–8, DBSR, IAC1–8, DAC1–4, and DVC1–2 are accessible through the serial OnCE interface in external debug mode. Setting the $EDBCR0_{EDM}$/$DBCR0_{EDM}$ bit to '1' through the OnCE interface enables external debug mode, and unless otherwise permitted by the settings in EDBRAC0, disables software updates to the debug control registers. When $EDBCR0_{EDM}$ is set, debug events enabled to set respective status bits will also cause the CPU to enter Debug Mode if the event is not masked in EDBSRMSK0, as opposed to generating Debug Interrupts, unless the specific events are allocated to software via the settings in EDBRAC0. In Debug Mode, the CPU is halted at a recoverable boundary, and an external Debug Control Module may control CPU operation through the On-Chip Emulation logic (OnCE).

Note that the descriptions of events in the subsections of Software Debug Events and Exceptions refer to setting DBSR status bits, however, when resources are owned by hardware, the events for those resources set the respective status bits in EDBSR0 instead of DBSR.

Note

On the initial setting of $EDBCR0_{EDM}$ to '1', other bits in DBCR0 will remain unchanged. After $EDBCR0_{EDM}$ has been set, all debug register resources may be subsequently controlled through the OnCE interface. The CPU should be placed into debug mode via the OCR_{DR} control bit prior to writing EDM to '1'. This gives the debugger the opportunity to cleanly write to the DBCRx registers and the DBSR to clear out any residual state / control information which could cause unintended operation.

Note

It is intended for the CPU to remain in external debug mode ($EDBCR0_{EDM}$=1) in order to single step or perform other debug mode entry/ reentry via the OCR_{DR}, by performing go+noexit commands, or by assertion of the **jd_de_b** signal.

Note

$EDBCR0_{EDM}$ operation will be blocked if OnCE operation is disabled (**jd_en_once** negated) regardless of whether it is set or cleared. This means that if $EDBCR0_{EDM}$ was previously set, and then **jd_en_once** is negated (this should not occur), entry into debug mode will be blocked, and all *hardware* debug events are blocked. Watchpoints are not blocked.

Due to clock domain design, the CPU clock (**m_clk**) must be active in order to perform writes to debug registers other than the OnCE Command register (OCMD), the OnCE Control register (OCR), External Debug Control Register 0 (EDBCR0), External Debug Status register 0 (EDBSR0), External Debug Status Register Mask 0 (EDBSRMSK0), or the $EDBCR0_{EDM}$ bit. Register read data is synchronized back to the **j_tclk** clock domain. The OnCE Control register provides the capability of signaling the system level clock controller that the CPU clock should be activated if not already active.

Updates to the DBCRx, DBSR, and most other debug registers via the OnCE interface should be performed with the CPU in debug mode to guarantee proper operation. Due to the various points in the CPU pipeline where control is sampled and event handshaking is

performed, it is possible that modifications to these registers while the CPU is running may result in early or late entry into debug mode, and may have incorrect status posted in the DBSR register.

If resource sharing is enabled via EDBRAC0, updates to the EDBRAC0, DBCRx, and DBSR registers must be performed with the CPU in debug mode, since simultaneous updates of register portions could otherwise be attempted, and such updates are not guaranteed to properly occur. The results of such an attempt are undefined.

19.5.1 External Debug Registers

The external debug registers are used for controlling several debug aspects of the core and reporting status while in External Debug Mode.

19.5.1.1 External Debug Control Register 0 (EDBCR0)

EDBCR0 is a control register accessible to an external debugger through the OnCE/Jtag port. An external development tool can write to this register in order to enable external debug mode or to enable Debugger Notify Halt instructions (**e_dnh**, **se_dnh**), as well as to control aspects of Debugger Notify Interrupt instructions (**e_dni**, **se_dni**).

EDBCR0 is not accessible by software, However, the state of $EDBCR0_{EDM}$ is reflected as a read-only bit in $DBCR0_{EDM}$ to software. There is only one physical EDM bit implemented; it is reflected in both the DBCR0 and EDBCR0 registers, and may be written and read using either register by the hardware debugger. For future compatibility, EDBCR0 updates are preferred.

EDBCR0 is shown in the following figure.

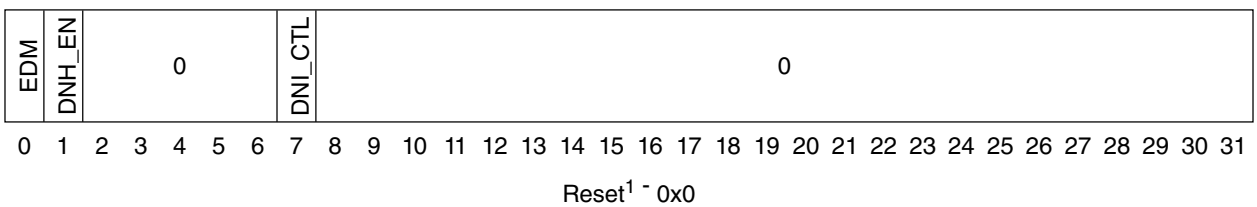

Figure 19-16. EDBCR0 Register

Note

[1] EDBCRO is affected (reset) by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state, but is not affected by **p_reset_b.**

The following table provides bit definitions for External Debug Control Register 0.

Table 19-19. EDBCR0 Bit Definitions

Bit(s)	Name	Description
0	EDM	External Debug Mode. This bit is also reflected in DBCR0 0 - External debug mode disabled. Internal debug events not mapped into external debug events. 1 - External debug mode enabled. Hardware-owned events will not cause the CPU to vector to interrupt code. Software is not permitted to write to debug registers {DBCRx, IAC1-8, DAC1-4, DVC1-2[U]} unless permitted by settings in EDBRAC0. When external debug mode is enabled, hardware-owned resources in debug registers are not affected by processor reset **p_reset_b**. This allows the debugger to set up hardware debug events which remain active across a processor reset.
1	DNH_EN	**dnh** Instruction Enable 0 - execution of **e_dnh** and **se_dnh** instructions cause illegal instruction exceptions to occur. 1 - execution of **e_dnh** and **se_dnh** instructions cause entry into debug mode and a debug halt occurs, regardless of the value of EDM.
2:6	---	Reserved
7	DNI_CTL	**dni** Instruction Control 0 - When the **dni** resource is owned by hardware, the MSR_{DE} bit is cared, and when MSRDE=0, execution of **e_dni** and **se_dni** instructions are nop'ed and no entry into debug mode occurs. 1 - When the **dni** resource is owned by hardware, the MSR_{DE} bit is don't-cared, and execution of **e_dni** and **se_dni** instructions cause entry into debug mode and a debug halt occurs, regardless of the value of MSR_{DE}. Note that this control bit is only used when the dni resource is owned by hardware via control in $EDBRAC0_{DNI}$, and thus also only when EDM=1
8:31	---	Reserved

19.5.1.2 External Debug Status Register 0 (EDBSR0)

The External Debug Status Register 0 (EDBSR0) contains status on debug events owned by hardware. The External Debug Status Register 0 is set via hardware, and read and cleared via OnCE access by the debugger. Clearing is done by writing to the External Debug Status Register via the OnCE port, with a '1' in any bit position that is to be cleared and '0' in all other bit positions. The write data to EDBSR0 is not direct data, but a mask. A '1' causes the bit to be cleared, and a '0' has no effect. The EDBSR0 register is shown in the following figure.

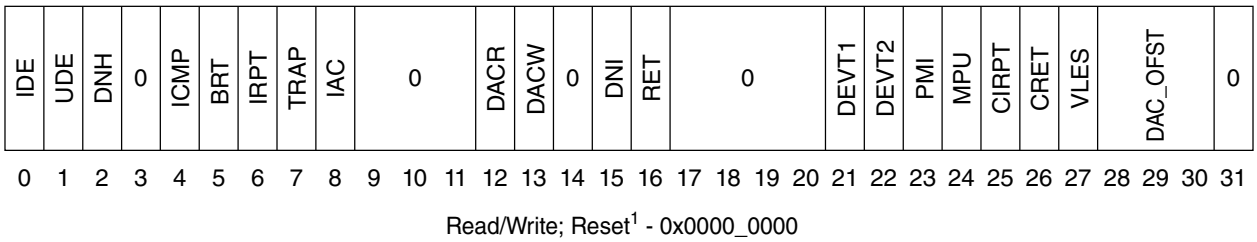

Figure 19-17. EDBSR0 Register

Note

[1] Reset by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state or while $EDBCRO_{EDM}$=O.

The following table provides bit definitions for External Debug Status Register 0.

Table 19-20. EDBSR0 Bit Definitions

Bit(s)	Name	Description
0	IDE	Imprecise Debug Event Set to 1 if $EDBCR0_{EDM}$=1 and an imprecise debug event occurs for a hardware-owned DAC event due to a load or store which is terminated with error, or if a hardware-owned ICMP event occurs in conjunction with a EFPU round exception. This bit will not be set for imprecise debug events which are masked via settings in EDBSRMSK0.
1	UDE	Unconditional Debug Event Set to 1 if a hardware-owned Unconditional debug event occurred.
2	DNH	Debugger Notify Halt Event Set to 1 if a debugger notify halt instruction was executed and caused a debug halt.
3	—	Reserved
4	ICMP	Instruction Complete Debug Event Set to 1 if a hardware-owned Instruction Complete debug event occurred.
5	BRT	Branch Taken Debug Event Set to 1 if a hardware-owned Branch Taken debug event occurred.
6	IRPT	Interrupt Taken Debug Event Set to 1 if a hardware-owned Interrupt Taken debug event occurred.
7	TRAP	Trap Taken Debug Event Set to 1 if a hardware-owned Trap Taken debug event occurred.
8	IAC	Instruction Address Compare 1 Debug Event Set to 1 if a hardware-owned IAC debug event occurred.
9:11	—	Reserved
12	DACR	Data Address Compare Read Debug Event Set to 1 if a hardware-owned read-type DAC debug event occurred
13	DACW	Data Address Compare Write Debug Event Set to 1 if a hardware-owned write-type DAC1 debug event occurred
14	—	Reserved

Table continues on the next page...

Table 19-20. EDBSR0 Bit Definitions (continued)

Bit(s)	Name	Description
15	DNI	DNI Debug Event Set to 1 if a hardware-owned DNI debug event occurred
16	RET	Return Debug Event Set to 1 if a hardware-owned Return debug event occurred
17:20	—	Reserved
21	DEVT1	External Debug Event 1 Debug Event Set to 1 if a hardware-owned DEVT1 debug event occurred
22	DEVT2	External Debug Event 2 Debug Event Set to 1 if a hardware-owned DEVT2 debug event occurred
23	PMI	Performance Monitor Interrupt Debug Event Set to 1 if a Performance Monitor Interrupt event occurred with $EDBRAC0_{PMI}$=0 regardless of the setting of $PMGC0_{UDI}$
24	MPU	Memory Protection Unit Debug Event Set to 1 if a hardware-owned MPU debug event occurred. For MPU debug events, if $EDBSRMSK0_{MPU}$ is cleared, the IAC, DACR, or DACW status bit will also be set, depending on the type of access which matched a region descriptor enabled to generate debug events, in order to further define the type of MPU debug event. If $EDBSRMSK0_{MPU}$ is set at the time a MPU debug event occurs, the IAC, DACR, and DACW status bits will not be set by MPU debug events, in order to properly mask the MPU debug event. Note that hardware MPU debug events on data accesses normally occur after the data access is performed and the instruction completes, thus act like a normal DAC debug event. The instruction may not complete if a DSI occurs. In this case, IDE will be set to indicate this occurrence.
25	CIRPT	Critical Interrupt Taken Debug Event Set to 1 if a hardware-owned Critical Interrupt Taken debug event occurred.
26	CRET	Critical Return Debug Event Set to 1 if a hardware-owned Critical Return debug event occurred
27	VLES	VLE Status Set to 1 if a hardware-owned ICMP, BRT, TRAP, RET, CRET, IAC, or DAC debug event occurred on a PowerISA VLE Instruction. Also set for execution of an e_dnh or se_dnh instruction when enabled by $EDBCR0_{DNH\_EN}$. Undefined for IRPT, CIRPT, DEVT[1,2], and UDE events
28:30	DAC_OFST	Data Address Compare Offset Indicates offset-1 of saved DSRR0 value from the address of the load or store instruction which took a hardware-owned DAC Debug exception, unless a simultaneous DSI error occurs, in which case this field is set to 3'b000 and $EDBSR0_{IDE}$ is set to 1. Normally set to 3'b000 by a non-DVC DAC. A DVC DAC may set this field to any value.
31	—	Reserved

19.5.1.3 External Debug Status Register Mask 0 (EDBSRMSK0)

The External Debug Status Register Mask 0 (EDBSRMSK0) is used to mask debug events set in EDBSR0 from causing entry into debug halted mode. A '1' stored in any mask bit prevents debug mode entry caused by the corresponding bit being set in EDBSR0. The mask has no effect on DBSR actions or on the setting of EDBSR0 status bits by hardware-owned events, except that the IDE bit will not be set by imprecise hardware-owned debug events which are masked. EDBSRMSK0 may be used to allow debug events owned by hardware to be configured for watchpoint generation purposes without causing debug mode entry when the watchpoint occurs. EDBSRMSK0 is read and written via OnCE access by the debugger. No software access is provided. The EDBSRMSK0 register is shown in the following figure.

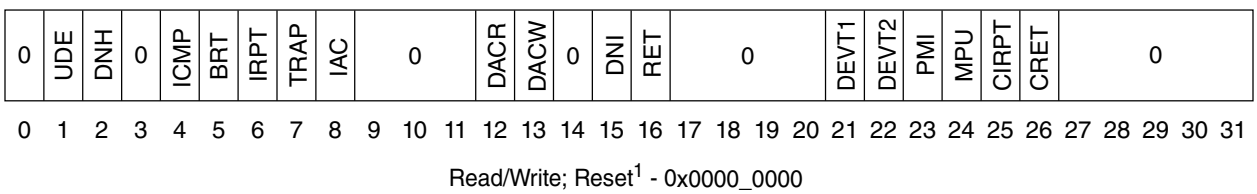

Figure 19-18. EDBSRMSK0 Register

Note

[1] Reset by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state or while $EDBCRO_{EDM}$=O.

The following table provides bit definitions for External Debug Status Register Mask 0.

Table 19-21. EDBSRMSK0 Bit Definitions

Bit(s)	Name	Description
0	—	Reserved
1	UDE	Unconditional Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{UDE}$
2	DNH	Debugger Notify Halt Event Set to 1 to mask debug mode entry by $EDBSR0_{DNH}$
3	—	Reserved
4	ICMP	Instruction Complete Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{ICMP}$
5	BRT	Branch Taken Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{BRT}$
6	IRPT	Interrupt Taken Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{IRPT}$
7	TRAP	Trap Taken Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{TRAP}$

Table continues on the next page...

Table 19-21. EDBSRMSK0 Bit Definitions (continued)

Bit(s)	Name	Description
8	IAC	Instruction Address Compare Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{IAC}$
9:11	—	Reserved
12	DACR	Data Address Compare 1 Read Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{DACR}$
13	DACW	Data Address Compare 1 Write Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{DACW}$
14	—	Reserved
15	DNI	DNI Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{DNI}$
16	RET	Return Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{RET}$
17:20	—	Reserved
21	DEVT1	External Debug Event 1 Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{DEVT1}$
22	DEVT2	External Debug Event 2 Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{DEVT2}$
23	PMI	Performance Monitor Interrupt Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{PMI}$
24	MPU	Memory Protection Unit Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{MPU}$
25	CIRPT	Critical Interrupt Taken Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{CIRPT}$
26	CRET	Critical Return Debug Event Set to 1 to mask debug mode entry by $EDBSR0_{CRET}$
22:31	—	Reserved

19.5.1.4 External Debug Data Effective Address Register (EDDEAR)

The External Debug Data Effective Address Register (EDDEAR) contains address information for hardware-owned data address compare debug events, including MPU DAC events. EDDEAR is update by hardware with the effective address of the load, store, or cache control operation when an unmasked data address compare event is recorded in EDBSR0 if the previous values of $EDBSR0_{DAC\{R,W\}}$ bits which are unmasked in EDBSRMSK0 are zero. Once an EDDEAR update is performed, these unmasked bits must be cleared by the hardware debugger prior to another EDDEAR

hardware update occurring. A subsequent hardware-owned unmasked DAC event will not update the EDDEAR register if either of the $EDBSR0_{DAC\{R,W\}}$ bits are set and are not masked by EDBSRMSK0, in order to capture the first unmasked event address. EDDEAR is read and written via OnCE access by the debugger. No software access is provided.

The EDDEAR register is shown in the following figure.

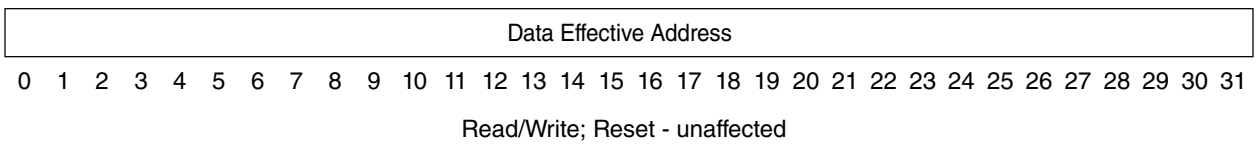

Figure 19-19. EDDEAR Register

19.5.2 OnCE Introduction

The e200z7260n3 on-chip emulation circuitry (OnCE™/Nexus Class 1 interface) provides a means of interacting with the e200z7260n3 core and integrated system so that a user may examine registers, memory, or on-chip peripherals facilitating hardware/ software development. OnCE operation is controlled via an industry standard IEEE 1149.1 TAP controller. By using public instructions, the external hardware debugger can freeze or halt the CPU, read and write internal state, and resume normal execution. The core does not contain IEEE 1149.1 standard boundary cells on its interface, as it is a building block for further integration. It does not support the JTAG related boundary scan instruction functionality, although JTAG public instructions may be decoded and signaled to external logic.

The OnCE logic provides for Nexus Class 1 static debug capability (utilizing the same set of resources available to software while in internal debug mode).

In order to enable full OnCE operation, the **jd_enable_once** input signal must be asserted. In some system integrations, this is automatic, since the input will be tied asserted. Other integrations may require the execution of the Enable OnCE command via the TAP and appropriate entry of serial data. Exact requirements will be documented by the integrated product specification. The **jd_enable_once** input signal should not change state during a debug session, or undefined activity may occur.

The following figures show the TAP controller state model and the TAP registers implemented by the OnCE logic.

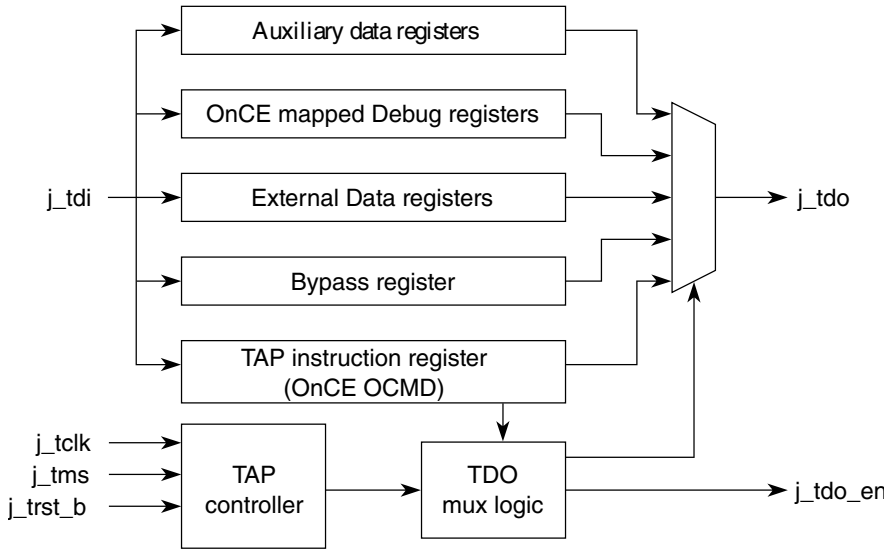

Figure 19-20. OnCE TAP Controller and Registers

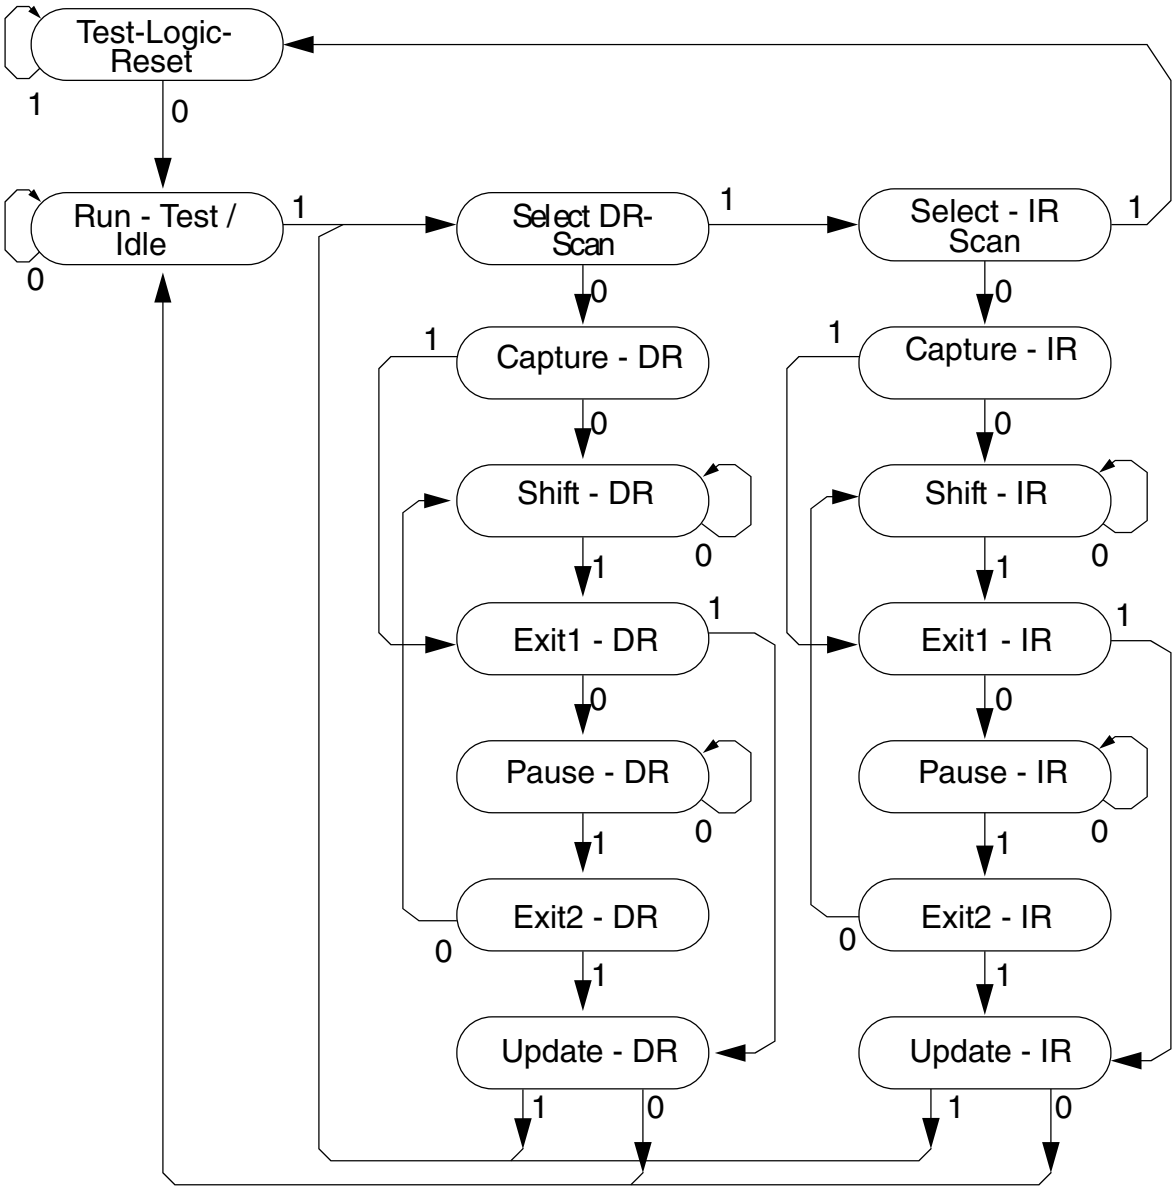
The OnCE controller is implemented as a 16-state FSM, with a one-to-one correspondence to the states defined for the JTAG TAP controller.



Access to processor registers and the contents of memory locations are performed by enabling external debug mode (setting $EDBCR0_{EDM}$ to '1'), placing the processor into debug mode, followed by scanning instructions and data into and out of the CPU Scan Chain (CPUSCR); execution of scanned instructions by the CPU is used as the method to access required data. Memory locations may be read by scanning a load instruction into the CPU core which will reference the desired memory location, executing the load instruction, and then scanning out the result of the load. Other resources are accessed in a similar manner.

The initial entry by the CPU into the debug state (or mode) from normal, Waiting, Stopped, or Halted states (all indicated via the OnCE Status Register (OSR), OnCE Status Register) by assertion of one or more debug requests, begins a *debug session*. The **jd_debug_b** output signal indicates that a debug session is in progress, and the OSR will

indicate the CPU is in the debug state. Instructions may the be single-stepped by scanning new values into the CPUSCR, and performing a OnCE go+noexit command (See OnCE Command Register (OCMD)). The CPU will then temporarily exit the debug state (but not the debug session) to execute the instruction, and will then return to the debug state (again indicated via the OnCE Status Register (OSR)). The debug session remains in force until the final OnCE go+exit command is executed, at which time the CPU will return to the previous state it was in (unless a new debug request is pending). A scan into the CPUSCR is required prior to executing each go+exit or go+noexit OnCE command.

19.5.3 JTAG/OnCE Pins

The JTAG/OnCE pin interface is used to transfer OnCE instructions and data to the OnCE control block. Depending on the particular resource being accessed, the CPU may need to be placed in the Debug mode. For resources outside of the CPU block and contained in the OnCE block, the processor is not disturbed, and may continue execution. If a processor resource is required, an internal debug request (**dbg_dbgrq**) may be asserted to the CPU by the OnCE controller, and causes the CPU to finish the current instruction being executed, save the instruction pipeline information, enter Debug Mode, and wait for further commands. Asserting **dbg_dbgrq** will cause the chip to temporarily exit the Waiting, Stopped or Halted power management states.

The following table details the primary JTAG/OnCE interface signals.

Table 19-22. JTAG/OnCE Primary Interface Signals

Signal name	Type	Description
j_trst_b	I	JTAG test reset
j_tclk	I	JTAG test clock
j_tms	I	JTAG test mode select
j_tdi	I	JTAG test data input
j_tdo	O	Test data out to master controller or pad
j_tdo_en[1]	O	Enables TDO output buffer

1. j_tdo_en is asserted when the TAP controller is in the shift_DR or shift_IR state.

A full description of JTAG pins is provided in the JTAG Support Signals section of the Core (e200z7260n3) Core Complex Overview.

19.5.4 OnCE Internal Interface Signals

The following paragraphs describe the OnCE interface signals to other internal blocks associated with the OnCE controller.

19.5.4.1 CPU Debug Request (dbg_dbgrq)

The **dbg_dbgrq** signal is asserted by the OnCE control logic to request the CPU to enter the debug state. It may be asserted for a number of different conditions, and causes the CPU to finish the current instruction being executed, save the instruction pipeline information, enter the debug mode, and wait for further commands.

19.5.4.2 CPU Debug Acknowledge (cpu_dbgack)

The **cpu_dbgack** signal is asserted by the CPU upon entering the debug state. This signal is used as part of the handshake mechanism between the OnCE control logic and the rest of the CPU. The CPU core may enter debug mode either through a software or hardware event.

19.5.4.3 CPU Address, Attributes

The CPU address and attribute information are used by the Nexus3 unit with information for real-time address trace information.

19.5.4.4 CPU Data

The CPU data buses are used to supply the Nexus3 debug unit with information for real-time data trace capability.

19.5.5 OnCE Interface Signals

The following paragraphs describe additional OnCE interface signals to other external blocks such as a Nexus controller and external blocks which may need information pertaining to debug operation.

19.5.5.1 OnCE Enable (jd_en_once)

The OnCE enable signal **jd_en_once** is used to enable the OnCE controller to allow certain instructions and operations to be executed. Assertion of this signal will enable the full OnCE command set, as well as operation of control signals and OnCE Control register functions. When this signal is disabled, only the Bypass, ID and Enable_OnCE

commands are executed by the OnCE unit, and all other commands default to a "Bypass" command. The OnCE Status register (OSR) is not visible when OnCE operation is disabled. In addition, OnCE Control register (OCR) functions are disabled, as is the operation of the **jd_de_b** input. Secure systems may choose to leave the **jd_en_once** signal negated until a security check has been performed. Other systems should tie this signal asserted to enable full OnCE operation. The **j_en_once_regsel** output signal is provided to assist external logic performing security checks.

The **jd_en_once** input must only change state during the Test-Logic-Reset, Run-Test/ Idle, or Update_DR TAP states. A new value will take affect after one additional **j_tclk** cycle of synchronization. In addition, **jd_enable_once** input signal must not change state during a debug session, or undefined activity may occur.

19.5.5.2 OnCE Debug Request/Event (jd_de_b, jd_de_en)

If implemented at the SoC level, a system level bidirectional open drain debug event pin **DE_b** (not part of the e200z7260n3 interface) provides a fast means of entering the Debug Mode of operation from an external command controller (when input) as well as a fast means of acknowledging the entering of the Debug Mode of operation to an external command controller (when output). The assertion of this pin by a command controller causes the CPU core to finish the current instruction being executed, save the instruction pipeline information, enter Debug Mode, and wait for commands to be entered. If **DE_b** was used to enter the Debug Mode then **DE_b** must be negated after the OnCE controller responds with an acknowledge and before sending the first OnCE command. The assertion of this pin by the CPU Core acknowledges that it has entered the Debug Mode and is waiting for commands to be entered.

To support operation of this system pin, the OnCE logic supplies the **jd_de_en** output and samples the **jd_de_b** input when OnCE is enabled (**jd_en_once** asserted). Assertion of **jd_de_b** will cause the OnCE logic to place the CPU into Debug Mode. Once Debug Mode has been entered, the **jd_de_en** output will be asserted for three **j_tclk** periods to signal an acknowledge. **jd_de_en** can be used to enable the open-drain pulldown of the system level **DE_b** pin.

For systems which do not implement a system level bidirectional open drain debug event pin **DE_b**, the **jd_de_en** and **jd_de_b** signals may still be used to handshake debug entry.

19.5.5.3 OnCE Debug Output (jd_debug_b)

The OnCE Debug output **jd_debug_b** is used to indicate to on-chip resources that a debug session is in progress. Peripherals and other units may use this signal to modify normal operation for the duration of a debug session, which may involve the CPU executing a sequence of instructions solely for the purpose of visibility/system control which are not part of the normal instruction stream the CPU would have executed had it not been placed in debug mode. This signal is asserted the first time the CPU enters the debug state, and remains asserted until the CPU is released by a write to the OnCE Command Register with the GO and EX bits set, and a register specified as either "No Register Selected" or the CPUSCR. This signal will remain asserted even though the CPU may enter and exit the debug state for each instruction executed under control of the OnCE controller. See OnCE Command Register (OCMD) for more information on the function of the GO and EX bits. This signal is not normally used by the CPU.

19.5.5.4 CPU Clock On Input (jd_mclk_on)

The CPU Clock On input **jd_mclk_on** is used to indicate that the CPU's **m_clk** input is active. This input signal is expected to be driven by system logic external to the e200z7260n3 core, is synchronized to the **j_tclk** (scan clock) clock domain, and is presented as a status flag on the **j_tdo** output during the Shift_IR state. External firmware may use this signal to ensure proper scan sequences will occur to access debug resources in the **m_clk** clock domain.

19.5.5.5 Watchpoint Events (jd_watchpt[0:31])

The **jd_watchpt[0:31]** signals may be asserted by the OnCE control logic to signal that a watchpoint condition has occurred. Watchpoints do not directly cause the CPU to be affected. They are provided to allow external visibility only or for triggering purposes. Watchpoint events are conditioned by the settings in the DBCRxx registers, as well as by the DEVENT register, the DTC/DTSA/DTEA registers, the Performance Monitor control register settings, and generation of MPU debug events. Refer to for details of the signal assignments. Note that assertion of most watchpoint outputs is conditioned on being in EDM or IDM. The Performance monitor, DEVENT, and DTC watchpoints are not conditioned however, and may assert regardless of the state of EDM or IDM. In addition, DAC1 or DAC3 watchpoints may be generated for stack limit violation occurrences when those resources are configured to perform stack limit checking, regardless of the state of EDM or IDM.

19.5.5.6 Update DR w/go+exit (j_ocmd_go_exit)

This signal indicates the TAP controller is in the Update_DR state and that the go and exit bits in the OnCE Command register are high, and RS indicates "no register selected". This signal will assert regardless of whether the CPU is currently in debug mode. It may be monitored by external logic to cause a synchronous exit from debug mode of other modules (but not other CPUs) in the system. A debugger can place all of the CPU tap controllers in parallel, scan in a go+exit command with "no register selected", and sequence through the Update_DR state to cause any CPU currently in debug mode to exit. CPUs which are not it debug mode will ignore the command.

19.5.6 OnCE Controller and serial interface

The OnCE Controller contains the OnCE command register, the OnCE decoder, and the status/control register. The following figure is a block diagram of the OnCE controller. In operation, the OnCE Command register acts as the IR for the TAP controller, and all other OnCE resources are treated as data registers (DR) by the TAP controller. The Command register is loaded by serially shifting in or parallel loading commands during the TAP controller Shift-IR state, and is loaded during the Update-IR state. The Command register selects a resource to be accessed as a data register (DR) during the TAP controller Capture-DR, Shift-DR and Update-DR states.

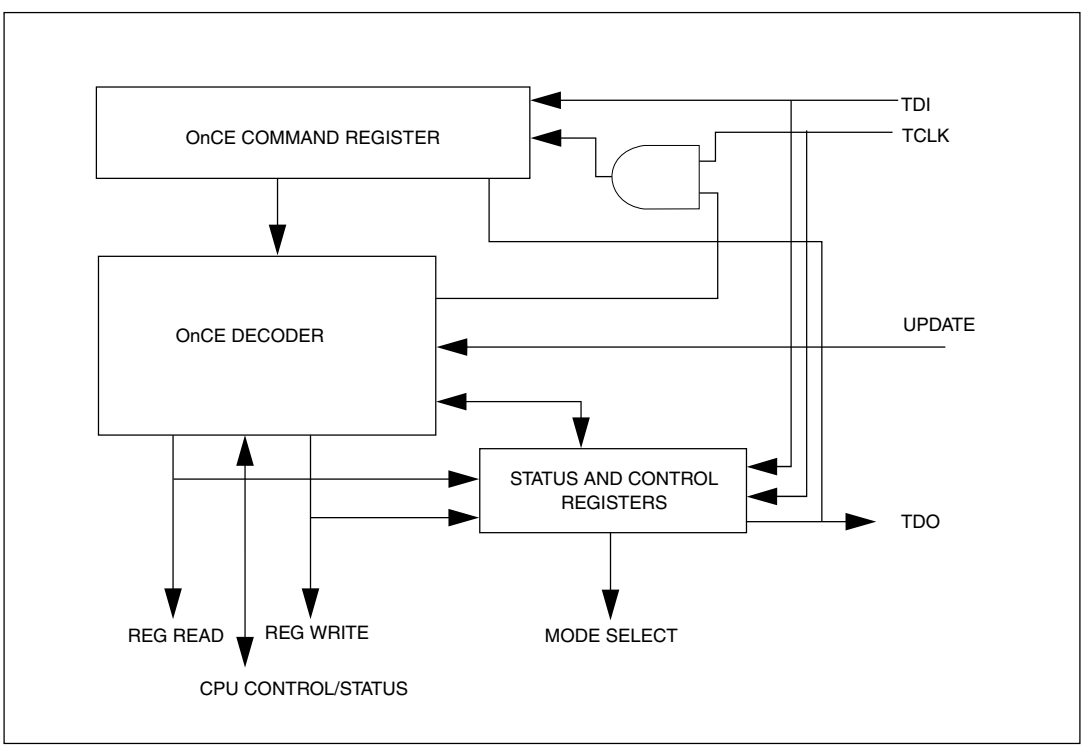


Figure 19-21. OnCE Controller and Serial Interface

19.5.6.1 OnCE Status Register

Status information regarding the state of the CPU is latched into the OnCE Status register when the OnCE controller state machine enters the Capture-IR state. When OnCE operation is enabled, this information is provided on the **j_tdo** output in serial fashion when the Shift_IR state is entered following a Capture-IR. Information is shifted out least significant bit first.

MCLK	ERR	0	RESET	HALT	STOP	DEBUG	WAIT	0	1
0	1	2	3	4	5	6	7	8	9

Figure 19-22. OnCE Status Register

The following table provides bit definitions for the Once Status Register.

Table 19-23. OnCE Status Register Bit Definitions

Bit(s)	Name	Description
0	MCLK	MCLK **m_clk** Status Bit 0 - Inactive state 1 - Active state This status bit reflects the logic level on the **jd_mclk_on** input signal after capture by **j_tclk**.
1	ERR	ERROR This bit is used to indicate that an error condition occurred during attempted execution of the last single-stepped instruction (GO+NoExit with CPUSCR or No Register Selected in OCMD), and that the instruction may not have been properly executed. This could occur if an Interrupt (all classes including External, Critical, machine check, Storage, Alignment, Program, etc.) occurred while attempting to perform the instruction single step. In this case, the CPUSCR will contain information related to the first instruction of the Interrupt handler, and no portion of the handler will have been executed.
3	RESET	RESET Mode This bit reflects the inverted logic level on the CPU **p_reset_b** input after capture by **j_tclk**.
4	HALT	HALT Mode This bit reflects the logic level on the CPU **p_halted** output after capture by **j_tclk**.
5	STOP	STOP Mode This bit reflects the logic level on the CPU **p_stopped** output after capture by **j_tclk**.
6	DEBUG	Debug Mode This bit is asserted once the CPU is in debug mode. It is negated once the CPU exits debug mode (even during a debug session)
7	WAIT	Waiting Mode This bit reflects the logic level on the CPU **p_waiting** output after capture by **j_tclk**.

Table continues on the next page...

Table 19-23. OnCE Status Register Bit Definitions (continued)

Bit(s)	Name	Description
8	0	Reserved, set to 0 for 1149.1 compliance
9	1	Reserved, set to 1 for 1149.1 compliance

19.5.6.2 OnCE Command Register (OCMD)

The OnCE Command Register (OCMD) is a 10-bit shift register that receives its serial data from the TDI pin and serves as the instruction register (IR). It holds the 10-bit commands to be used as input for the OnCE Decoder. The Command Register is shown in Figure 19-23. The OCMD is updated when the TAP controller enters the Update-IR state. It contains fields for controlling access to a resource, as well as controlling single-step operation and exit from OnCE mode.

Although the OCMD is updated during the Update-IR TAP controller state, the corresponding resource is accessed in the DR scan sequence of the TAP controller, and as such, the Update-DR state must be transitioned through in order for an access to occur. In addition, the Update-DR state must also be transitioned through in order for the single-step and/or exit functionality to be performed, even though the command appears to have no data resource requirement associated with it.

Reset - 10'b1000000010 on assertion of **j_trst_b** or **m_por** , or while in the Test_Logic_Reset state

Figure 19-23. OnCE Command Register

Table 19-24 provides bit definitions for the Once Command Register.

Table 19-24. OnCE Command Register Bit Definitions

Bit(s)	Name	Description
0	R/W	Read/Write Command Bit The R/W bit specifies the direction of data transfer. The table below describes the options defined by the R/W bit. **Note:** The R/W bit generally ignored for read-only or write-only registers, although the PC FIFO pointer is only guaranteed to be update when R/W=1. In addition, it is ignored for all bypass operations. When performing writes, most registers are sampled in the Capture-DR state into a 32-bit shift register, and subsequently shifted out on **j_tdo** during the first 32 clocks of Shift-DR. 0 - Write the data associated with the command into the register specified by RS[0:6]

Table continues on the next page...

Table 19-24. OnCE Command Register Bit Definitions (continued)

Bit(s)	Name	Description
		1 - Read the data contained in the register specified by RS[0:6]
1	GO	Go Go Command Bit If the GO bit is set, and the CPU is currently in debug mode, the CPU will execute the instruction which resides in the IR register in the CPUSCR. To execute the instruction, the processor leaves the debug mode, executes the instruction, and if the EX bit is cleared, returns to the debug mode immediately after executing the instruction. The processor goes on to normal operation if the EX bit is set, and no other debug request source is asserted. The GO command is executed only if the operation is a read/write to CPUSCR or a read/write to "No Register Selected". Otherwise the GO bit is ignored.The processor will leave the debug mode after the TAP controller Update-DR state is entered. On a GO+NoExit operation, returning to debug mode is treated as a debug event, thus exceptions such as machine checks and interrupts may take priority and prevent execution of the intended instruction. Debug firmware should mask these exceptions as appropriate. The OSR_{ERR} bit indicates such an occurrence. If the CPU is not currently in debug mode, then the GO command will be ignored. Note that asynchronous interrupts are blocked on a GO+Exit operation until the first instruction to be executed begins execution. See Exiting Debug Mode and Interrupt Blocking. 0 - Inactive (no action taken) 1 - Execute instruction in IR
2	EX	Exit Command Bit 0 - Remain in debug mode 1 - Leave debug mode If the EX bit is set, the processor will leave the debug mode and resume normal operation until another debug request is generated. The Exit command is executed only if the Go command is issued, and the operation is a read/write to CPUSCR or a read/write to "No Register Selected". Otherwise the EX bit is ignored. The processor will leave the debug mode after the TAP controller Update-DR state is entered. Note that if the DR bit in the OnCE control register is set or remains set, or if a bit in EDBSR0 is set and $EDBCR0_{EDM}$=1 (external debug mode is enabled), or if another debug request source is asserted, then the processor may return to the debug mode *without* execution of an instruction, even though the EX bit was set. Note that asynchronous interrupts are blocked on a GO+Exit operation until the first instruction to be executed begins execution. See Exiting Debug Mode and Interrupt Blocking.
3:9	RS	Register Select The Register Select bits define which register is source (destination) for the read (write) operation. Table 19-25 indicates the OnCE register addresses. Attempted writes to read-only registers are ignored.

Table 19-25 indicates the OnCE register addresses.

1. Causes assertion of the j_en_once_regsel output.

The Once Decoder receives as input the 10-bit command from the OCMD, and status signals from the processor, and generates all the strobes required for reading and writing the selected OnCE registers.

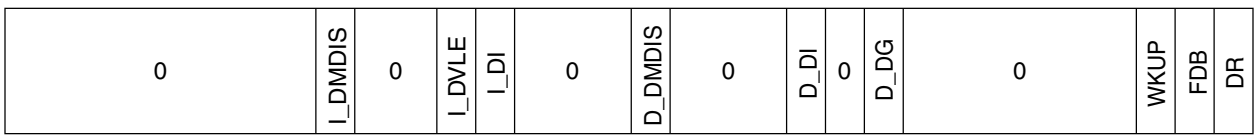
Single stepping of instructions is performed by placing the CPU in debug mode, scanning in appropriate information into the CPUSCR, and setting the Go bit (with the EX bit cleared) with the RS field indicating either the CPUSCR or No Register Selected. After executing a single instruction, the CPU will re-enter debug mode and await further commands. During single-stepping, exception conditions may occur if not properly masked by debug firmware (interrupts, machine checks, bus error conditions, etc.) and may prevent the desired instruction from being successfully executed. The OSR_{ERR} bit is set to indicate this condition. In these cases, values in the CPUSCR will correspond to the first instruction of the exception handler.

Additionally, the $EDBCR0_{EDM}$ bit is forced to '1' internally while single-stepping to prevent Debug events from generating Debug interrupts. Also, during a debug session, the DBSR register is frozen from updates due to debug events other than execution of a DNI-type instruction, regardless of EDBCR0EDM. DBSR may still be modified during a debug session via a single-stepped **mtspr** instruction, or via OnCE access.

If the CPU is not currently in debug mode, go+exit and go+noexit commands are ignored, although for a go+exit command with "No Register Selected", the j_ocmd_go_exit output will be asserted.

19.5.6.3 OnCE Control Register (OCR)

The OnCE Control Register is a 32-bit register used to force the e200z7260n3 core into debug mode and to enable / disable sections of the OnCE control logic. It also provides control over the MPU during a debug session (see MPU Operation During Debug). The control bits are read/write. These bits are only effective while OnCE is enabled (**jd_en_once** asserted). The OCR is shown in the following figure.



Reset - 0xo000_0000 on **m_por, j_trst_b,** or entering Test_logic_Reset state

Figure 19-24. OnCE Control Register

The following table provides bit definitions for the OnCE Control Register.

Table 19-26. OnCE Control Register Bit Definitions

Bit(s)	Name	Description
0:7	—	Reserved
8	I_DMDIS	Instruction Side Debug MPU Disable Control Bit (I_DMDIS) 0 - MPU not disabled for debug sessions 1 - MPU disabled for debug sessions This bit may be used to control whether the MPU is enabled normally, or whether the MPU is disabled during a debug session for Instruction Accesses. When enabled, the MPU functions normally. When disabled, for Instruction Accesses, the I bit is taken from the OCR bit I_DI. The SX and UX access permission control bits are set to'1' to allow full access. When disabled, no MPU exceptions are generated for Instruction accesses. External access errors can still occur. MPU entries with DEBUG=1 are not affected by this control bit.
9:10	—	Reserved
11	I_DVLE	Instruction Side Debug 'VLE' Attribute Bit (I_DVLE) This bit is used to provide the 'VLE' attribute bit to be used during a debug session. Note: this bit is ignored, since VLE is always enabled.
12	I_DI	Instruction Side Debug 'I' Attribute Bit (I_DI) This bit is used to provide the 'I' attribute bit to be used for Instruction accesses for Instruction accesses during a debug session.
13:15	—	Reserved
16	D_DMDIS	Data Side Debug MPU Disable Control Bit (D_DMDIS) 0 - MPU not disabled for debug sessions 1 - MPU disabled for debug sessions

Table continues on the next page...

Table 19-26. OnCE Control Register Bit Definitions (continued)

Bit(s)	Name	Description
		This bit may be used to control whether the MPU is enabled normally, or whether the MPU is disabled during a debug session for Data Accesses. When enabled, the MPU functions normally. When disabled, for Data Accesses, the MPU I and G bits are taken from the OCR bits D_DI and D_DG. The SR, SW, UR, and UW access permission control bits are set to'1' to allow full access. When disabled, no MPU exceptions are generated for Data accesses. External access errors can still occur. MPU entries with DEBUG=1 are not affected by this control bit.
17:19	—	Reserved
20	D_DI	Data Side Debug 'I' Attribute Bit (D_DI) This bit is used to provide the 'I' attribute bit to be used for Data accesses during a debug session.
21	—	Reserved
22	D_DG	Data Side Debug 'G' Attribute Bit (D_DG) This bit is used to provide the 'G' attribute bit to be used for Data accesses during a debug session.
23:28	—	Reserved
29	WKUP	Wakeup Request Bit (WKUP) This control bit may be used to force the **p_wakeup** output signal to be asserted. This control function may be used by debug firmware to request that the chip-level clock controller restore the **m_clk** input to normal operation regardless of whether the CPU is in a low power state to ensure that debug resources may be properly accessed by external hardware through scan sequences.
30	FDB	Force Breakpoint Debug Mode Bit (FDB) This control bit is used to determine whether the processor is operating in breakpoint debug enable mode or not. The processor may be placed in breakpoint debug enable mode by setting this bit. In breakpoint debug enable mode, execution of the '**bkpt**' pseudo- instruction will cause the processor to enter debug mode, as if the **jd_de_b** input had been asserted. This bit is qualified with $EDBCR0_{EDM}$, which must be set for FDB to take effect. Note that this bit has no effect on **e_dnh** or **se_dnh** instruction operation.
31	DR	CPU Debug Request Control Bit This control bit is used to unconditionally request the CPU to enter the Debug Mode. The CPU will indicate that Debug Mode has been entered via the data scanned out in the shift-IR state. 0 - No Debug Mode request 1 - Unconditional Debug Mode request When the DR bit is set the processor will enter Debug mode at the next instruction boundary.

19.5.7 Access to Debug Resources

Resources contained in the OnCE Module which do not require the processor core to be halted for access may be accessed while the e200z7260n3 core is running, and will not interfere with processor execution. Accesses to other resources such as the CPUSCR require the e200z7260n3 core to be placed in debug mode to avoid synchronization hazards. Debug firmware may ensure that it is safe to access these resources by determining the state of the e200z7260n3 core prior to access. Note that a scan operation to update the CPUSCR is required prior to exiting debug mode if debug mode has been entered.

Some cases of write accesses other than accesses to the OnCE Command and Control registers, or the EDM bit of DBCR0 require **m_clk** to be running for proper operation. The OnCE control register provides a means of signaling this need to a system level clock control module via the OCR_{WKUP} control bit.

In addition, since the CPU may cause multiple bits of certain registers to change state, reads of certain registers while the CPU is running (DBSR, etc.) may not have consistent bit settings unless read twice with the same value indicated. In order to guarantee that the contents are consistent, the CPU should be placed into debug mode, or multiple reads should be performed until consistent values have been obtained on consecutive reads.

The following table provides a list of access requirements for OnCE registers.

Table 19-27. OnCE Register Access Requirements

Register name	Access requirements					Notes
	Requires jd_en_once to be asserted	Requires EDBCR0 $_{EDM}$ = 1 for write access	Requires m_clk active for Write Access	Requires CPU to be halted for Read Access	Requires CPU to be halted for Write Access	
Enable_OnCE	N	N	N	N	—	
Bypass	N	N	N	N	N	
CPUSCR	Y	Y	Y	Y	Y	
DAC1–4	Y	Y	Y	N	*[1]	
DBCR0	Y	Y	Y	N	*[1]	*$EDBCR0_{EDM}$ access only requires **jd_en_once** asserted
DBCR1–8	Y	Y	Y	N	*[1]	
DEVENT	Y	Y	Y	N	*[1]	
EDBRAC0 (DBERC0)	Y	N	Y	N	*[1]	
DBSR	Y	Y	Y	N[2]	*[1]	
EDBCR0	Y	N	N	N	N	
EDBSR0	Y	N	Y	N	N	

Table continues on the next page...

Table 19-27. OnCE Register Access Requirements (continued)

Register name	Access requirements					Notes
	Requires jd_en_once to be asserted	Requires EDBCR0 EDM = 1 for write access	Requires m_clk active for Write Access	Requires CPU to be halted for Read Access	Requires CPU to be halted for Write Access	
EDBSRMSK0	Y	N	N	N	N	
IAC1–8	Y	Y	Y	N	*[1]	
JTAG ID	N	N	—	N	—	Read-only
MPU0CSR0	Y	N	Y	N	N	
OCR	Y	N	N	N	N	
OSR	Y	N	—	N	—	Read-only, accessed by scanning out IR while **jd_en_once** is asserted
Cache Debug Access Control (CDACNTL)	Y	N	Y	N	N	CPU gives lowest priority to a Cache access request when it is not debug halted
Cache Debug Access Data (CDADATA)	Y	N	Y	N	N	CPU gives lowest priority to a Cache access request when it is not debug halted
Nexus3-Access	Y	N	N	N	N	
PMR-Access	Y	N	N	N	N	
PMR Registers	Y	Y	Y	N	N	
External GPRs	Y	N	N	N	N	
LSRL Select	Y	N	?	?	?	System Test logic implementation determines LSRL functionality

1. Writes to these registers while the CPU is running may have unpredictable results due to the pipelined nature of operation, and the fact that updates are not synchronized to a particular clock, instruction, or bus cycle boundary, therefore it is strongly recommended to ensure the processor is first placed into debug mode before updates to these registers are performed.
2. Reads of these registers while the CPU is running may not give data that is self-consistent due to synchronization across clock domains.

19.5.8 Methods of Entering Debug Mode

The OnCE Status Register indicates that the CPU has entered the debug mode via the DEBUG status bit. The following sections describe how Debug Mode is entered assuming the OnCE circuitry has been enabled. OnCE operation is enabled by the assertion of the **jd_en_once** input See OnCE Enable (jd_en_once).

19.5.8.1 External Debug Request During RESET

Holding the **jd_de_b** signal asserted during the assertion of **p_reset_b,** and continuing to hold it asserted following the negation of **p_reset_b** causes the e200z7260n3 core to enter Debug Mode. After receiving an acknowledge via the OnCE Status Register DEBUG bit, the external command controller should negate the **jd_de_b** signal before sending the first command. Note that in this case the e200z7260n3 core does not execute an instruction before entering Debug Mode, although the first instruction to be executed will be fetched prior to entering Debug Mode in order to properly initialize the CPUSCR.

19.5.8.2 Debug Request During RESET

Asserting a debug request by setting the DR bit in the OCR during the assertion of **p_reset_b** and then negating **p_reset_b** causes the chip to enter debug mode. In this case the CPU will fetch the first instruction of the reset exception handler in order to properly initialize the CPUSCR, but does not execute an instruction before entering debug mode.

19.5.8.3 Debug Request During Normal Activity

Asserting a debug request by setting the DR bit in the OCR during normal chip activity causes the chip to finish the execution of the current instruction and then enter the debug mode. Note that in this case the chip completes the execution of the current instruction and stops after the newly fetched instruction enters the CPU instruction register. This process is the same for any newly fetched instruction including instructions fetched by the interrupt processing, or those that will be aborted by the interrupt processing.

19.5.8.4 Debug Request During Waiting, Halted or Stopped State

Asserting a debug request by setting the DR bit in the OCR when the chip is in the Waiting state (**p_waiting** asserted), Halted state (**p_halted** asserted) or Stopped state (**p_stopped** asserted) causes the CPU to exit the state and enter the debug mode once the CPU clock **m_clk** has been restored. Note that in this case, the CPU will negate the **p_waiting, p_halted** and **p_stopped** outputs. Once the debug session has ended, the CPU will return to the state it was in prior to entering debug mode.

To signal the chip-level clock generator to re-enable **m_clk**, the **p_wakeup** output will be asserted whenever the debug block is asserting a debug request to the CPU due to OCR_{DR} being set, or **jd_de_b** assertion, and will remain set from then until the debug session ends (**jd_debug_b** goes from asserted to negated). In addition, the status of the **jd_mclk_on** input (after synchronization to the **j_tclk** clock domain) may be sampled

along with other status bits from the **j_tdo** outputs during the Shift_IR TAP controller state. This status may be used if necessary by external debug firmware to ensure proper scan sequences occur to registers in the **m_clk** clock domain.

19.5.8.5 Software Request During Normal Activity

Upon executing a '**bkpt**' pseudo-instruction (for e200z7260n3, defined to be an all 0's instruction opcode) when the OCR register's (FDB) bit is set (debug mode enable control bit is true), and $EDBCR0_{EDM}$=1, the CPU enters the debug mode after the instruction following the '**bkpt**' pseudo-instruction has entered the instruction register.

19.5.8.6 Debug Notify Halt Instructions

The **e_dnh** and **se_dnh** instructions allow software to transition the core from a running state to a debug halted state if enabled by $EDBCR0_{DNH\_EN}$, and provide the external debugger with bits reserved in the instruction itself to pass additional information. Entry into debug mode is ***not*** conditioned on $EDBCR0_{EDM}$, allowing for debug of software debug handlers as well as other software. For e200z7260n3, when the CPU enters a debug halted state due to a **e_dnh** or **se_dnh** instruction, the instruction will be stored in the CPUSCR[IR] portion, and the CPUSCR[PC] value will point to the instruction. The external debugger should update the CPUSCR prior to exiting the debug halted state to point past the **e_dnh** or **se_dnh** instruction.

19.5.9 CPU Status and Control Scan Chain Register (CPUSCR)

A number of on-chip registers store the CPU pipeline status and are configured in a single scan chain for access by the OnCE controller. The CPUSCR register contains these processor resources, which are used to restore the pipeline and resume normal chip activity upon return from the debug mode, as well as a mechanism for the emulator software to access processor and memory contents. The following figure shows the block diagram of the pipeline information registers contained in the CPUSCR. Once debug mode has been entered, it is required to scan in and update this register prior to exiting debug mode.

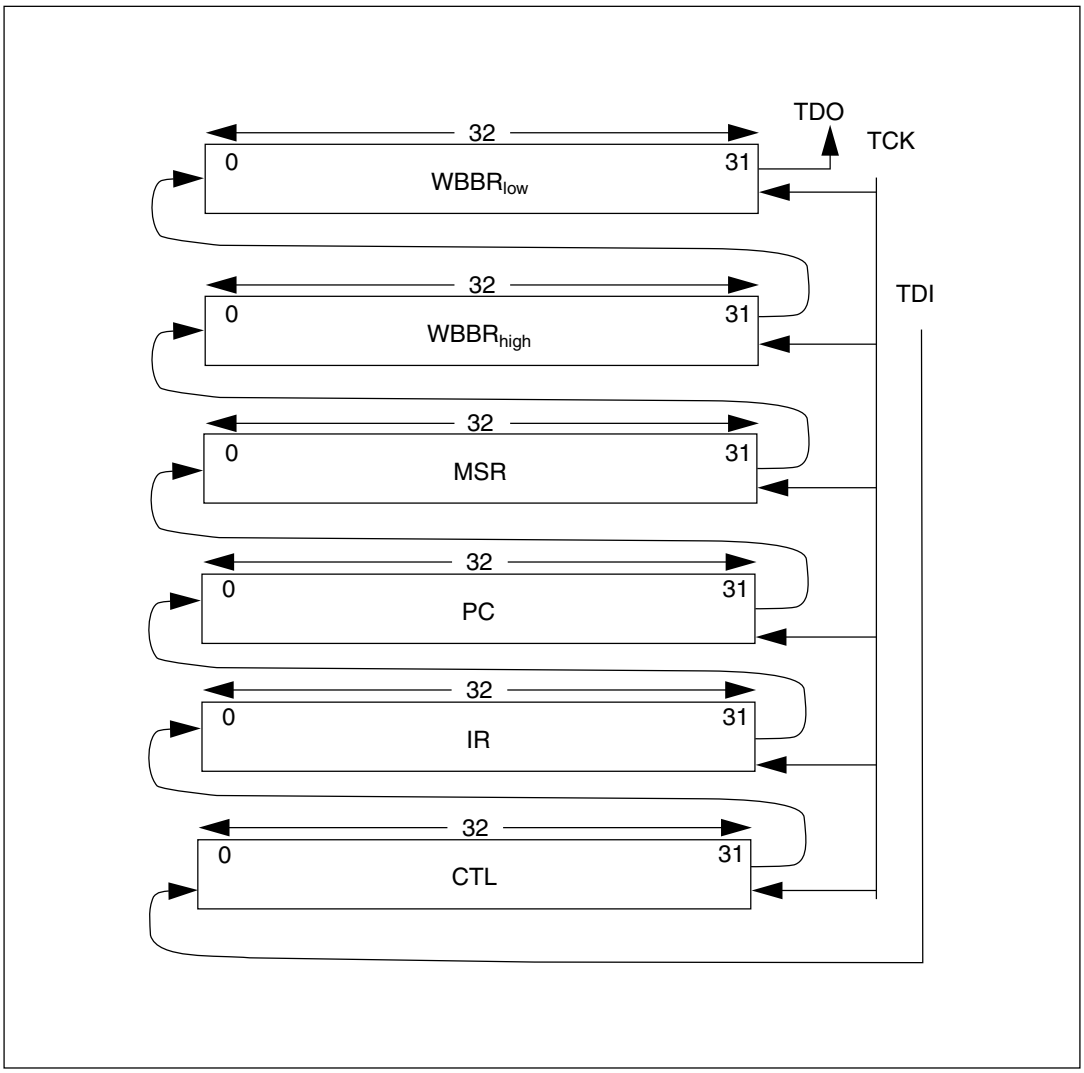


Figure 19-25. CPU Scan Chain Register (CPUSCR)

19.5.9.1 Instruction Register (IR)

The Instruction Register (IR) provides a mechanism for controlling the debug session by serving as a means for forcing in selected instructions, and then causing them to be executed in a controlled manner by the debug control block. The opcode of the next instruction to be executed when entering debug mode is contained in this register when the scan-out of this chain begins. This value should be saved for later restoration if continuation of the normal instruction stream is desired.

On scan-in, in preparation for exiting debug mode, this register is filled with an instruction opcode selected by debug control software. By selecting appropriate instructions and controlling the execution of those instructions, the results of execution may be used to examine or change memory locations and processor registers. The debug

control module external to the processor core will control execution by providing a single-step capability. Once the debug session is complete and normal processing is to be resumed, this register may be loaded with the value originally scanned out.

19.5.9.2 Control State Register (CTL)

The Control State Register (CTL) is a 32-bit register that stores the value of certain internal CPU state variables before the debug mode is entered. This register is affected by the operations performed during the debug session and should normally be restored by the external command controller when returning to normal mode. In addition to saved internal state variables, two of the bits are used by emulation firmware to control the debug process. In certain circumstances, emulation firmware must modify the content of this register as well as the PC and IR values in the CPUSCR before exiting debug mode. These cases are described below.

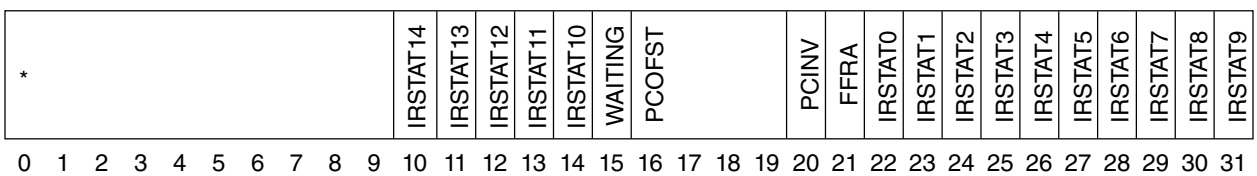

Figure 19-26. Control State Register (CTL)

WAITING — WAITING State Status

This bit indicates whether the CPU was in the waiting state prior to entering debug mode. If set, the CPU was in the waiting state. Upon exiting a debug session, the value of this bit in the restored CPUSCR will determine whether the CPU re-enters the waiting state on a go+exit.

0- CPU was not in the waiting state when debug mode was entered

1- CPU was in the waiting state when debug mode was entered

PCOFST — PC Offset Field

This field indicates whether the value in the PC portion of the CPUSCR must be adjusted prior to exiting debug mode. Due to the pipelined nature of the CPU, the PC value must be backed-up by emulation software in certain circumstances. The PCOFST field specifies the value to be subtracted from the original value of the PC. This adjusted PC value should be restored into the PC portion of the CPUSCR just prior to exiting debug mode with a go+exit. In the event the PCOFST is non-zero, the IR should be loaded with a nop instruction instead of the original IR value, other wise the original value of IR should be restored. (But see PCINV which overrides this field)

0000 - No correction required.

0001 - Subtract 0x04 from PC.

0010 - Subtract 0x08 from PC.

0011 - Subtract 0x0C from PC.

0100 - Subtract 0x10 from PC.

0101 - Subtract 0x14 from PC.

all other encodings are reserved

* — Internal State Bits

Table continues on the next page...

These control bits represent internal processor state and should be restored to their original value after a debug session is completed, i.e when a OnCE command is issued with the GO and EX bits set and not ignored. When performing instruction execution during a debug session. See OnCE Debug Output (jd_debug_b), which is not part of the normal program execution flow, these bits should be set to a 0.

PCINV — PC and IR Invalid Status Bit

This status bit indicates that the values in the IR and PC portions of the CPUSCR are invalid. Exiting debug mode with the saved values in the PC and IR will have unpredictable results. Debug firmware should initialize the PC and IR values in the CPUSCR with desired values prior to exiting debug mode if this bit was set when debug mode was initially entered.

0= No error condition exists.

1= Error condition exists. PC and IR are corrupted.

FFRA— Feed Forward RA Operand Bit

This control bit causes the content of the $WBBR_{lo}$ to be used as the RA operand value (RS for logical, mtspr, mtdcr, cntlzw, and shift operations, RX for VLE se_ instructions, RT for e_{logical_op}2i type instructions, RB for evaddiw, evsubifw, and the value to use as the PC for calculating the LR update value for branch with link type instructions) of the first instruction to be executed following an update of the CPUSCR.

This allows the debug firmware to update processor registers — initialize the $WBBR_{lo}$ with the desired value, set the FFRA bit, and execute a ori Rx,Rx,0 instruction to the desired register.

Note: not all instructions support using the FFRA control. FFRA is mainly intended for use with the ori instruction to allow the debugger to write to a GPR. Support for other instructions is implementation-dependent.

0= No action.

1= Content of $WBBR_{lo}$ used as operand value

IRStat0 — IR Status Bit 0

This control bit indicates a TEA status for the IR.

0= No TEA occurred on the fetch of this instruction.

1= TEA occurred on the fetch of this instruction.

IRStat1 — IR Status Bit 1

This control bit is reserved.

IRStat2 — IR Status Bit 2

This control bit indicates an Instruction Address Compare 1 event status for the IR.

0= No Instruction Address Compare event 1 occurred on the fetch of this instruction.

1= An Instruction Address Compare event 1 occurred on the fetch of this instruction.

IRStat3 — IR Status Bit 3

This control bit indicates an Instruction Address Compare 2 event status for the IR.

0= No Instruction Address Compare 2 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 2 event occurred on the fetch of this instruction.

IRStat4 — IR Status Bit 4

This control bit indicates an Instruction Address Compare 3 event status for the IR.

0= No Instruction Address Compare event 3 occurred on the fetch of this instruction.

1= An Instruction Address Compare event 3 occurred on the fetch of this instruction.

IRStat5 — IR Status Bit 5

This control bit indicates an Instruction Address Compare 4 event status for the IR.

Table continues on the next page...

0= No Instruction Address Compare 4 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 4 event occurred on the fetch of this instruction.

IRStat6 — IR Status Bit 6

This control bit indicates a Parity Error status for the IR.

0= No Parity Error occurred on the fetch of this instruction.

1= Parity Error occurred on the fetch of this instruction from the I-Cache .

IRStat7 — IR Status Bit 7

This control bit indicates a Precise External Termination Error status for the IR.

0= No Precise External Termination Error occurred on the fetch of this instruction.

1= A Precise External Termination Error occurred on the fetch of this instruction.

IRStat8 — IR Status Bit 8

This control bit indicates the PowerISA VLE status for the IR.

0= IR contains a booke instruction. (unused encoding)

1= IR contains a PowerISA VLE instruction, aligned in the Most Significant Portion of IR if 16-bit.

- this bit should not be modified by the debugger, otherwise the resulting operation is boundedly undefined. It should always indicate VLE (=1).

IRStat9 — IR Status Bit 9

This control bit is reserved.

IRStat10 — IR Status Bit 10

This control bit indicates an Instruction Address Compare 5 event status for the IR.

0= No Instruction Address Compare 5 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 5 event occurred on the fetch of this instruction.

IRStat11 — IR Status Bit 11

This control bit indicates an Instruction Address Compare 6 event status for the IR.

0= No Instruction Address Compare 6 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 6 event occurred on the fetch of this instruction.

IRStat12 — IR Status Bit 12

This control bit indicates an Instruction Address Compare 7 event status for the IR.

0= No Instruction Address Compare 7 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 7 event occurred on the fetch of this instruction.

IRStat13 — IR Status Bit 13

This control bit indicates an Instruction Address Compare 8 event status for the IR.

0= No Instruction Address Compare 8 event occurred on the fetch of this instruction.

1= An Instruction Address Compare 8 event occurred on the fetch of this instruction.

IRStat14 — IR Status Bit 14

This control bit indicates an MPU Instruction Address Compare event status for the IR.

0= No MPU Instruction Address Compare event occurred on the fetch of this instruction.

1= An MPU Instruction Address Compare event occurred on the fetch of this instruction.

Emulation firmware should modify the content of the CTL, PC, and IR values in the CPUSCR during execution of debug related instructions as well as just prior to exiting debug with a go+exit command. During the debug session, the CTL register should be

written with the FFRA bit set as appropriate, and all other bit set to '0', and the IR set to the value of the desired instruction to be executed. IRStat8 will be used to determine the type of instruction present in the IR.

Just prior to exiting debug mode with a go+exit, the PCINV status bit which was originally present when debug mode was first entered should be tested, and if set, the PC and IR initialized for performing whatever recovery sequence is appropriate for a faulted exception vector fetch. If the PCINV bit is cleared, then the PCOFST bits should be examined to determine whether the PC value must be adjusted. Due to the pipelined nature of the CPU, the PC value must be backed-up by emulation software in certain circumstances. The PCOFST field specifies the value to be subtracted from the original value of the PC. This adjusted PC value should be restored in to the PC portion of the CPUSCR just prior to exiting debug mode with a go+exit. In the event the PCOFST is non-zero, the IR should be loaded with a nop instruction (such as **ori r0,r0,0**) instead of the original IR value, otherwise the original value of IR should be restored. Note that when a correction is made to the PC value, it will generally point to the last completed instruction, although that instruction will not be re-executed. The nop instruction is executed instead, and instruction fetch and execution will resume at location PC+4. IRStat8 will be used to determine the type of instruction present in the IR, thus should be cleared in this case. Note that debug events which may occur on the nop (ICMP) will be generated if enabled.

For the CTL register, the internal state bits should be restored to their original value. The IRStatus bits should be set to '0's if the PC was adjusted. If no PC adjustment was performed, emulation firmware should determine whether other IRStat flags should be set to '0' to avoid re-entry into debug mode for an instruction breakpoint request. Upon exiting debug mode with go+exit, if one of these bits is set, debug mode will be re-entered prior to any further instruction execution.

19.5.9.3 Program Counter Register (PC)

The PC is a 32-bit register that stores the value of the program counter which was present when the chip entered the debug mode. It is affected by the operations performed during the debug mode and must be restored by the external command controller when the CPU returns to normal mode. PC normally points to the instruction contained in the IR portion of CPUSCR. If debug firmware wishes to redirect program flow to an arbitrary location, the PC and IR should be initialized to correspond to the first instruction to be executed upon resumption of normal processing. Alternatively, the IR may be set to a nop and the PC set to point to the location prior to the location at which it is desired to redirect flow to. On exiting debug mode, the nop will be executed, and instruction fetch and execution will resume at PC+4.

19.5.9.4 Write-Back Bus Register ($WBBR_{low}$, $WBBR_{high}$)

WBBR is used as a means of passing operand information between the CPU and the external command controller. Whenever the external command controller needs to read the contents of a register or memory location, it will force the chip to execute an instruction that brings that information to WBBR. $WBBR_{low}$ holds the 32-bit result of most instructions including load data returned for a load or load with update instruction. $WBBR_{high}$ holds the updated effective address calculated by a load with update instruction. It is undefined for other instructions.

As an example, to read the 32 bits of processor register **r1**, an **ori r1,r1,0** instruction is executed, and the result value of the instruction will be latched into $WBBR_{low}$. The contents of $WBBR_{low}$ can then be delivered serially to the external command controller. To update a processor resource, this register is initialized with a data value to be written, and an **ori** instruction is executed which uses this value as a substitute data value. The Control State register FFRA bit forces the value of the $WBBR_{low}$ to be substituted for the normal RS source value of the **ori** instruction, thus allowing updates to processor registers to be performed. (Refer to Control State Register (CTL) for more detail on the CTL_{FFRA} bit.)

$WBBR_{low}$ and $WBBR_{high}$ are generally undefined on instructions which do not writeback a result, and due to control issues are not defined on **lmw** or branch instructions as well.

19.5.9.5 Machine State Register (MSR)

The MSR is a 32-bit register used to read/write the Machine State Register. Whenever the external command controller needs to save or modify the contents of the Machine State Register, this register is used.This register is affected by the operations performed during the debug mode and must be restored by the external command controller when returning to normal mode.

19.5.9.6 Exiting Debug Mode and Interrupt Blocking

When exiting debug mode with a Go+Exit, "asynchronous" interrupts are blocked until the first instruction to be executed begins execution. This includes External and Critical input, NMI, and machine check interrupts. Asynchronous debug interrupts are not blocked however, and the CPU will re-enter debug mode without executing an instruction

following Go+Exit, although it may fetch an instruction and discard it. Exceptions due to an illegal instruction or error flags set within the CPUSCR CTL register are not blocked, since they apply to the instruction in the CPUSCR IR.

19.5.10 Reserved Registers (Reserved)

The Reserved Registers are used to control various test control logic. These registers are not intended for customer use. To preclude device and/or system damage, these registers should not be accessed.

19.6 MPU Operation During Debug

A debug session begins when the CPU initially enters debug mode, and ends when a OnCE command with GO+EXIT is executed, releasing the CPU for normal operation. If desired during a debug session, the debug firmware may substitute default values obtained from the OnCE Control Register for Access Attribute (I, G) bits. Refer to the bit definitions in the OCR (OnCE Control Register (OCR) for more detail.

Normal operation of the MPU may be modified during a 'debug session' via the OnCE Control Register (OCR). A debug session begins when the CPU initially enters debug mode, and ends when a OnCE command with GO+EXIT is executed, releasing the CPU for normal operation. If desired during a debug session, the debug firmware may disable the MPU protection mechanism and may substitute default values for the Access Protection (UX, UR, UW, SX, SR, SW) bits, and values obtained from the OnCE Control Register for Memory Attributes (I, G) bits normally provided by a matching MPU entry.

When disabled during a debug session, no MPU-related storage interrupt conditions will occur. If the debugger desires to use the normal protection mechanism, the MPU may be left enabled in the OnCE OCR, and normal protections provided by the MPU (including the possibility of a storage interrupt) will remain in effect.

The OCR control bits are used when debug mode is entered. Refer to the bit definitions in the OCR (OnCE Control Register (OCR) for more detail. When the MPU is disabled for instruction accesses (OCR_{I_DMDIS}) or for data accesses (OCR_{D_DMDIS}), substituted access attribute bits will control operation on respective accesses initiated during debug.

19.7 Cache Array Access During Debug

The cache arrays may be read and written during debug mode via the CDACNTL and CDADATA debug registers.

19.8 Basic Steps for Enabling, Using, and Exiting External Debug Mode

The following steps show one possible scenario for a debugger wishing to use the external debug facilities. *This simplified flow is intended to illustrate basic operations, but does not cover all potential methods in depth.*

Enabling External Debug Mode and initializing Debug registers

- The debugger should ensure that the **jd_en_once** control signal is asserted in order to enable OnCE operation
- Select the OCR and write a value to it in which OCR_{DR}, OCR_{WKUP}, are set to '1'. The tap controller must step through the proper states as outlined earlier. This step will place the CPU in a debug state in which it is halted and awaiting single-step commands or a release to normal mode
- Scan out the value of the OSR to determine that the CPU clock is running and the CPU has entered the Debug state. This can be done in conjunction with a Read of the CPUSCR. The OSR is shifted out during the Shift_IR state. The CPUSCR will be shifted out during the Shift_DR state. The debugger should save the scanned-out value of CPUSCR for later restoration.
- Select the DBCR0 register and update it with the $EDBCR0_{EDM}$ bit set
- Clear the DBSR status bits
- Write appropriate values to the DBCR0–8, IAC, and DAC registers. Note that the initial write to DBCR0 will only affect the EDM bit, so the remaining portion of the register must now be initialized, keeping the EDM bit set

At this point the system is ready to commence debug operations. Depending on the desired operation, different steps must occur.

- Optionally, ensure that the values entered into the MSR portion of the CPUSCR during the following steps cause interrupt to be disabled (clearing MSR_{EE} and MSR_{CE}). This will ensure that external interrupt sources do not cause single-step errors.

To single-step the CPU:

- debugger scans in either a new or a previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in Control State Register (CTL)), with a Go+Noexit OnCE Command value.
- The debugger scans out the OSR with "no-register selected", Go cleared, and determines that the CPU has re-entered the Debug state and that no ERR condition occurred

To return the CPU to normal operation (without disabling external debug mode)

- The OCR_{DR} control bit should be cleared, leaving the OCR_{WKUP} bit set
- The debugger restores the CPUSCR with a previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in Control State Register (CTL)), with a Go+Exit OnCE Command value.
- The OCR_{WKUP} bit may then be cleared

To exit External Debug Mode

- The debugger should place the CPU in the debug state via the OCR_{DR} with OCR_{WKUP} asserted, scanning out and saving the CPUSCR
- The debugger should write the DBCR0–8 registers as needed, likely clearing every enable except the $EDBCR0_{EDM}$ bit
- The debugger should write the DBSR to a cleared state
- The debugger should re-write the DBCR0 with all bits including EDM cleared
- The debugger should clear the OCR_{DR} bit
- The debugger restores the CPUSCR with the previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in Control State Register (CTL)), with a Go+Exit OnCE Command value.
- The OCR_{WKUP} bit may then be cleared

Note

These steps are meant by way of examples, and are not meant to be an exact template for debugger operation.

Chapter 20
Signal Processing Extension (SPE)

20.1 Introduction

This chapter provides an overview of the signal processing engine, version 2.1, which is designed to accelerate signal processing applications normally suited to DSP operation. This is accomplished using short vectors (two, four, or eight elements) within 64-bit GPRs and using single instruction multiple data (SIMD) operations to perform the requisite computations. SPE2.1 also architects an accumulator register to allow for certain back to back operations without loop unrolling. SPE2.1 is fully backward compatible with the original SPE. The remainder of this document uses the term SPE to refer to version 2.1 unless otherwise noted.

20.2 Nomenclature and Conventions

Several conventions regarding nomenclature are used in this chapter:

- Due to historical precedent, the terms SPE and SIMD are sometimes used interchangeably.
- The signal processing engine is abbreviated as SPE.
- All register bit numbering is 64-bit with bit 0 being the most significant bit. Registers that are only 32-bit define bit 32 as the most significant bit. For both 32-bit and 64-bit registers, bit 63 is the least significant bit.
- Bits 0–31 of a 64-bit register are referenced as word 0, upper word, even word, or high word element of the register. Bits 32–63 are referred to as word 1, lower word, odd word, or low word element of the register. Each word is an element of a 64-bit GPR.

- Bits 0–15 of a 64-bit register are referenced as half word 0. Bits 16–31 are referred to as half word 1. Bits 32–47 are referenced as half word 2. Bits 48–63 are referred to as half word 3. Each half word is an element of a 64-bit GPR.
- Bits 0–7 of a 64-bit register are referenced as byte 0. Bits 8–15 are referred to as byte 1. Bits 16–23 are referenced as byte 2. Bits 24–31 are referred to as byte 3. Bits 32–39 are referred to as byte 4. Bits 40–47 are referenced as byte 5. Bits 48–55 are referred to as byte 6. Bits 56–63 are referenced as byte 7. Each byte is an element of a 64-bit GPR.
- Bits 0–15 and bits 32–47 are referenced as even half words. Bits 16–31 and bits 48–63 are referenced as odd half words. Bits 0–15 and bits 16–31 are referenced as upper half words. Bits 32–47 and bits 48–63 are referenced as lower half words.
- Mnemonics for SPE instructions generally begin with the letters 'ev' (embedded vector).

The following table shows RTL conventions that are used in this chapter.

Table 20-1. RTL Notation

Notation	Meaning
x_{sf}	Signed fractional multiplication. Result of multiplying 2 quantities having bit lengths x and y taking the least significant x + y – 1 bits of the product and concatenating a 0 to the least significant bit forming a signed fractional result of x + y bits.
x_{si}	Signed integer multiplication
x_{su}, x_{sui}	Signed by Unsigned multiplication (same for int and frac)
x_{ui}	Unsigned integer multiplication
<<	Logical shift left. x << y shifts value x left by y bits, leaving zeros in the vacated bits.
>>	Logical shift right. x >> y shifts value x right by y bits, leaving zeros in the vacated bits.

20.3 SPE Programming Model

The z7260n3 core provides a register file with thirty-two 64-bit registers. The embedded category in the Power ISA instructions operate on the lower (least significant) 32 bits of the 64-bit register. SPE instructions generally take elements from each source register and operate on them with the corresponding elements of a second source register (and/or the accumulator) to produce results. Results are placed in the destination register and/or the accumulator. Vector instructions (i.e. produce results of more than one element)

provide results for each element that are independent of the computation of the other elements. These instructions can also be used to perform scalar DSP operations by ignoring the results of the upper 32-bit half of the register file.

SPE compare instructions and set instructions with record store the comparison result into the condition register (CR). The meaning of the CR bits are now overloaded for SPE operations. SPE compare instructions specify a CR field, two source registers, and the type of compare: greater than, less than, or equal. Two bits of the CR field are written with the result of the vector compare: one for each of the high and low 32-bits of the result. The remaining two bits reflect the ANDing and ORing of the vector compare results. An additional set of compare instructions (**evset$_{xx}$**[.]) return a set of Boolean values into a destination register, allowing for subsequent predicated computational operations, such as a select operation to be performed.

A partially visible accumulator register is architected for the SPE integer and fractional multiply accumulate forms of instructions. Its usage is described in Accumulator Register.

20.3.1 GPR Registers

The SPE requires a GPR register file with thirty-two 64-bit registers. For 32-bit implementations, the embedded category of the Power ISA instructions that normally operate on a 32-bit register, access and change only the least significant 32-bits of the GPRs. They leave the most significant 32-bits unchanged. SPE instructions view the 64-bit register as being composed of a vector of elements, each of which is 32 bits, 16 bits, or 8 bits wide.

Nomenclature is as follows:

- The most significant 32 bits are called word 0 (W0), the upper word, high word or even word.
- The least significant 32 bits are called word 1 (W1), the lower word, low word or odd word.
- Half word elements are called half word 0, 1, 2, or 3, from most significant to least significant.
- Byte elements are called byte 0, 1, 2, 3, 4, 5, 6, or 7, from most significant to least significant.

Unless otherwise specified, SPE instructions write all 64 bits of the destination register.

The following figure shows vector storage in GPRs.

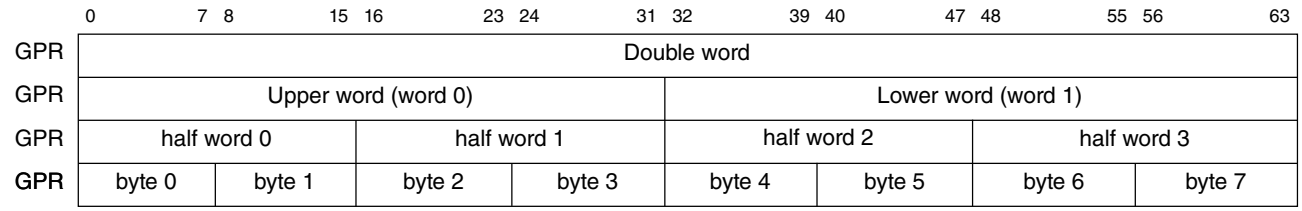

Figure 20-1. Vector Storage in GPRs

20.3.2 Accumulator Register

The accumulator is a 64-bit register that allows the back-to-back execution of dependent MAC and dot product instructions, something that is found in the inner loops of DSP code such as FIR and FFT filters. The accumulator is partially visible to the programmer in that its results do not have to be explicitly read to use them. Instead, they are always copied into a 64-bit destination GPR that is specified as part of the instruction. However, the accumulator has to be explicitly initialized when starting a new accumulation loop.

The accumulator is for used the following kinds of instructions:

- Certain integer/fractional accumulation
- Multiply accumulate (MAC)
- Dot product
- Summation forms

Based upon the type of instruction, the accumulator can hold either a single 64-bit value or a vector of two 32-bit elements, a vector of four 16-bit elements, or vector of eight 8-bit elements. In addition, for certain instructions, the accumulator can be updated along with the destination register.

The following figure shows accumulator storage.

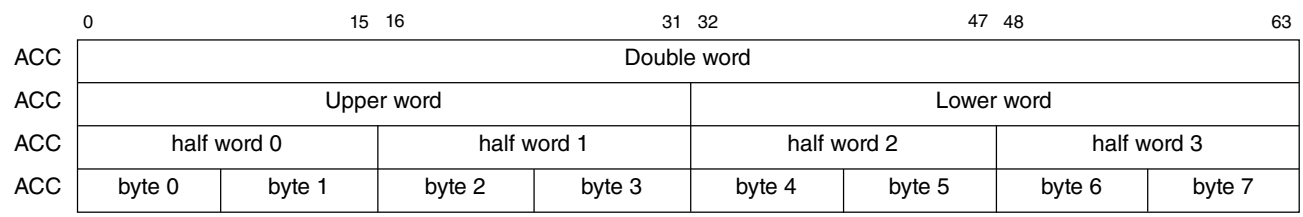

Figure 20-2. Accumulator Storage

An example of a MAC instruction is **evmhossfaawr**D**,r**A**,r**B. In this instruction, the least significant 16 bits of **r**A and **r**B are multiplied for both elements of the vector; the result is shifted left one bit and added to the accumulator; and the result is possibly saturated to 32 bits in case of overflow. The final result is placed both in the accumulator and also in **r**D. Therefore, the result of this instruction can be used by accessing **r**D.

To read the accumulator contents into a **register**, the **evmar** instruction is used. To initialize the accumulator, the **evmra** instruction or another instruction targeting the accumulator such as **evsplati$_{xx}$a** is used.

20.3.3 SPE Status and Control Register (SPEFSCR)

The z7260n3 core implements the SPEFSCR register for status reporting and control of SPE instructions. This register is also used by the embedded floating-point units. Status and control bits are shared for floating-point operations and SPE operations. The SPEFSCR register is implemented as special purpose register (SPR) number 512 and is read and written by the **mfspr** and **mtspr** instructions in both user and supervisor mode. SPE instructions affect both the high element (bits 0–1) and low element status flags (bits 16–17).

The following figure shows the SPEFSCR.

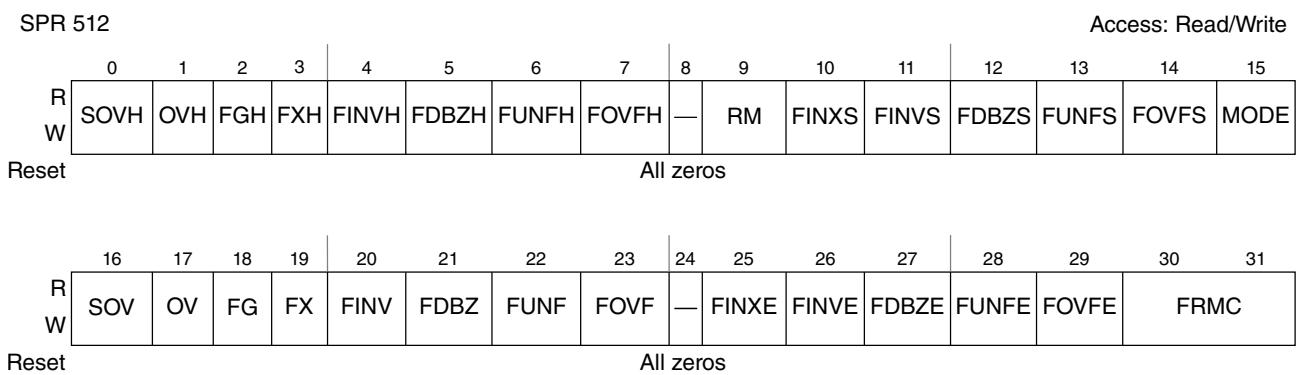

Figure 20-3. SPE/EFPU Status and Control Register (SPEFSCR)

The following table describes the SPEFSCR bits.

Table 20-2. SPE Status and Control Register

Bits	Name	Description
0 (32)	SOVH	Summary Integer Overflow High The SOVH bit is set to 1 whenever an instruction sets OVH. The SOVH bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR register.
1 (33)	OVH	Integer Overflow High

Table continues on the next page...

Table 20-2. SPE Status and Control Register (continued)

Bits	Name	Description
		The OVH bit is set to 1 whenever an integer or fractional SPE instruction signals an overflow in the upper half of the result.
2 (34)	FGH	Embedded Floating-Point Guard bit High Defined by Embedded Floating-Point APUs.
3 (35)	FXH	Embedded Floating-Point Inexact bit High Defined by Embedded Floating-Point APUs.
4 (36)	FINVH	Embedded Floating-Point Invalid Operation/Input error High Defined by Embedded Floating-Point APUs.
5 (37)	FDBZH	Embedded Floating-Point Divide by Zero High Defined by Embedded Floating-Point APUs.
6 (38)	FUNFH	Embedded Floating-Point Underflow High Defined by Embedded Floating-Point APUs.
7 (39)	FOVFH	Embedded Floating-Point Overflow High Defined by Embedded Floating-Point APUs.
8 (40)	—	Reserved
9 (41)	RM	Rounding Mode - Fixed Point 0 Normal Rounding (Biased-rounding), rounding performed by adding 1/2 lsb 1 Round to Nearest Even Rounding (convergent rounding), round to nearest even value
10 (42)	FINXS	Embedded Floating-Point Inexact Sticky Flag Defined by Embedded Floating-Point APUs.
11 (43)	FINVS	Embedded Floating-Point Invalid Operation Sticky Flag Defined by Embedded Floating-Point APUs.
12 (44)	FDBZS	Embedded Floating-Point Divide by Zero Sticky Flag Defined by Embedded Floating-Point APUs.
13 (45)	FUNFS	Embedded Floating-Point Underflow Sticky Flag Defined by Embedded Floating-Point APUs.
14 (46)	FOVFS	Embedded Floating-Point Overflow Sticky Flag Defined by Embedded Floating-Point APUs.
15 (47)	MODE	Embedded Floating-Point Operating Mode Defined by Embedded Floating-Point APUs.
16 (48)	SOV	Summary Integer Overflow The SOV bit is set to 1 whenever an instruction sets OV. The SOV bit remains set until it is cleared by an **mtspr** instruction specifying the SPEFSCR register.
17 (49)	OV	Integer Overflow The OV bit is set to 1 whenever an integer or fractional SPE instruction signals an overflow in the low element result.
18 (50)	FG	Embedded Floating-Point Guard bit (low/scalar) Defined by Embedded Floating-Point APUs.

Table continues on the next page...

Table 20-2. SPE Status and Control Register (continued)

Bits	Name	Description
19 (51)	FX	Embedded Floating-Point Inexact bit (low/scalar) Defined by Embedded Floating-Point APUs.
20 (52)	FINV	Embedded Floating-Point Invalid Operation / Input error (low/scalar) Defined by Embedded Floating-Point APUs.
21 (53)	FDBZ	Embedded Floating-Point Divide by Zero (low/scalar) Defined by Embedded Floating-Point APUs.
22 (54)	FUNF	Embedded Floating-Point Underflow (low/scalar) Defined by Embedded Floating-Point APUs.
23 (55)	FOVF	Embedded Floating-Point Overflow (low/scalar) Defined by Embedded Floating-Point APUs.
24 (56)	—	Reserved
25 (57)	FINXE	Embedded Floating-Point Round (Inexact) Exception Enable Defined by Embedded Floating-Point APUs.
26 (58)	FINVE	Embedded Floating-Point Invalid Operation / Input Error Exception Enable Defined by Embedded Floating-Point APUs.
27 (59)	FDBZE	Embedded Floating-Point Divide by Zero Exception Enable Defined by Embedded Floating-Point APUs.
28 (60)	FUNFE	Embedded Floating-Point Underflow Exception Enable Defined by Embedded Floating-Point APUs.
29 (61)	FOVFE	Embedded Floating-Point Overflow Exception Enable Defined by Embedded Floating-Point APUs.
30–31 (62–63)	FRMC	Embedded Floating-Point Rounding Mode Control Defined by Embedded Floating-Point APUs.

20.3.3.1 Context Switch

When a context switch occurs, the OS process must explicitly save the accumulator as part of the context of the swapped-out task and then explicitly load the accumulator from the context of the new task that is being swapped in. When the old task is restarted, its accumulator must be restored before restarting the task.

20.3.4 GPRs and Power ISA Instructions

The z7260n3 core implements the 32-bit forms of the embedded category instructions in the Power ISA. All 32-bit Power ISA instructions operate upon the lower half of the 64-bit GPR. These instructions do not affect the upper half of a GPR.

20.3.5 SPE Available Bit in MSR

MSR[SPE] is defined as the SPE available bit. If this bit is clear and software attempts to execute any of the SPE instructions other than the **brinc** instruction (which does not affect the upper 32-bits of a GPR), the SPE unavailable exception is taken. If this bit is set, software can execute any of the SPE instructions.

20.3.6 SPE Exception Bit in ESR

ESR[SPE] is defined as the SPE exception bit. This bit is set whenever the processor takes an exception related to the execution of the SPE instructions.

20.3.7 Data Formats

The SPE provides two different data formats, integer and fractional. Integer data formats can be treated as signed or unsigned quantities. Fractional data formats are usually treated as signed quantities

20.3.7.1 Integer Format

Integer data format is the same as what is conventionally used in computing.

Unsigned integers consist of 8, 16, 32, or 64-bit binary integer values. The largest representable value is $2^n – 1$ where n represents the number of bits in the value. The smallest representable value is 0. Certain computations that produce values larger than $2^n – 1$ or smaller than 0 set OV or OVH in the SPEFSCR.

Signed integers consist of 8, 16, 32, or 64-bit binary values in twos-complement form. The largest representable value is $2^{n-1} – 1$ where n represents the number of bits in the value. The smallest representable value is $–2^{n-1}$. Certain computations that produce values larger than $2^{n-1} – 1$ or smaller than $–2^{n-1}$ set OV or OVH in the SPEFSCR.

20.3.7.2 Fractional Format

Fractional data format is the same that is conventionally used for DSP fractional arithmetic. Fractional data is useful for representing data converted from analog devices.

Unsigned fractions consist of 16, 32, or 64-bit binary fractional values that range from 0 to less than 1. Unsigned fractions place the decimal point immediately to the left of the most significant bit. The most significant bit of the value represents the value 2^{-1}, the next most significant bit represents the value 2^{-2} and so on. The largest representable value is $1 – 2^{-n}$ where n represents the number of bits in the value. The smallest representable value is 0. Certain computations that produce values larger than $1 – 2^{-n}$ or smaller than 0 set OV or OVH in the SPEFSCR. SPE does not contain explicit instructions that manipulate unsigned fractional data. Unsigned integer forms produce the same bit exact results as unsigned fractional values would, therefore unsigned fractional instruction forms are not defined for SPE.

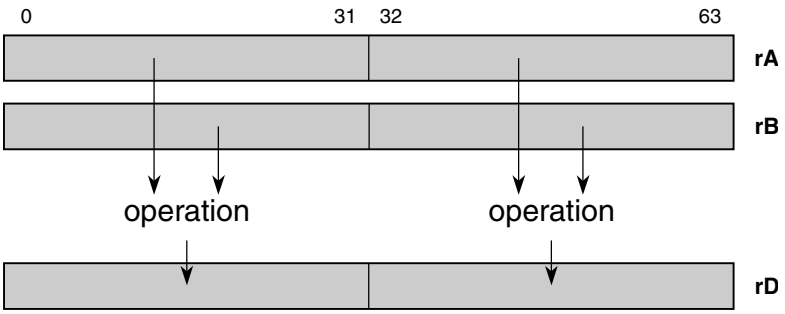
Signed fractions consist of 16, 32, or 64-bit binary fractional values in twos complement form that range from –1 to less than 1. Signed fractions in 1.31 or 1.63 format place the decimal point immediately to the right of the most significant bit. The largest representable value is $1 – 2^{-(n-1)}$ where n represents the number of bits in the value. The smallest representable value is –1. Certain computations that produce values larger than $1 – 2^{-(n-1)}$or smaller than –1 set OV or OVH in the SPEFSCR. Multiplication of two signed fractional values causes the result to be shifted left one bit to remove the resultant redundant sign bit in the product. In this case, a 0 bit is concatenated as the least significant bit of the shifted result.

Guarded fractional representations are also available in 33.31 format and in 17.47 format for a subset of operations, providing for significant guarding capabilities.

20.3.8 Computational Operations

SPE supports several different computational capabilities. Both modulo and saturation results can be performed. Modulo results produce truncation of the overflow bits in a calculation. Saturation provides a maximum or minimum representable value (for the data type) for overflow or underflow respectively. Instructions are provided for a wide range of computational capability. The operation types can be divided into several basic categories:

- Simple vector instructions. These instructions use the corresponding elements of the operands to produce a vector result that is placed in the destination register, the accumulator, or both.



- arithmetic, logical, shift, and rotate of vector elements
- Averaging, summation, rounding, min, max, sum of absolute differences, absolute differences, saturation, operations
- vector permutation, packing, unpacking, merge, swap, extraction, interleave, de-interleave operations

- Multiply and accumulate instructions. These instructions perform multiply operations, optionally add the result to the accumulator and place the result into the destination register and optionally into the accumulator. These instructions are composed of different multiply forms, data formats and data accumulate options.
- Dot product instructions. These instructions perform multiple multiply operations, optionally add the results to the accumulator, and place the result into the destination register and optionally into the Accumulator. These instructions are composed of different forms, data formats and data accumulate options.
- Load and store instructions. These instructions provide load and store capabilities for moving data to and from memory. A variety of forms are provided that position data for efficient computation.
- Compare instructions and set instructions.
- Miscellaneous instructions. These instructions perform miscellaneous functions such as field manipulation, bit-reversed and circular incrementing, count leading, and more.

20.3.8.1 Simple Vector Arithmetic Instructions

Simple vector arithmetic instructions are outlined in the following table.

Table 20-3. Simple Vector Arithmetic Instructions

Basic Operation	Variants	Description	ACC?
Absolute Value	evabsb, evabsh, evabs, evabsd	absolute value byte, half word, word, double word elements	—
	evabsbs, evabshs, evabss, evabsds	abs b, h, w, d with saturation	—
Absolute Difference	evabsdifsb, evabsdifsh, evabsdifsw, evabsdifub, evabsdifuh, evabsdifuw	absolute difference signed/unsigned byte, half word, word elements	—
Add	evaddb, evaddh, evaddw, evaddd	add byte, half word, word, double word elements	—
	evaddbss, evaddhss, evaddwss, evadddssevaddbus, evaddhus, evaddwus, evadddus	add byte, half word, word, double word elements with signed or unsigned saturation	—
	evaddhx, evaddhxss, evaddhxus	add exchanged half word elements with optional signed or unsigned saturation. The even and odd half word elements of operand rA are pairwise exchanged before adding	—
	evaddwx, evaddwxss, evaddwxus	add exchanged word elements with optional signed or unsigned saturation. The high and low word elements of operand rA are exchanged before adding	—
	evaddib, evaddih, evaddiw	add unsigned imm value UIMM to all elements	—
	evaddsmiaaw, evaddssiaaw, evaddumiaaw, evaddusiaaw	add word elements from rA and Accumulator using signed/unsigned modulo/saturation operations, results into rD and Accumulator	Y
	evaddsmiaa, evaddssiaa, evaddusiaa	add 64-bit value in rA and Accumulator with optional signed/unsigned saturation, result into rD and Accumulator	Y
AddSubf	evadd2subf2h, evadd2subf2hss	add for upper 2 half word elements, subf for lower 2 elements, with optional signed saturation.	—
	evaddsubfh, evaddsubfhss	add for even half word elements, subf for odd elements, with optional signed saturation.	—
	evaddsubfhx, evaddsubfhxss	The even and odd half word elements of operand rA are pairwise exchanged and then the resulting even elements are added and the odd elements are subtracted to/from elements in rB, with optional signed saturation.	—
	evaddsubfw, evaddsubfwss	The high word element of rA is added and the low word element of rA is subtracted to/from the corresponding element of rB, with optional signed saturation.	—
	evaddsubfwx, evaddsubfwxss	The word elements of rA are exchanged and then the resulting high word element is added and low word elements is subtracted to/from word elements of rB, with optional signed saturation.	—
Average	evavgbs, evavghs, evavgws, evavgds, evavgbsr, evavghsr, evavgwsr, evavgdsr evavgbu, evavghu, evavgwu, evavgdu evavgbur, evavghur, evavgwur, evavgdur	compute the average of corresponding elements in rA and rB, signed/unsigned with optional rounding	—

Table continues on the next page...

Table 20-3. Simple Vector Arithmetic Instructions (continued)

Basic Operation	Variants	Description	ACC?
Count Leading	evcntlsh, evcntlzh	count leading sign/zero bits in each half word	—
	evcntlsw, evcntlzw	count leading sign/zero bits in each word	
Divide	evdivws, evdivwu,	32 / 32 → 32 signed, unsigned integer	—
	evdivwsf, evdivwuf	32 / 32 → 32 signed, unsigned fractional	
	evdivs, evdivu	64 / 64 → 64, signed, unsigned	
Extend	evextsb, evextzb	the low byte of each word element in rA is sign/zero extended to a word and placed into rD	—
	evextsbh	the odd bytes of rA are sign extended to half words and placed into rD	—
	evextsh, *evextzh* (use evclrh)	the odd half word elements in rA are sign/zero extended to a word and placed into rD	—
	evextsw	the low word element in rA is sign extended to 64-bits and placed into rD	—
Maximum	evmaxbs, evmaxhs, evmaxws, evmaxds	maximum of elements in rA signed; b, h, w, d	—
	evmaxbu, evmaxhu, evmaxwu, evmaxdu	maximum of elements in rA unsigned; b, h, w, d	
	evmaxbpsh, evmaxbpuh	pairwise maximum of bytes in rA extended to half word, signed/unsigned	—
	evmaxhpsw, evmaxhpuw	pairwise maximum of half words in rA extended to word, signed/unsigned	—
	evmaxwpsd, evmaxwpud	pairwise maximum of words in rA extended to double word, signed/unsigned	—
Maximum Magnitude	evmaxmagws	pairwise maximum of magnitude values of signed words in rA	—
Minimum	evminbs, evminhs, evminws, evminds	minimum of elements in rA signed; b, h, w, d	—
	evminbu, evminhu, evminwu, evmindu	minimum of elements in rA unsigned; b, h, w, d	
	evminbpsh, evminbpuh	pairwise minimum of bytes in rA extended to half word, signed/unsigned	—
	evminhpsw, evminhpuw	pairwise minimum of half words in rA extended to word, signed/unsigned	—
	evminwpsd, evminwpud	pairwise minimum of words in rA extended to double word, signed/unsigned	—
Negate	evnegb, evnegh, evneg, evnegd	negate signed elements in rA; b,h,w,d	—
	evnegbs, evneghs, evnegs, evnegds	negate signed elements in rA with saturation; b,h,w,d	—
	evnegbo, evnegho, evnegwo	negate signed odd elements in rA; b,h,w	—
	evnegbos, evneghos, evnegwos	negate signed odd elements in rA with saturation; b,h,w	—
Round	evrndhb, evrndhbss, evrndhbus	The four half word elements of rA are rounded into 8-bits and placed into the even bytes of rD with optional signed or unsigned saturation	—

Table continues on the next page...

Table 20-3. Simple Vector Arithmetic Instructions (continued)

Basic Operation	Variants	Description	ACC?
	evrndhnb, evrndhnbss, evrndhnbus	The four half word elements of rA are rounded into 8-bits using round to nearest even rounding and placed into the even bytes of rD with optional signed or unsigned saturation	—
	evrndwh, evrndwhss, evrndwhus	The two word elements of rA are rounded into 16-bits and placed into the even half words of rD with optional signed or unsigned saturation	—
	evrndwnh, evrndwnhss, evrndwnhus	The two word elements of rA are rounded into 16-bits using round to nearest even rounding and placed into the even half words of rD with optional signed or unsigned saturation	—
	evrnddw, evrnddwss, evrnddwus	The double word element of rA is rounded into 32-bits and placed into the high word of rD with optional signed or unsigned saturation. The low word is cleared.	—
	evrndndw, evrndndwss, evrndndwus	The double word element of rA is rounded into 32-bits using round to nearest even rounding and placed into the high word of rD with optional signed or unsigned saturation. The low word is cleared.	—
Sum of Absolute Differences	evsad2sh, evsad2sha, evsad2shaaw	Sums of pairs of absolute differences of 2 signed half words, optionally loading the Accumulator, or accumulating with the Accumulator values	opt.
	evsad2uh, evsad2uha, evsad2uhaaw	Sums of pairs of absolute differences of 2 unsigned half words, optionally loading the Accumulator, or accumulating with the Accumulator values	opt.
	evsad4sb, evsad4sba, evsad4sbaaw	Sums of four absolute differences of 2 signed bytes, optionally loading the Accumulator, or accumulating with the Accumulator values	opt.
	evsad4ub, evsad4uba, evsad4ubaaw	Sums of four absolute differences of 2 unsigned bytes, optionally loading the Accumulator, or accumulating with the Accumulator values	opt.
	evsadsw, evsadswa, evsadswaa	Sum of pair of absolute differences of 2 signed words, optionally loading the Accumulator, or accumulating with the Accumulator value	opt.
	evsaduw, evsaduwa, evsaduwaa	Sum of pair of absolute differences of 2 unsigned words, optionally loading the Accumulator, or accumulating with the Accumulator value	opt.
Saturate	evsatsbub	Saturate signed byte to unsigned byte range	
	evsatubsb	Saturate unsigned byte to signed byte range	—
	evsatsdsw, evsatsduw	Saturate signed double word to signed or unsigned word range	—
	evsatuduw	Saturate unsigned double word to unsigned word range	—
	evsatshsb, evsatshub	Saturate signed half word to signed or unsigned byte range	—
	evsatshuh	Saturate signed half word to unsigned half word range	—
	evsatuhub	Saturate unsigned half word to unsigned byte range	—
	evsatuhsh	Saturate unsigned half word to signed half word range	—

Table continues on the next page...

Table 20-3. Simple Vector Arithmetic Instructions (continued)

Basic Operation	Variants	Description	ACC?
	evsatswgsdf	Saturate signed word guarded (17.47) to signed double word fractional (1.63) range	—
	evsatswsh, evsatswuh	Saturate signed word to signed or unsigned half word range	—
	evsatswuw	Saturate signed word to unsigned word range	—
	evsatuwuh	Saturate unsigned word to unsigned half word range	—
	evsatuwsw	Saturate unsigned word to signed word range	—
Subf	evsubfb, evsubfh, evsubfw, evsubfd	subtract byte, half word, word, double word elements	—
	evsubfbss, evsubfhss, evsubfwss, evsubfdss evsubfbus, evsubfhus, evsubfwus, evsubfdus	subtract byte, half word, word, double word elements with signed or unsigned saturation	—
	evsubfhx, evsubfhxss, evsubfhxus	subtract exchanged half word elements with optional signed or unsigned saturation. The even and odd half word elements of operand rA are pairwise exchanged before subtracting	—
	evsubfwx, evsubfwxss, evsubfwxus	subtract exchanged word elements with optional signed or unsigned saturation. The high and low word elements of operand rA are exchanged before subtracting	—
	evsubifb, evsubifh, evsubifw	subtract unsigned imm value UIMM from all elements	—
	evsubfsmiaaw, evsubfssiaaw, evsubfumiaaw, evsubfusiaaw	subtract word elements in rA from Accumulator using signed/unsigned modulo/saturation operations, results into rD and Accumulator	Y
	evsubfsmiaa, evsubfssiaa, evsubfusiaa	subtract 64-bit value in rA from Accumulator with optional signed/unsigned saturation, result into rD and Accumulator	Y
SubfAdd	evsubf2add2h, evsubf2add2hss	subtract for upper 2 half word elements, add for lower 2 elements, with optional signed saturation.	—
	evsubfaddh, evsubfaddhss	subtract for even half word elements, add for odd elements, with optional signed saturation.	—
	evsubfaddhx, evsubfaddhxss	The even and odd half word elements of operand rA are pairwise exchanged and then the resulting even elements are subtracted and the odd elements are added from/to elements in rB, with optional signed saturation.	—
	evsubfaddw, evsubfaddwss	The low word element of rA is added and the high word element of rA is subtracted to/from the corresponding element of rB, with optional signed saturation.	—
	evsubfaddwx, evsubfaddwxss	The word elements of rA are exchanged and then the resulting high word element is subtracted and low word element is added from/to word elements of rB, with optional signed saturation.	—
Summation/Diff	evsumws, evsumwu, evsumwsa, evsumwua	The signed or unsigned word elements of rA are summed together into 64 bits and placed into rD and optionally into the Accumulator	opt

Table continues on the next page...

Table 20-3. Simple Vector Arithmetic Instructions (continued)

Basic Operation	Variants	Description	ACC?
	evsumwsaa, evsumwuaa	The signed or unsigned word elements of rA are summed together along with the contents of the Accumulator and placed into rD and the Accumulator	Y
	evsum2hs, evsum2hu, evsum2hsa, evsum2hua	Signed or unsigned pairs of half word elements of rA are summed together into words and placed into rD and optionally into the Accumulator	opt
	evsum2hsaaw, evsum2huaaw	Signed or unsigned pairs of half word elements of rA are summed together along with the contents of the corresponding word element of the accumulator, into words, and placed into rD and the Accumulator	Y
	evsum4bs, evsum4bu, evsum4bsa, evsum4bua	Signed or unsigned quads of byte elements of rA are summed together into words and placed into rD and optionally into the Accumulator	opt
	evsum4bsaaw, evsum4buaaw	Signed or unsigned quads of byte elements of rA are summed together along with the contents of the corresponding word element of the accumulator, into words, and placed into rD and the Accumulator	Y
	evsum2his, evsum2hisa	Signed pairs of interleaved half word elements of rA are summed together into words and placed into rD and optionally into the Accumulator	opt
	evsum2hisaaw	Signed pairs of interleaved half word elements of rA are summed together along with the contents of the corresponding word element of the accumulator, into words, and placed into rD and the Accumulator	Y
	evdiff2his, evdiff2hisa	Signed pairs of interleaved half word elements of rA are subtracted to produce a pair of word differences and placed into rD and optionally into the Accumulator	opt
	evdiff2hisaaw	Signed pairs of interleaved half word elements of rA are subtracted to produce a pair of word differences and the differences are added together with the contents of the corresponding word element of the accumulator, into words, and placed into rD and the Accumulator	Y

20.3.8.1.1 Vector Logical Instructions

Vector logical instructions are outlined in the following table.

Table 20-4. Simple Vector Logical Instructions

Basic Operation	Variants	Description
AND	evand	AND word elements of rA and rB
ANDC	evandc	AND word elements of rA with complemented elements of rB

Table continues on the next page...

Table 20-4. Simple Vector Logical Instructions (continued)

Basic Operation	Variants	Description
Clear	evclrbe, evclrbo	Clear (zero) even bytes of source value in rA using immediate mask (mask). Clear (zero) odd bytes of source value in rA using immediate mask (mask).
	evclrh	Clear (zero) half word elements of source value in rA using immediate mask (mask).
NAND	evnand	NAND word elements of rA and rB
NOR	evnor	NOR word elements of rA and rB
OR	evor	OR word elements of rA and rB
ORC	evorc	OR word elements of rA with complemented elements of rB
XNOR	eveqv	XNOR word elements of rA and rB
XOR	evxor	XOR word elements of rA and rB

20.3.8.1.2 Vector Shift/Rotate Instructions

Vector shift and rotate instructions are outlined in the following table.

Table 20-5. Simple Vector Shift/Rotate Instructions

Basic Operation	Variants	Description
Shift Left	evslb, evslh, evslw, evslev slbi, evslhi, evslwi, evsli	Logical shift left of the 8,16, 32 or 64-bit element(s) in rA by the amount(s) in rB or by the immediate value UIMM
	evsloi	Logical shift left of the value in rA by 0 to 7 bytes
Logical Shift Right	evsrbu, evsrhu, evsrwu, evsru evsrbiu, evsrhiu, evsrwiu, evsriu	Logical shift right of the 8,16, 32 or 64-bit element(s) in rA by the amount(s) in rB or by the immediate value UIMM
	evsroiu	Logical shift right of the value in rA by 0 to 7 bytes
Arithmetic Shift Right	evsrbs, evsrhs, evsrws, evsrs evsrbis, evsrhis, evsrwis, evsris	Arithmetic shift right of the 8,16, 32 or 64-bit element(s) in rA by the amount(s) in rB or by the immediate value UIMM
	evsrois	Arithmetic shift right of the value in rA by 0 to 7 bytes
Rotate Left	evrlb, evrlh, evrlw evrlbi, evrlhi, evrlwi	Rotate left of the 8,16, or 32-bit elements in rA by the amount(s) in rB or by the immediate value UIMM

20.3.8.1.3 Vector Compare and Vector Set Instructions

Vector compare and set instructions are outlined in Table 20-6 and Table 20-7. The compare operations update the condition register with the results of the comparison.

Table 20-6. Vector Compare Instructions

Basic Comparison Operation	Variants	Description
=	evcmpeq, evcmpeqd	Compare word or double word elements for equal
>	evcmpgts, evcmpgtu, evcmpgtds, evcmpgtdu	Compare word or double word elements for greater than signed/ unsigned
<	evcmplts, evcmpltu, evcmpltds, evcmpltdu	Compare word or double word elements for less than signed/ unsigned

Table 20-7. Vector Set Instructions

Basic Comparison Operation	Variants	Description
=	evseteqb[.], evseteqh[.], evseteqw[.]	Compare byte, half word or word elements in rA and rB for equal. For each byte, half word or word, set destination byte half word or word to all '1's if condition met. Optionally set CR0 with comparison results.
>	evsetgtbs[.], evsetgtbu[.], evsetgths[.], evsetgthu[.], evsetgtws[.], evsetgtwu[.]	Compare byte, half word or word elements in rA and rB for greater than signed or unsigned. For each byte, half word or word, set destination byte half word or word to all '1's if condition met. Optionally set CR0 with comparison results.
<	evsetltbs[.], evsetltbu[.], evsetlths[.], evsetlthu[.], evsetltws[.], evsetltwu[.]	Compare byte, half word or word elements in rA and rB for greater than signed or unsigned. For each byte, half word or word, set destination byte half word or word to all '1's if condition met. Optionally set CR0 with comparison results.

20.3.8.1.4 Vector Select Instructions

Vector select instructions are outlined in the following table.

Table 20-8. Vector Select Instructions

Operation	Variants	Description
Select	evsel	Select word elements from rA or rB based on crS condition register field
Select Bits	evselbit	Select bit elements from rA or rB based on select bit vector in rD, place results into rD
	evselbitm0	Insert bit elements from rB into rD based on select bit mask in rA of 0, place results into rD
	evselbitm1	Insert bit elements from rB into rD based on select bit mask in rA of 1, place results into rD

20.3.8.1.5 Vector Data Arrangement Instructions

Vector data arrangement instructions are outlined in the following table. These instructions are used to rearrange fields of elements from one or more source vector registers.

Table 20-9. Vector Data Arrangement Instructions

Basic Operation	Variants	Description
De-interleave	evdlveb	de-interleave even bytes; the vector of even byte elements in rA and even byte elements in rB are concatenated and placed into rD
	evdlveob	de-interleave even/odd bytes; the vector of even byte elements in rA and odd byte elements in rB are concatenated and placed into rD
	evdlvob	de-interleave odd bytes; the vector of odd byte elements in rA and odd byte elements in rB are concatenated and placed into rD
	evdlvoeb	de-interleave odd/even bytes; the vector of odd byte elements in rA and even byte elements in rB are concatenated and placed into rD
	evdlveh	de-interleave even half words; the even half word elements in rA and even half word elements in rB are concatenated and placed into rD
	evdlveoh	de-interleave even/odd half words; the even half word elements in rA and odd half word elements in rB are concatenated and placed into rD
	evdlvoh	de-interleave odd half word; the odd half word elements in rA and odd half word elements in rB are concatenated and placed into rD
	evdlvoeh	de-interleave odd/even half words; the odd half word elements in rA and even half word elements in rB are concatenated and placed into rD
Interleave	evilveh	interleave even half words; the even half words from rA are placed into the even half words of rD and the even half words of rB are placed into the odd half words of rD
	evilveoh	interleave even/odd half words; the even half words from rA are placed into the even half words of rD and the odd half words of rB are placed into the odd half words of rD
	evilvhih	interleave high half words; the high half words from rA are placed into the even half words of rD and the high half words of rB are placed into the odd half words of rD
	evilvhiloh	interleave high/low half words; the high half words from rA are placed into the even half words of rD and the low half words of rB are placed into the odd half words of rD
	evilvloh	interleave low half words; the low half words from rA are placed into the even half words of rD and the low half words of rB are placed into the odd half words of rD
	evilvlohih	interleave low/high half words; the low half words from rA are placed into the even half words of rD and the high half words of rB are placed into the odd half words of rD
	evilvoeh	interleave odd/even half words; the odd half words from rA are placed into the even half words of rD and the even half words of rB are placed into the odd half words of rD

Table continues on the next page...

Table 20-9. Vector Data Arrangement Instructions (continued)

Basic Operation	Variants	Description
	evilvoh	interleave odd half words; the odd half words from rA are placed into the even half words of rD and the odd half words of rB are placed into the odd half words of rD
Merge	evmergehi	merge high words; the high word from rA is placed into the high word of rD and the high word of rB is placed into the low word of rD
	evmergehilo	merge high/low words; the high word from rA is placed into the high word of rD and the low word of rB is placed into the low word of rD
	evmergelo	merge low words; the low word from rA is placed into the high word of rD and the low word of rB is placed into the low word of rD
	evmergelohi	merge low/high words; the low word from rA is placed into the high word of rD and the high word of rB is placed into the low word of rD
Permute	evperm	Permute the byte elements in rB according to the permute vector in rA and place the results in rD
	evperm2	Permute the vector of concatenated byte elements from rA and rB according to the permute vector in rD and place the results in rD
	evperm3	Permute the vector of concatenated byte elements from rD and rB according to the permute vector in rA and place the results in rD
Pack	evpksdsws, evpkuduws	Pack the signed or unsigned double word elements from rA and rB into a pair of signed or unsigned word elements in rD, saturating if necessary
	evpksdswfrs	Pack the signed double word fractional elements from rA and rB into a pair of signed word elements in rD using the current rounding mode in SPEFSCR, saturating if necessary
	evpksdshefrs	Pack the signed 33.31 guarded fractional elements from rA and rB into a pair of signed half word even elements in rD using the current rounding mode in SPEFSCR, saturating if necessary
	evpkshsbs, evpkshubs, evpkuhubs	Pack the 8 signed or unsigned half word elements from rA and rB into 8 signed or unsigned byte elements in rD, saturating if necessary
	evpkswgshefrs	Pack the signed 17.47 guarded fractional elements from rA and rB into a pair of signed half word even elements in rD using the current rounding mode in SPEFSCR, saturating if necessary
	evpkswgswfrs	Pack the signed 17.47 guarded fractional elements from rA and rB into a pair of signed word elements in rD using the current rounding mode in SPEFSCR, saturating if necessary
	evpkswshs, evpkswuhs, evpkuwuhs	Pack the 4 signed or unsigned word elements from rA and rB into 4 signed or unsigned half word elements in rD, saturating if necessary
	evpkswshilvs	Pack the 4 signed word elements from rA and rB into 4 signed half word elements in rD with interleaving, saturating if necessary
	evpkswshfrs	Pack the 4 signed fractional word elements from rA and rB into 4 signed or fractional half word elements in rD using the current rounding mode in SPEFSCR, saturating if necessary
	evpkswshilvfrs	Pack the 4 signed fractional word elements from rA and rB into 4 signed or fractional half word elements in rD with interleaving using the current rounding mode in SPEFSCR, saturating if necessary
Splat	evsplatb	splat (replicate) the byte from rA selected by the immediate field into all byte elements of rD

Table continues on the next page...

Table 20-9. Vector Data Arrangement Instructions (continued)

Basic Operation	Variants	Description
	evsplath	splat (replicate) the half word from rA selected by the immediate field into all half word elements of rD
	evsplatfib, splatfih, splatfi	Splat the 5-bit SIMM field as a signed fraction into all byte, half word, or word elements of rD
	evsplatfiba, splatfiha, splatfia	Splat the 5-bit SIMM field as a signed fraction into all byte, half word, or word elements of rD and the accumulator
	evsplatfid	Splat the 5-bit SIMM field as a signed fraction into rD
	evsplatfida	Splat the 5-bit SIMM field as a signed fraction into rD and the accumulator
	evsplatfibo, splatfiho, splatfio	Splat the 5-bit SIMM field as a signed fraction into the odd byte, half word, or word elements of rD
	evsplatfiboa, splatfihoa, splatfioa	Splat the 5-bit SIMM field as a signed fraction into the odd byte, half word, or word elements of rD and the accumulator
	evsplatib, evsplatih, evsplati	Splat the 5-bit SIMM field as a signed integer into all byte, half word, or word elements of rD
	evsplatiba, evsplatiha, evsplatia	Splat the 5-bit SIMM field as a signed integer into all byte, half word, or word elements of rD and the accumulator
	evsplatid	Splat the 5-bit SIMM field as a signed integer into rD
	evsplatida	Splat the 5-bit SIMM field as a signed integer into rD and the accumulator
	evsplatibe, evsplatihe, evsplatie	Splat the 5-bit SIMM field as a signed integer into the even byte, half word, or word elements of rD
	evsplatibea, evsplatihea, evsplatiea	Splat the 5-bit SIMM field as a signed integer into the even byte, half word, or word elements of rD and the accumulator
Swap	evswapbhilo	bytes within the upper 2 byte pairs in rA are swapped, and concatenated with swapped bytes in the lower 2 byte pairs of rB.
	evswapblohi	bytes within the lower 2 byte pairs in rA are swapped, and concatenated with swapped bytes in the upper 2 byte pairs of rB.
	evswaphe	The even half words in rA are swapped, and merged with the odd half words of rB.
	evswaphhi	The upper 2 half words in rA are swapped, and concatenated with the lower 2 half words of rB.
	evswaphhilo	The upper 2 half words in rA are swapped, and concatenated with swapped lower 2 half words of rB.
	evswaphlo	The lower 2 half words in rA are swapped, and concatenated after the upper 2 half words of rB.
	evswaphlohi	The lower 2 half words in rA are swapped, and concatenated with swapped upper 2 half words of rB.
	evswapho	The odd half words in rA are swapped, and then merged with even half words of rB.
Unpack	evunpkhibsi, evunpkhibui, evunpklobsi, evunpklobui	Unpack the high or low 4 bytes of rA into signed or unsigned integer half words
	evunpkhihf, evunpkhihsi, evunkpkhihui, evunpklohf, evunpklohsi, evunkpklohui	Unpack the high or low 2 half words of rA into signed fractional, signed integer, or unsigned integer words

Table continues on the next page...

Table 20-9. Vector Data Arrangement Instructions (continued)

Basic Operation	Variants	Description
	evunpkhiwgsf, evunpklowgsf	Unpack the high or low word of rA into guarded signed fractional (17.47) format
Extract	evxtrb	A specified byte in rA is placed into a specified byte of rD, zeroing all other bytes of rD
	evxtrd	a double word is extracted from the concatenated byte elements of rA and rB and placed into rD
	evxtrh	A specified half word in rA is placed into a specified half word of rD, zeroing all other half words of rD
Insert	evinsb	A specified byte in rA is placed into a specified byte of rD; all other bytes of rD are unchanged.
	evinsh	A specified half word in rA is placed into a specified half word of rD; all other half words of rD are unchanged.

20.3.8.1.6 Multiply and accumulate instructions

These instructions perform multiply operations, optionally add the result to the accumulator and place the result into the destination register and optionally into the accumulator. These instructions are composed of different multiply forms, data formats and data accumulate options. The mnemonics for these instructions indicate their various characteristics. These are shown in the following table.

Table 20-10. Mnemonic Extensions for Multiply Accumulate Instructions

Extension	Meaning	Comments
Multiply Form		
he	half word even	16 × 16 → 32
heg	half word even guarded	16 × 16 → 32, 64-bit final accumulate result
ho	half word odd	16 × 16 → 32
hog	half word odd guarded	16 × 16 → 32, 64-bit final accumulate result
w	word	32 × 32 → 64
wehg	word even high guarded	32 × 32 → 64 in 17.47 format
wh	word high	32 × 32 → 32 (high order 32 bits of product)
wl	word low	32 × 32 → 32 (low order 32 bits of product)
wohg	word odd high guarded	32 × 32 ® 64 in 17.47 format
Data Format		
smf	signed modulo fractional	modulo, no saturation or overflow
smfr	signed modulo fractional round	modulo, no saturation or overflow, rounding based on current rounding mode
smi	signed modulo integer	modulo, no saturation or overflow
ssf	signed saturate fractional	saturation on product and accumulate

Table continues on the next page...

Table 20-10. Mnemonic Extensions for Multiply Accumulate Instructions (continued)

Extension	Meaning	Comments
ssfr	signed saturate fractional round	saturation on product and accumulate, rounding based on current rounding mode
ssi	signed saturate integer	saturation on accumulate
umi	unsigned modulo integer	modulo, no saturation or overflow
usi	unsigned saturate integer	saturation on accumulate
Accumulate Option		
a	place in Accumulator	result → rD, Accumulator
aa	add to Accumulator	Accumulator + result → rD, Accumulator
aaw	add to Accumulator as word elements	Accumulator[0:31] + result[0:31] → rD[0:31], Accumulator[0:31] Accumulator[32:63] + result[32:63] → rD[32:63], Accumulator[32:63]
aaw3	add to rD as word elements	rD[0:31] + result[0:31] → rD[0:31], Accumulator[0:31] rD[32:63] + result[32:63] → rD[32:63], Accumulator[32:63]
an	add negated to Accumulator	Accumulator – result → rD, Accumulator
anw	add negated to Accumulator as word elements	Accumulator[0:31] – result[0:31] → rD[0:31], Accumulator[0:31] Accumulator[32:63] – result[32:63] → rD[32:63], Accumulator[32:63]
anw3	add negated to rD as word elements	rD[0:31] – result[0:31] → rD[0:31], Accumulator[0:31] rD[32:63] – result[32:63] → rD[32:63], Accumulator[32:63]

20.3.8.1.7 Dot product instructions

These instructions perform multiple multiply operations, optionally add the results to the accumulator, and place the result into the destination register and optionally into the accumulator. These instructions are composed of different forms, data formats and data accumulate options. The mnemonics for these instructions indicate their various characteristics. These are shown in the following table.

Table 20-11. Mnemonic Extensions for Dot Product Instructions

Extension	Meaning	Comments
Multiply Form		
b	byte	8 × 8 + 8 × 8 + 8 × 8 + 8 × 8 → 32, high and low
4h	four half words	16 × 16 + 16 × 16 + 16 × 16 + 16 × 16 → 32
4hg	four half words guarded	16 × 16 + 16 × 16 + 16 × 16 + 16 × 16 → 64
h	half word	16 × 16 op 16 × 16 → 32, high and low
hih	high half words	16 × 16 op 16 × 16 → 32, high half words, used for complex mul
loh	low half words	16 × 16 op 16 × 16 → 32, low half words, used for complex mul

Table continues on the next page...

Table 20-11. Mnemonic Extensions for Dot Product Instructions (continued)

Extension	Meaning	Comments
4hxga	four half words exchanged guarded add	(16 × 16 + 16 × 16) + (16 × 16 + 16 × 16) → 64, even and odd rA half words changed
4hxgs	four half words exchanged guarded subtract	(16 × 16 - 16 × 16) + (16 × 16 - 16 × 16) → 64, even and odd rA half words changed
w	word	32 × 32 op 32 × 32 → 64
wg	word guarded	32 × 32 op 32 × 32 → 64 in 17.47 fractional format
wxga	word exchanged guarded add	32 × 32 + 32 × 32 → 64 in 17.47 fractional format, words in rA are changed
wxgs	word exchanged guarded subtract	32 × 32 - 32 × 32 → 64 in 17.47 fractional format, words in rA are changed
Operation		
a	add	addition of intermediate products
s	subtract	subtraction of intermediate products
c	complex	complex format arithmetic
Data Format		
smf	add signed modulo fractional	modulo, no saturation or overflow
smi	signed modulo integer	modulo, no saturation or overflow
ssf	signed saturate fractional	saturation on product and accumulate
ssfr	signed saturate fractional round	saturation on product and accumulate, rounding based on current rounding mode
ssi	signed saturate integer	saturation on product and accumulate
umi	unsigned modulo integer	modulo, no saturation or overflow
usi	unsigned saturate integer	saturation on product and accumulate
Accumulate Option		
a	place in Accumulator	result → rD, Accumulator
aa	add to Accumulator	Accumulator + result → rD, Accumulator
aa3	add to Accumulator, 3op	rD + result → rD, Accumulator
aaw	add to Accumulator as word elements	Accumulator[0:31] + result[0:31] → rD[0:31], Accumulator[0:31] Accumulator[32:63] + result[32:63] → rD[32:63], Accumulator[32:63]
aaw3	add to Accumulator as word elements, 3 op	rD[0:31] + result[0:31] → rD[0:31], Accumulator[0:31] rD[32:63] + result[32:63] → rD[32:63], Accumulator[32:63]

20.3.8.1.8 Miscellaneous Vector Instructions

Miscellaneous vector instructions are outlined in Table 20-4.

Table 20-12. Misc. Vector Instructions

Operation	Variants	Description
load vector for shift	evlvsl	load vector for shift left; place a vector of constant values for a vector permute for left shift
	evlvsr	load vector for shift right; place a vector of constant values for a vector permute for right shift
store Accumulator	evmar	move Accumulator to register rA
load Accumulator	evmra	move register rA to Accumulator
Bit reversed increment	brinc	Compute a bit-reversed increment for a memory offset for bit-reversed addressing
Circular Increment	circinc	Computes a modulo increment for supporting circular buffer index pointer modification

20.3.8.2 Load and Store Instructions

SPE provides a number of load and store instructions. These instructions provide load and store capabilities for moving data elements between the GPRs and memory. Data elements of 8, 16, 32, and 64 bits are supported. A variety of forms are provided that position data for efficient computation.

20.3.8.2.1 Addressing Modes—Non-Update forms

Base + index and base + scaled immediate addressing modes are provided. Base registers hold 64-bit pointer values (32-bit pointers in a 32-bit implementation of the architecture), while registers used as index values provide 32-bit index values. Scaled immediate values are unsigned and are scaled by the size of the access.

20.3.8.2.1.1 Base + Scaled Immediate Addressing—Non-Update Form

In the base + scaled immediate addressing mode, register rA holds a 32-bit pointer value or a value of zero (if rA = 0), and an immediate field in the instruction word provides a 5-bit unsigned immediate value which is zero-extended and scaled (shifted left) by 1, 2, or 3, depending on the size (half word, word, or double word) of the access. The sum of the value in rA and the zero-extended scaled immediate form the effective address:

```
if (rA = 0) then b ← 0
else b ← (rA32:63)
SCL ← {1,2,3} // half word, word, or double word
EA ← b + EXTZ(UIMM*SCL)
```

20.3.8.2.1.2 Base + Index Addressing

In the Base + Index addressing mode, register rA holds a 32-bit pointer value or a value of zero (if rA = 0), while register rB provides a 32-bit index. The sum forms the effective address:

```
if (rA = 0) then b ← 0
else b ← (rA32:63)
EA ← b + (rB)
```

20.3.8.2.2 Addressing Modes—Update forms

The base + scaled immediate addressing mode is also provided with an update form. As in the non-update form, base register rA holds 32-bit pointer values. For the update form of the base + scaled immediate addressing mode, the same effective address calculation is used as defined in Base + Scaled Immediate Addressing—Non-Update Form, and the calculated effective address is placed into rA by the instruction.

For the base + scaled immediate with update addressing mode, scaled immediate values of 0 are reserved for future definition and are treated as illegal. Instruction encodings with rA = 0 are also reserved for future definition and treated as illegal instructions.

20.3.8.2.3 Addressing Modes—Modify forms

The base + index addressing mode is also provided with a set of modify forms. In the modify forms, register rB holds 32-bit pointer values, while register rA is used to provide an index value as well as to provide specialized control information for performing a post-modification to the lower 32 bits of rA.

Modify forms are provided to allow for parallel address computations to occur, which are useful for sequential accessing of arrays, lists, circular buffers, and other complex data structures. Modify forms of load and store instructions cause a calculated update value to be placed in the lower portion of register rA. Support for specialized addressing modes are available when using base + index modify forms.

For the base + index modify forms, the modify calculation mode selection is based on a **mode** field in register rA (rA[0:3]). Modify forms modify the original value in rA based on an addressing calculation performed in parallel with the load or store instruction, which may or may not be the value of the effective address of the load or store instruction, depending on the actual calculation mode. This is in contrast to normal update forms of the Power Arch load and store instructions since the new value placed into rA need not correspond to the effective address of the load or store.

The following three modify calculation modes are currently defined and selected by the value in rA[0:3]:

- Linear addressing: mode = 0000
- Circular addressing: mode = 1000
- Bit-reversed addressing: mode = 1010

All other mode encodings are reserved, and either result in an unimplemented instruction exception, or a boundedly undefined result depending on the implementation.

Instruction encodings with rA = 0 are reserved for future definition and are treated as illegal instructions.

20.3.8.2.3.1 Linear Addressing Update Mode

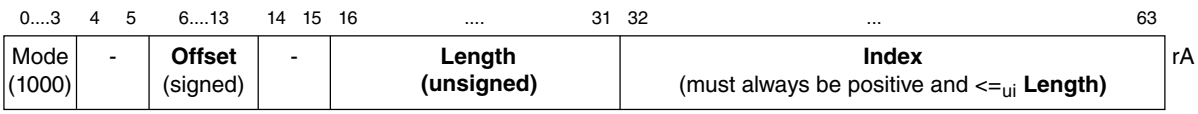
Linear addressing update calculation mode causes the sum of rA[32:63] and rB[32:63] to be placed into rA[32:63]:

```
if(mode=0000) then
   rA32:63 ← rA32:63 + rB32:63
```

20.3.8.2.3.2 Circular Addressing Modify Mode

Circular addressing modify mode is provided to support addressing of circular buffers. Circular addressing mode causes a circular increment to be performed on a portion of rA[32:63] (the circular buffer index portion of rA) after the EA calculation, using the offset and length specifiers in rA and the result is placed into rA[32–63]. rA[0–31] is left unchanged. rA[32–63] must be $\geq_{si}$ 0 and $\leq_{ui}$ Length, and the magnitude of Offset must be ≤ Length + 1, or the resulting value is boundedly undefined. rB must point to a double-word boundary in memory, and Length + 1 must be a multiple of eight bytes or an alignment error will be generated.

The following figureshows how rA is used in forming the update value for mode 1000 (circinc).



Listing 20-1. rA Used to Form Update Value for Mode 1000

```
Offset0:7 ← rA8:15;  //  signed byte offset, must be <= Length+1
Length0:15 ← rA16:31;  // unsigned buffer length-1 in bytes. Length is byte index of
                       // last byte in buffer.
                       // buffer must be aligned on a doubleword boundary, and be a
                       // multiple of 8 bytes, i.e. Length13:15 =3'b111.
Index0:31 ← rA32:63; // index into buffer, must be <=ui Length0:15, (so always >=si 0).

if ((Offset0 = 0) & ((EXTS32(Offset0:7) + Index0:31) >ui EXTZ32(Length0:15))) then
    rA32:63 ← Index0:31 + EXTS32(Offset0:7) - EXTZ32(Length0:15) - 1; // wrap at end

elseif (Offset0 = 1) & ((EXTS32(Offset0:7) + Index0:31) <si 0)) then
    rA32:63 ← Index0:31 + EXTS32(Offset0:7) + EXTZ32(Length0:15) + 1; // wrap at start
```

```
else rA32:63 ← Index0:31 + EXTS32(Offset0:7);
```

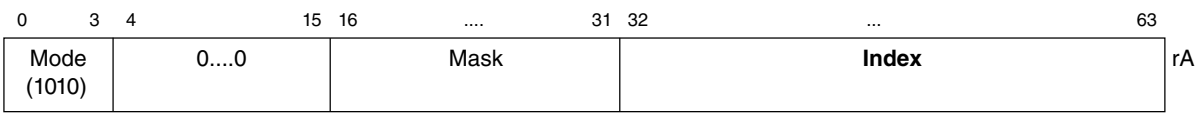
Note that **misalignment** may cause the operand fetched to span the virtual boundary between the last byte of the buffer at byte Buffer[Length] and the first byte of the Buffer at byte Buffer[0].

20.3.8.2.3.3 Bit-Reversed Addressing Modify Mode

Bit-reversed addressing modify calculation mode is provided to support addressing of buffers and arrays used in FFT calculations.

When using bit-reversed addressing modify mode, a bit-reversed increment is performed on rA[32:63] after the EA calculation, using a mask specifier in rA. The mask specifier is also used to indicate the bits of rA[32:63] which are updated.

Listing 20-2 on page 875 shows how rA is used in forming the update value for bit-reversed addressing update mode. Note that the computation is similar to the **brinc** instruction computation, but the mask is applied to updating only those bits of rA indicated by a '1' in the mask value, unlike in the **brinc** instruction, in which all low order bits of rD corresponding to the maximum mask size are updated.



Listing 20-2. rA Used to Form Update Value for Bit-Reversed Addressing Update Mode

```
Mask ← rA16:31
// mask value is log2(#points)1, zero extended, then left shifted log2(element size
// in bytes). e.g., a 16 point FFT on half words has a mask of 16'b0000000000011110

a ← rA48:63 // up to 64KB in a single FFT
d ← bitreverse(1 + bitreverse(a | ~Mask)))
rA32:63 ← rA32:47 || ((rA48:63 & ~Mask) |(d & Mask)) // different than brinc. allows main
pointer sharing to multiple buffers less than 64KB in size.
```

20.3.8.2.4 Vector Load and Store Instruction Summary

Vector load and store instructions are provided to load and store various size vectors of byte, half-word, word or double-word size. These instructions allow for endian-neutral code to be written. In addition, update forms of the non-indexed instructions are provided to allow for base register updates. Variations of the load instructions provide splat (replication) capability for placing a smaller vector element into multiple element positions in a vector register.

Vector load and store instructions are outlined in the following table.

Table 20-13. Vector Load and Store Instructions

Operation	Variants	Description
Load Byte	evlbbsplatb, evlbbsplatbu, evlbbsplatbx, evlbbsplatbmx	load byte and splat byte into 8 byte element positions
Load Double Word	evldb, evldbu, evldbx, evldbmx	load double word as byte elements
	evldd, evlddu, evlddx, evlddmx	load double word as double word
	evldh, evldhu, evldhx, evldhmx	load double word as half word elements
	evldw, evldwu, evldwx, evldwmx	load double word as word elements
Load Half Word	evlhhesplat, evlhhesplatu, evlhhesplatx, evlhhesplatmx	load half word into even half word elements, zeroing the odd half word s elements
	evlhhossplat, evlhhossplatu, evlhhossplatx, evlhhossplatmx	load half word into odd half word elements, sign-extending to word elements
	evlhhousplat, evlhhousplatu, evlhhousplatx, evlhhousplatmx	load half word into odd half word elements, zero-extending to word elements
	evlhhsplath, evlhhsplathu, evlhhsplathx, evlhhsplathmx	load half word into all half word elements
Load Word	evlwbe, evlwbeu, evlwbex, evlwbemx	load word as four byte elements into the four even byte elements, zeroing the odd byte elements
	evlwbos, evlwbosu, evlwbosx, evlwbosmx	load word as four byte elements into the four odd byte elements, sign-extending to half word elements
	evlwbou, evlwbouu, evlwboux, evlwboumx	load word as four byte elements into the four odd byte elements, zero-extending to half word elements
	evlwbsplatw, evlwbsplatwu, evlwbsplatwx, evlwbsplatwmx	load word as four byte elements into both word elements
	evlwhe, evlwheu, evlwhex, evlwhemx	load word as two half word elements into the two even half word elements, zeroing the odd half word elements
	evlwhos, evlwhosu, evlwhosx, evlwhosmx	load word as two half word elements into the two odd half word elements, sign-extending to word elements
	evlwhou, evlwhouu, evlwhoux, evlwhoumx	load word into the two odd half word elements, zero-extending to word elements
	evlwhsplat, evlwhsplatu, evlwhsplatx, evlwhsplatmx	load word as two half word elements, placing the first half word into both upper half word elements, second half word into both lower half word elements
	evlwhsplatw, evlwhsplatwu, evlwhsplatwx, evlwhsplatwmx	load word as two half word elements, into both word elements
	evlwwsplat, evlwhsplatu, evlwhsplatx, evlwhsplatmx	load word as word element, into both word elements
Store Double Word	evstdb, evstdbu, evstdbx, evstdbmx	store double word as byte elements
	evstdd, evstddu, evstddx, evstddmx	store double word as double word
	evstdh, evstdhu, evstdhx, evstdhmx	store double word as half word elements
	evstdw, evstdwu, evstdwx, evstdwmx	store double word as word elements
Store Half Word	evsthb, evsthbu, evsthbx, evsthbmx	store half word as byte elements
Store Word	evstwb, evstwbu, evstwbx, evstwbmx	store word as four byte elements
	evstwbe, evstwbeu, evstwbex, evstwbemx	store word from four even byte elements
	evstwbo, evstwbou, evstwbox, evstwbomx	store word from four odd byte elements
	evstwhe, evstwheu, evstwhex, evstwhemx	store word from two even half word elements

Table continues on the next page...

Table 20-13. Vector Load and Store Instructions (continued)

Operation	Variants	Description
	evstwho, evstwhou, evstwhox, evstwhomx	store word from two odd half word elements
	evstwwe, evstwweu, evstwwex, evstwwemx	store word from even word element
	evstwwo, evstwwou, evstwwox, evstwwomx	store word from odd word element

20.3.8.3 SPE Exceptions

The architecture defines the following SPE exceptions:

- SPE unavailable exception
- SPE vector alignment exception

Interrupt vector offset registers (IVOR) IVOR32 (SPE/embedded floating point unavailable interrupt) and IVOR5 (alignment interrupt), are used by the interrupt model. The SPR number for IVOR32 is 528, IVOR5 is defined by Power ISA. These registers are privileged.

20.3.8.3.1 SPE/Embedded Floating-point Unavailable Exception

The SPE/embedded floating-point unavailable exception is taken if MSR[SPE] is cleared and execution of a SPE instruction other than the **brinc** instruction is attempted. When the SPE/embedded floating-point unavailable exception occurs, the processor suppresses execution of the instruction causing the exception. The SRR0, SRR1, MSR, and ESR registers are modified as follows:

- SRR0 is set to the effective address of the instruction causing the exception.
- SRR1 is set to the contents of the MSR at the time of the exception.
- MSR[CE, ME, DE] are unchanged. All other bits are cleared.
- ESR[SPE] is set. All other ESR bits are cleared.

Instruction execution resumes at address IVPR[0–15]||IVOR32[16–27]||0b0000.

20.3.8.3.2 SPE Vector Alignment Exception

For z7260n3, the SPE vector alignment exception is taken if the effective address of any of the following instructions is not aligned to a 32-bit boundary: **evldd[u]**, **evlddx**, **evldw[u]**, **evldwx**, **evldh[u]**, **evldhx**, **evstdd[u]**, **evstddx**, **evstdw[u]**, **evstdwx**, **evstdh[u]**, and **evstdhx**. When an SPE vector alignment exception occurs, the processor suppresses the execution of the instruction causing the alignment exception and takes an alignment interrupt.

SRR0, SRR1, MSR, ESR, and DEAR are modified as follows:

- SRR0 is set to the effective address of the instruction causing the alignment exception.
- SRR1 is set to the contents of the MSR at the time of the exception.
- MSR[CE, ME, DE] are unchanged. All other bits are cleared.
- ESR[SPE] (bit 24) is set. ESR[ST] is set only if the instruction causing the exception is a store and is cleared for a load. All other bits are cleared.
- DEAR is updated with the effective address of a byte of the load or store.

Instruction execution resumes at address IVPR[0–15]||IVOR5[16–27]||0b0000.

20.3.8.4 Exception Priorities

The following list shows the priority order in which exceptions are taken:

1. SPE Unavailable exception
2. SPE Vector Alignment exception

An SPE vector alignment exception is taken if an SPE double-word vector load or store access is attempted with an address which is not 32-bit aligned.

20.3.9 SPE Instruction Timing

Instruction timing in number of processor clock cycles for SPE instructions are shown in the following tables. Pipelined instructions are shown with cycles of total latency and throughput cycles. Divide instructions are not pipelined and block other instructions from executing during divide execution.

20.3.9.1 SPE Simple Vector Arithmetic Instructions Timing

The following table shows instruction timing for SPE integer simple instructions. The table is sorted by opcode. These instructions are issued as a pair of operations.

Table 20-14. Simple Vector Arithmetic Instruction Timing

Basic Operation	Instruction	Latency	Throughput
Absolute Value	evabsb, evabsh, evabs, evabsd	1	1
	evabsbs, evabshs, evabss, evabsds	1	1
Absolute Difference	evabsdifsb, evabsdifsh, evabsdifsw, evabsdifub, evabsdifuh, evabsdifuw	1	1
Add	evaddb, evaddh, evaddw, evaddd	1	1
	evaddbss, evaddhss, evaddwss, evadddss evaddbus, evaddhus, evaddwus, evadddus	1	1
	evaddhx, evaddhxss, evaddhxus	1	1
	evaddwx, evaddwxss, evaddwxus	1	1
	evaddib, evaddih, evaddiw	1	1
	evaddsmiaaw, evaddssiaaw, evaddumiaaw, evaddusiaaw	1	1
	evaddsmiaa, evaddssiaa, evaddusiaa	1	1
AddSubf	evadd2subf2h, evadd2subf2hss	1	1
	evaddsubfh, evaddsubfhss	1	1
	evaddsubfhx, evaddsubfhxss	1	1
	evaddsubfw, evaddsubfwss	1	1
	evaddsubfwx, evaddsubfwxss	1	1
Average	evavgbs, evavghs, evavgws, evavgds, evavgbsr, evavghsr, evavgwsr, evavgdsr evavgbu, evavghu, evavgwu, evavgdu evavgbur, evavghur, evavgwur, evavgdur	1	1
Count Leading	evcntlsh, evcntlzh evcntlsw, evcntlzw	1	1
Extend	evextsb, evextzb	1	1
	evextsbh	1	1
	evextsh, *evextzh* (use evclrh)	1	1
	evextsw	1	1

20.3.9.2 SPE Complex Integer Instruction Timing

The following table shows instruction timing for SPE complex integer instructions. For the divide instructions, the number of stall cycles is (latency) for following instructions.

Table 20-15. SPE Complex Integer Instruction Timing

Operation	Instruction	Latency	Throughput
Divide	evdivws, evdivwu, evdivwsf, evdivwuf evdivs, evdivu	12-32	12-32[1]

1. Timing is data dependent

20.3.9.3 SPE Vector Logical Instruction Timing

The following table shows instruction timing for SPE simple vector logical instructions.

Table 20-16. SPE Vector Logical Instruction Timing

Basic Operation	Instruction	Latency	Throughput
AND	evand	1	1
ANDC	evandc	1	1
Clear	evclrbe, evclrbo	1	1
	evclrh	1	1
NAND	evnand	1	1
NOR	evnor	1	1
OR	evor	1	1
ORC	evorc	1	1
XNOR	eveqv	1	1
XOR	evxor	1	1

20.3.9.4 SPE Vector Shift/Rotate Instruction Timing

Instruction timing for SPE vector shift/rotate instructions is shown in the following table.

Table 20-17. SPE Vector Shift/Rotate Instruction Timing

Basic Operation	Instruction	Latency	Throughput
Shift Left	evslb, evslh, evslw, evsl evslbi, evslhi, evslwi, evsli	1	1
	evsloi	1	1
Logical Shift Right	evsrbu, evsrhu, evsrwu, evsru evsrbiu, evsrhiu, evsrwiu, evsriu	1	1
	evsroiu	1	1
Arithmetic Shift Right	evsrbs, evsrhs, evsrws, evsrs evsrbis, evsrhis, evsrwis, evsris	1	1
	evsrois	1	1
Rotate Left	evrlb, evrlh, evrlw evrlbi, evrlhi, evrlwi	1	1

20.3.9.5 SPE Vector Compare and Vector Set Instruction Timing

Instruction timing for SPE vector compare and set instructions is shown in Table 20-18 and Table 20-19. Table 20-18 shows the SPE vector compare instruction timing.

Table 20-18. SPE Vector Compare Instruction Timing

Basic Comparison Operation	Instruction	Latency	Throughput
=	evcmpeq, evcmpeqd	1	1
>	evcmpgts, evcmpgtu, evcmpgtds, evcmpgtdu	1	1
<	evcmplts, evcmpltu, evcmpltds, evcmpltdu	1	1

Table 20-19 shows the SPE vector set instruction timing.

Table 20-19. SPE Vector Set Instruction Timing

Comparison Operation	Instruction	Latency	Throughput
=	evseteqb[.], evseteqh[.], evseteqw[.]	1	1
>	evsetgtbs[.], evsetgtbu[.], evsetgths[.], evsetgthu[.], evsetgtws[.], evsetgtwu[.]	1	1
<	evsetltbs[.], evsetltbu[.], evsetlths[.], evsetlthu[.], evsetltws[.], evsetltwu[.]	1	1

20.3.9.6 SPE Vector Select Instruction Timing

The following table shows instruction timing for SPE vector select instructions.

Table 20-20. SPE Vector Select Instruction Timing

Operation	Instruction	Latency	Throughput
Select	evsel	1	1
Select Bits	evselbit	1	1
	evselbitm0	1	1
	evselbitm1	1	1

20.3.9.7 SPE Vector Data Arrangement Instruction Timing

The following table shows the instruction timing for SPE vector data arrangement instructions.

Table 20-21. SPE Vector Data Arrangement Instruction Timing

Operation	Instruction	Latency	Throughput
De-interleave	evdlveb	1	1

20.3.9.8 SPE Multiply and Multiply/Accumulate Instruction Timing

The following table shows instruction timing for SPE multiply and multiply/accumulate instructions.

Table 20-22. SPE Multiply and Multiply/Accumulate Instruction Timing

Instruction	Latency	Throughput
all evm{b,h,w} instructions	4	1

20.3.9.9 SPE Dot Product Instruction Timing

The following table shows instruction timing for SPE dot product instructions.

Table 20-23. SPE Dot Product Instruction Timing

Instruction	Latency	Throughput
all evdotp instructions	4	1

20.3.9.10 SPE Misc. Vector Instruction Timing

The following table shows instruction timing for SPE miscellaneous instructions.

Table 20-24. SPE Misc. Vector Instruction Timing

Operation	Instruction	Latency	Throughput
load vector for shift	evlvsl	1	1
	evlvsr	1	1
store Accumulator	evmar	1	1
load Accumulator	evmra	1	1
Bit reversed increment	brinc	1	1

20.3.9.11 SPE Load and Store Instruction Timing

The following table shows instruction timing for SPE load and store instructions.

Table 20-25. SPE Load and Store Instruction Timing

Instruction	Latency	Throughput
all ev loads	3	1
all ev stores	3	1

Chapter 21
Crossbar Switch (AXBS)

21.1 Chip-specific AXBS information

21.1.1 Crossbar switch configuration

NOTE

For logical bus master assignments refer SMPU_x Logical bus Master Assignments.

This device contains three crossbar switch modules - Data Crossbar (AXBS_0), Instruction Crossbar (AXBS_1) and PRAM XBAR. The following figure illustrates that AXBS_0 and AXBS_1 are connected via a cross-lake, which is composed of intelligent bridging bus gaskets. These bus gaskets handle the traffic that crosses between the crossbars and do not require any interaction with the user. This dual-crossbar architecture allows all masters to access all slaves.

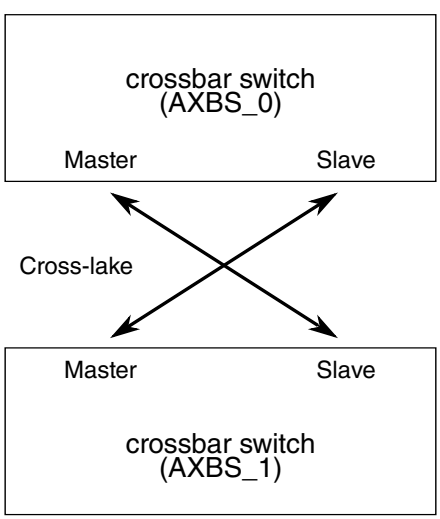

Figure 21-1. Crossbar switch configuration

For details about PRAM XBAR, please refer PRAM XBAR Overview section.

21.1.1.1 AXBS_0 configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the chapter for that module.

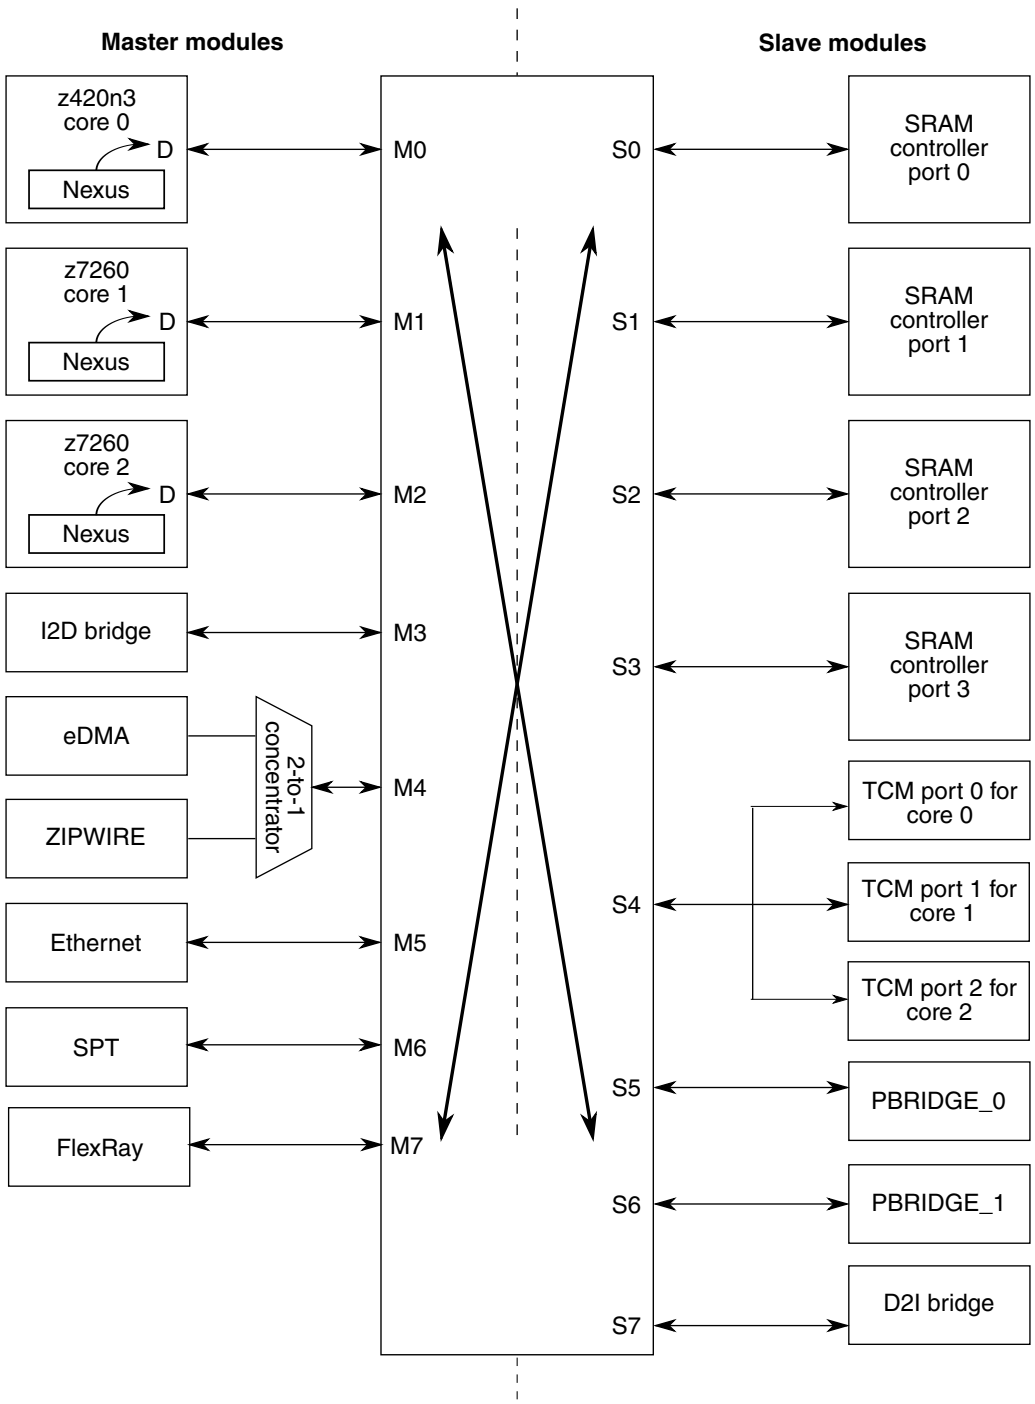

Figure 21-2. AXBS_0 Configuration

NOTE

Z4 TCM should not be accessed by any master while it is in STOP mode. No TCM should be accessed by any master if the corresponding core is still being held in reset.

21.1.1.1.1 AXBS_0 master assignments

This device contains eight masters connected to AXBS_0. The master assignments are shown in the table below:

Table 21-1. AXBS_0 master assignments

Master module	Physical master port number
Core0 data bus and Core0 Nexus	0
Core1 data bus and Core1 Nexus	1
Core2 data bus and Core2 Nexus	2
Instruction-to-Data (I2D) bus bridge	3
eDMA, Zipwire (merged via port concentrator)	4
Ethernet	5
Signal Processing Toolbox (SPT)	6
FlexRay	7

21.1.1.1.2 AXBS_0 slave assignments

This device contains eight slaves connected to AXBS_0. The slave assignments are shown in the table below:

Table 21-2. AXBS_0 slave assignments

Slave Module	Physical slave number
SRAM controller port for accesses from Core0/ CSE/ eDMA/ Zipwire/ Ethernet/FlexRay	0
SRAM controller port 1 for accesses from Core1	1
SRAM controller port 2 for accesses from Core2	2
SRAM controller port 3 for accesses from SPT [1]	3
TCM backdoor ports	4
PBRIDGE_0	5
PBRIDGE_1	6
Data-to-Instruction (D2I) bus bridge	7

1. SPT performance is optimized with a dedicated AXBS slave port. Since it is a direct master to slave port, arbitration and AXBS configuration of that slave will have no effect.

21.1.1.1.3 AXBS_0 High Priority Elevation

This device contains masters connected to AXBS_0. The master assignments are shown in the table below:

Table 21-3. AXBS_0 High Priority Elevation Feature

Master Module	Physical Master Port Number	High Priority Elevation	Additional Programming
Core0 data bus	0	x	In addition to setting HPE0 to 1 in AXBS_CRSn register for the applicable slave , set to 1 either or both of these fields in the special-purpose HID1 register for Core0: • Elevate External Exceptions (EEE), bit 22 • Elevate Critical Exceptions (ECE), bit 23
Core1 data bus	1	x	In addition to setting HPE1 to 1 in AXBS_CRSn register for the applicable slave , set to 1 either or both of these fields in the special-purpose HID1 register for Core1: • Elevate External Exceptions (EEE), bit 22 • Elevate Critical Exceptions (ECE), bit 23
Core2 data bus	2	x	In addition to setting HPE2 to 1 in AXBS_CRSn register for the applicable slave , set to 1 either or both of these fields in the special-purpose HID1 register for Core2: • Elevate External Exceptions (EEE), bit 22 • Elevate Critical Exceptions (ECE), bit 23
Instruction-to-Data (I2D) bus bridge	3	x	High priority access will pass from Instruction Crossbar to Data crossbar.
eDMA/Zipwire	4	x[1]	For eDMA , in addition to setting HPE4 bit to 1 , BWC field in the eDMA_TCDn_CSR also needs to be configured for 1.
Ethernet	5	-	-

Table continues on the next page...

Table 21-3. AXBS_0 High Priority Elevation Feature (continued)

Signal Processing Toolbox (SPT)	6	-	-
FlexRay	7	x	No additional programming needed other than setting HPE7 bit for the applicable slave, to 1.

1. Zipwire doesn't support High Priority Elevation feature

21.1.1.1.4 AXBS_0 register reset values

All reset values for the AXBS_0 registers that are device specific are shown in the following table.

Table 21-4. AXBS_0 reset values

Register	Reset value
AXBS_0_PRSn	0x76543210
AXBS_0_CRSn	0x00100010

21.1.1.2 AXBS_1 configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the chapter for that module.

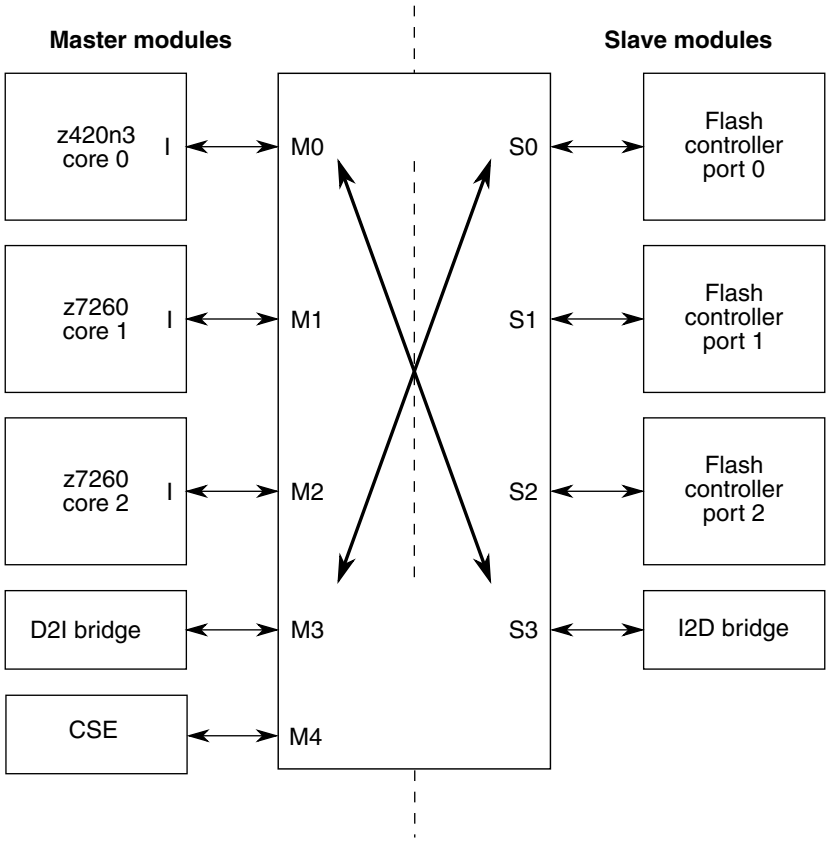

Figure 21-3. AXBS_1 Configuration

21.1.1.2.1 AXBS_1 master assignments

This device contains five masters connected to AXBS_1. The master assignments are shown in the table below:

NOTE

Slave ports 4-7 for AXBS_1 are not present, therefore AXBS_1_PRS4-7 registers and AXBS_1_CRS4-7 registers are 'reserved'.

Table 21-5. AXBS_1 master assignments

Master module	Physical master port number
Core0 instruction bus	0
Core1 instruction bus	1
Core2 instruction bus	2
Data-to-Instruction bus bridge.	3
CSE	4

21.1.1.2.2 AXBS_1 slave assignments

This device contains four slaves connected to AXBS_1. The slave assignments are shown in the table below:

Table 21-6. AXBS_1 slave assignments

Slave Module	Physical slave number
Flash controller port 0 for accesses from Core0 and all data-side masters (DMA, FlexRay, SPT, ENET)	0
Flash controller port 1 for accesses from Core1	1
Flash controller port 2 for accesses from Core2 and CSE	2
Instruction-to-Data (I2D) bus bridge	3

21.1.1.2.3 AXBS_1 High Priority Elevation

This device contains masters connected to AXBS_1. The master assignments are shown in the table below:

Table 21-7. AXBS_1 High Priority Elevation Feature

Master Module	Physical Master Port Number	High Priority Elevation	Additional Programming
Core0 instruction bus	0	x	In addition to setting HPE0 to 1 in AXBS_CRSn register for the applicable slave , set to 1 either or both of these fields in the special-purpose HID1 register for Core0: • Elevate External Exceptions (EEE), bit 22 • Elevate Critical Exceptions (ECE), bit 23
Core1 instruction bus	1	x	In addition to setting HPE1 to 1 in AXBS_CRSn register for the applicable slave , set to 1 either or both of these fields in the special-purpose HID1 register for Core1: • Elevate External Exceptions (EEE), bit 22 • Elevate Critical Exceptions (ECE), bit 23
Core2 instruction bus	2	x	In addition to setting HPE2 to 1 in AXBS_CRSn register for the applicable slave , set to 1

Table continues on the next page...

Table 21-7. AXBS_1 High Priority Elevation Feature (continued)

			either or both of these fields in the special-purpose HID1 register for Core2: • Elevate External Exceptions (EEE), bit 22 • Elevate Critical Exceptions (ECE), bit 23
Data-to-Instruction (D2I) bus bridge	3	x	High priority access will pass from Data crossbar to Instruction Crossbar.
CSE	4	-	-

21.1.1.2.4 AXBS_1 register reset values

All reset values for the AXBS_1 registers that are device specific are shown in the following table.

Table 21-8. AXBS_1 reset values

Register	Reset value
AXBS_1_PRSn	0x00043210
AXBS_1_CRSn	0x000F0010

21.2 Introduction

The information found here provides information on the layout, configuration, and programming of the crossbar switch.

The crossbar switch connects bus masters and bus slaves using a crossbar switch structure. This structure allows all bus masters to access different bus slaves simultaneously, while providing arbitration among the bus masters when they access the same slave. A variety of bus arbitration methods and attributes may be programmed on a slave-by-slave basis.

21.2.1 Features

The crossbar switch includes these features:

- Symmetric crossbar bus switch implementation

  - Allows concurrent accesses from different masters to different slaves
  - Slave arbitration attributes configured on a slave-by-slave basis
- Up to single-clock 64-bit transfer
- Support for burst transfers of up to 16 beats of data
- Low-Power Park mode support
- Dynamic master priority elevation

21.3 Memory Map / Register Definition

Each slave port of the crossbar switch contains configuration registers. Read- and write-transfers require two bus clock cycles. The registers can be read from and written to only in supervisor mode. Additionally, these registers can be read from or written to only by 32-bit accesses.

A bus error response is returned if an unimplemented location is accessed within the crossbar switch.

The CRS*n* and PRS*n* registers can be programmed to be read-only to prevent changes to their configuration. After being read-only protected, future writes to them will terminate with an error.

NOTE

This section shows the registers for all eight master and slave ports. If a master or slave is not used on this particular device, then unexpected results occur when writing to its registers. See the chip configuration details for the exact master/slave assignments for your device.

All references to the crossbar switch registers are based on the physical port connections.

AXBS memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Priority Registers Slave (AXBS_PRS0)	32	R/W	See section	21.3.1/896

410	Control Register (AXBS_CRS4)	32	R/W	See section	21.3.2/899
500	Priority Registers Slave (AXBS_PRS5)	32	R/W	See section	21.3.1/896
510	Control Register (AXBS_CRS5)	32	R/W	See section	21.3.2/899
600	Priority Registers Slave (AXBS_PRS6)	32	R/W	See section	21.3.1/896
610	Control Register (AXBS_CRS6)	32	R/W	See section	21.3.2/899
700	Priority Registers Slave (AXBS_PRS7)	32	R/W	See section	21.3.1/896
710	Control Register (AXBS_CRS7)	32	R/W	See section	21.3.2/899

21.3.1 Priority Registers Slave (AXBS_PRS*n*)

The priority registers (PRSn) set the priority of each master port on a per slave port basis and reside in each slave port. The priority register can be accessed only with 32-bit accesses. After the CRSn[RO] bit is set, the PRSn register can only be read; attempts to write to it have no effect on PRSn and result in a bus-error response to the master initiating the write.

Two available masters must not be programmed with the same priority level. Attempts to program two or more masters with the same priority level result in a bus-error response and the PRSn is not updated.

NOTE

Valid values for the M*n* priority fields depend on which masters are available on the chip. This information can be found in the chip-specific information for the crossbar.

- If the chip contains fewer than five masters, only two bits are valid.
- If five or more masters are present, all three bits of the priority field are used.

NOTE

Field	Description
	101 This master has level 6 priority when accessing the slave port. 110 This master has level 7 priority when accessing the slave port. 111 This master has level 8, or lowest, priority when accessing the slave port.
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 M0	Master 0 Priority. Sets the arbitration priority for this port on the associated slave port. 000 This master has level 1, or highest, priority when accessing the slave port. 001 This master has level 2 priority when accessing the slave port. 010 This master has level 3 priority when accessing the slave port. 011 This master has level 4 priority when accessing the slave port. 100 This master has level 5 priority when accessing the slave port. 101 This master has level 6 priority when accessing the slave port. 110 This master has level 7 priority when accessing the slave port. 111 This master has level 8, or lowest, priority when accessing the slave port.

21.3.2 Control Register (AXBS_CRS*n*)

These registers control several features of each slave port and must be accessed using 32-bit accesses. After CRSn[RO] is set, the PRSn can only be read; attempts to write to it have no effect and result in an error response.

NOTE

See the chip-specific crossbar information for the reset value of this register.

Not all HPE*n* fields may be active. See the chip-specific crossbar information for which masters support high priority elevation. Setting a field corresponding to a master that does not support high-priority elevation has no effect.

Address: 0h base + 10h offset + (256d × i), where i=0d to 7d

Field	Description
	0 Priority elevation for master 1 is disabled on this slave port 1 Priority elevation for master 1 is enabled on this slave port
15 HPE0	On this slave port, enable priority elevation for master 0. If enabled, the master is able to elevate its priority to the highest. 0 Priority elevation for master 0 is disabled on this slave port 1 Priority elevation for master 0 is enabled on this slave port
16–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–23 ARB	Arbitration Mode Selects the arbitration policy for the slave port. 00 Fixed priority 01 Round-robin (rotating) priority 10 Reserved 11 Reserved
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–27 PCTL	Parking Control Determines the slave port's parking control. The low-power park feature results in an overall power savings if the slave port is not saturated; however, this forces an extra latency clock when any master tries to access the slave port while not in use because it is not parked on any master. 00 When no master makes a request, the arbiter parks the slave port on the master port defined by the PARK bit field 01 When no master makes a request, the arbiter parks the slave port on the last master to be in control of the slave port 10 Low-power park. When no master makes a request, the slave port is not parked on a master and the arbiter drives all outputs to a constant safe state 11 Reserved
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 PARK	Park Determines which master port the current slave port parks on when no masters are actively making requests and the PCTL bits are cleared. **NOTE:** Select only master ports that are present on the chip. Otherwise, undefined behavior might occur. 000 Park on master port M0 001 Park on master port M1 010 Park on master port M2 011 Park on master port M3 100 Park on master port M4 101 Park on master port M5 110 Park on master port M6 111 Park on master port M7

21.4 Functional Description

21.4.1 General operation

When a master accesses the crossbar switch, the access is immediately taken. If the targeted slave port of the access is available, then the access is immediately presented on the slave port. Single-clock or zero-wait-state accesses are possible through the crossbar. If the targeted slave port of the access is busy or parked on a different master port, the requesting master simply sees wait states inserted until the targeted slave port can service the master's request. The latency in servicing the request depends on each master's priority level and the responding slave's access time.

Because the crossbar switch appears to be just another slave to the master device, the master device has no knowledge of whether it actually owns the slave port it is targeting. While the master does not have control of the slave port it is targeting, it simply waits.

After the master has control of the slave port it is targeting, the master remains in control of the slave port until it relinquishes the slave port by running an IDLE cycle or by targeting a different slave port for its next access.

The master can also lose control of the slave port if another higher-priority master makes a request to the slave port. However, if the master is running a fixed-length burst transfer it retains control of the slave port until that transfer completes.

The crossbar terminates all master IDLE transfers, as opposed to allowing the termination to come from one of the slave buses. Additionally, when no master is requesting access to a slave port, the crossbar drives IDLE transfers onto the slave bus, even though a default master may be granted access to the slave port.

When a slave bus is being idled by the crossbar, it can park the slave port on the master port indicated by CRS*n*[PARK] . This is done to save the initial clock of arbitration delay that otherwise would be seen if the same master had to arbitrate to gain control of the slave port. The slave port can also be put into Low Power Park mode to save power, by using CRS*n*[PCTL].

21.4.2 Register coherency

The operation of the crossbar is affected as soon as a register is written. The values of the registers do not track with slave-port-related master accesses, but instead track only with slave accesses.

21.4.3 Arbitration

The crossbar switch supports two arbitration algorithms:

- Fixed priority
- Round-robin

The arbitration scheme is independently programmable for each slave port.

21.4.3.1 Fixed-priority operation

When operating in fixed-priority mode, each master is assigned a unique priority level in the priority registers (PRS*n*). If two masters request access to the same slave port, the master with the highest priority in the selected priority register gains control over the slave port.

NOTE

In this arbitration mode, a higher-priority master can monopolize a slave port, preventing accesses from any lower-priority master to the port.

When a master makes a request to a slave port, the slave port checks whether the new requesting master's priority level is higher than that of the master that currently has control over the slave port, unless the slave port is in a parked state. The slave port performs an arbitration check at every clock edge to ensure that the proper master, if any, has control of the slave port.

The following table describes possible scenarios based on the requesting master port:

Table 21-9. How the Crossbar Switch grants control of a slave port to a master

When	Then the Crossbar Switch grants control to the requesting master
Both of the following are true: • The current master is not running a transfer. • The new requesting master's priority level is higher than that of the current master.	At the next clock edge
Both of the following are true: • The current master is running a fixed length burst transfer or a locked transfer. • The requesting master's priority level is higher than that of the current master.	At the end of the burst transfer or locked transfer
The requesting master's priority level is lower than the current master.	At the conclusion of one of the following cycles: • An IDLE cycle • A non-IDLE cycle to a location other than the current slave port

21.4.3.2 Round-robin priority operation

When operating in round-robin mode, each master is assigned a relative priority based on the master port number. This relative priority is compared to the master port number (ID) of the last master to perform a transfer on the slave bus. The highest priority requesting master becomes owner of the slave bus at the next transfer boundary, accounting for locked and fixed-length burst transfers. Priority is based on how far ahead the ID of the requesting master is to the ID of the last master.

After granted access to a slave port, a master may perform as many transfers as desired to that port until another master makes a request to the same slave port. The next master in line is granted access to the slave port at the next transfer boundary, or possibly on the next clock cycle if the current master has no pending access request.

As an example of arbitration in round-robin mode, assume the crossbar is implemented with master ports 0, 1, 4, and 5. If the last master of the slave port was master 1, and master 0, 4, and 5 make simultaneous requests, they are serviced in the order: 4 then 5 then 0.

Parking may continue to be used in a round-robin mode, but does not affect the round-robin pointer unless the parked master actually performs a transfer. Handoff occurs to the next master in line after one cycle of arbitration. If the slave port is put into low-power park mode, the round-robin pointer is reset to point at master port 0, giving it the highest priority.

21.4.3.3 Priority assignment

Each master port must be assigned a unique 3-bit priority level. If an attempt is made to program multiple master ports with the same priority level within the priority registers (PRS*n*), the crossbar switch responds with a bus error and the registers are not updated.

21.5 Initialization/application information

No initialization is required for the crossbar switch.

Hardware reset ensures that all the register bits used by the crossbar switch are properly initialized to a valid state. However, settings and priorities may be programmed to achieve maximum system performance.

NOTE

- During configuration of the crossbar switch, all other masters must be idle.
- To prevent reconfiguration of the crossbar switch, write 1 to CRS*n*[RO].

Chapter 22
Crossbar Integrity Checker (XBIC)

22.1 Chip-specific XBIC information

There are 5 instances of XBIC in this chip.

Table 22-1. XBIC configuration

Instance	Available on cross-bar	Master/Slave assignments
XBIC_1	AXBS_1 (instruction)	See AXBS_1 configuration
XBIC_0	AXBS_0 (data)	See AXBS_0 configuration
XBIC_2	PRAM AXBS	See PRAM_XBAR master assignments See PRAM_XBAR slave assignments
XBIC_3	DMA/SIPI splitter AXBS	Master: DMA, SIPI Slave: Data AXBS Master M4
XBIC_4	TCM splitter AXBS	Master: Data AXBS Slave port 4 Slave: Z4 TCM, Z7a TCM, Z7b TCM

Please see memory map spreadsheet attached with this document for more details.

22.2 Overview

The Crossbar Integrity Checker (XBIC) verifies the integrity of the crossbar transfers.

22.3 Features

The XBIC has the following features:

- Verification of attribute information for all crossbar transfers
  - EDC (72,64) code protects against single and double bit errors

- Verification of feedback information for each data phase during crossbar transfer
- Error injection for testing
  - Programmable master and slave port specifiers
  - Programmable 8-bit toggle vector to insert error in master EDC checkbit value
  - Address, EDC syndrome, master and slave port information captured on error
- Programmable integrity check enable on a per-slave-port basis
- Programmable integrity feedback check enable on a per-master-port basis

22.4 Block diagram

The crossbar transfer attribute information for all master and slave ports is routed to the XBIC, which calculates and checks the EDC parity over the attribute information as shown in the following diagram.

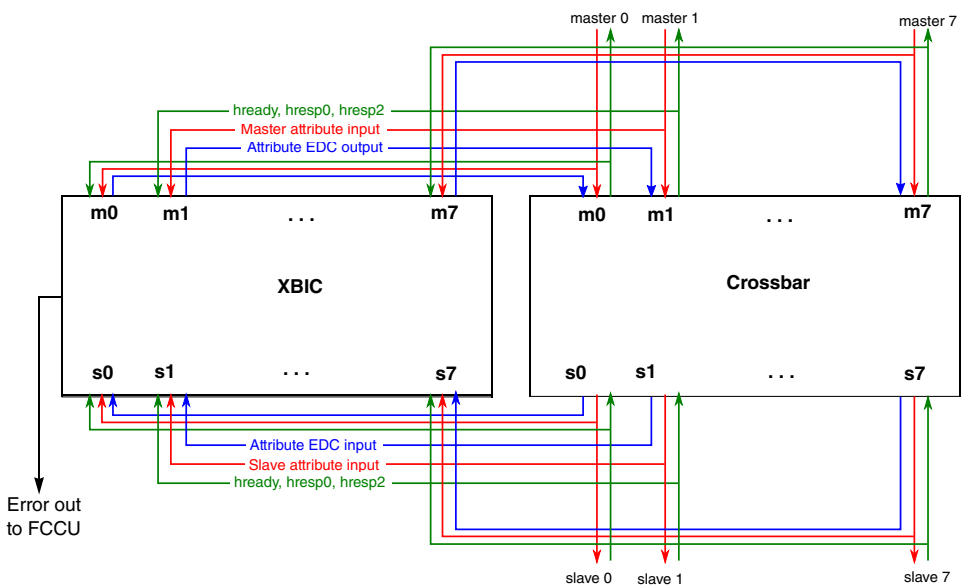

Figure 22-1. XBIC system block diagram

22.5 External signal description

The XBIC has no external interface signals.

22.6 Memory map and register definition

The XBIC programming model has four 32-bit registers. The programming model can only be accessed in supervisor mode using 32-bit (word) accesses. Attempted references with a different access size, to an undefined (reserved) address, with a non-supported access type (a write to a read-only register), or in user mode generate an error termination.

16–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

22.6.2 XBIC Error Injection Register (XBIC_EIR)

The XBIC_EIR contains fields for controlling the XBIC error injection function. When an error is injected, the EDC syndrome associated with the programmed master and slave ports is modified, causing the XBIC to assert the error indication to the FCCU and capturing the transfer information in the XBIC_ESR and XBIC_EAR registers. Otherwise, transfers are not affected by XBIC error injection.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	EIE	0														
W

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

XBIC_EIR field descriptions

Field	Description
0 EIE	Error Injection Enable. 0 Error injection disabled 1 Error injection enabled
1–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–19 SLV	Target Slave Port. Error injection is enabled for the designated slave port. Other slave ports are unaffected.
20–23 MST	Target Master ID. Error injection is enabled for the designated master ID. Transfers with other master IDs are not affected.
24–31 SYN	Syndrome. This value is exclusive-ored with the calculated syndrome (which should be zero) to generate an error with the specified syndrome. A value of zero does not generate an error.

22.6.3 XBIC Error Status Register (XBIC_ESR)

The Error Status Register (XBIC_ESR) contains two types of error information about the last transfer. If an attribute integrity check error was detected, the slave port, the master port, and the syndrome are captured in the SLV, MST, and SYN fields. If there is a mismatch among internal signals (hready, hresp0, and hresp2) during the data phase, the slave and master port are catured in the DPSE0-7 and DPME0-7 fields.

This register is cleared only on reset.

NOTE

When the XBIC detects back-to-back faults on a system bus path through the crossbar switch, the fault information captured in the XBIC_ESR does not correspond to the initial fault event but rather the subsequent fault event. While the fault event is properly detected, diagnostic status information in the XBIC_ESR register describing the initial fault event is lost. This can only occur in the event of a series of bus transactions targeting the same crossbar slave target where the series of bus transactions are not separated by idle or stall cycles.

XBIC_ESR field descriptions (continued)

Field	Description
	0 No error on slave port 7 1 Data phase error on slave port 7
9 DPME0	Data phase master port error. 0 No error on master port 0 1 Data phase error on master port 0
10 DPME1	Data phase master port error. 0 No error on master port 1 1 Data phase error on master port 1
11 DPME2	Data phase master port error. 0 No error on master port 2 1 Data phase error on master port 2
12 DPME3	Data phase master port error. 0 No error on master port 3 1 Data phase error on master port 3
13 DPME4	Data phase master port error. 0 No error on master port 4 1 Data phase error on master port 4
14 DPME5	Data phase master port error. 0 No error on master port 5 1 Data phase error on master port 5
15 DPME6	Data phase master port error. 0 No error on master port 6 1 Data phase error on master port 6
16 DPME7	Data phase master port error. 0 No error on master port 7 1 Data phase error on master port 7
17–19 SLV	Slave Port. The slave port targeted by the last transfer with an error.
20–23 MST	Master ID. The master ID value of the last transfer with an error.
24–31 SYN	Syndrome. The syndrome calculated for the last transfer with an error. For single bit errors the signal in error can be determined, see Table 22-2 .

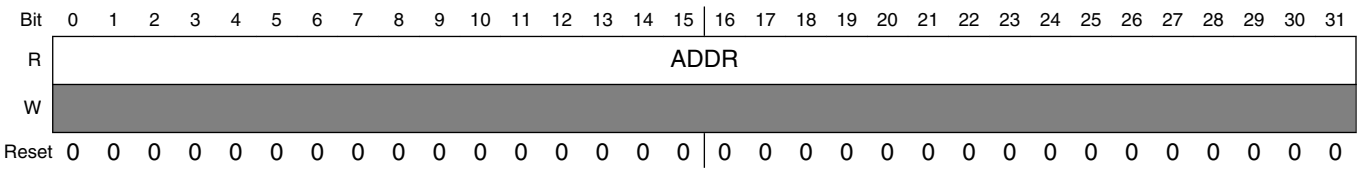
22.6.4 XBIC Error Address Register (XBIC_EAR)

The Error Address Register (XBIC_EAR) contains the address of the first transfer in which an attribute integrity check error was detected on an enabled slave port. This register is only cleared on reset.

NOTE

When the XBIC detects back-to-back faults on a system bus path through the crossbar switch, the fault information captured in the XBIC_EAR does not correspond to the initial fault event but rather the subsequent fault event. While the fault event is properly detected, diagnostic status information in the XBIC_ESR register describing the initial fault event is lost. This can only occur in the event of a series of bus transactions targeting the same crossbar slave target where the series of bus transactions are not separated by idle or stall cycles.

Address: 0h base + Ch offset = Ch



XBIC_EAR field descriptions

Field	Description
0–31 ADDR	The address of the last transfer with an error.

22.7 Functional description

The Crossbar Integrity Checker (XBIC) verifies the integrity of the crossbar interface. The Module Control Register (XBIC_MCR) allows integrity checking to be enabled on a individual port basis. When an error is detected, it is captured in XBIC_ESR register and XBIC also sends out an error signal to the Fault Collection and Control Unit (FCCU). Detection of an error does not generate a bus error. The XBIC integrity checking is independent from the end-to-end ECC that covers the transfer address and data.

During the AHB address phase, the crossbar attribute information is checked using an 8-bit Error Detection Code (EDC), which detects any single- or double-bit errors. When an error is detected, due either to hardware fault or error injection, information related to the error is captured and reported in XBIC_ESR and XBIC_EAR. The cause of a single-bit error can be determined by the syndrome value reported in the XBIC_ESR as shown in Table 22-2. Any other syndrome indicates a multi-bit error.

During the AHB data phase, the responding signals from the slave to master are checked when passing through the crossbar. When an error is detected, the information is captured in the XBIC_ESR DPSE0-7 and DPME0-7 fields.

The XBIC can also be programmed to intentionally inject EDC errors for testing. Error injection is targeted toward a single slave port and a single master ID at a time as determined by the settings in the Error Injection Register (XBIC_EIR). When an error is injected, the EDC syndrome is modified which causes the XBIC to assert the error indication to the FCCU. Otherwise transfers are unaffected by XBIC error injection. This approach allows the check logic to be verified without compromising the integrity of the data transfer. Once the error injection function is enabled by setting XBIC_EIR[EIE], errors are induced on all subsequent targeted transactions until XBIC_EIR[EIE] is cleared

Chapter 23
Peripheral Bridge (AIPS-Lite)

23.1 Chip-specific AIPS information

23.1.1 Number of peripheral bridges

This device contains two identical peripheral bridges.

23.1.2 Memory maps

The peripheral bridges are used to access the registers of most of the modules on this device. See Memory Map chapter for the memory slot assignment for each module.

23.1.3 MPR registers

Each of the two peripheral bridges supports a maximum of sixteen crossbar switch masters, each assigned to MTR*n*,MTW*n* and MPL*n* field in the MPRA and MPRB registers. However, fewer are supported on this device. See Chip-specific AXBS information for details of the master port assignments for this device.

See Chip-specific SMPU information for details of the Logical bus Master Assignments for this device.

The reset value for MPRA is 0x7700_0007 in both bridges.

The reset value for MPRB is 0x7700_5007 in both bridges.

NOTE

In MPRB register , the MTR12, MTW12 & MPL12 bit fields belongs to CSE. By default MTR12 = 1 & MPL12 = 1 and these values cannot be changed by software. Only MTW12 value can be changed to 0/1.

23.1.4 PACR/OPACR registers

The peripherals attached to the peripheral bridges each are assigned to a PACR*n* or OPACR*n* field within the PACR A-H and OPACR A-AF registers. See memory map spreadsheet attached with this document for details of the peripheral slot assignments for this device. Unused PACR*n* fields are reserved.

The reset values for the OPACR registers are given in the following table.

Table 23-1. OPACR reset values

23.2 Introduction

The peripheral bridge converts the crossbar switch interface to an interface that can access most of the slave peripherals on this chip.

The peripheral bridge occupies 64 MB of the address space, which is divided into peripheral slots of 16 KB. (It might be possible that all the peripheral slots are not used. See the memory map chapter for details on slot assignments.) The bridge includes separate clock enable inputs for each of the slots to accommodate slower peripherals.

23.2.1 Features

Key features of the peripheral bridge are:

- Supports peripheral slots with 8-, 16-, and 32-bit datapath width
- Supports a pair of 32-bit transactions for selected 64-bit memory accesses
- Programming model provides memory protection functionality

23.2.2 General operation

The slave devices connected to the peripheral bridge are modules which contain a programming model of control and status registers. The system masters read and write these registers through the peripheral bridge.

The register maps of the peripherals are located on 16 KB boundaries. Each peripheral is allocated one or more 16-KB block(s) of the memory map.

23.3 Memory map/register definition

The 32-bit peripheral bridge registers can be accessed only in supervisor mode by trusted bus masters. Additionally, these registers must be read from or written to only by a 32-bit aligned access. The peripheral bridge registers are mapped into the Peripheral Access Control Register A PACRA[PACR0] address space.

23.3.1 Master Privilege Register A (AIPS_MPRA)

This register specifies eight identical 4-bit fields defining the access-privilege level associated with a bus master in the device to various peripherals. The register provides one field per bus master. Each master is assigned a logical master number. See the device configuration information for details.

23.3.3 Peripheral Access Control Register (AIPS_PACR*n*)

Each of the on-platform peripherals has a 4-bit PACR*n* field, which defines the access levels supported by the given module. Eight PACR fields are grouped together to form a 32-bit PACR*x* register.

The peripheral assignment for each PACR field is defined by the memory map slot that the peripheral is assigned to. See the device's memory map details for the assignments for a particular device.

If a peripheral is absent, the corresponding PACR field is not implemented. Reads or writes to the location of an unimplemented PACR register (because all eight of its peripherals are absent) should be avoided to prevent undesired behavior.

The following table shows the top-level structure of PACRs.

Offset	Register	[0:3]	[4:7]	[8:11]	[12:15]	[16:19]	[20:23]	[24:27]	[28:31]
0x100	PACRA	PACR0	PACR1	PACR2	PACR3	PACR4	PACR5	PACR6	PACR7
0x104	PACRB	PACR8	PACR9	PACR10	PACR11	PACR12	PACR13	PACR14	PACR15

AIPS_PACR*n* field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 SP0	Supervisor Protect Determines whether the peripheral requires supervisor privilege level for accesses. When this field is set, the master privilege level must indicate the supervisor access attribute, and the MPR *x* [MPL *n*] control field for the master must be set. If not, access terminates with an error response and no peripheral access initiates. 0 This peripheral does not require supervisor privilege level for accesses. 1 This peripheral requires supervisor privilege level for accesses.
2 WP0	Write Protect Determines whether the peripheral allows write access. When this bit is set and a write access is attempted, access terminates with an error response and no peripheral access initiates. 0 This peripheral allows write accesses. 1 This peripheral is write protected.
3 TP0	Trusted Protect Determines whether the peripheral allows accesses from an untrusted master. When this field is set and an access is attempted by an untrusted master, the access terminates with an error response and no peripheral access initiates.

Table continues on the next page...

AIPS_PACR*n* field descriptions (continued)

Field	Description
	0 Accesses from an untrusted master are allowed. 1 Accesses from an untrusted master are not allowed.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 SP1	Supervisor Protect Determines whether the peripheral requires supervisor privilege level for accesses. When this field is set, the master privilege level must indicate the supervisor access attribute, and the MPR *x* [MPL *n*] control field for the master must be set. If not, access terminates with an error response and no peripheral access initiates. 0 This peripheral does not require supervisor privilege level for accesses. 1 This peripheral requires supervisor privilege level for accesses.
6 WP1	Write Protect Determines whether the peripheral allows write accesses. When this field is set and a write access is attempted, access terminates with an error response and no peripheral access initiates. 0 This peripheral allows write accesses. 1 This peripheral is write protected.
7 TP1	Trusted Protect Determines whether the peripheral allows accesses from an untrusted master. When this bit is set and an access is attempted by an untrusted master, the access terminates with an error response and no peripheral access initiates. 0 Accesses from an untrusted master are allowed. 1 Accesses from an untrusted master are not allowed.
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 SP2	Supervisor Protect Determines whether the peripheral requires supervisor privilege level for accesses. When this field is set, the master privilege level must indicate the supervisor access attribute, and the MPR *x* [MPL *n*] control field for the master must be set. If not, access terminates with an error response and no peripheral access initiates. 0 This peripheral does not require supervisor privilege level for accesses. 1 This peripheral requires supervisor privilege level for accesses.
10 WP2	Write Protect Determines whether the peripheral allows write access. When this bit is set and a write access is attempted, access terminates with an error response and no peripheral access initiates. 0 This peripheral allows write accesses. 1 This peripheral is write protected.
11 TP2	Trusted Protect Determines whether the peripheral allows accesses from an untrusted master. When this field is set and an access is attempted by an untrusted master, the access terminates with an error response and no peripheral access initiates.

Table continues on the next page...

AIPS_PACR*n* field descriptions (continued)

Field	Description
	0 Accesses from an untrusted master are allowed. 1 Accesses from an untrusted master are not allowed.
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 SP7	Supervisor Protect Determines whether the peripheral requires supervisor privilege level for accesses. When this field is set, the master privilege level must indicate the supervisor access attribute, and the MPR *x* [MPL *n*] control field for the master must be set. If not, access terminates with an error response and no peripheral access initiates. 0 This peripheral does not require supervisor privilege level for accesses. 1 This peripheral requires supervisor privilege level for accesses.
30 WP7	Write Protect Determines whether the peripheral allows write accesses. When this field is set and a write access is attempted, access terminates with an error response and no peripheral access initiates. 0 This peripheral allows write accesses. 1 This peripheral is write protected.
31 TP7	Trusted Protect Determines whether the peripheral allows accesses from an untrusted master. When this field is set and an access is attempted by an untrusted master, the access terminates with an error response and no peripheral access initiates. 0 Accesses from an untrusted master are allowed. 1 Accesses from an untrusted master are not allowed.

23.3.4 Off-Platform Peripheral Access Control Register (AIPS_OPACR*n*)

Each of the on-platform peripherals has a 4-bit OPACR*n* field, which defines the access levels supported by the given module. Eight OPACR fields are grouped together to form a 32-bit OPACR*x* register.

The peripheral assignment for each OPACR field is defined by the memory map slot that the peripheral is assigned to. See the device's memory map details for the assignments for a particular device.

If a peripheral is absent, the corresponding OPACR field is not implemented. Reads or writes to the location of an unimplemented OPACR register (because all eight of its peripherals are absent) should be avoided to prevent undesired behavior.

The following table shows the top-level structure of OPACRs.

Offset	Register	[0:3]	[4:7]	[8:11]	[12:15]	[16:19]	[20:23]	[24:27]	[28:31]

When this field is set, the master privilege level must indicate the supervisor access attribute, and the MPR *x* [MPL *n*] control field for the master must be set. If not, access terminates with an error response and no peripheral access initiates. 0 This peripheral does not require supervisor privilege level for accesses. 1 This peripheral requires supervisor privilege level for accesses.
14 WP3	Write Protect Determines whether the peripheral allows write access. When this bit is set and a write access is attempted, access terminates with an error response and no peripheral access initiates. 0 This peripheral allows write accesses. 1 This peripheral is write protected.
15 TP3	Trusted Protect Determines whether the peripheral allows accesses from an untrusted master. When this field is set and an access is attempted by an untrusted master, the access terminates with an error response and no peripheral access initiates. 0 Accesses from an untrusted master are allowed. 1 Accesses from an untrusted master are not allowed.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 SP4	Supervisor Protect Determines whether the peripheral requires supervisor privilege level for access. When this bit is set, the master privilege level must indicate the supervisor access attribute, and the MPR *x* [MPL *n*] control bit for the master must be set. If not, access terminates with an error response and no peripheral access initiates. 0 This peripheral does not require supervisor privilege level for accesses. 1 This peripheral requires supervisor privilege level for accesses.
18 WP4	Write Protect Determines whether the peripheral allows write accesses. When this field is set and a write access is attempted, access terminates with an error response and no peripheral access initiates. 0 This peripheral allows write accesses. 1 This peripheral is write protected.
19 TP4	Trusted Protect Determines whether the peripheral allows accesses from an untrusted master. When this bit is set and an access is attempted by an untrusted master, the access terminates with an error response and no peripheral access initiates. 0 Accesses from an untrusted master are allowed. 1 Accesses from an untrusted master are not allowed.

AIPS_OPACR*n* field descriptions (continued)

Field	Description
20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 SP5	Supervisor Protect Determines whether the peripheral requires supervisor privilege level for accesses. When this field is set, the master privilege level must indicate the supervisor access attribute, and the MPR *x* [MPL *n*] control field for the master must be set. If not, access terminates with an error response and no peripheral access initiates. 0 This peripheral does not require supervisor privilege level for accesses. 1 This peripheral requires supervisor privilege level for accesses.
22 WP5	Write Protect Determines whether the peripheral allows write accesses. When this field is set and a write access is attempted, access terminates with an error response and no peripheral access initiates. 0 This peripheral allows write accesses. 1 This peripheral is write protected.
23 TP5	Trusted Protect Determines whether the peripheral allows accesses from an untrusted master. When this field is set and an access is attempted by an untrusted master, the access terminates with an error response and no peripheral access initiates. 0 Accesses from an untrusted master are allowed. 1 Accesses from an untrusted master are not allowed.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 SP6	Supervisor Protect Determines whether the peripheral requires supervisor privilege level for accesses. When this field is set, the master privilege level must indicate the supervisor access attribute, and the MPR *x* [MPL *n*] control field for the master must be set. If not, access terminates with an error response and no peripheral access initiates. 0 This peripheral does not require supervisor privilege level for accesses. 1 This peripheral requires supervisor privilege level for accesses.
26 WP6	Write Protect Determines whether the peripheral allows write accesses. When this field is set and a write access is attempted, access terminates with an error response and no peripheral access initiates. 0 This peripheral allows write accesses. 1 This peripheral is write protected.
27 TP6	Trusted Protect Determines whether the peripheral allows accesses from an untrusted master. When this field is set and an access is attempted by an untrusted master, the access terminates with an error response and no peripheral access initiates. 0 Accesses from an untrusted master are allowed. 1 Accesses from an untrusted master are not allowed.

AIPS_OPACR*n* field descriptions (continued)

Field	Description
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 SP7	Supervisor Protect Determines whether the peripheral requires supervisor privilege level for accesses. When this field is set, the master privilege level must indicate the supervisor access attribute, and the MPR *x* [MPL *n*] control field for the master must be set. If not, access terminates with an error response and no peripheral access initiates. 0 This peripheral does not require supervisor privilege level for accesses. 1 This peripheral requires supervisor privilege level for accesses.
30 WP7	Write Protect Determines whether the peripheral allows write accesses. When this field is set and a write access is attempted, access terminates with an error response and no peripheral access initiates. 0 This peripheral allows write accesses. 1 This peripheral is write protected.
31 TP7	Trusted Protect Determines whether the peripheral allows accesses from an untrusted master. When this field is set and an access is attempted by an untrusted master, the access terminates with an error response and no peripheral access initiates. 0 Accesses from an untrusted master are allowed. 1 Accesses from an untrusted master are not allowed.

23.4 Functional description

The peripheral bridge functions as a bus protocol translator between the crossbar switch and the slave peripheral bus.

Support is provided for generating a pair of 32-bit slave accesses when performing certain 64-bit peripheral accesses.

The peripheral bridge manages all transactions destined for the attached slave devices and generates select signals for modules on the peripheral bus by decoding accesses within the attached address space.

23.4.1 Access support

All combinations of access size and peripheral data port width are supported. An access that is larger than the target peripheral's data width will be decomposed to multiple, smaller accesses. Bus decomposition is terminated by a transfer error caused by an access to an empty register area.

Chapter 24
System Memory Protection Unit (SMPU)

24.1 Chip-specific SMPU information

This chip contains two instances of the System Memory Protection Unit (SMPU):

- SMPU_0 for the data XBAR (XBAR_0)
- SMPU_1 for the instruction XBAR (XBAR_1)

The following sections explain how each SMPU is configured on this chip.

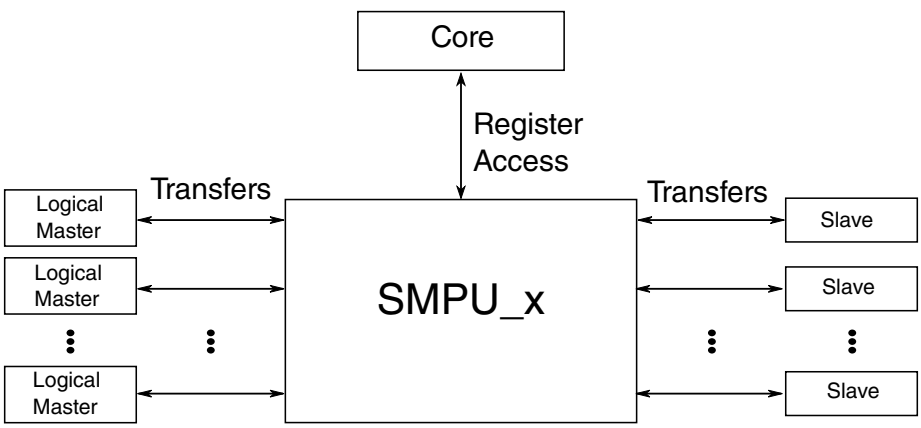

Figure 24-1. SMPU_x configuration

24.1.1 SMPU_x Logical bus Master Assignments

The logical bus master assignments for the SMPU_0/1 are shown in the following table.

Table 24-1. Master IDs

Module	Master ID
Core0 (Instruction and Data Bus)	0
Core1 (Instruction and Data Bus)	1
eDMA	2[1]

Table continues on the next page...

Table 24-1. Master IDs (continued)

Module	Master ID
FlexRay	3
Zipwire	4
ENET	5
SPT (PDMA)	6
Core2 (Instruction and Data Bus)	7
Core0 (Nexus)	8
Core1 (Nexus)	9
SPT (SDMA (MIPI_CSI image data and channel5))	10
CSE	12
SPT (Command Sequencer)	13
SPT (SDMA (ADC/MIPI_CSI))	14
Core2 (Nexus)	15

1. eDMA can emulate other master IDs, with exception of the CSE master ID

24.1.2 SMPU_EDRn[EATTR] fixed values for some masters

For each of the following masters, SMPU_EDRn[EATTR] always has the indicated fixed value:

- ENET : 01
- FlexRay : 11
- SPT : 11

24.2 Overview

The System Memory Protection Unit (SMPU) provides hardware access control for system bus memory references. The SMPU concurrently monitors system bus transactions and evaluates their appropriateness using preprogrammed region descriptors that define memory spaces and their access rights. Memory references that have sufficient access control rights are allowed to complete, while references that are not mapped to any region descriptor or have insufficient rights are terminated with an access error response.

24.2.1 Block diagram

A simplified block diagram of the SMPU module is shown in the following figure. The access signals coming from the crossbar switch slave ports are shown on the left. The access evaluation macros and region descriptors are in the middle, and the peripheral bus interface is on the right side.

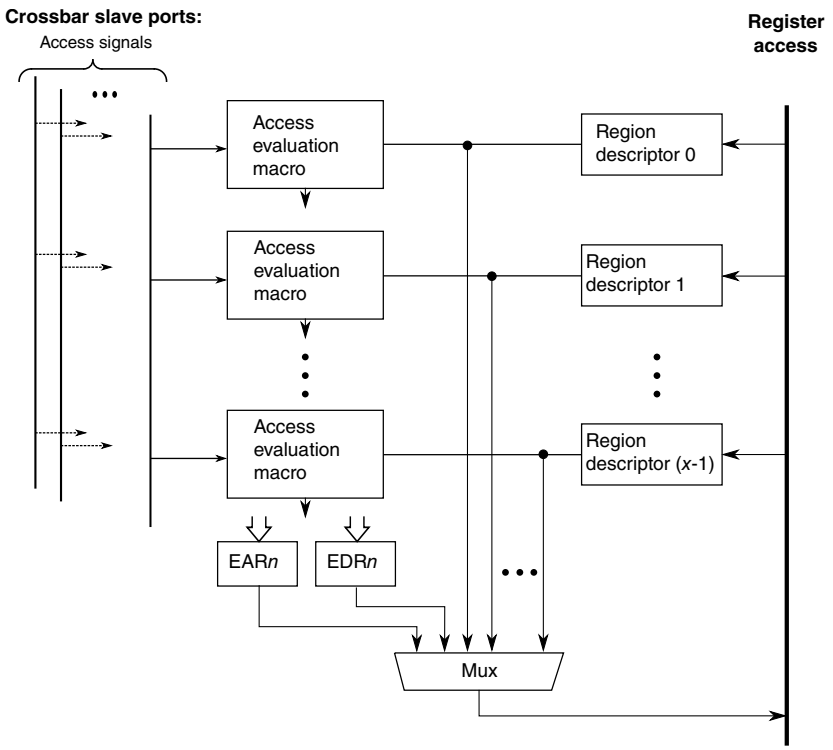

Figure 24-2. SMPU block diagram

The access evaluation macros determine hits to memory regions and detect violations to access protections. If a violation is detected, the macros update the appropriate master's error registers. For details of the access evaluation macro, see Access evaluation macro.

24.2.2 Features

The SMPU feature set includes:

- Arbitrarily sized protection regions alignable anywhere in memory.
  - Region sizes can vary from a minimum of 1 byte to a maximum of 4 GB.
- Read/write access control permissions are defined in the region descriptor.

- Global cache-inhibit attribute indicator.
- Hardware-assisted maintenance of the descriptor valid bit minimizes coherency issues.
- Priority given to granting permission over denying access for overlapping region descriptors.
- Detection of access errors if a memory reference does not hit in any memory region, or if the reference is illegal in all hit memory regions. If an access error occurs, the reference is terminated with an error response, and the SMPU inhibits the bus cycle being sent to the targeted slave device.
- Instruction storage (ISI) or data storage (DSI) interrupts generated by aborted core accesses. Buffered writes generate Machine check exception (refer to the documentation related to the core for details).
- Error registers (per bus master ID) capture the last faulting address, attributes, and other information.
- Global SMPU enable/disable control bit.

24.3 Memory map/register definition

The programming model is partitioned into three groups:

- Control registers
- Error capture registers
- Data structure containing the region descriptors

The programming model can be referenced only in supervisor mode using 32-bit accesses. Attempted references with a different access size, to an undefined (reserved) address, with a non-supported access type (a write to a read-only register, or a read of a write-only register), or in user mode generate an error termination.

NOTE

See the chip configuration details for any chip-specific register information for this module. For example, a specific instance of the module may support only eight or fewer region descriptors.

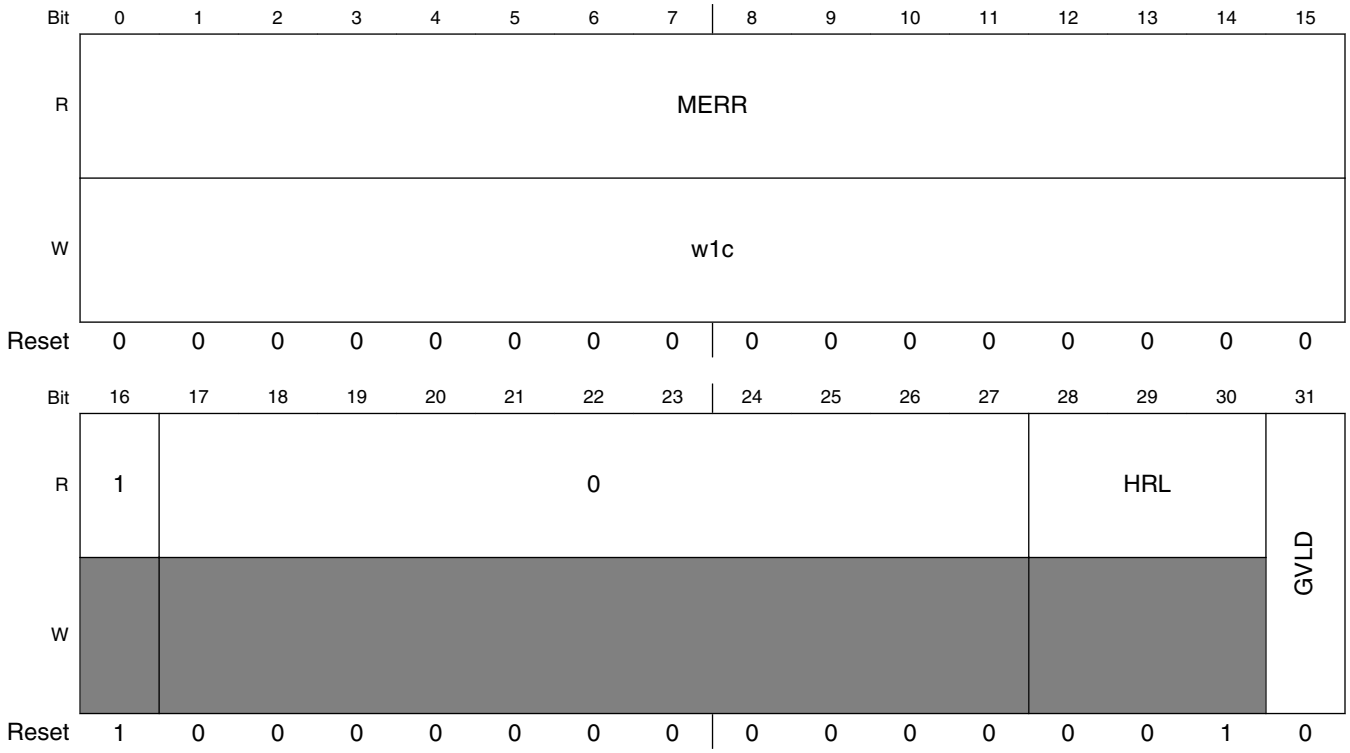
24.3.1 Control/Error Status Register 0 (SMPU_CESR0)

Address: 0h base + 0h offset = 0h

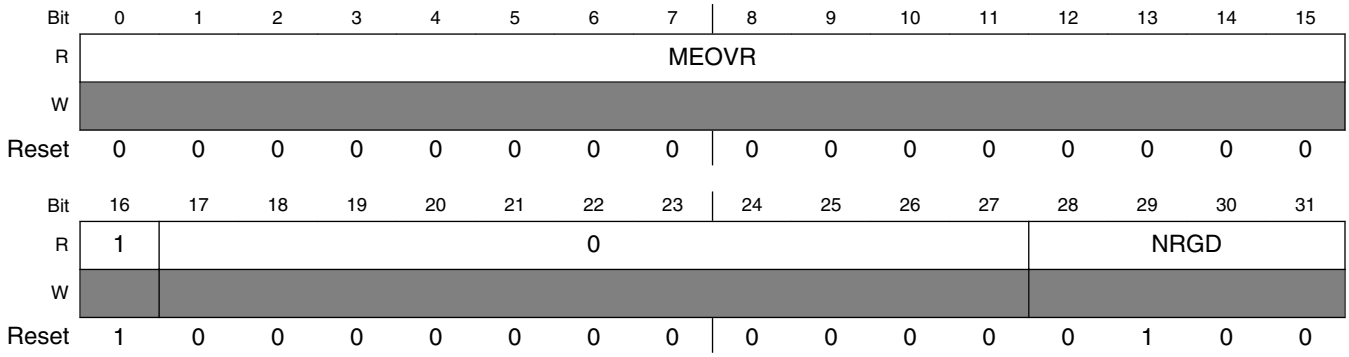


SMPU_CESR0 field descriptions

Field	Description
0–15 MERR	Master n error, where the bus master number matches the bit number Indicates a captured error in EARn and EDRn. A bit is set when the hardware detects an error and records the faulting address and attributes. It is cleared by writing one to it. If another error is captured at the exact same cycle as the write, the flag remains set. A find-first-one instruction (or equivalent) can detect the presence of a captured error. 0 No error has occurred for bus master n. 1 An error has occurred for bus master n.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
17–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–30 HRL	Hardware revision level Specifies the SMPU's hardware and definition revision level. It can be read by software to determine the functional definition of the module.
31 GVLD	Global Valid (global enable/disable for the SMPU) 0 SMPU is disabled. All accesses from all bus masters are allowed. 1 SMPU is enabled.

24.3.2 Control/Error Status Register 1 (SMPU_CESR1)

Address: 0h base + 4h offset = 4h



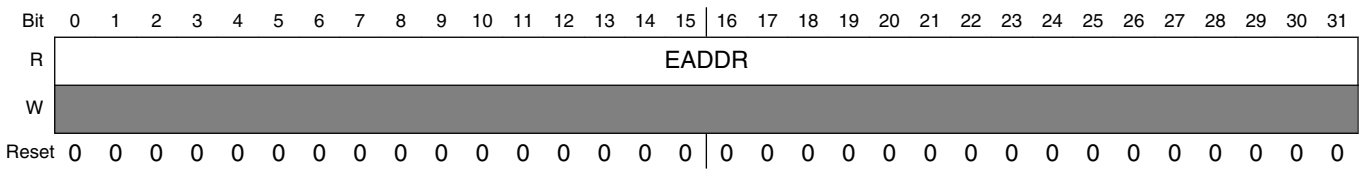
SMPU_CESR1 field descriptions

Field	Description
0–15 MEOVR	Master n error overrun, where the bus master number matches the bit number Each bit in this field signals that another SMPU error for bus master n has occurred before the previous error was processed. The details of the first error are recorded in the EARn and EDRn registers and no information on subsequent errors is recorded until the associated CESR0[MERR] flag is cleared. 0 No error overrun condition has been detected for bus master n. 1 An error overrun condition has been detected for bus master n.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
17–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 NRGD	Number of region descriptors Indicates the number of region descriptors implemented in the SMPU. The number of region descriptors is (4 x NRGD). 0001 4 region descriptors 0010 8 region descriptors 0011 12 region descriptors 0100 16 region descriptors 0101 20 region descriptors 0110 24 region descriptors

24.3.3 Error Address Register, Bus Master n (SMPU_EAR*n*)

When the SMPU detects an access error on bus master n, the 32-bit reference address is captured in this read-only register and the corresponding bit in CESR0[MERR] set. Additional information about the faulting access is captured in the corresponding EDRn at the same time.[1]

Address: 0h base + 100h offset + (8d × i), where i=0d to 15d



SMPU_EAR*n* field descriptions

Field	Description
0–31 EADDR	Error address Indicates the reference address from bus master n that generated the access error.

1. The corresponding EARn and EDRn registers contain information on the original access error; subsequent errors associated with the given master are recorded as overruns in the CESR1[MEOVR] field until the CESR0[MERR] flag associated with the original error is cleared (by writing a 1).

24.3.4 Error Detail Register, Bus Master n (SMPU_EDR*n*)

When the SMPU detects an access error associated with bus master n, 32 bits of error detail are captured in this read-only register and the corresponding bit in CESR0[MERR] is set. Information on the faulting address is captured in the corresponding EARn register at the same time. [2]

Address: 0h base + 104h offset + (8d × i), where i=0d to 15d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0

SMPU_EDR*n* field descriptions

Field	Description
0–23 EACD	Error access control detail Indicates the region descriptor with the access error, where the region descriptor number matches the bit number. If EDRn contains a captured error and EACD is all zeroes, the access did not hit in any region descriptor. If only a single EACD bit is set, the access error was caused by a single non-overlapping region descriptor. If two or more EACD bits are set, the access error was caused by an overlapping set of region descriptors.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
25–26 EATTR	Error attributes Indicates attribute information about the faulting reference. 00 User mode, instruction access 01 User mode, data access 10 Supervisor mode, instruction access 11 Supervisor mode, data access
27 ERW	Error read/write Indicates the access type of the faulting reference.

Table continues on the next page...

2. The corresponding EARn and EDRn registers contain information on the original access error; subsequent errors associated with the given master are recorded as overruns in the CESR1[MEOVR] field until the CESR0[MERR] flag associated with the original error is cleared (by writing a 1).

SMPU_EDR*n* field descriptions (continued)

Field	Description
	0 Read 1 Write
28–31 EMN	Error master number Indicates the logical bus master number of the faulting reference.

24.3.5 Region Descriptor n, Word 0 (SMPU_RGD*n*_WORD0)

The first word of the region descriptor defines the byte start address of the memory region. Writes to this register clear the region descriptor's valid bit (RGDn_WORD3[VLD]).

Address: 0h base + 400h offset + (16d × i), where i=0d to 15d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	SRTADDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SMPU_RGD*n*_WORD0 field descriptions

Field	Description
0–31 SRTADDR	Start address Defines the byte start address of the memory region.

24.3.6 Region Descriptor n, Word 1 (SMPU_RGD*n*_WORD1)

The second word of the region descriptor defines the end address of the memory region. (RGDn_WORD3[VLD]).

Address: 0h base + 404h offset + (16d × i), where i=0d to 15d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	ENDADDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SMPU_RGD*n*_WORD1 field descriptions

Field	Description
0–31 ENDADDR	End address Defines the byte end address of the memory region. **NOTE:** The SMPU does not verify that ENDADDR ≥ SRTADDR.

24.3.7 Region Descriptor n, Word 2 (SMPU_RGD*n*_WORD2)

RGD_WORD2 defines the access control rights of the memory region. The access control rights are defined by separate read and write permissions. For these fields, the bus master number refers to the *logical* bus master number.

For the access control rights, there are two flags:

- Read (r) permission refers to the ability to access the referenced memory address using an operand (data) fetch or an instruction fetch.
- Write (w) permission refers to the ability to update the referenced memory address using a store (data) operation.

Each field consists of the two flags, with (r) being in the more significant position. For example, M0P has (r) as bit 0 and (w) as bit 1.

The bit settings are as follows:

- If set, the corresponding flag allows the specific access type (r = memory read, w = memory write).
- If cleared, the specific access type is not allowed.

Writes to this word clear the region descriptor's valid bit.

Address: 0h base + 408h offset + (16d × i), where i=0d to 15d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

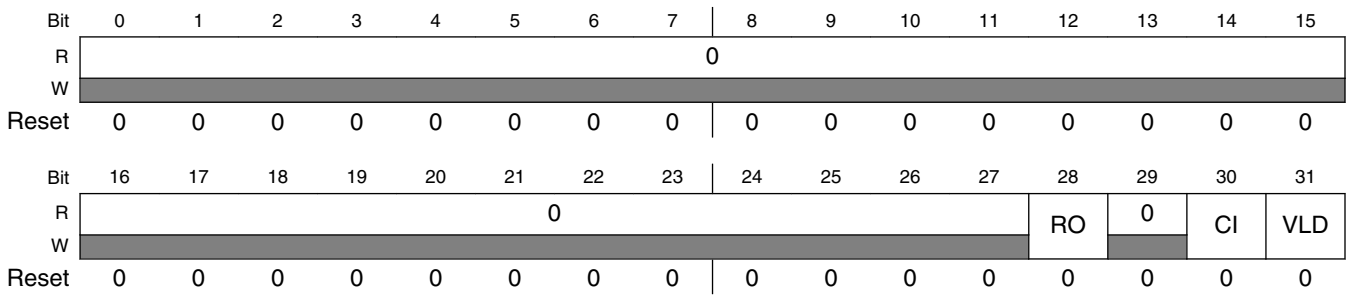
24–25 M12P	Bus master 12 permissions
26–27 M13P	Bus master 13 permissions
28–29 M14P	Bus master 14 permissions
30–31 M15P	Bus master 15 permissions

24.3.8 Region Descriptor n, Word 3 (SMPU_RGD*n*_WORD3)

The final word of the SMPU region descriptor contains the valid bit, plus other miscellaneous flags.

Address: 0h base + 40Ch offset + (16d × i), where i=0d to 15d



SMPU_RGD*n*_WORD3 field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 RO	Read-Only This bit is intended to prevent accidental writes of an SMPU region descriptor. **NOTE:** The valid bit of the RGD and the global valid bit have no effect on this bit functionality (once set, even if the RGD is not valid or SMPU is not global enabled, the RO functionality is present). 0 The region descriptor can be read or written. 1 Attempted writes to any location in the region descriptor are ignored with an error-free data transfer termination.
29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 CI	Cache Inhibit Defines the cacheability attribute of the memory region. This bit is returned to the bus master that initiated the memory reference. **NOTE:** An address range specified in an SMPU region descriptor for a cacheable space (that is, CI = 0) must be defined with a starting address aligned on a 0-modulo-32 byte address and with a multiple of the 32 byte cache line size factoring into the end address. 0 References to this region can be cached. 1 References to this region cannot be cached.
31 VLD	Valid Signals the region descriptor is valid. Any write to RGDn_WORD0–2 clears this bit. 0 Region descriptor is invalid. 1 Region descriptor is valid.

24.4 Functional description

In this section, the functional operation of the SMPU is detailed, including the operation of the access evaluation macro and the handling of error-terminated bus cycles.

24.4.1 Access evaluation macro

The basic operation of the SMPU is performed in the access evaluation macro, a hardware structure replicated in the connection matrix. The following block diagram represents an individual macro.

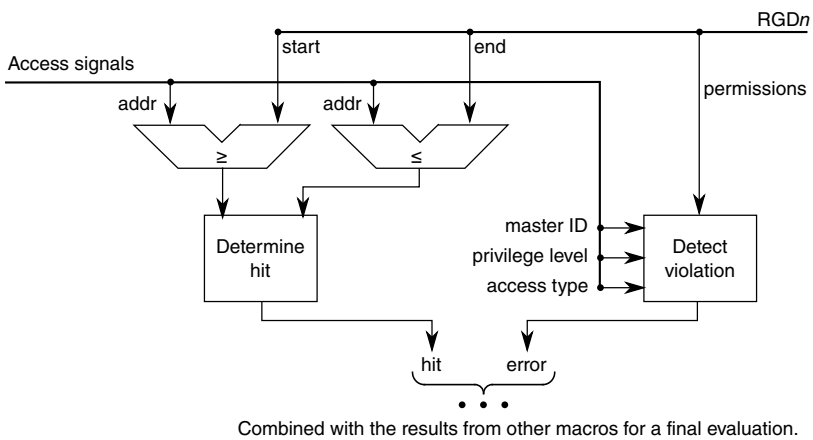


Figure 24-3. SMPU access evaluation macro

Each macro uses the information contained in the access signals (the address, the access type, and the master's ID and privilege level) and the contents of its corresponding region descriptor (RGD*n*) to perform two major functions: Hit determination and Violation determination. The individual hit and error results from each macro are then combined for a final evaluation; see Final evaluation and error terminations.

24.4.1.1 Hit determination

To determine if the current reference hits in the given region, two magnitude comparators are used with the region's start and end addresses. When RGD*n*_Word3[VLD] is 1, a region hit occurs when the requested address is between the start address (RGD*n*_Word0[SRTADDR]) and the end address (RGD*n*_Word1[ENDADDR]), inclusive.

NOTE

If ENDADDR < SRTADDR, no hit occurs.

NOTE

Region hit determination is based only on an address comparison of the first byte being accessed; that is, the SMPU does not check the size of the access to make sure it fits within an allowed region.

24.4.1.2 Violation determination

While the access evaluation macro is determining region hit, the logic is also evaluating if the current access is allowed by the permissions defined in the region descriptor. Using the master ID, a set of effective permissions is generated from the appropriate fields in the region descriptor. The protection violation logic then evaluates the access against the effective permissions using the specification shown below.

Table 24-2. Protection violation definition

Access type	Access permissions		Protection violation?
	r	w	
Instruction fetch read	0	—	Yes, no execute permission
	1	—	No, access is allowed
Data read	0	—	Yes, no read permission
	1	—	No, access is allowed
Data write	—	0	Yes, no write permission
	—	1	No, access is allowed

24.4.2 Final evaluation and error terminations

For each slave port monitored, the SMPU performs a reduction-AND of all the individual terms from each access evaluation macro. This expression then terminates the bus cycle with an error and reports an access error for three conditions:

1. The access does not hit in any region descriptor.
2. The access hits in a single region descriptor and that region has a protection violation.

3. The access hits in multiple (overlapping) regions and all regions have protection violations.

As shown in the third condition, granting permission is a higher priority than denying access for overlapping regions. This approach is more flexible to system software in region descriptor assignments. For an example of the use of overlapping region descriptors, see Application information.

NOTE

Similarly, the cache inhibit function gives a higher priority to the less restrictive result of overlapping regions. If two regions are hit and one has cache inhibit set, and the other does not, the result will not include a cache inhibit. It should also be noted that only the hit logic is taken into account for cache inhibit. For example, two region hits, one has protection violation and no cache inhibit, one has no violation and cache inhibit set. The result will be a granted access with no cache inhibit.

24.5 Initialization information

At system startup, load the appropriate number of region descriptors, including setting RGD*n*_Word3[VLD]. Setting CESR0[GVLD] enables the module.

If the system requires that all the loaded region descriptors be enabled simultaneously, first ensure that the entire SMPU is disabled (CESR0[GVLD]=0). Next, load the appropriate region descriptors (RGDn), including the setting of the RGDn_Word3[VLD] bits. Finally, set CESR0[GVLD] to enable the entire module.

Note

A region descriptor must be set to allow access to the SMPU registers if further changes are needed.

24.6 Application information

In an operational system, interfacing with the SMPU is generally classified into the following activities.

24.6.1 Creating a new memory region

Load the appropriate region descriptor into an available RGD*n*, using four sequential 32-bit writes. The hardware assists in the maintenance of the valid bit, so if this approach is followed, there are no coherency issues with the multi-cycle descriptor writes.

24.6.2 Modifying a region descriptor

Load the updates into the region descriptor using sequential 32-bit writes. Writing to Word 3 re-enables the region descriptor valid bit. The hardware assists in the maintenance of the valid bit, so if this approach is followed, there are no coherency issues with the multi-cycle descriptor writes.

24.6.3 Removing a region descriptor

Clearing RGD*n*_Word3[VLD] deletes an existing region descriptor.

24.6.4 Accessing the SMPU

Allocate a region descriptor to restrict SMPU access to supervisor mode from specific masters as appropriate.

24.6.5 Detecting an access error

The current bus cycle is terminated with an error response and EAR*n* and EDR*n* capture information on the faulting reference. The error-terminated bus cycle typically initiates an error response in the originating bus master. For example, a processor core may respond with a bus error exception, while a data movement bus master may respond with an error interrupt. The processor can retrieve the captured error address and detail information simply by reading E{A,D}R*n*. CESR0[MERR] signals which error registers contain captured fault data. Once the error information is retrieved, write a 1 to the appropriate CESR0[MERR] bit to clear it, thereby rearming the error capture logic associated with the EAR*n* and EDR*n* registers.

24.6.6 Overlapping region descriptors

Applying overlapping regions often reduces the number of descriptors required for a given set of access controls. In the overlapping memory space, the protection rights of the corresponding region descriptors are logically summed together (the boolean OR operator).

24.6.7 EAR*n* address capture considerations

When the SMPU detects an access error and the cache is enabled, the captured address in EAR*n* can differ from the expected address due to pipeline execution.

An instruction fetch for a master can cause the master's corresponding bit in CESR1[MEOVR] to set to 1 automatically in certain circumstances. For example, when the pipeline mechanism prefetches several instructions from multiple addresses in the same memory area, more than one fetch can result in an access error for the master.

Chapter 25
Semaphores2 (SEMA42)

25.1 Chip-specific SEMA42 information

The SEMA42 module uses the same logical bus master assignments as the SMPUs. The logical bus master assignments for the SEMA42 are same as SMPU, see SMPU_x Logical bus Master Assignments.

25.2 Introduction

The SEMA42 is a memory-mapped module that provides robust hardware support needed in multi-core systems for implementing semaphores and provides a simple mechanism to achieve "lock and unlock" operations via a single write access. The hardware semaphore module provides hardware-enforced gates as well as other useful system functions related to the gating mechanisms.

25.2.1 Features

- Supports 16 hardware-enforced gates in a multi-processor configuration
  - Gates appear as an 16-entry byte-size array with read and write accesses.
    - Processors lock gates by writing "processor_number+1" to the appropriate gate and must read back the gate value to verify the lock operation was successful.
    - Once locked, the gate is unlocked by a write of zeroes from the locking processor.
    - The number of implemented gates is specified by a hardware configuration define.
  - Each hardware gate appears as a 16-state, 4-bit state machine.

- 16-state implementation

  if gate = 0x0, then state = unlocked
  if gate = 0x1, then state = locked by processor (master) 0
  if gate = 0x2, then state = locked by processor (master) 1
  …
  if gate = 0xF, then state = locked by processor (master) 14
- Uses the logical bus master number as a reference attribute plus the specified data patterns to validate all write operations.
- Once locked, the gate can (and must) be unlocked by a write of zeroes from the locking processor.

- Secure reset mechanisms are supported to clear the contents of individual gates, as well as a clear_all capability.

A simplified block diagram of the Semaphores module is shown in the following figure. In the diagram, the register blocks named gate0, gate1,…, gate (n-2), gate (n-1) include the finite state machines implementing the semaphore gates.

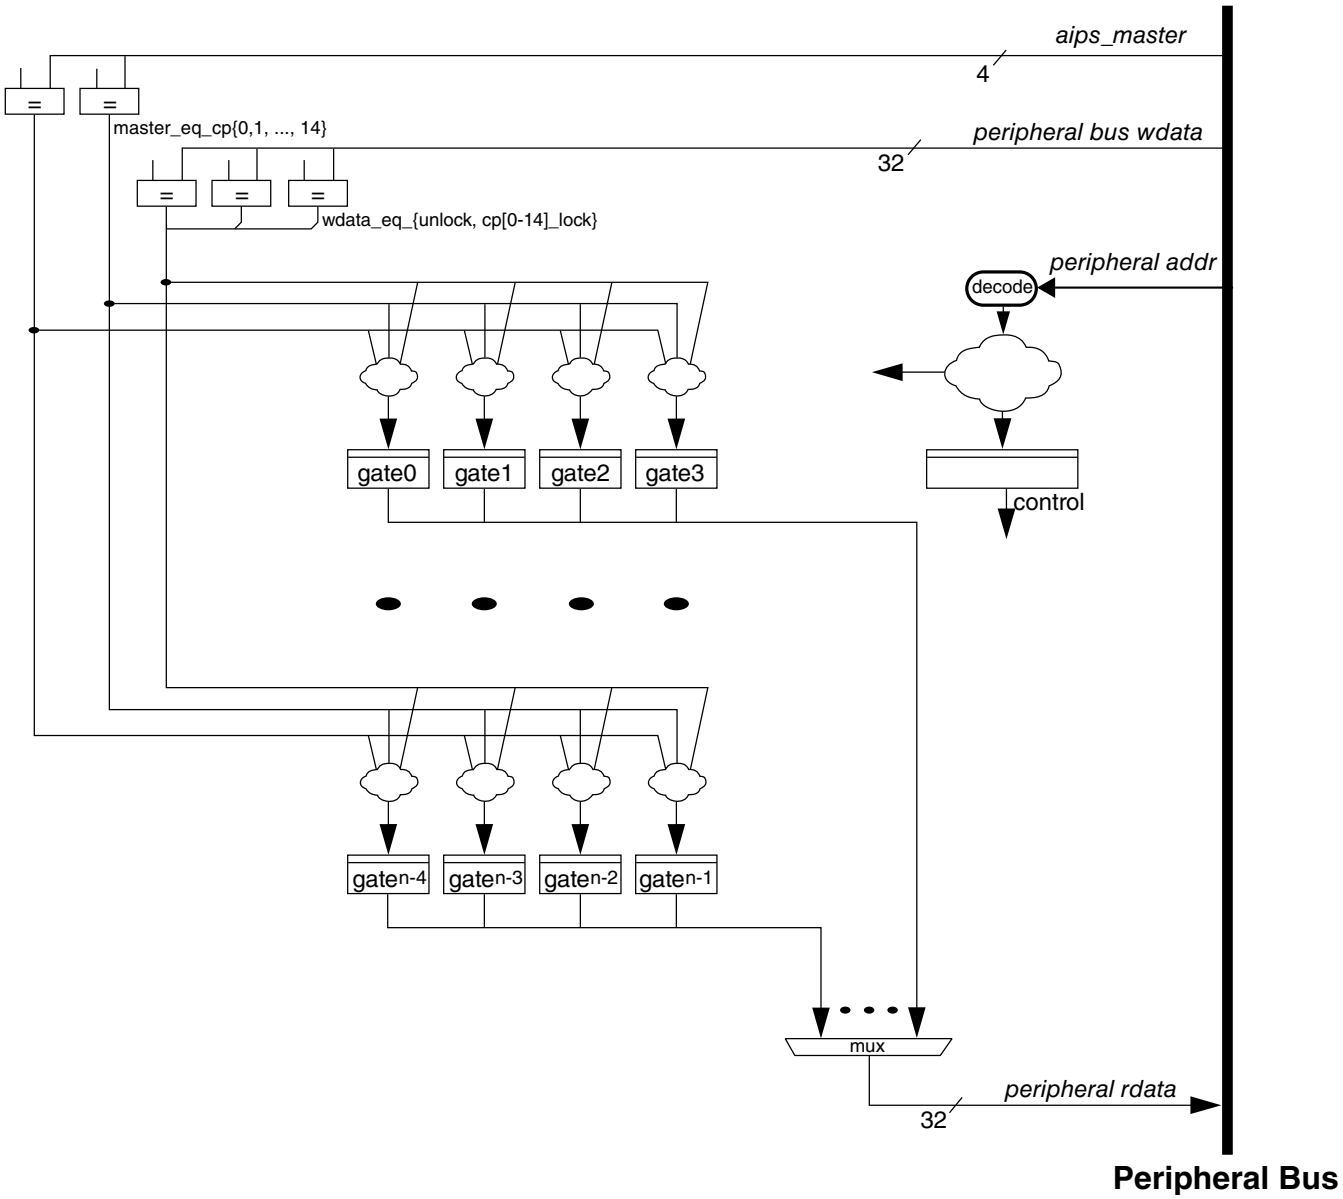

Figure 25-1. Semaphores2 block diagram

25.3 Memory map/register definition

Only Supervisor Mode accesses are allowed on these registers. User accesses will be terminated with an error.

SEMA42 memory map

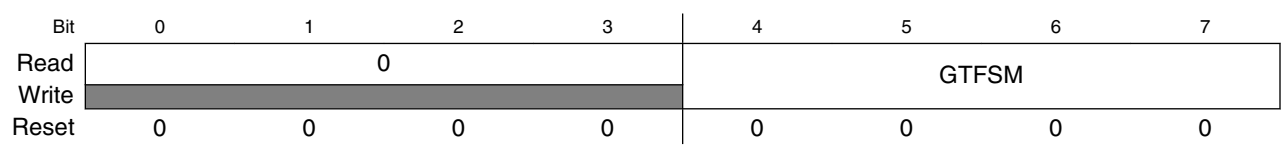
25.3.1 Gate Register (SEMA42_GATE*n*)

Each semaphore gate is implemented in a 4-bit finite state machine, right-justified in a byte data structure. The hardware uses the logical bus master number in conjunction with the data patterns to validate all attempted write operations. Only processor bus masters can modify the gate registers. Once locked, a gate can (and must) be opened (unlocked) by the locking processor core.

Multiple gate values can be read in a single access, but only a single gate can be updated via a write operation at a time. Attempted writes with a data value that is neither the unlock value (0x00) nor the appropriate lock value (processor_number + 1) are simply treated as "no operation" and do not affect any gate state. Attempts to write multiple gates in a single aligned access with a size larger than an 8-bit (byte) reference generate an error termination and do not allow any gate state changes.

Address: 0h base + 0h offset + (1d × i), where i=0d to 15d



SEMA42_GATE*n* field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–7 GTFSM	Gate Finite State Machine. The state of the gate reflects the last processor that locked it, which can be useful during system debug. The hardware gate is maintained in a 16-state implementation, defined as: 0000 The gate is unlocked (free). 0001 The gate has been locked by processor 0. 0010 The gate has been locked by processor 1. 0011 The gate has been locked by processor 2. 0100 The gate has been locked by processor 3. 0101 The gate has been locked by processor 4. 0110 The gate has been locked by processor 5. 0111 The gate has been locked by processor 6. 1000 The gate has been locked by processor 7. 1001 The gate has been locked by processor 8. 1010 The gate has been locked by processor 9. 1011 The gate has been locked by processor 10. 1100 The gate has been locked by processor 11. 1101 The gate has been locked by processor 12. 1110 The gate has been locked by processor 13. 1111 The gate has been locked by processor 14.

25.3.2 Reset Gate Write (SEMA42_RSTGT_W)

NOTE

This section and the following section, Reset Gate Read (SEMA42_RSTGT_R), describe the same register. This section describes the general operation of the register and also shows how the register fields appear when the register is written. Reset Gate Read (SEMA42_RSTGT_R) shows how the register fields appear when the register is read.

Although the intent of the hardware gate implementation specifies a protocol where the locking domain must unlock the gate, it is recognized that system operation may require a reset function to re-initialize the state of any gate(s) without requiring a system-level reset.

To support this special gate reset requirement, the Semaphores module implements a "secure" reset mechanism that allows a hardware gate (or all the gates) to be initialized by following a specific dual-write access pattern. Using a technique similar to that

required for the servicing of a software watchdog timer, the secure gate reset requires two consecutive writes with predefined data patterns from the same domain to force the clearing of the specified gate(s). The required access pattern is:

1. A domain performs a 16-bit write to the SEMA42_RSTGT memory location. The most significant byte (SEMA42_RSTGT[RSTGDP]) must be E2h; the least significant byte is a "don't_care" for this reference.
2. The same domain then performs a second 16-bit write to the SEMA42_RSTGT location. For this write, the upper byte (SEMA42_RSTGT[RSTGDP]) is the logical complement of the first data pattern (1Dh) and the lower byte (SEMA42_RSTGT[RSTGTN]) specifies the gate(s) to be reset. This gate field can specify a single gate be cleared, or that all gates are to be cleared. If the same domain writes incorrect data on the second access or another domain performs the second write access, the special gate reset sequence is aborted and no error signal is asserted.
3. Reads of the SEMA42_RSTGT location return information on the 2-bit state machine (SEMA42_RSTGT[RSTGSM]) that implements this function, the domain performing the reset (SEMA42_RSTGT[RSTGMS]), and the gate number(s) last cleared (SEMA42_RSTGT[RSTGTN]). Reads of the SEMA42_RSTGT register do not affect the secure reset finite state machine in any manner.

Address: 0h base + 40h offset = 40h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*

* Notes:
- Reset value is not applicable for writes.

SEMA42_RSTGT_W field descriptions

Field	Description
0–7 RSTGDP	Reset Gate Data Pattern. This write-only field is accessed with the specified data patterns on the two consecutive writes to enable the gate reset mechanism. For the first write, RSTGDP = E2h while the second write requires RSTGDP = 1Dh.
8–15 RSTGTN	Reset Gate Number. This 8-bit field specifies the specific hardware gate to be reset. This field is updated by the second write. If RSTGTN < 64, then reset the single gate defined by RSTGTN, else reset all the gates.

25.3.3 Reset Gate Read (SEMA42_RSTGT_R)

This section describes how the Reset Gate register fields appear when the register is read. See Reset Gate Write (SEMA42_RSTGT_W) for the description of the register's overall operation and how the register fields appear when the register is written.

Address: 0h base + 40h offset = 40h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	ROZ		RSTGSM		RSTGMS				RSTGTN							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SEMA42_RSTGT_R field descriptions

Field	Description
0–1 ROZ	This field always returns the value 0 when read.
2–3 RSTGSM	Reset Gate Finite State Machine. Reads of the SEMA42_RSTGT register return the encoded state machine value. Note the RSTGSM = 10 state is valid for only a single machine cycle, so it is impossible for a read to return this value. The reset state machine is maintained in a 2-bit, 3-state implementation, defined as: 00 Idle, waiting for the first data pattern write. 01 Waiting for the second data pattern write. 10 The 2-write sequence has completed. Generate the specified gate reset(s). After the reset is performed, this machine returns to the idle (waiting for first data pattern write) state. The "01" state persists for only one clock cycle. Software cannot observe this state. 11 This state encoding is never used and therefore reserved.
4–7 RSTGMS	Reset Gate Bus Master. This 4-bit read-only field records the logical number of the bus master performing the gate reset function. The reset function requires that the two consecutive writes to this register must be initiated by the same bus master to succeed. This field is updated each time a write to this register occurs. The association between system bus master port numbers, the associated bus master device, and the logical processor number is SoC-specific. Consult the device reference manual for this information.
8–15 RSTGTN	Reset Gate Number. This 8-bit field specifies the specific hardware gate to be reset. This field is updated by the second write. If RSTGTN < 64, then reset the single gate defined by RSTGTN, else reset all the gates.

25.4 Functional description

Functional operation of the Semaphores module and specific details of the state machines of the SEMA42_GATEn registers are provided as follows.

As described previously, each of the SEMA42_GATEn registers implements a 4-bit, 16-state machine. A *simplified* diagram of the state transitions for each gate is shown in Figure 25-2.

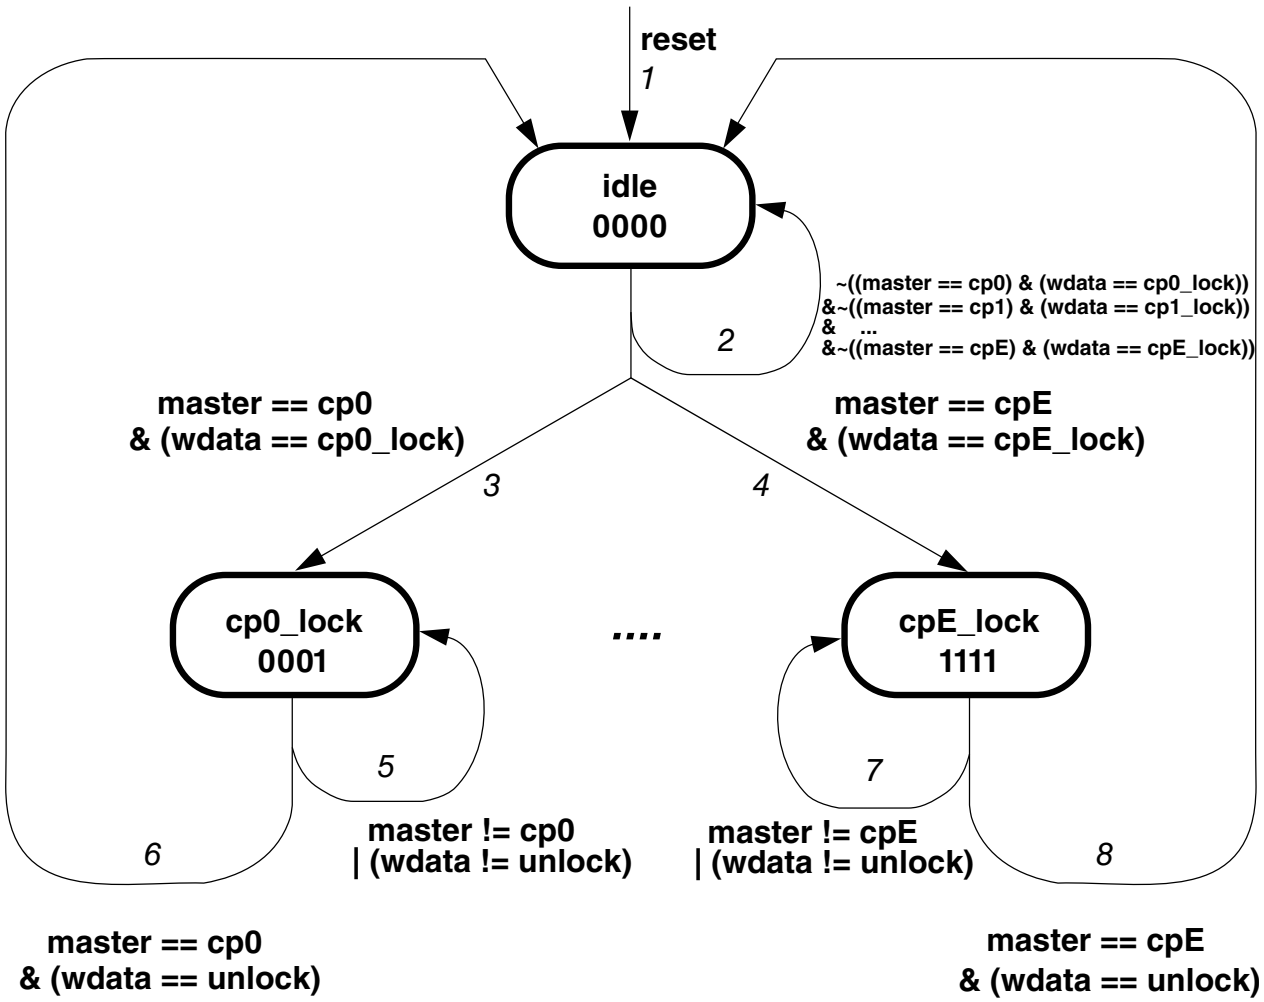

Figure 25-2. SEMA42_GATEn state machine

The bus master number is used to identify core processor *X* (cp*X*) where the notation cpE is used to represent core processor 14 (= 0xE). The platform passes the AHB bus master number through the peripheral bridge controller and drives a signal to the Semaphores module.

The state transitions for SEMA42_GATEn are defined in Table 25-1.

Table 25-1. SEMA42_GATEn state transitions

Current State	Next State	Transition	Description
–	idle	1	Any reset, whether a system reset or a software-initiated gate reset, unconditionally forces the gate into the idle state.

Table continues on the next page...

Table 25-1. SEMA42_GATEn state transitions (continued)

Current State	Next State	Transition	Description
idle	idle	2	Unless a write of the appropriate lock value from the corresponding processor occurs, the gate remains in the idle state.
idle	cp0_lock	3	When a write of the "cp0_lock" data value is initiated by processor 0, the gate transitions into the cp0_lock state.
idle	cpE_lock	4	When a write of the "cpE_lock" value is initiated by processor 0xE, the gate transitions into the cpE_lock state.
cp0_lock	cp0_lock	5	Once in this state, the gate remains here if any attempted write is not from cp0 with the unlock data value.
cp0_lock	idle	6	The gate returns to the idle (unlocked) state once a write from cp0 with the unlock data value occurs.
cpE_lock	cpE_lock	7	Once in this state, the gate remains here if any attempted write is not from cpE with the unlock data value.
cpE_lock	idle	8	The gate returns to the idle (unlocked) state once a write from cpE with the unlock data value occurs.

The following gate data values are used:

- The lock data value is (processor number + 1) where the processor number and the platform bus master number are the same.
- The unlock data value is 0x00.

Chapter 26
Development Trigger Semaphore (DTS)

26.1 Chip-specific DTS information

Writes from Nexus to DTS are little endian. For example, writing 0x00000001 leads to 0x00000001 being reflected in DTS registers.

26.2 Introduction

The Development Trigger Semaphore (DTS) module enables software to signal an external tool by driving a persistent (affected only by reset or an external tool) signal on an external device pin. There are a variety of ways this module can be used, including as a component of an external real-time data acquisition system.

Note

When used as a component of a triggered data acquisition system, Nexus read/write access is different than the data acquisition protocol defined in the IEEE-ISTO 5001-2003 or IEEE-ISTO 5001-2012 Nexus standards, which use the Nexus Auxiliary port.

26.3 Overview

The Development Trigger Semaphore (DTS) module consists of registers and a small amount of combinational logic to generate an output signal—DTS Trigger Output (DTO). The registers are as follows:

- DTS_SEMAPHORE register—Any bit in this 32-bit register, when set to a value of logic '1', causes the DTS module output signal to be asserted if the corresponding DTS_EN bit is set in the DTS_ENABLE register. This enables an external tool to

detect up to 32 signals from the application software. In an application, each bit is generally associated with a specific data set. Only the processor core and DMA module can set bits in this register. The bits can only be cleared by a tool access via Nexus Read/Write Access.

- DTS_SEMAPHORE_B register—Any bit in this 32-bit register, when set to a value of logic '1', causes the DTS module output signal to be asserted if the corresponding DTS_EN_B bit is set in the DTS_ENABLE register. This enables an external tool to detect an additional 32 signals from the application software. In an application, each bit is generally associated with a specific data set. Only the processor core and DMA module can set bits in this register. The bits can only be cleared by a tool access via Nexus Read/Write Access.
- DTS_STARTUP register—This register provides a mechanism for the external tool to notify software running on the CPU that the tool is connected and can provide information about either the type of tool or options that can be used by the software.
- DTS_ENABLE register—This register provides an enable/disable capability for the DTS feature.

The architecture is shown in the following figure.

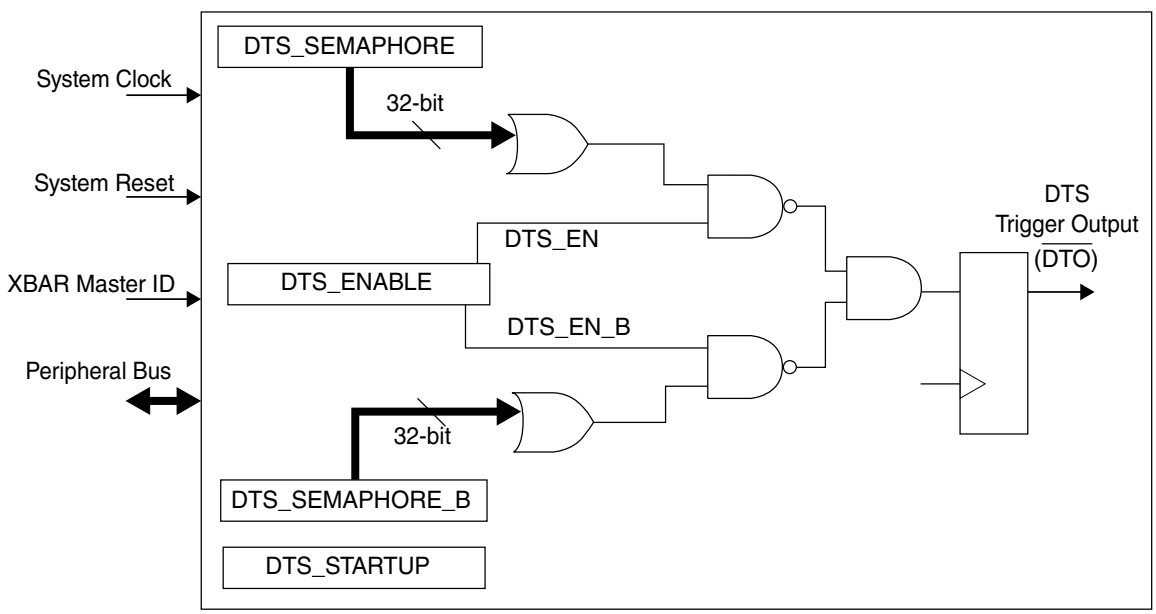

Figure 26-1. DTS block diagram

The DTS Trigger Output (DTO) signal is connected to one of the EVTO inputs of the Nexus Port Controller (NPC). The other EVTO inputs are connected to the other Nexus modules in the device. DTO is asserted when any bit in a semaphore register is set and the DTS function of that register is enabled.

Note

When the DTS module is enabled (DTS_ENABLE[DTS_EN] = 0b1 or DTS_ENABLE[DTS_EN_B] = 0b1), all other Nexus EVTO functions associated should be disabled by the tool and EVTO becomes the DTO. Unlike the EVTO function that only asserts for one clock, the DTO function remains asserted until the tool reads the semaphore register that is the source of the assertion, clearing the register's contents.

The following figure shows an example of the chain of events that begins with setting of a bit in the DTS_SEMPAHORE register and the clearing of the register caused by a Nexus read.

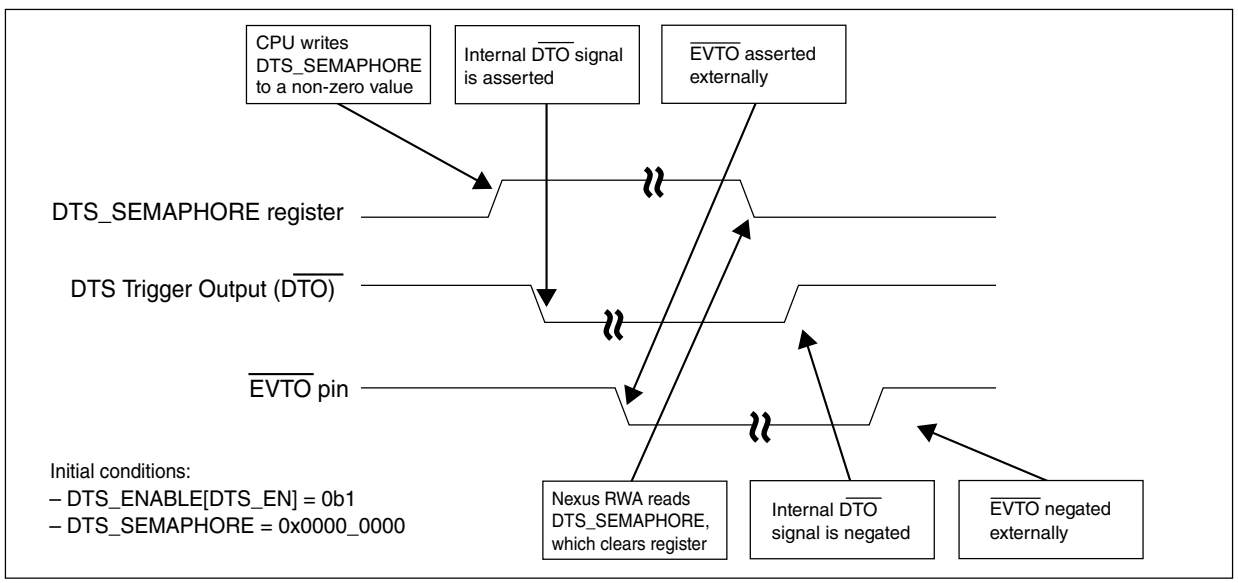

Figure 26-2. DTO event sequence example

26.4 DTS device connections

The following figure shows the DTS device connections. The DTS module connects to the Peripheral Bridge (PBRIDGE) for access to the registers. The PBRIDGE is connected to the device modules through a slave port of the Crossbar bus interface (XBAR).

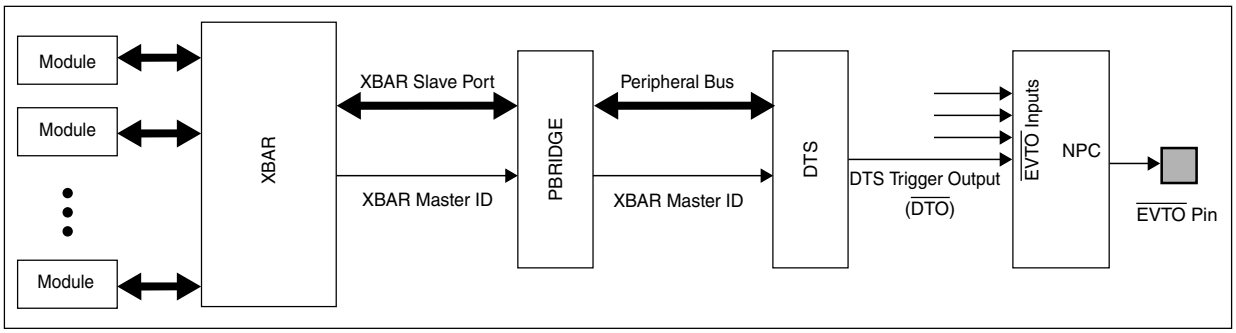

Figure 26-3. DTS device connections

The registers have limited access as described in DTS register access. Access is based on the XBAR Master ID of the accessing module. Writing to the semaphore registers is limited to the cores and the eDMA module and is restricted to only setting bits. Only an access via a Nexus Read/Write Access from an external tool can clear bits in the semaphore registers (semaphore register bits are cleared automatically when read). Similarly, the DTS_ENABLE and DTS_STARTUP registers can only be written via a Nexus Read/Write Access.

Note

Nexus Read/Write Accesses use the core load/store bus to perform accesses, but Nexus accesses have a different Master ID than normal core load/stores.

26.4.1 DTS register access

A summary of accesses to all DTS registers by bus masters is provided in the following table. Only proper 32-bit accesses are valid. The effects of write accesses that are not 32 bits are not defined.

Table 26-1. DTS register access effects

Register	32-bit read				32-bit write			
	RWA[1]	Core	eDMA	Other crossbar masters	RWA [1]	Core	eDMA	Other crossbar masters
DTS_ENABLE	Data	Data	Data	Data	Data	No effect	No effect	No effect
DTS_STARTUP	Data	Data	Data	Data	Data	No effect	No effect	No effect
DTS_SEMAPHORE	Data and Clear[2]	Data	Data	Data	No effect	Bit OR	Bit OR	No effect
DTS_SEMAPHORE_B	Data and Clear[2]	Data	Data	Data	No effect	Bit OR	Bit OR	No effect

1. Nexus Read/Write access via an external tool
2. A read of the semaphore registers by Nexus Read/Write Access module is destructive and clears all bits in the register

Access to DTS module registers is controlled based on the XBAR Master ID of the accessing module.

Note

The XBAR Master ID should not be confused with the Master Port number of the XBAR. See the Crossbar Switch (XBAR) chapter for details.

Tools must access the DTS registers through the Nexus Read/Write Access mechanism of a core. External tool accesses through either core appear as if the access is via the core and therefore do not have the same level of access as a Nexus Read/Write Access.

26.5 Memory mapped registers

Only certain types of accesses are allowed to the DTS registers. See the description for each register to determine the accesses that are allowed.

DTS memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Output Enable Register (DTS_ENABLE)	32	R/W	0000_0000h	26.5.1/975
4	Startup Register (DTS_STARTUP)	32	R/W	0000_0000h	26.5.2/977
8	Semaphore Register (DTS_SEMAPHORE)	32	R/W	FFFF_FFFFh	26.5.3/977
C	Semaphore Extension (DTS_SEMAPHORE_B)	32	R/W	FFFF_FFFFh	26.5.4/978

26.5.1 Output Enable Register (DTS_ENABLE)

The DTS_ENABLE register controls the DTS Trigger Output ($\overline{\text{DTO}}$) and whether $\overline{\text{DTO}}$ is active on the $\overline{\text{EVTO}}$ output pin of the device. The DTS_ENABLE register can be read by the core, but can only be written by a Nexus Read Write Access (RWA).

NOTE

Access to the DTS_SEMAPHORE, DTS_SEMAPHORE_B, and DTS_STARTUP registers are unaffected by the state of this register.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	Reserved

R W	Reserved														DTS_EN_B	DTS_EN
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DTS_ENABLE field descriptions

Field	Description
0–29 Reserved	This field is reserved.
30 DTS_EN_B	DTS Enable B. Controls whether the $\overline{\text{DTO}}$ signal is routed to the $\overline{\text{EVTO}}$ pin. The DTS Enable bit is cleared by a device reset (either the assertion of the external $\overline{\text{RESET}}$ or by an internally generated reset). A Nexus reset does not change the state of this register. 0 DTS output disabled. Any bit set in the DTS_SEMAPHORE_B register does not assert the DTS trigger output signal. 1 DTS output enabled. Any bit set in the DTS_SEMAPHORE_B register asserts the DTS trigger output signal ($\overline{\text{DTO}}$).
31 DTS_EN	DTS Enable. Controls whether the $\overline{\text{DTO}}$ signal is routed to the $\overline{\text{EVTO}}$ pin. The DTS Enable bit is cleared by a device reset (either the assertion of the external $\overline{\text{RESET}}$ or by an internally generated reset). A Nexus reset does not change the state of this register. 0 DTS output disabled. Any bit set in the DTS_SEMAPHORE register does not assert the DTS trigger output signal. 1 DTS output enabled. Any bit set in the DTS_SEMAPHORE register asserts the DTS trigger output signal ($\overline{\text{DTO}}$).

26.5.2 Startup Register (DTS_STARTUP)

The DTS_STARTUP register is used for tool detection and startup information exchange between external data acquisition tool and the embedded controller. DTS_STARTUP register can be read by the core, the eDMA module and Nexus but can only be updated by a Nexus Read Write Access (RWA).

Address: 0h base + 4h offset = 4h

DTS_STARTUP field descriptions

Field	Description
0–31 AD	Application Dependent register bits. The bits have no defined meaning to the microcontroller. They are used to by an external tool to pass information (for example, application options and status) to application software running on target microcontroller at startup time. Use a Nexus RWA 32-bit write access to update the contents of this register. A device reset (either from the $\overline{\text{RESET}}$ pin or an internally generated reset) clears all bits in the register. A Nexus reset does not change the contents of the register.

26.5.3 Semaphore Register (DTS_SEMAPHORE)

The DTS_SEMAPHORE register is used by software to assert the $\overline{\text{DTO}}$ signal on the device $\overline{\text{EVTO}}$ pin. A one in any bit of this register causes the $\overline{\text{DTO}}$ signal on the $\overline{\text{EVTO}}$ pin to be driven low. The intended use of this register is for the $\overline{\text{DTO}}$ signal to notify tools that data is available. Individual bits are used to identify the specific data.

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DTS_SEMAPHORE field descriptions

Field	Description
0–31 ST	Semaphore Trigger. When a core or eDMA writes a logical '1' to a bit, the bit is set. A write of '0' by the core or DMA does not change the state of the bit. • All register bits are set to '1' by a device reset.

DTS_SEMAPHORE field descriptions (continued)

Field	Description
	• A Nexus reset does not change the state of this register. • The register can be accessed, with restrictions, by any core, DMA or any Nexus RWA. • For the core or DMA, only 32-bit write or read accesses are valid. • A core or DMA valid read access returns the current value of the register and leaves the register unchanged. 0 No flag 1 Flag is set

26.5.4 Semaphore Extension (DTS_SEMAPHORE_B)

The DTS_SEMAPHORE_B register is used by software to assert the $\overline{\text{DTO}}$ signal on the device $\overline{\text{EVTO}}$ pin. A one in any bit of this register causes the $\overline{\text{DTO}}$ signal on the $\overline{\text{EVTO}}$ pin to be driven low. The intended use of this register is for the $\overline{\text{DTO}}$ signal to notify tools that data is available. Individual bits are used to identify the specific data.

Address: 0h base + Ch offset = Ch

DTS_SEMAPHORE_B field descriptions

Field	Description
0–31 ST_B	Semaphore Trigger Extension. When a core or eDMA writes a logical '1' to a bit, the bit is set. A write of '0' by the core or DMA does not change the state of the bit. • All register bits are set to '1' by a device reset. • A Nexus reset does not change the state of this register. • The register can be accessed, with restrictions, by any core, DMA or any Nexus RWA. • For the core or DMA, only 32-bit write or read accesses are valid. • A core or DMA valid read access returns the current value of the register and leaves the register unchanged. 0 No flag 1 Flag is set

26.6 Example application

The calibration process of a new engine requires real-time access to calibration tables and the ability to update the tables in real-time The DTS module enables this capability by enabling software to assert a signal to an external device pin to notify an external tool that data is available. The tool can then retrieve the data.

In this type of application the DTS_SEMAPHORE register and DTS Trigger Output (DTO) signal provide a mechanism to notify the calibration tool that the calibration variable or variables (or sets of measurements), up to 32, have been updated with new values and are available for the tool to access.

Note

It is the user's responsibility to ensure that the tool has time to retrieve the data prior to that particular trigger being set a second time. It is also permissible to have multiple triggers active at the same time or for a second trigger to be set before a previous trigger has been serviced, as long as it is not the same trigger (unless it is acceptable to the tool to not receive every data set).

The following table shows an example DTS startup sequence for an external real-time data acquisition system. The startup and synchronization sequence can be as simple or as complicated as the need requires. However, a typical startup sequence is as follows:

1. The DTS_STARTUP register is cleared by a power on reset or any CPU reset.
2. The tool writes a non-zero value to the DTS_STARTUP register.
3. The CPU (user application software) then reads the value of the DTS_STARTUP register. Based on this value, different initialization options can be selected. The bits can be used for any application specific definitions.
4. Since the DTS_SEMAPHORE register is cleared when the tool reads the current value. The tool should perform all necessary initialization before reading this register. The application software can then check that the DTS_SEMAPHORE register was cleared by the tool, to determine that it is safe to start using it for its intended raster trigger semaphore function.
5. An optional hand shake from the CPU can be used to inform the tool that the user software has detected that the tool is attached and the CPU has performed the proper initialization for the tool by writing a predefined value to the DTS_SEMAPHORE

register (the example shown in the figure above uses 0xAAAA_AAAA—all A's was used since it is unrealistic that 16 channels could be enabled very quickly after start up after a reset).

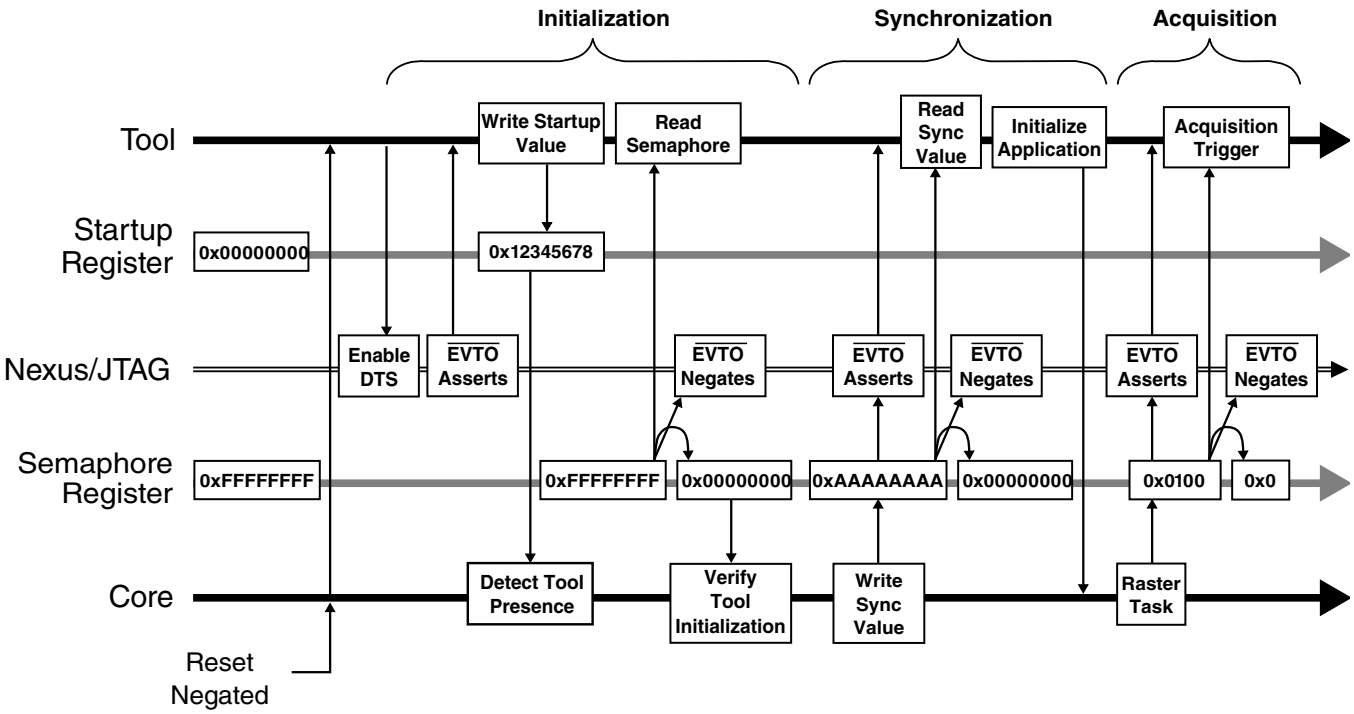

Figure 26-4. DTS startup sequence example

Chapter 27
Wakeup Unit (WKPU)

27.1 Chip-specific WKPU information

27.1.1 Chip-specific WKPU configuration

The S32R274 device WKPU supports only one external source from the NMI pad that can cause non-maskable interrupts to on-chip cores, and wakeup events to the system.

For Pad details, see "IO Signal Description and Input multiplexing tables" spreadsheet attached with this document.

27.1.2 Register reset values

Some of the registers in this module have chip-specific reset values. They are listed below.

Register	Reset value
WKPU_NCR	0x0000_0000

27.1.3 Clocking limitation for Core1 and Core2 NMIs

For the NMI interface of Core1 and Core2 to work, the CORE0_CLK should be kept on.

27.2 Introduction

The Wakeup Unit (WKPU) supports three external sources that can cause non-maskable interrupts to on-chip cores and wakeup events to the system. The figure below shows the WKPU block diagram and its interfaces to other system components.

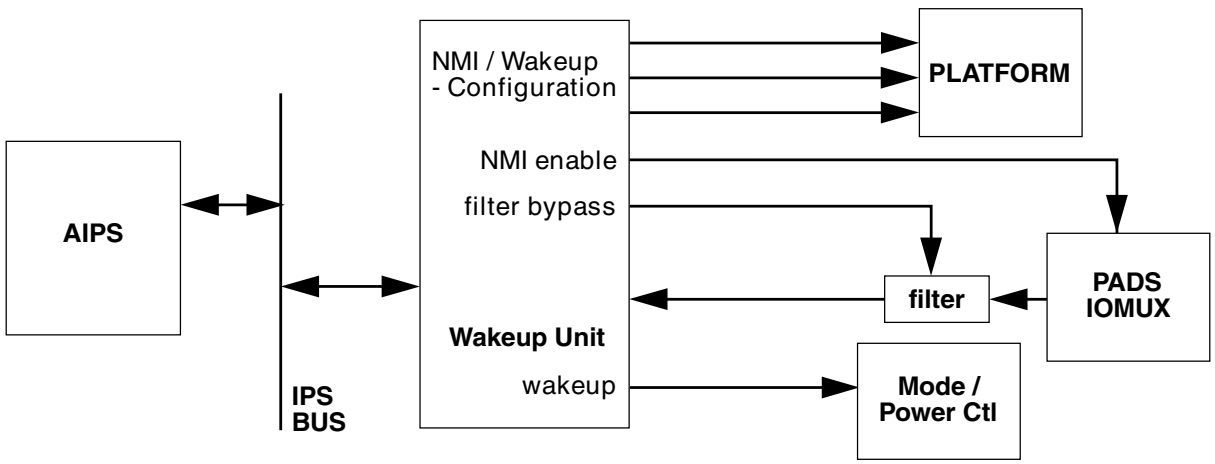

Figure 27-1. WKPU and connected system components

27.3 Features

The WKPU supports these features:

- Non-maskable Interrupt support with:
  - External NMI sources
  - Analog glitch filters
- Independent interrupt destination for each core:
  - Non-maskable interrupt
- Active edge selection control for events to each core
- Configurable system wakeup triggering from NMI source(s)

27.4 External signal description

The WKPU has signal inputs that can be used as external interrupt sources in normal run mode or as system wakeup sources in certain power down modes.

27.5 WKPU memory map and register definition

This section provides a detailed description of all registers accessible in the WKPU module.

NOTE

Reserved registers will read as 0, writes will have no effect. Transfer error will be generated when trying to access completely reserved register space.

WKPU memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	NMI Status Flag Register (WKPU_NSR)	32	w1c	0000_0000h	27.5.1/983
8	NMI Configuration Register (WKPU_NCR)	32	R/W	See section	27.5.2/985

27.5.1 NMI Status Flag Register (WKPU_NSR)

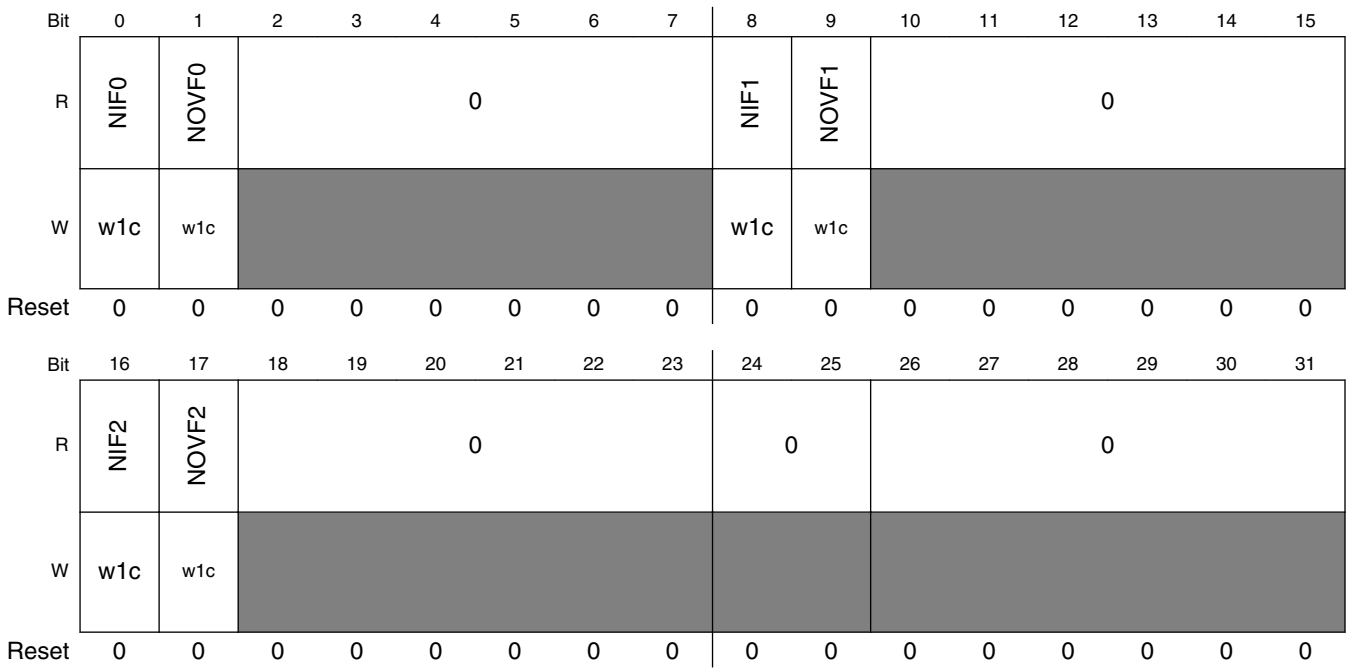
This register holds the non-maskable interrupt status flags.

NOTE

This register is accessible by 8-, 16-, and 32-bit read/write operations.

Access: User read/write

Address: 0h base + 0h offset = 0h



WKPU_NSR field descriptions

Field	Description
0 NIF0	NMI Status Flag 0. This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (NREE0 or NFEE0 set), NIF0 causes an interrupt request. 0 No event has occurred on the pad 1 An event as defined by NREE0 and NFEE0 has occurred
1 NOVF0	NMI Overrun Status Flag 0. This flag can be cleared only by writing a 1. Writing a 0 has no effect. It will be a copy of the current NIF0 value whenever a NMI event occurs, thereby indicating to the software that a NMI occurred while the last one was not yet serviced. If enabled (NREE0 or NFEE0 set), NOVF0 causes an interrupt request. 0 No overrun has occurred on NMI input 0 1 An overrun has occurred on NMI input 0
2–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 NIF1	NMI Status Flag 1. This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (NREE1 or NFEE1 set), NIF1 causes an interrupt request. 0 No event has occurred on the pad 1 An event as defined by NREE1 and NFEE1 has occurred
9 NOVF1	NMI Overrun Status Flag 1. This flag can be cleared only by writing a 1. Writing a 0 has no effect. It will be a copy of the current NIF1 value whenever a NMI event occurs, thereby indicating to the software that a NMI occurred while the last one was not yet serviced. If enabled (NREE1 or NFEE1 set), NOVF1 causes an interrupt request. 0 No overrun has occurred on NMI input 1 1 An overrun has occurred on NMI input 1
10–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

WKPU_NSR field descriptions (continued)

Field	Description
16 NIF2	NMI Status Flag 2. This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (NREE2 or NFEE2 set), NIF2 causes an interrupt request. 0 No event has occurred on the pad 1 An event as defined by NREE2 and NFEE2 has occurred
17 NOVF2	NMI Overrun Status Flag 2. This flag can be cleared only by writing a 1. Writing a 0 has no effect. It will be a copy of the current NIF2 value whenever a NMI event occurs, thereby indicating to the software that a NMI occurred while the last one was not yet serviced. If enabled (NREE2 or NFEE2 set), NOVF2 causes an interrupt request. 0 No overrun has occurred on NMI input 2 1 An overrun has occurred on NMI input 2
18–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

27.5.2 NMI Configuration Register (WKPU_NCR)

This register holds the configuration bits for the non-maskable interrupt settings.

NOTE

- This register is accessible by 8-, 16-, and 32-bit read/write operations.
- Writing a 0 to both NREE[*n*] and NFEE[*n*] disables the NMI functionality completely (i.e., no system wakeup or interrupt will be generated on any pad activity).

Access: User read/write

27.6 Functional description

This section provides a functional description of the WKPU.

27.6.1 Non-maskable interrupts

The WKPU supports the generation of 3 types of interrupts per NMI input to the SoC. The WKPU supports the capturing of a second event per NMI input before the interrupt is cleared, thus reducing the chance of losing an NMI event, though it creates an overrun condition.

Each NMI passes through a bypassable analog glitch filter.

NOTE

Glitch filter control and pad configuration should be done while the NMI is disabled in order to avoid erroneous triggering by glitches caused by the configuration process itself.

NOTE

The figure below represents a generic configuration and might not represent this particular device's configuration. See the chip-specific information for details on this chip's WKPU.

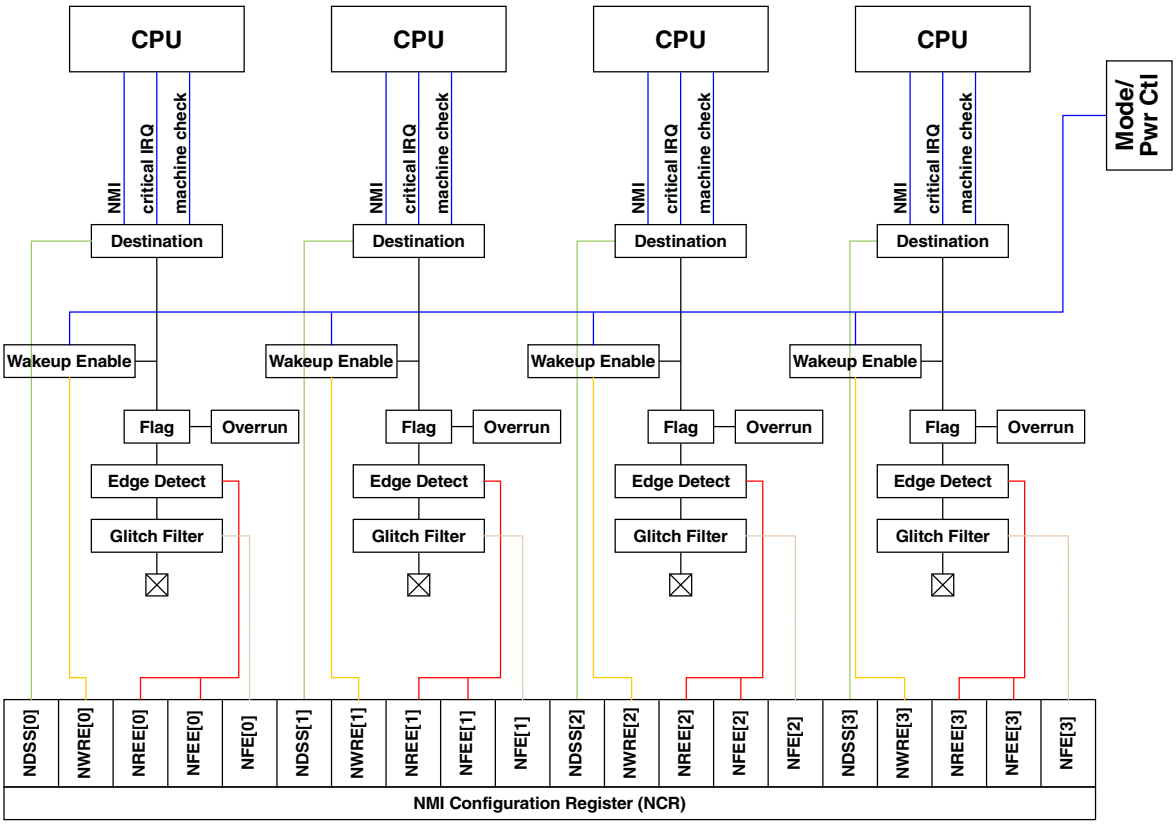

Figure 27-2. NMI pad diagram

27.6.1.1 NMI management

Each NMI can be enabled or disabled independently. This can be performed using the single NCR register laid out to contain all configuration bits for a given NMI in a single byte (see NMI Configuration Register (WKPU_NCR)). A pad defined as an NMI can be configured by the user to recognize interrupts with an active rising edge, an active falling edge or both edges being active. A setting of having both edge events disabled results in no interrupt being detected and should not be configured.

The active NMI edge is controlled by the user through the configuration of the NREE and NFEE bits.

Note

After reset, NREE and NFEE are set to '0', therefore the NMI functionality is disabled after reset and must be enabled explicitly by software.

Once a pad's NMI functionality has been enabled, the pad cannot be reconfigured in the IOMUX to override or disable the NMI. Please see chip specific section for details on NMI implementation.

The NMI destination interrupt is controlled by the user through the configuration of the NDSS bits. See NMI Configuration Register (WKPU_NCR) for details.

Each NMI supports a status flag and an overrun flag which are located in the NSR register (see NMI Status Flag Register (WKPU_NSR)). This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register. The status flag is set whenever an NMI event is detected. The overrun flag is set whenever an NMI event is detected and the status flag is set (i.e. has not yet been cleared).

Note

The overrun flag is cleared by writing a '1' to the appropriate overrun bit in the NSR register. If the status bit is cleared and the overrun bit is still set, the pending interrupt will not be cleared.

During an NMI ISR, on wakeup of the SoC from an NMI, any writes to ECC-protected memory must have the correct ECC.

Chapter 28
Interrupt Controller (INTC)

28.1 Introduction

The INTC:

- Provides priority-based preemptive scheduling of interrupt requests
- Schedules interrupt requests (IRQs) from software and internal peripherals to one or more processors (PRCs)
- Provides interrupt prioritization and preemption, interrupt masking, interrupt priority elevation, and protocol support

This scheduling scheme is suitable for statically scheduled hard real-time systems.

The INTC is targeted to work with a Power Architecture processor and is capable of processing high-demand interrupt sources where the Interrupt Service Routines (ISRs) nest to multiple levels, but it also can be used with other processors and applications.

For high-priority interrupt requests in these target applications, it is necessary to minimize the interval between the assertion of the interrupt request from the peripheral and the point at which the processor is performing useful work to service the interrupt request. The INTC supports this goal by providing a unique vector for each interrupt request source. It also provides 32 priorities so that lower priority ISRs do not delay the execution of higher priority ISRs. Since each individual application will have different priorities for each source of interrupt request, the priority of each interrupt request is configurable.

When multiple tasks share a resource, coherent accesses to that resource need to be supported. The INTC supports the Priority Ceiling Protocol for coherent accesses. By providing a modifiable priority mask, the priority can be raised temporarily so that all tasks which share the resource are unable to preempt each other.

Multiple processors can assert interrupt requests to each other through software-settable interrupt requests. These same software-settable interrupt requests can also be used to separate the work involved in servicing an interrupt request into two parts, a high-priority portion and a low-priority portion. The high-priority portion is initiated by a peripheral interrupt request, but then the ISR can assert a software-settable interrupt request to finish the servicing in a lower priority ISR. Therefore these software-settable interrupt requests can be used instead of having the peripheral ISR schedule a task through the RTOS.

28.2 Block diagram

The following figure shows the block diagram of an INTC with four processors (PRC0...PRC3). The actual number of processors is described in the chip-specific INTC information. The structure of the INTC remains the same for each implemented processor.

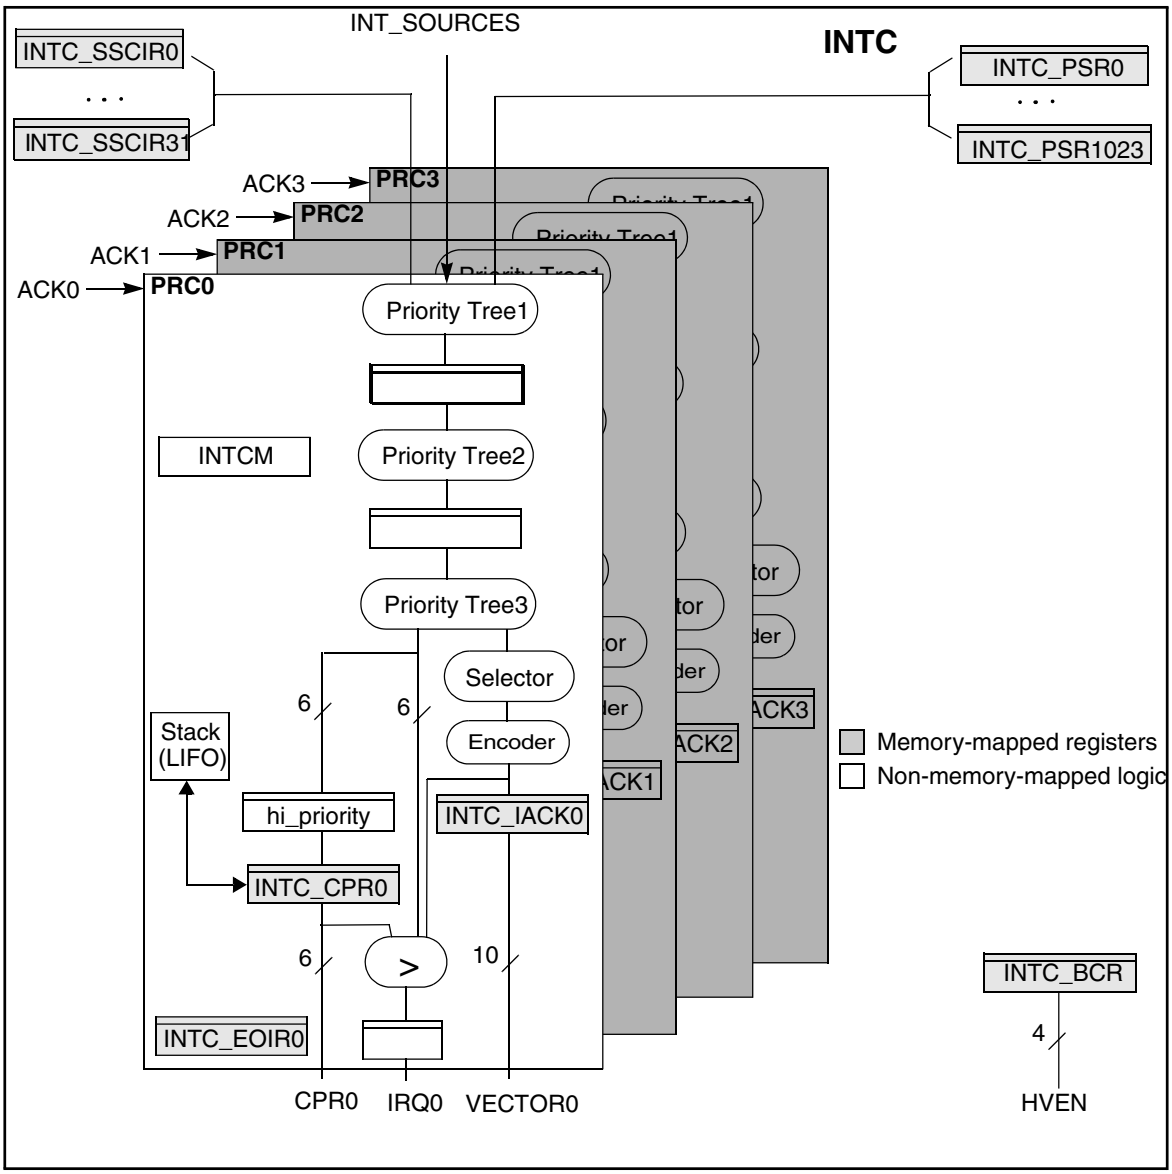

Figure 28-1. Block diagram for an INTC with four processors

28.3 Features

- Each peripheral interrupt source is software-steerable to any combination of interrupt request outputs to the following:
  - Processor 0
  - Processor 1
  - Processor 2
- 16 software-settable interrupt request sources

- 10-bit vector
  - Unique vector for each interrupt request source
  - Hardware connection to processor or read from register
- Each interrupt source can be programmed to one of 32 priorities
- Each interrupt source can be triggered by software
- Preemption
  - Preemptive prioritized interrupt requests to processor
  - ISR with higher priority preempts ISRs or tasks with lower priorities
  - Automatic pushing or popping of preempted priority to or from a LIFO
  - Ability to modify the ISR or task priority; modifying the priority can be used to implement the Priority Ceiling Protocol for accessing shared resources
  - 3 INTC clock cycles from interrupt request into interrupt request to CPU
- Low latency
  - 3 INTC clock cycles from receipt of interrupt request from peripheral to interrupt request to processor; four clock cycles from receipt of software request
- Monitor
  - The Interrupt Controller Monitor (INTCM) provides a way to set a maximum timer count for the interrupt latency from interrupt request (IRQ) to interrupt acknowledge (IACK) or from IRQ to return from interrupt (RFI). The purpose of this function is to provide a mechanism to monitor the latency of interrupt sources for a corresponding Processor to ensure that these critical interrupts execute within the expected window of time, increasing the reliability of the device. The hardware for this function is isolated in its own hierarchy to decrease the risk of fault interference.

28.4 Modes of operation

The interrupt controller has two handshaking modes with the processor: software vector mode and hardware vector mode. The state of the hardware vector enable bit, INTC_BCR[HVEN], determines which mode is used. In Power Architecture devices, software vector mode uses the autovector mode of the Processor for a single entry point

for the ISR (16 bytes of vector space available), whereas the hardware vector mode uses the non-autovector mode where the vector offset from the INTC is provided to the Processor (4 bytes for each IRQ).

In debug mode the interrupt controller operation is identical to its normal operation of software vector mode or hardware vector mode.

28.4.1 Software vector mode

In software vector mode, software (that is, the interrupt exception handler) must read a register in the INTC to obtain the vector associated with the interrupt request to the processor. The INTC will use software vector mode for a given processor when its associated HVEN_PRCn bit in the INTC_BCR is negated. The hardware vector enable signal to any processor is driven as negated when its associated HVEN_PRC*n* bit is negated. The vector is read from the INTC_IACKRn registers. Reading the INTC_IACKR*n* negates the interrupt request to the associated processor. Even if a higher priority interrupt request has arrived while waiting for this interrupt acknowledge, the interrupt request to the processor will negate for at least one clock. The reading also pushes the PRI value in the INTC_CPRn onto the associated LIFO, and updates PRI in the associated INTC_CPR_PRC*n* with the new priority.

28.4.2 Hardware vector mode

In hardware vector mode, the hardware causes the first instruction that will be executed (when handling the interrupt request to the processor) to be an instruction that is specific to that vector. Therefore the interrupt exception handler is specific to a peripheral or software-settable interrupt request, rather than being common to all of them. The INTC will use hardware vector mode for a given processor when its associated HVENn bit in the INTC_BCR is asserted. The hardware vector enable signal to the associated processor is driven as asserted.

When the interrupt request to the associated processor asserts, the interrupt vector signal is updated. The value of that interrupt vector is the unique vector associated with the preempting peripheral or software-settable interrupt request. The vector value matches the value of the INTVEC field in the INTC_IACKRn, depending on which processor was assigned to handle a given interrupt source.

The assertion of the interrupt acknowledge signal for a given processor pushes the associated PRI value in the associated INTC_CPR*n* register onto the associated LIFO and updates the associated PRI in the associated INTC_CPR*n* register with the new priority. This pushing of the PRI value onto the associated LIFO and updating PRI in the

associated INTC_CPR*n* does not occur when the associated interrupt acknowledge signal asserts and the INTC_SSCIRs is written at a time such that the PRI value in the associated INTC_CPR*n* register would need to be pushed and the previously last pushed PRI value would need to be popped simultaneously. In this case, PRI in the associated INTC_CPR*n* is updated with the new priority, and the associated LIFO is neither pushed or popped.

28.5 Memory map and register definition

A transfer error will be asserted if an access is attempted outside of the memory map or for any unimplemented registers. For example, if the design has only 512 interrupt sources and a source > 512 is accessed, a transfer error is asserted.

With the exception of the INTC_SSCIR *n* and INTC_PSR *n* registers, all of the registers are 32-bit. Any combination of accessing the four bytes of a register with a single access is supported, provided that the access does not cross a register boundary. These supported accesses include types and sizes of 8 bits, aligned 16 bits, misaligned 16 bits to the middle two bytes, and aligned 32 bits.

Although INTC_SSCIR*n* are 8 bits wide and INTC_PSR*n* are 16 bits wide, they can be accessed with a single 16-bit or 32-bit access, provided that the access does not cross a 32-bit boundary.

Some registers have specific exceptions to these rules, as outlined in their definitions.

When writing to INTC_PSRs or INTC_SSCIRs, the following restrictions (illustrated in Figure 28-2) apply:

- For PSRs, write accesses must not span 16-bit boundaries where one register is implemented and one is unimplemented (unimplemented interrupt source).
- For SSCIRs, write accesses must not span 8-bit boundaries where one register is implemented and one is unimplemented (unimplemented interrupt source).

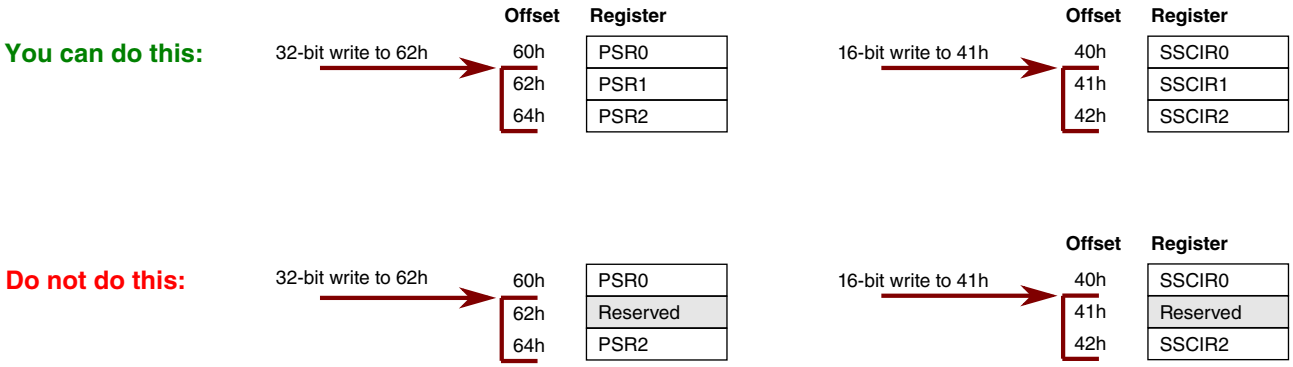

Figure 28-2. INTC_PSR*n* and INTC_SSCIR*n* write restrictions

In software vector mode, the effects of a read of the INTC Interrupt Acknowledge register (INTC_IACKR *n*) are the same regardless of the size of the read. In either software or hardware vector mode, the size of a write to the INTC end-of-interrupt register (INTC_EOIR *n*) does not affect the operation of the write.

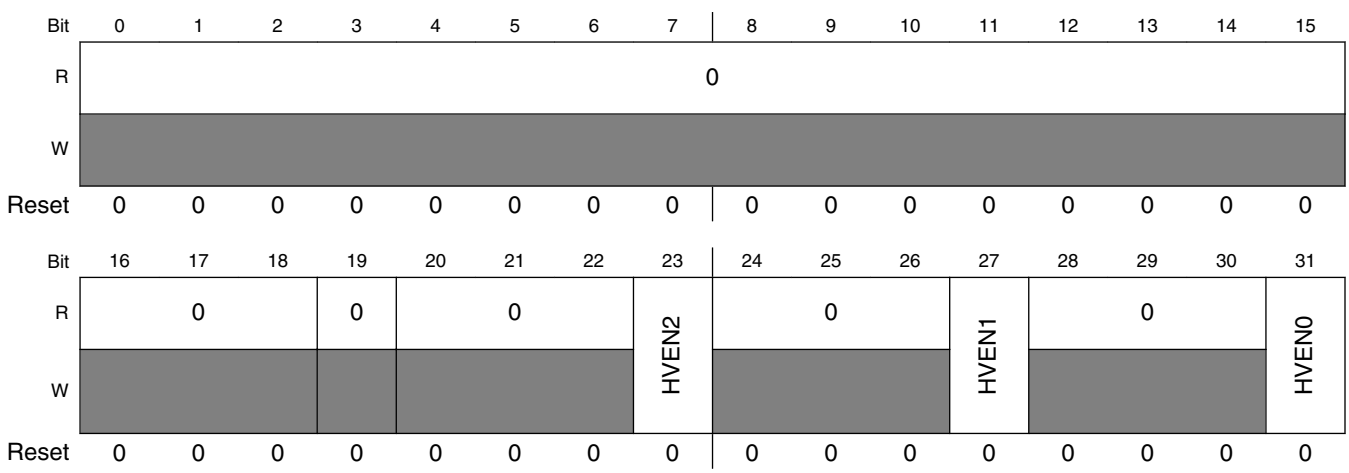
28.5.1 INTC Block Configuration Register (INTC_BCR)

The Block Configuration Register is used to configure options of the INTC.

Address: 0h base + 0h offset = 0h



INTC_BCR field descriptions

Field	Description
0–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 HVEN2	Hardware vector enable for processor 2. Controls whether the INTC is in hardware vector mode or software vector mode. See Modes of operation for the details of the handshaking with the processor in each mode. 0 Software vector mode 1 Hardware vector mode
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 HVEN1	Hardware vector enable for processor 1. Controls whether the INTC is in hardware vector mode or software vector mode. See Modes of operation for the details of the handshaking with the processor in each mode. 0 Software vector mode 1 Hardware vector mode
28–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 HVEN0	Hardware vector enable for processor 0. Controls whether the INTC is in hardware vector mode or software vector mode. See Modes of operation for the details of the handshaking with the processor in each mode. 0 Software vector mode 1 Hardware vector mode

28.5.2 INTC Current Priority Register for Processor 0 (INTC_CPR0)

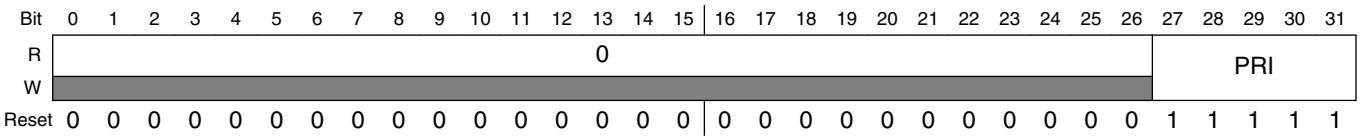
The INTC_CPRn masks any peripheral or software-settable interrupt request that is set at the same or lower priority as the current value of the INTC_CPR*n*[PRI] field from generating an interrupt request to the processor. When the INTC Interrupt Acknowledge register (INTC_IACKR*n*) is read in software vector mode or the interrupt acknowledge signal from the processor is asserted in hardware vector mode, the value of PRI is pushed onto the LIFO, and PRI is updated with the priority of the preempting interrupt request. When the INTC end-of-interrupt register (INTC_EOIR*n*) is written, the LIFO is popped into the INTC_CPR*n* PRI field. An exception case in hardware vector mode to this behavior is described in Hardware vector mode.

The masking priority can be raised or lowered by writing to the PRI field, supporting the priority ceiling protocol. See Priority ceiling protocol.

NOTE

A store to modify the PRI field that closely precedes or follows an access to a shared resource may result in a non-coherent access to that resource. See Ensuring coherency for example code to ensure coherency.

Address: 0h base + 10h offset = 10h



INTC_CPR0 field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 PRI	Priority of the currently executing ISR, according to the field values 31 (highest priority) down to 0 (lowest priority).

28.5.3 INTC Current Priority Register for Processor 1 (INTC_CPR1)

The INTC_CPRn masks any peripheral or software-settable interrupt request that is set at the same or lower priority as the current value of the INTC_CPR*n*[PRI] field from generating an interrupt request to the processor. When the INTC Interrupt Acknowledge register (INTC_IACKR*n*) is read in software vector mode or the interrupt acknowledge signal from the processor is asserted in hardware vector mode, the value of PRI is pushed onto the LIFO, and PRI is updated with the priority of the preempting interrupt request. When the INTC end-of-interrupt register (INTC_EOIR*n*) is written, the LIFO is popped into the INTC_CPR*n* PRI field. An exception case in hardware vector mode to this behavior is described in Hardware vector mode.

The masking priority can be raised or lowered by writing to the PRI field, supporting the priority ceiling protocol. See Priority ceiling protocol.

NOTE

A store to modify the PRI field that closely precedes or follows an access to a shared resource may result in a non-coherent access to that resource. See Ensuring coherency for example code to ensure coherency.

Address: 0h base + 14h offset = 14h

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 PRI	Priority of the currently executing ISR, according to the field values 31 (highest priority) down to 0 (lowest priority).

28.5.4 INTC Current Priority Register for Processor 2 (INTC_CPR2)

The INTC_CPRn masks any peripheral or software-settable interrupt request that is set at the same or lower priority as the current value of the INTC_CPR*n*[PRI] field from generating an interrupt request to the processor. When the INTC Interrupt Acknowledge register (INTC_IACKR*n*) is read in software vector mode or the interrupt acknowledge signal from the processor is asserted in hardware vector mode, the value of PRI is pushed onto the LIFO, and PRI is updated with the priority of the preempting interrupt request. When the INTC end-of-interrupt register (INTC_EOIR*n*) is written, the LIFO is popped into the INTC_CPR*n* PRI field. An exception case in hardware vector mode to this behavior is described in Hardware vector mode.

The masking priority can be raised or lowered by writing to the PRI field, supporting the priority ceiling protocol. See Priority ceiling protocol.

NOTE

A store to modify the PRI field that closely precedes or follows an access to a shared resource may result in a non-coherent access to that resource. See Ensuring coherency for example code to ensure coherency.

Address: 0h base + 18h offset = 18h

INTC_CPR2 field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 PRI	Priority of the currently executing ISR, according to the field values 31 (highest priority) down to 0 (lowest priority).

28.5.5 INTC Interrupt Acknowledge Register for Processor 0 (INTC_IACKR0)

The Interrupt Acknowledge Register for Processor *n* provides a value which can be used to load the address of an ISR from a vector table. The vector table can be composed of addresses of the ISRs specific to their respective interrupt vectors.

Also, in software vector mode, the INTC_IACKR*n* has side effects from reads. Therefore, it must not be read speculatively while in this mode. The side effects are the same regardless of the size of the read. Reading the INTC_IACKRn does not have side effects in hardware vector mode.

NOTE

When the corresponding INTC_BCR[HVENn] = 1, a read of the INTC_IACKR has no side effects.

Address: 0h base + 20h offset = 20h

Bit	0–15	16–19	20–29	30–31
R	VTBA		INTVEC	0
W

INTC_IACKR2 field descriptions

Field	Description
0–19 VTBA	Vector table base address. Can be the base address of a vector table of addresses of ISRs.
20–29 INTVEC	Interrupt vector. Vector of the peripheral or software-settable interrupt request that caused the interrupt request to the processor. When the interrupt request to the processor asserts, the INTVEC is updated, whether the INTC is in software or hardware vector mode.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

28.5.8 INTC End Of Interrupt Register for Processor 0 (INTC_EOIR0)

Writing to the INTC_EOIR*n* signals the end of the servicing of the interrupt request. When the INTC_EOIR*n* is written, the priority last pushed on the LIFO is popped into INTC_CPR*n*. The values and size of data written to the INTC_EOIR*n* are ignored. Those values and sizes written to this register neither update the INTC_EOIR*n* contents nor affect whether the LIFO pops. Typically, when you write to this register, write four all-zero bytes.

Address: 0h base + 30h offset = 30h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

INTC_EOIR1 field descriptions

Field	Description
0–31 EOI	End of Interrupt. Write four all-zero bytes to this field to signal the end of the servicing of an interrupt request.

28.5.10 INTC End Of Interrupt Register for Processor 2 (INTC_EOIR2)

Writing to the INTC_EOIR*n* signals the end of the servicing of the interrupt request. When the INTC_EOIR*n* is written, the priority last pushed on the LIFO is popped into INTC_CPR*n*. The values and size of data written to the INTC_EOIR*n* are ignored. Those values and sizes written to this register neither update the INTC_EOIR*n* contents nor affect whether the LIFO pops. Typically, when you write to this register, write four all-zero bytes.

Address: 0h base + 38h offset = 38h

Bit	0–15	16–31
R		
W	EOI	
Reset	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

INTC_EOIR2 field descriptions

Field	Description
0–31 EOI	End of Interrupt. Write four all-zero bytes to this field to signal the end of the servicing of an interrupt request.

28.5.11 INTC Software Set/Clear Interrupt Register (INTC_SSCIR*n*)

The INTC_SSCIR registers support the setting or clearing of software-settable interrupt requests. These registers contain independent sets of bits to set and clear a corresponding flag bit by software. Unlike the SWT bit in the PSRs, the INTC_SSCIR registers do not require a read-modify-write. With the exception of being set by software, this flag bit behaves the same as a flag bit set within a peripheral. This flag bit generates an interrupt request within the INTC just like a peripheral interrupt request. Writing a 1 to SET will leave SET unchanged at 0 but will set CLR. Writing a 0 to SET will have no effect. CLR is the flag bit. Writing a 1 to CLR will clear it. Writing a 0 to CLR will have no effect. If a 1 is written to a pair of SET and CLR bits at the same time, CLR is asserted, regardless of whether CLR was asserted before the write.

See Figure 28-2 for limitations on writing to this register.

Address: 0h base + 40h offset + (1d × i), where i=0d to 15d

Bit	0–3	4	5	6	7
Read	0	0		0	CLR
Write				SET	w1c
Reset	0	0	0	0	0

INTC_SSCIR*n* field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 SET	Set flag bits. Writing a 1 will set the corresponding CLR bit. Writing a 0 will have no effect. Each SET is read as a 0.
7 CLR	Clear flag bits. CLR is the flag bit. Writing a 1 to CLR will clear it provided that a 1 is not written simultaneously to its corresponding SET bit. Writing a 0 to CLR will have no effect. 0 Interrupt request not pending within INTC. 1 Interrupt request pending within INTC.

28.5.12 INTC Priority Select Register (INTC_PSR*n*)

The Priority Select Registers support the selection of an individual priority for each source of interrupt request, and the routing of the request to one or more processors. The unique vector of each peripheral or software-settable interrupt request determines which INTC_PSRn is assigned to that interrupt request. The software-settable interrupt requests are assigned the lowest numbered vectors, and their priorities are configured in the lowest numbered INTC_PSR registers. The peripheral interrupt requests are assigned to vectors immediately following the software-settable interrupt requests, and their priorities are configured in the immediately following INTC_PSR registers. The peripheral interrupt requests are assigned vectors 32-1023, and their priorities are configured in INTC_PSR32-1023, respectively.

See Figure 28-2 for limitations on writing to this register.

NOTE

Unlike the peripheral interrupt request PSRs, there is no SWT bit in the PSRs corresponding to the software-settable interrupt requests.

NOTE

Interrupts are not detected while the PSRs are being written.

Address: 0h base + 60h offset + (2d × i), where i=0d to 1023d

Bit	0	1	2	3	4	5	6	7
Read	PRC_SELN0	PRC_SELN1	PRC_SELN2	0	0			SWTN
Write								
Reset	1	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15

INTC_PSR*n* field descriptions

Field	Description
0 PRC_SELN0	Processor select 0. If an interrupt source is enabled, this field selects whether the interrupt request is to be sent to processor 0. 0 Interrupt request not sent to processor 0 1 Interrupt request sent to processor 0
1 PRC_SELN1	Processor select 1. If an interrupt source is enabled, this field selects whether the interrupt request is to be sent to processor 1.

Table continues on the next page...

INTC_PSR*n* field descriptions (continued)

Field	Description
	0 Interrupt request not sent to processor 1 1 Interrupt request sent to processor 1
2 PRC_SELN2	Processor select 2. If an interrupt source is enabled, this field selects whether the interrupt request is to be sent to processor 2. 0 Interrupt request not sent to processor 2 1 Interrupt request sent to processor 2
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 SWTN	This bit is only available in PSRs that do not correspond to the SSCIRs. The SWT bit supports triggering an interrupt by software rather than hardware. This is an alternative to setting a flag bit in a peripheral. This flag bit generates an interrupt request within the INTC just like a peripheral interrupt request. Writing a '1' to SWT*n* sets the bit. On the interrupt acknowledge cycle, the SWT*n* bit is cleared. The SWT function works both in hardware and software vector mode. It is only cleared by the enabled Processor(s) defined in the PRC_SEL*n* field of the PSR.
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–15 PRIN	Priority select. Selects the priority for the interrupt requests. PRI has values 31 (highest priority) down to 0 (lowest priority).

28.5.13 INTC Monitor Mode Register 0 (INTC_MMRC0)

The Monitor Mode Register is used to configure measurement options of the INTC.

Address: 0h base + 1000h offset = 1000h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

INTC_MMRC0 field descriptions

Field	Description
0–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30–31 MM	Monitor Mode. Controls whether the INTC monitors the latency or interrupt handler time 00 Disabled 01 IACK - Interrupt Acknowledge - timer is active from assertion of IRQ until interrupt acknowledge. An error is signaled if timer exceeds the programmed interrupt latency and the programmed interrupt latency is non-zero.

Table continues on the next page...

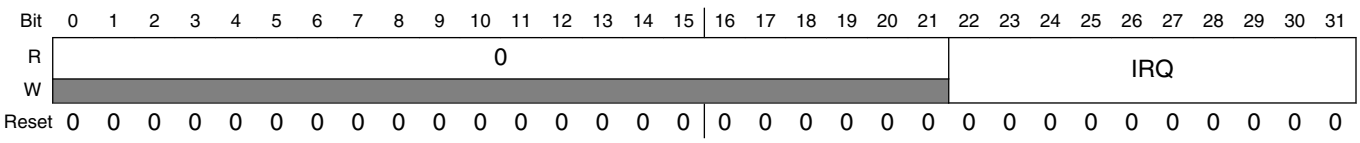
INTC_MMRC0 field descriptions (continued)

Field	Description
	10 EOI - End Of Interrupt - timer is active from assertion of IRQ until the end of the interrupt handler. The timer will continue to run even if interrupt handler is preempted. An error is signaled if timer exceeds the programmed interrupt latency and the programmed interrupt latency is non-zero. 11 SW - Software - timer is active from assertion of IRQ until the end of the interrupt handler unless it is preempted. A return from interrupt will start the timer if it is the timer associated with the active IRQ. No error is signaled; rather software can read the timer at any time.

28.5.14 INTC HIPRI Register (INTC_HIPRI*n*C0)

The HIPRI log2(SOURCES)-bit registers are used to indicate which IRQ is to be monitored or checked. The mnemonic is of the form HIPRImCn, where the 'n' is the corresponding Processor and the ‘m’ is the monitor instance for that Processor.

Address: 0h base + 1004h offset + (4d × i), where i=0d to 2d



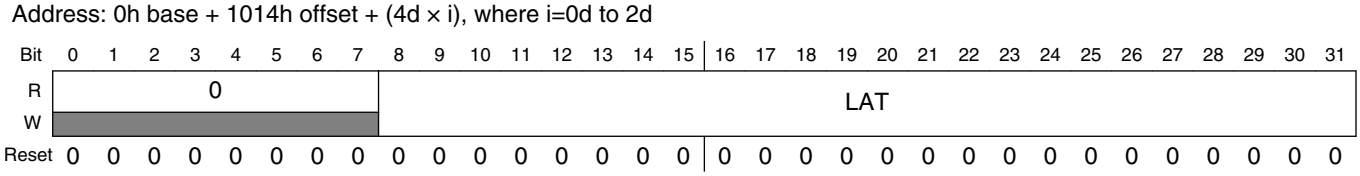
INTC_HIPRI*n*C0 field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–31 IRQ	Select the IRQ to monitor (input the hex value of the IRQ)

28.5.15 INTC LAT Register (INTC_LAT*n*C0)

These registers are used to indicate the maximum time before an error signal is asserted for a detected IRQ to either IACK or RFI based on the Mode. The mnemonic is of the form LATmCn, where the n is the corresponding Processor and the ‘m’ is the monitor instance for that Processor.

Address: 0h base + 1014h offset + (4d × i), where i=0d to 2d



INTC_LAT*n*C0 field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–31 LAT	Select the maximum number of INTC clock cycles allowed for the monitored IRQ.

28.5.16 INTC Timer Register (INTC_TIMER*n*C0)

These registers are used to indicate the time for a detected IRQ to either IACK or RFI based on the Mode. The mnemonic is of the form TIMERmCn, where the n is the corresponding Processor and the 'm' is the monitor instance for that Processor are used to indicate the maximum time for a detected IRQ to either IACK or RFI based on the Mode.

Address: 0h base + 1024h offset + (4d × i), where i=0d to 2d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

28.6 Functional description

The functional description involves the areas of interrupt request sources, priority management, and handshaking with the processor. In addition, spaces in the memory map have been reserved for other possible implementations of the INTC.

28.6.1 Interrupt request sources

The INTC has two types of interrupt requests, peripheral and software-settable. These interrupt requests can assert on any clock cycle.

The INTC has no spurious vector support. Therefore, if an asserted peripheral or software-settable interrupt request, whose PRI*n* value in INTC_PSR*n* is higher than the PRI value in INTC_CPR*n*, negates before the interrupt request to the processor for that peripheral or software-settable interrupt request is acknowledged, then the interrupt request to the processor still can assert (or will remain asserted) for that peripheral or software-settable interrupt request. In this case, the interrupt vector will correspond to that peripheral or software-settable interrupt request. Also, the PRI value in the associated INTC_CPR*n* is updated with the corresponding PRI*n* value in INTC_PSR*n*.

Furthermore, clearing the peripheral interrupt request's enable bit in the peripheral, or (alternatively) setting its mask bit, has the same consequences as clearing its flag bit. Setting its enable bit or clearing its mask bit while its flag bit is asserted has the same effect on the INTC as an interrupt event setting the flag bit.

28.6.1.1 Peripheral interrupt requests

An interrupt event in a peripheral's hardware sets a flag bit which resides in that peripheral. The interrupt request from the peripheral is driven by that flag bit.

The time from when the peripheral starts to drive its peripheral interrupt request to the INTC, to the time that the INTC starts to drive the interrupt request to the processor, is three clocks.

28.6.1.2 Software-settable interrupt requests

The software set/clear interrupt registers (INTC_SSCIR*n*) support the setting or clearing of software-settable interrupt requests. These registers contain independent sets of bits to set and clear a corresponding flag bit by software. An interrupt request is triggered by software by writing a 1 to a SET bit in INTC_SSCIR*n*. This write sets the corresponding CLR bit, which is a flag bit, resulting in the interrupt request. The interrupt request is cleared by writing a 1 to the CLR bit. Specific behavior includes the following:

- Writing a 1 to SET leaves SET unchanged at 0 but sets the flag bit (which is the CLR bit).
- Writing a 0 to SET has no effect.
- Writing a 1 to CLR clears the flag (CLR) bit.
- Writing a 0 to CLR has no effect.
- If a 1 is written to a pair of SET and CLR bits at the same time, the flag (CLR) is set, regardless of whether CLR was asserted before the write.

The time from the write to the SET bit, to the time that the INTC starts to drive the interrupt request to the processor, is four clocks.

Any Processor n will be allowed to write to any of the SET bits in the Software Set/Clear Interrupt registers. The CLR bit will only be writable by the Processor n which has been assigned to handle that interrupt request, as determined by the setting of the INTC_PSRn[PRC_SELn] bits.

28.6.1.3 Unique vector for each interrupt request source

Each peripheral and software-settable interrupt request is assigned a hardwired unique 10-bit vector. Software-settable interrupts 0–15 are assigned vectors 0–15, respectively. The peripheral interrupt requests are assigned vectors from 16 to a number as high as needed to cover all peripheral interrupt requests.

28.6.2 Priority management

The asserted interrupt requests are compared to each other based on their PRI*n* and PRC_SEL*n* values set in INTC_PSR*n*. The result of that comparison also is compared to PRI in the associated INTC_CPR*n*. The results of those comparisons are used to manage the priority of the ISR being executed by the associated processor. The associated LIFO also assists in managing that priority.

28.6.2.1 Current priority and preemption

The priority arbitrator, selector, encoder, and comparator logic shown in Figure 28-1 are used to compare the priority of the asserted interrupt requests to the current priority. If the priority of any asserted peripheral or software-settable interrupt request is higher than the current priority for a given processor, then the interrupt request to the processor is asserted. Also, a unique vector for the preempting peripheral or software-settable interrupt request is generated for the associated INTC_IACKR*n*, and if in hardware vector mode, for the interrupt vector provided to the processor.

28.6.2.1.1 Priority tree

The priority tree for each processor compares all the priorities of all of the asserted interrupt requests assigned to that processor, both peripheral and software-settable. The output of the priority tree is the highest of those priorities assigned to a given processor. Also, any interrupt requests which have this highest priority are output as asserted interrupt requests to the associated selector logic.

28.6.2.1.2 Selector

If only one interrupt request from the associated priority tree is asserted, then it is passed as asserted to the associated encoder logic. If multiple interrupt requests from the associated priority tree are asserted, then only the one with the lowest vector is passed as asserted to the associated encoder logic. The lower vector is chosen regardless of the time order of the assertions of the peripheral or software-settable interrupt requests.

28.6.2.1.3 Encoder

The encoder logic generates the unique 10-bit vector for the asserted interrupt request from the request selector subblock for the associated processor.

28.6.2.1.4 Comparator

The comparator logic compares the highest priority output from the associated priority arbitrator subblock with PRI in the associated INTC_CPR*n*. If the comparator detects that this highest priority is higher than the current priority, then it asserts the interrupt request to the associated processor. This interrupt request to the processor asserts whether this highest priority is raised above the value of PRI in the associated INTC_CPR*n*, or the PRI value in the associated INTC_CPR*n* is lowered below this highest priority. This highest priority then becomes the new priority which is written to PRI in the associated INTC_CPR*n* when the interrupt request to the processor is acknowledged. Interrupt requests whose PRI*n* in INTC_PSR*n* are zero will not cause a preemption because their PRI*n* will not be higher than PRI in the associated INTC_CPR*n*.

Another function of the comparator is to signal an update of the INTC_IACKR*n* with the vector number of the first interrupt that arrives that has a priority higher than the current priority. Once the vector number and priority are captured, they cannot be superseded by a higher priority interrupt until an update of the INTC_CPR*n* occurs. In software vector mode, higher priority interrupts can supersede the previously captured interrupt vector number and priority until the time a hardware or software interrupt acknowledge is processed.

28.6.2.2 Stack (LIFO)

The LIFO stores the preempted PRI values from the associated INTC_CPR*n*. Therefore, because these priorities are stacked within the INTC, if interrupts need to be enabled during the ISR, at the beginning of the interrupt exception handler the PRI value in the associated INTC_CPR*n* does not need to be loaded from the associated INTC_CPR*n* and stored onto the context stack. Likewise at the end of the interrupt exception handler, the priority does not need to be loaded from the context stack and stored into the associated INTC_CPR*n*.

The PRI value in the associated INTC_CPR*n* is pushed onto the LIFO when the associated INTC_IACKR*n* is read in software vector mode or the interrupt acknowledge signal from the associated processor is asserted in hardware vector mode. The priority is popped into PRI in the associated INTC_CPR*n* whenever the associated INTC_EOIR*n* is written. An exception case in hardware vector mode to this behavior is described in Hardware vector mode.

Although the INTC supports up to 32 priorities, an ISR executing with PRI in the INTC_CPR*n* equal to 31 will not be preempted. Therefore, the LIFO supports the stacking of 31 priorities. However, the LIFO is only 30 entries deep. An entry for a priority of 0 is not needed because of the ways that pushing onto a full LIFO and popping

an empty LIFO are treated. If the LIFO is pushed 31 or more times than it is popped, the priorities first pushed are overwritten. A priority of 0 would be an overwritten priority. However, the LIFO will pop zeroes if it is popped more times than it is pushed. Therefore, although a priority of 0 was overwritten, it is regenerated with the popping of an empty LIFO.

28.6.3 Handshaking with processor

This section describes handshaking with the processor.

28.6.3.1 Software vector mode handshaking

This section describes the software vector mode handshaking.

28.6.3.1.1 Acknowledging interrupt request to processor

The software vector mode handshaking can be used with processors that only support an interrupt request to them, or processors that support both an interrupt request by itself as well as an interrupt request with an interrupt vector. The software vector mode handshaking even supports processors that always expect an interrupt vector with the interrupt request to them. Refer to Figure 28-3.

A timing diagram of the interrupt request and acknowledge handshaking in software vector mode, along with the handshaking near the end of the interrupt exception handler, is shown in Figure 28-3. The INTC examines the peripheral and software-settable interrupt requests. When it finds an asserted peripheral or software-settable interrupt request with a higher priority than PRI in the associated INTC_CPR*n*, it asserts the interrupt request to the associated processor. The INTVEC field in the associated INTC_IACKR*n* is updated with the preempting interrupt request's vector when the interrupt request to the processor is asserted. The INTVEC field retains that value until the next time the interrupt request to the processor is asserted. The rest of the handshaking is described in Software vector mode.

28.6.3.1.2 End of interrupt exception handler

Before the interrupt exception handling completes, INTC_EOIR*n* must be written. When it is written, the associated LIFO is popped so that the preempted priority is restored into PRI of the associated INTC_CPR*n*. Before it is written, the peripheral or software-settable flag bit must be cleared so that the peripheral or software-settable interrupt request is negated.

When returning from the preemption, the INTC does not search for the peripheral or software-settable interrupt request whose ISR was preempted. Depending on how much the ISR has progressed, that interrupt request may no longer even be asserted. When PRI in the associated INTC_CPR*n* is lowered to the priority of the preempted ISR, the interrupt request for the preempted ISR or any other asserted peripheral or software-settable interrupt request at or below that priority will not cause a preemption. Instead, after the restoration of the preempted context, the processor will return to the instruction address that it had been going to execute next, before it was preempted. This next instruction is part of the preempted ISR or the interrupt exception handler's prolog or epilog.

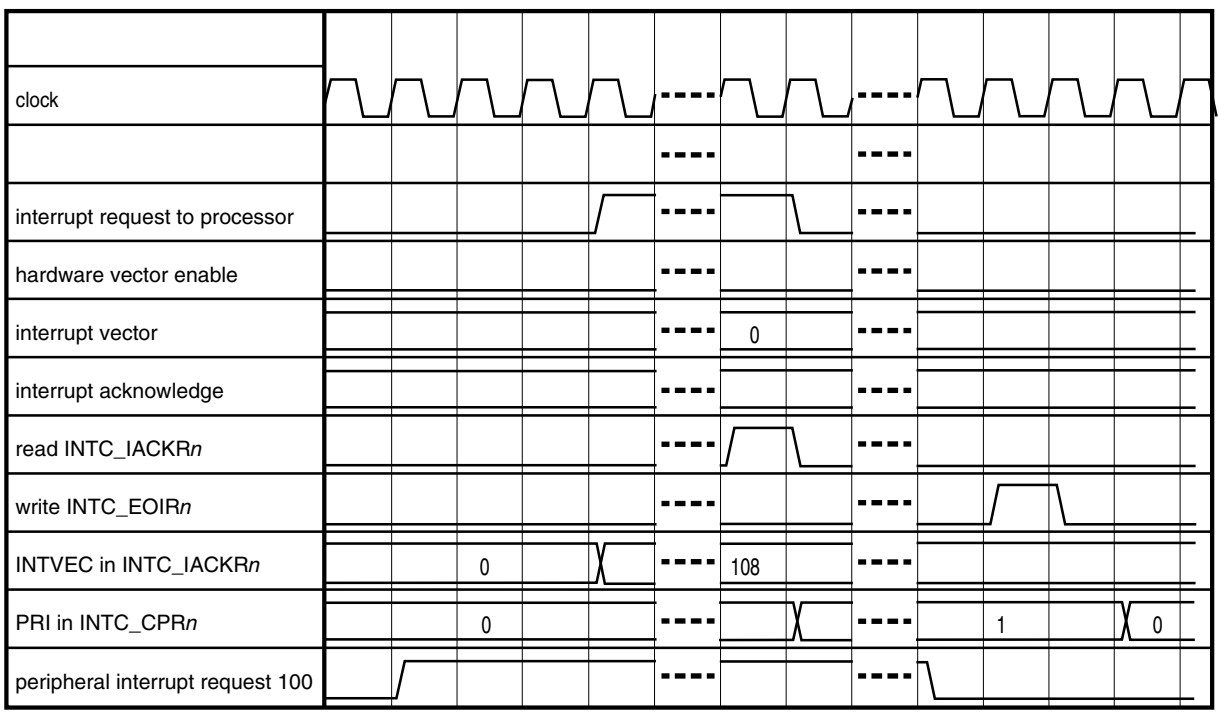

Figure 28-3. Timing diagram of software vector mode handshaking

28.6.3.2 Hardware vector mode handshaking

A timing diagram of the interrupt request and acknowledge handshaking in hardware vector mode, along with the handshaking near the end of the interrupt exception handler, is shown in Figure 28-4. As in software vector mode, the INTC examines the peripheral and software-settable interrupt requests, and when it finds an asserted interrupt request with a higher priority than PRI in the associated INTC_CPR*n*, it asserts the interrupt request to the associated processor. The INTVEC field in the associated INTC_IACKR*n* is updated with the preempting peripheral or software-settable interrupt request's vector when the interrupt request to the processor is asserted. The INTVEC field retains that value until the next time the interrupt request to the associated processor is asserted. In

addition, the value of the interrupt vector to the associated processor matches the value of the INTVEC field in the associated INTC_IACKR*n*. The rest of the handshaking is described in Hardware vector mode.

The handshaking near the end of the interrupt exception handler, that is the writing to the associated INTC_EOIR*n*, is the same as in software vector mode. See End of interrupt exception handler.

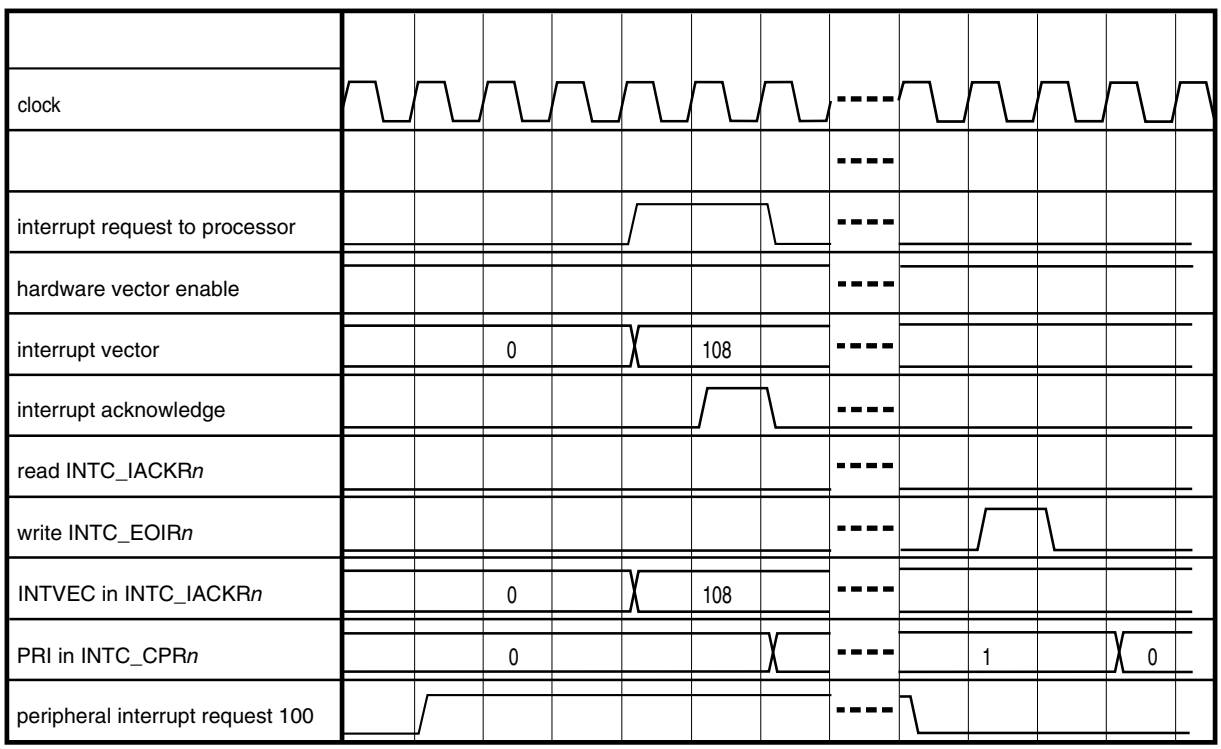

Figure 28-4. Timing diagram for hardware vector mode handshaking

28.6.4 Interrupt Controller Monitor (INTCM)

Isolated in its own hierarchy, the interrupt latency monitor logic is used to monitor or check interrupt latency for reliability, safety, and interrupt software requirements.

28.6.4.1 Operation

The following section lists the operation of the INTCM.

28.6.4.1.1 TIMERn

A clear of TIMERn will clear the corresponding error.

The TIMERn will not run if there is a corresponding error.

If the INTC_MMRn[MM] is enabled and an error is signaled, disable TIMERn.

If the INTC_MMRn[MM] is enabled, for a transition from 0 to 1 of SOURCE input that is being monitored by INTC_HIPRIn registers, clear and enable TIMERn. Once the timer reaches the maximum count, it will stop and not roll over. Software can read the TIMERn value at any time.

If the INTC_MMRn[MM] is enabled and if the TIMERn is enabled, then it should increment each cycle.

If the INTC_MMRn[MM] is enabled and if INTC_LATn is non-zero, an error will be signaled if the timer exceeds INTC_LATn or if the TIMERn reaches the maximum count.

If the INTC_MMRn[MM] is IACK and an interrupt acknowledge asserts for the monitored source, INTC_HIPRIn[IRQ], then the enabled TIMERn should stop. As an extra check, the IRQ is used to ensure that the acknowledged interrupt matches the monitored interrupt INTC_HIPRIn[IRQ].

If the INTC_MMRn[MM] is SW and an interrupt acknowledge occurs where a monitored interrupt is preempted, the enabled TIMERn should stop.

If the INTC_MMRn[MM] is EOI or SW for a monitored interrupt which has an INTC_EOIRn, the enabled TIMERn should stop.

If the INTC_MMRn[MM] is SW and if INTC_EOIRn, and if the previous one is monitored, it will be re-enabled.

28.7 Initialization/application information

This section contains initialization/application information.

28.7.1 Initialization flow

After exiting reset, all of the PRI*n* and PRC_SEL*n* fields in INTC_PSR*n* are zero, and PRI in the INTC_CPRn registers is 31. These reset values will prevent the INTC from asserting the interrupt request to the processors. The enable or mask bits in the peripherals are reset such that the peripheral interrupt requests are negated. An initialization sequence for allowing the peripheral and software-settable interrupt requests to cause an interrupt request to the processor is:

- interrupt_request_initialization:

- Configure HVENn in INTC_BCR.
- Configure VTBAn in INTC_IACKRn.
- Raise the PRIn fields and set the PRC_SELn fields to the desired processor in INTC_PSRn.
- Set the enable bits or clear the mask bits for the peripheral interrupt requests.
- Lower PRI in INTC_CPRn to zero.
- Enable processor(s) recognition of interrupts.

28.7.2 Interrupt exception handler

These example interrupt exception handlers excerpts use Power Architecture assembly code.

28.7.2.1 Software vector mode

In software vector mode for Power Architecture, there are 16 bytes of vector space available at the single ISR entry point.

```

blr        # branch to epilog
```

28.7.3 ISR, RTOS, and task hierarchy

The RTOS and all of the tasks under its control typically execute with PRI in INTC_CPR*n* having a value of 0. The RTOS will execute the tasks according to whatever priority scheme it may have, but that priority scheme is independent and has a lower priority of execution than the priority scheme of the INTC. In other words, the ISRs

execute above INTC_CPR*n* priority 0 and outside the control of the RTOS, the RTOS executes at INTC_CPR*n* priority 0, and while the tasks execute at different priorities under the control of the RTOS, they also execute at INTC_CPRn priority 0.

If a task shares a resource with an ISR and the Priority Ceiling Protocol (PCP) is being used to manage that shared resource, then the task's priority can be elevated in the INTC_CPR*n* while the shared resource is being accessed.

An ISR whose PRI*n* in INTC_PSR*n* has a value of 0 will not cause an interrupt request to the selected processor, even if its peripheral or software-settable interrupt request is asserted. For a peripheral interrupt request, not setting its enable bit or disabling the mask bit will cause it to remain negated, which consequently also will not cause an interrupt request to the processor. Since the ISRs are outside the control of the RTOS, this ISR will not run unless called by another ISR or the interrupt exception handler, perhaps after executing another ISR.

28.7.4 Order of execution

An ISR with a higher priority can preempt an ISR with a lower priority, regardless of the unique vectors associated with each of their peripheral or software-settable interrupt requests. However, if multiple peripheral or software-settable interrupt requests are asserted, more than one of these interrupt requests has the highest priority and that priority is high enough to cause preemption, the INTC selects the one with the lowest unique vector regardless of the order in time that they asserted. However, the ability to meet deadlines with this scheduling scheme is no less than if the ISRs execute in the time order that their peripheral or software-settable interrupt requests asserted.

The example in the following table shows the order of execution of both cases, ISRs with different priorities and ISRs with the same priority.

Table 28-1. Order of ISR execution example

Step #	Step Description	Code executing at end of step						PRI in INTC_CPR at end of step
		RTOS	ISR108 [1]	ISR208	ISR308	ISR408	interrupt exception handler	
1	RTOS at priority 0 is executing.	X						0
2	Peripheral interrupt request 100 at priority 1 asserts. Interrupt taken.		X					1
3	Peripheral interrupt request 400 at priority 4 asserts. Interrupt taken.					X		4
4	Peripheral interrupt request 300 at priority 3 asserts.					X		4

Table continues on the next page...

Table 28-1. Order of ISR execution example (continued)

Step #	Step Description	Code executing at end of step						PRI in INTC_CPR at end of step
		RTOS	ISR108 [1]	ISR208	ISR308	ISR408	interrupt exception handler	
5	Peripheral interrupt request 200 at priority 3 asserts.					X		4
6	ISR408 completes. Interrupt exception handler writes to INTC_EOIR*n*.						X	1
7	Interrupt taken. ISR208 starts to execute, even though peripheral interrupt request 300 asserted first.			X				3
8	ISR208 completes. Interrupt exception handler writes to INTC_EOIR*n*.						X	1
9	Interrupt taken. ISR308 starts to execute.				X			3
10	ISR308 completes. Interrupt exception handler writes to INTC_EOIR*n*.						X	1
11	ISR108 completes. Interrupt exception handler writes to INTC_EOIR*n*.						X	0
12	RTOS continues execution.	X						0

1. ISR108 executes for peripheral interrupt request 100 because the first eight ISRs are for software-settable interrupt requests.

28.7.5 Priority ceiling protocol

This section describes the priority ceiling protocol.

28.7.5.1 Elevating priority

The PRI field in INTC current priority register (INTC_CPR*n*) is elevated in the OSEK PCP to the ceiling of all of the priorities of the ISRs that share a resource. This protocol therefore allows coherent accesses of the ISRs to that shared resource.

For example, ISR1 has a priority of 1, ISR2 has a priority of 2, and ISR3 has a priority of 3. They all share the same resource. Before ISR1 or ISR2 can access that resource, they must raise the PRI value in INTC_CPR*n* to 3, the ceiling of all of the ISR priorities. After they release the resource, they must lower the PRI value in INTC_CPR*n* to prevent further priority inversion. If they do not raise their priority, then ISR2 can preempt ISR1, and ISR3 can preempt ISR1 or ISR2, possibly corrupting the shared resource. Another possible failure mechanism is deadlock if the higher priority ISR needs the lower priority

ISR to release the resource before it can continue, but the lower priority ISR cannot release the resource until the higher priority ISR completes and execution returns to the lower priority ISR.

Using the PCP instead of disabling processor recognition of all interrupts eliminates the time when accessing a shared resource that all higher priority interrupts are blocked. For example, while ISR3 cannot preempt ISR1 while it is accessing the shared resource, all of the ISRs with a priority higher than 3 can preempt ISR1.

28.7.5.2 Ensuring coherency

This section discusses how to ensure coherency.

28.7.5.2.1 Interrupt with blocked priority

A scenario can exist that can cause non-coherent accesses to the shared resource. As an example, ISR1 and ISR2 both share a resource. ISR1 has a lower priority than ISR2. ISR1 is executing, and it writes to the INTC_CPR*n*. The instruction following this store is a store to a value in a shared coherent data block. Either just before or at the same time as the first store, the INTC asserts the interrupt request to the processor because the peripheral interrupt request for ISR2 has asserted. As the processor is responding to the interrupt request from the INTC, and as it is aborting transactions and flushing its pipeline, it is possible (in some implementations) that both of these stores are executed. ISR2 thereby assumes that it can access the data block coherently, but the data block has been corrupted.

OSEK uses the GetResource and ReleaseResource system services to manage access to a shared resource. To prevent this corruption of a coherent data block, modifications to PRI in INTC_CPR*n* can be made by those system services with the code sequence:

```
GetResource:
        wrteei 0                # disable external interrupts to the Processor
        raise PRI                # Write to CPR, cache inhibit, guarded
        mbar                    # flush out writes from store buffer
        wrteei 1                # enable external interrupts to the Processor
        isync                    # re-fetch Processor pipeline

ReleaseResource:
        mbar                    # flush out writes from store buffer
        wrteei 0                # disable external interrupts to the Processor
        lower PRI                # Write to CPR, cache inhibit, guarded
        wrteei 1                # enable external interrupts to the Processor
```

28.7.5.2.1.1 Interrupt request to processor

Referencing Figure 28-1, the interrupt request logic to the processor is shown in the following figure.

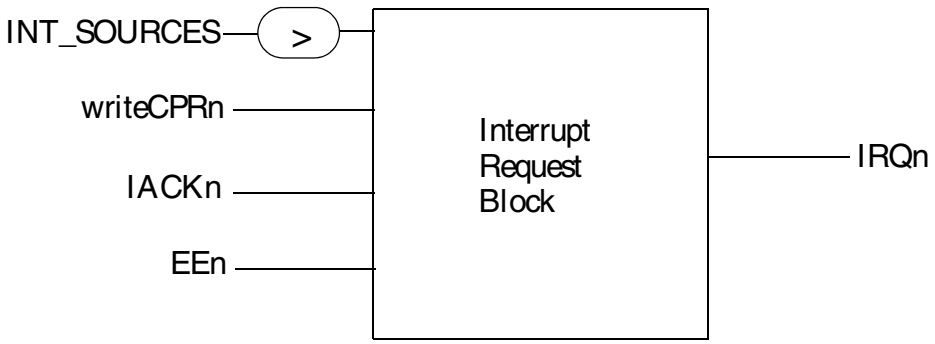

Figure 28-5. Interrupt Request Block Diagram

Assuming that there are no IRQn deasserted (no pending interrupt requests to processor n), if one of the external interrupt sources (INT_SOURCES) has a priority higher than the INTC_CPRn, then interrupt request to the processor (IRQn) is asserted. It will stay asserted until one of the following conditions is true:

- Interrupt acknowledge (IACK) is asserted
- If the EEn bit has been cleared by the wrteei instruction (see the code sequence in Interrupt with blocked priority), IRQn will be re-evaluated when processor n writes to the INTC_CPRn while processor n ignores IRQn

This provides a safe way to guarantee that no interrupts will be recognized by processor n while updating the INTC_CPRn.

28.7.5.2.2 Raised priority preserved

Before the instruction after the GetResource system service executes, all pending transactions have completed. These pending transactions can include an ISR for a peripheral or software-settable interrupt request whose priority was equal to or lower than the raised priority. The shared coherent data block now can be accessed coherently. The following figure shows the timing diagram for this scenario, and the following table explains the events. The example is for software vector mode. Except for the method of retrieving the vector and acknowledging the interrupt request to the processor, hardware vector mode is identical.

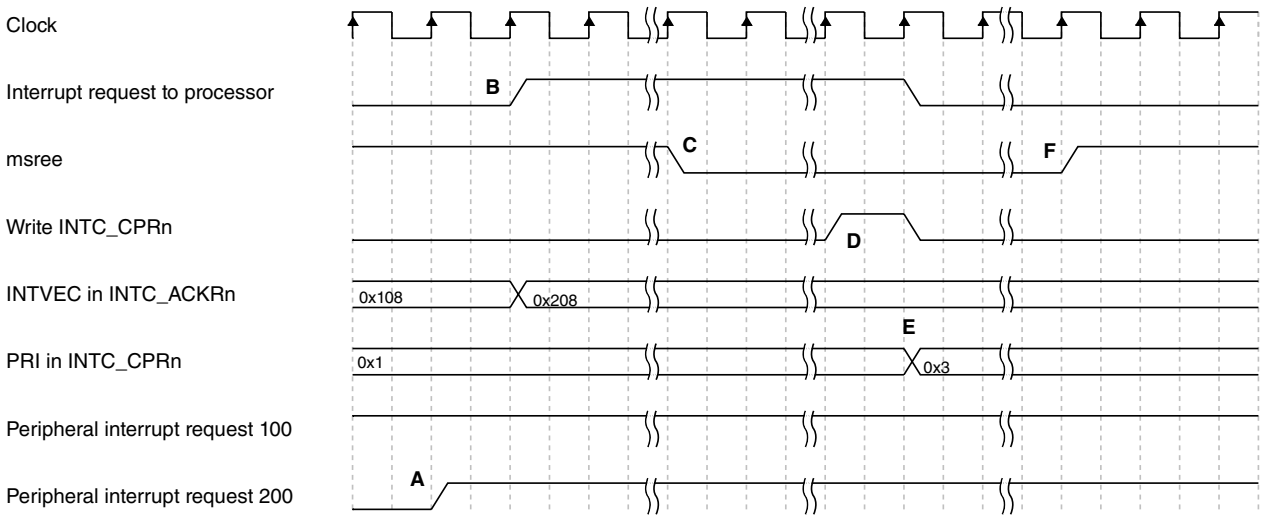

Figure 28-6. Timing diagram of raised priority preserved

Table 28-2. Raised priority preserved events

Event	Description
A	Peripheral interrupt request 200 of priority 2 asserts during execution of ISR108 running at priority 1.
B	Interrupt request to processor asserts. INTVEC in INTC_IACKRn updates with vector for that peripheral interrupt request.
C	Write to msree bit to disable external interrupts
D	ISR108 writes to INTC_CPRn to raise priority to 3 before accessing shared coherent data block.
E	PRI in INTC_CPRn now at 3, reflecting the write. This write, just before accessing data block, is the last instruction the processor executes before being interrupted.
F	Write to msree bit to enable external interrupts

28.7.6 Selecting priorities according to request rates and deadlines

The selection of the priorities for the ISRs can be made using Rate Monotonic Scheduling (RMS) or a superset of it, Deadline Monotonic Scheduling (DMS). In RMS, the ISRs which have higher request rates have higher priorities. In DMS, if the deadline is before the next time the ISR is requested, then the ISR is assigned a priority according to the time from the request for the ISR to the deadline, not from the time of the request for the ISR to the next request for it.

For example, ISR1 executes every 100 µs, ISR2 executes every 200 µs, and ISR3 executes every 300 µs. ISR1 has a higher priority than ISR2 which has a higher priority than ISR3. However, if ISR3 has a deadline of 150 µs, then it has a higher priority than ISR2.

The INTC supports 32 priorities, which may be many fewer than the number of ISRs. In this case, the ISRs should be grouped with other ISRs that have similar deadlines. For example, a priority could be allocated for every time the request rate doubles. ISRs with request rates around 1 ms would share a priority, ISRs with request rates around 500 µs would share a priority, ISRs with request rates around 250 µs would share a priority, and so on. With this approach, a range of ISR request rates of 2^{16} could be covered, regardless of the number of ISRs.

Reducing the number of priorities does cause some priority inversion, which reduces the processor's ability to meet its deadlines. However, reducing the number of priorities can reduce the size and latency through the interrupt controller. It also allows easier management of ISRs with similar deadlines that share a resource. They can be placed at the same priority without any further priority inversion, and they do not need to use the PCP to access the shared resource.

28.7.7 Software-settable interrupt requests

The software-settable interrupt requests can be used in two ways. They can be used to schedule a lower priority portion of an ISR and for processors to interrupt other processors in a multiple processor system.

28.7.7.1 Scheduling a lower priority portion of an ISR

A portion of an ISR needs to be executed at the PRIn value in INTC_PSR*n*, which becomes the PRI value in INTC_CPR*n* with the interrupt acknowledge. The ISR, however, can have a portion of it which does not need to be executed at this higher priority. Therefore, executing this later portion which does not need to be executed at this higher priority can prevent the execution of ISRs which do not have a higher priority than the earlier portion of the ISR but do have a higher priority than the later portion of the ISR needs. This preemptive scheduling inefficiency reduces the processor's ability to meet its deadlines.

One option is for the ISR to complete the earlier higher priority portion, but then schedule through the RTOS a task to execute the later lower priority portion. However, some RTOSs can require a large amount of time for an ISR to schedule a task. Therefore, a second option is for the ISR, after completing the higher priority portion, to set a SET bit

in INTC_SSCIR*n*. Writing a '1' to SET causes a software-settable interrupt request. This software-settable interrupt request, which usually will have a lower PRI*n* value in the INTC_PSR*n*, therefore will not cause preemptive scheduling inefficiencies.

28.7.7.2 Scheduling an ISR on another processor

Since the SET bits in the INTC_SSCIR*n* are memory mapped, processors in multiple processor systems can schedule ISRs on the other processors. One possible application is if one processor simply wants to command another processor to perform a piece of work, and the initiating processor does not need to use the results of that work. If the initiating processor needs to know if the processor executing the software-settable ISR has not completed the work before asking it to again execute that ISR, it can check if the corresponding CLR bit in INTC_SSCIR*n* is asserted before again writing a 1 to the SET bit.

Another application is the sharing of a block of data. For example, a first processor has completed accessing a block of data and wants a second processor to then access it. Furthermore, after the second processor has completed accessing the block of data, the first processor again wants to access it. The accesses to the block of data must be done coherently. The procedure is that the first processor writes a 1 to a SET bit on the second processor. The second processor, after accessing the block of data, clears the corresponding CLR bit and then writes 1 to a SET bit on the first processor, informing it that it now can access the block of data.

28.7.8 Lowering priority within an ISR

In implementations without the software-settable interrupt requests in INTC_SSCIR*n*, one way (besides scheduling a task through an RTOS) to prevent preemptive scheduling inefficiencies with an ISR whose work spans multiple priorities (as described in Scheduling a lower priority portion of an ISR) is to lower the current priority. However, the INTC has a LIFO whose depth is determined by the number of priorities.

Note

Lowering the PRI value in INTC_CPR*n* within an ISR to below the ISR's corresponding PRI value in INTC_PSR*n* allows more preemptions than the depth of the LIFO can support.

Therefore, through its use of the LIFO the INTC does not support lowering the current priority within an ISR as a way to avoid preemptive scheduling inefficiencies.

28.7.9 Negating an interrupt request outside of its ISR

This section discusses the negation of an interrupt service request outside of its ISR.

28.7.9.1 Negating an interrupt request as a side effect of an ISR

Some peripherals have flag bits which can be cleared as a side effect of servicing a peripheral interrupt request. For example, reading a specific register can clear the flag bits, and consequently their corresponding interrupt requests too. This clearing as a side effect of servicing a peripheral interrupt request can cause the negation of other peripheral interrupt requests besides the peripheral interrupt request whose ISR presently is executing. This negating of a peripheral interrupt request outside of its ISR can be a desired effect.

28.7.9.2 Negating multiple interrupt requests in one ISR

An ISR can clear other flag bits besides its own flag bit. One reason that an ISR clears multiple flag bits is because it serviced those other flag bits, and therefore the ISRs for these other flag bits do not need to be executed.

28.7.9.3 Proper setting of interrupt request priority

Whether an interrupt request negates outside of its own ISR due to the side effect of an ISR execution or the intentional clearing of a flag bit, the priorities of the peripheral or software-settable interrupt requests for these other flag bits must be selected properly. Their PRI*n* values in INTC_PSR*n* must be selected to be at or lower than the priority of the ISR that cleared their flag bits. Otherwise, those flag bits still can cause the interrupt request to the processor to assert. Furthermore, the clearing of these other flag bits also has the same timing relationship to the writing to INTC_SSCIR*n* as the clearing of the flag bit that caused the present ISR to be executed. Refer to End of interrupt exception handler for more information.

A flag bit whose enable bit or mask bit is negating its peripheral interrupt request can be cleared at any time, regardless of the peripheral interrupt request's PRI*n* value in INTC_PSR*n*.

28.7.10 Examining LIFO contents

There are multiple methods for tracking interrupts in a system, one of which is described here using existing hardware (LIFO) within the INTC. Although the LIFO contents are not memory-mapped, the user can read the contents by popping the LIFO and reading the PRI field in the INTC current priority register (INTC_CPR*n*). To avoid a lower-level interrupt being serviced because the popping of the LIFO updates the INTC_CPR*n*, the processor recognition of interrupts should be disabled when examining LIFO contents. The pseudo-code is as follows:

```
      wrteei 0                # disable processor recognition of external interrupts
      oldCPRn = INTC_CPRn;    # save INTC_CPRn
      (branch to the pop_lifo)

pop_lifo:
      store INTC_EIORn        # pop INTC_CPR from LIFO, examine PRI, etc...
      examine INTC_CPRn[PRI], and store onto stack
      if PRI is not zero or value when interrupts were enabled, branch to pop_lifo
      branch to push_lifo
```

When the examination is complete, the LIFO can be restored using this code sequence:

```
push_lifo:
      load stacked PRI value and store to INTC_CPRn
      load INTC_IACKn         # IACK; push INTC_CPRn into LIFO
      if stacked PRI values are not depleted, branch to push_lifo

      INTC_CPRn    = oldCPRn; # restore original INTC_CPRn and re-evaluate pending external
interrupts
      wrteei 1                # enable processor recognition of interrupts
```

NOTE

Disabling the processor recognition of interrupts during LIFO examination will introduce latency, but none of the interrupt requests will be missed.

28.8 Interrupt sources

The list of interrupt sources is chip-specific. For this list, see the chip-specific INTC information.

Chapter 29
Direct Memory Access Multiplexer (DMAMUX)

29.1 DMA triggers to eDMA channels

The following diagram shows how the DMAMUXs trigger the eDMA.

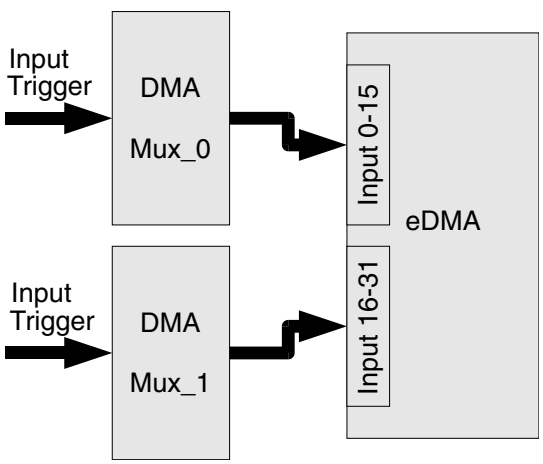

Figure 29-1. DMA triggers to eDMA channels

Table 29-1. DMAMUX to eDMA Channel Mapping

eDMA channel	DMAMUX output
DMAMUX_0 output 0 - 15	eDMA channel 0 - 15
DMAMUX_1 output 0 - 15	eDMA channel 16 - 31

29.2 Introduction

29.2.1 Overview

The Direct Memory Access Multiplexer (DMAMUX) routes DMA sources, called slots, to any of the 16 DMA channels. This process is illustrated in the following figure.

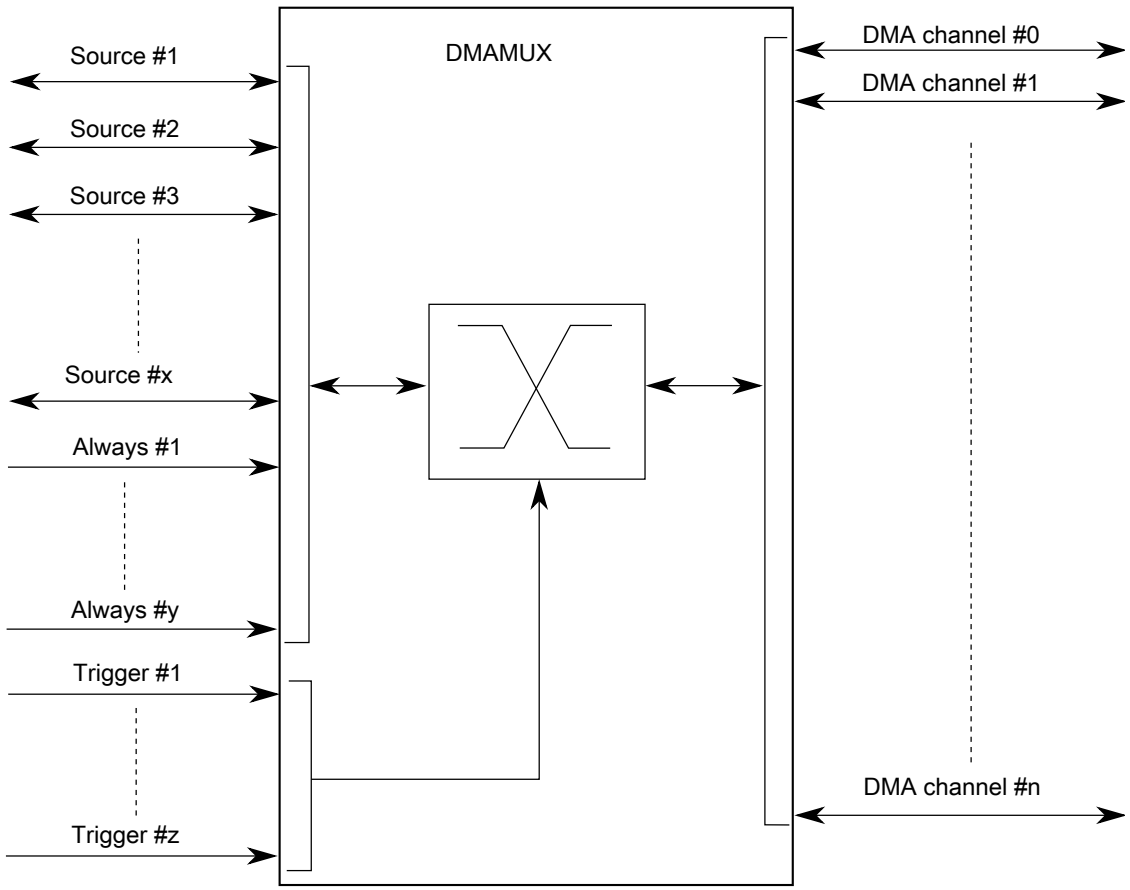

Figure 29-2. DMAMUX block diagram

29.2.2 Features

The DMAMUX module provides these features:

- Up to 34 peripheral slots and up to six always-on slots can be routed to 16 channels.
- 16 independently selectable DMA channel routers.
  - The first eight channels additionally provide a trigger functionality.
- Each channel router can be assigned to one of the possible peripheral DMA slots or to one of the always-on slots.

29.2.3 Modes of operation

The following operating modes are available:

- Disabled mode

  In this mode, the DMA channel is disabled. Because disabling and enabling of DMA channels is done primarily via the DMA configuration registers, this mode is used mainly as the reset state for a DMA channel in the DMA channel MUX. It may also be used to temporarily suspend a DMA channel while reconfiguration of the system takes place, for example, changing the period of a DMA trigger.

- Normal mode

  In this mode, a DMA source is routed directly to the specified DMA channel. The operation of the DMAMUX in this mode is completely transparent to the system.

- Periodic Trigger mode

  In this mode, a DMA source may only request a DMA transfer, such as when a transmit buffer becomes empty or a receive buffer becomes full, periodically.

  Configuration of the period is done in the registers of the periodic interrupt timer (PIT). This mode is available only for channels 0–7.

29.3 External signal description

The DMAMUX has no external pins.

29.4 Memory map/register definition

This section provides a detailed description of all memory-mapped registers in the DMAMUX.

DMAMUX memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Channel Configuration register (DMAMUX_CHCFG0)	8	R/W	00h	29.4.1/1086
1	Channel Configuration register (DMAMUX_CHCFG1)	8	R/W	00h	29.4.1/1086
2	Channel Configuration register (DMAMUX_CHCFG2)	8	R/W	00h	29.4.1/1086
3	Channel Configuration register (DMAMUX_CHCFG3)	8	R/W	00h	29.4.1/1086
4	Channel Configuration register (DMAMUX_CHCFG4)	8	R/W	00h	29.4.1/1086

Table continues on the next page...

DMAMUX memory map (continued)

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
5	Channel Configuration register (DMAMUX_CHCFG5)	8	R/W	00h	29.4.1/1086
6	Channel Configuration register (DMAMUX_CHCFG6)	8	R/W	00h	29.4.1/1086
7	Channel Configuration register (DMAMUX_CHCFG7)	8	R/W	00h	29.4.1/1086
8	Channel Configuration register (DMAMUX_CHCFG8)	8	R/W	00h	29.4.1/1086
9	Channel Configuration register (DMAMUX_CHCFG9)	8	R/W	00h	29.4.1/1086
A	Channel Configuration register (DMAMUX_CHCFG10)	8	R/W	00h	29.4.1/1086
B	Channel Configuration register (DMAMUX_CHCFG11)	8	R/W	00h	29.4.1/1086
C	Channel Configuration register (DMAMUX_CHCFG12)	8	R/W	00h	29.4.1/1086
D	Channel Configuration register (DMAMUX_CHCFG13)	8	R/W	00h	29.4.1/1086
E	Channel Configuration register (DMAMUX_CHCFG14)	8	R/W	00h	29.4.1/1086
F	Channel Configuration register (DMAMUX_CHCFG15)	8	R/W	00h	29.4.1/1086

29.4.1 Channel Configuration register (DMAMUX_CHCFG*n*)

Each of the DMA channels can be independently enabled/disabled and associated with one of the DMA slots (peripheral slots or always-on slots) in the system.

NOTE

Setting multiple CHCFG registers with the same source value will result in unpredictable behavior. This is true, even if a channel is disabled (ENBL==0).

Before changing the trigger or source settings, a DMA channel must be disabled via CHCFGn[ENBL].

Address: 0h base + 0h offset + (1d × i), where i=0d to 15d

Bit	0	1	2	3	4	5	6	7
Read Write	ENBL	TRIG	SOURCE					
Reset	0	0	0	0	0	0	0	0

DMAMUX_CHCFG*n* field descriptions

Field	Description
0 ENBL	DMA Channel Enable Enables the DMA channel. 0 DMA channel is disabled. This mode is primarily used during configuration of the DMAMux. The DMA has separate channel enables/disables, which should be used to disable or reconfigure a DMA channel. 1 DMA channel is enabled

Table continues on the next page...

DMAMUX_CHCFG*n* field descriptions (continued)

Field	Description
1 TRIG	DMA Channel Trigger Enable Enables the periodic trigger capability for the triggered DMA channel. 0 Triggering is disabled. If triggering is disabled and ENBL is set, the DMA Channel will simply route the specified source to the DMA channel. (Normal mode) 1 Triggering is enabled. If triggering is enabled and ENBL is set, the DMAMUX is in Periodic Trigger mode.
2–7 SOURCE	DMA Channel Source (Slot) Specifies which DMA source, if any, is routed to a particular DMA channel. See the chip-specific DMAMUX information for details about the peripherals and their slot numbers.

29.5 Functional description

The primary purpose of the DMAMUX is to provide flexibility in the system's use of the available DMA channels.

As such, configuration of the DMAMUX is intended to be a static procedure done during execution of the system boot code. However, if the procedure outlined in Enabling and configuring sources is followed, the configuration of the DMAMUX may be changed during the normal operation of the system.

Functionally, the DMAMUX channels may be divided into two classes:

- Channels that implement the normal routing functionality plus periodic triggering capability
- Channels that implement only the normal routing functionality

29.5.1 DMA channels with periodic triggering capability

Besides the normal routing functionality, the first 8 channels of the DMAMUX provide a special periodic triggering capability that can be used to provide an automatic mechanism to transmit bytes, frames, or packets at fixed intervals without the need for processor intervention.

The trigger is generated by the periodic interrupt timer (PIT); as such, the configuration of the periodic triggering interval is done via configuration registers in the PIT. See the section on periodic interrupt timer for more information on this topic.

Note

Because of the dynamic nature of the system (due to DMA channel priorities, bus arbitration, interrupt service routine lengths, etc.), the number of clock cycles between a trigger and the actual DMA transfer cannot be guaranteed.

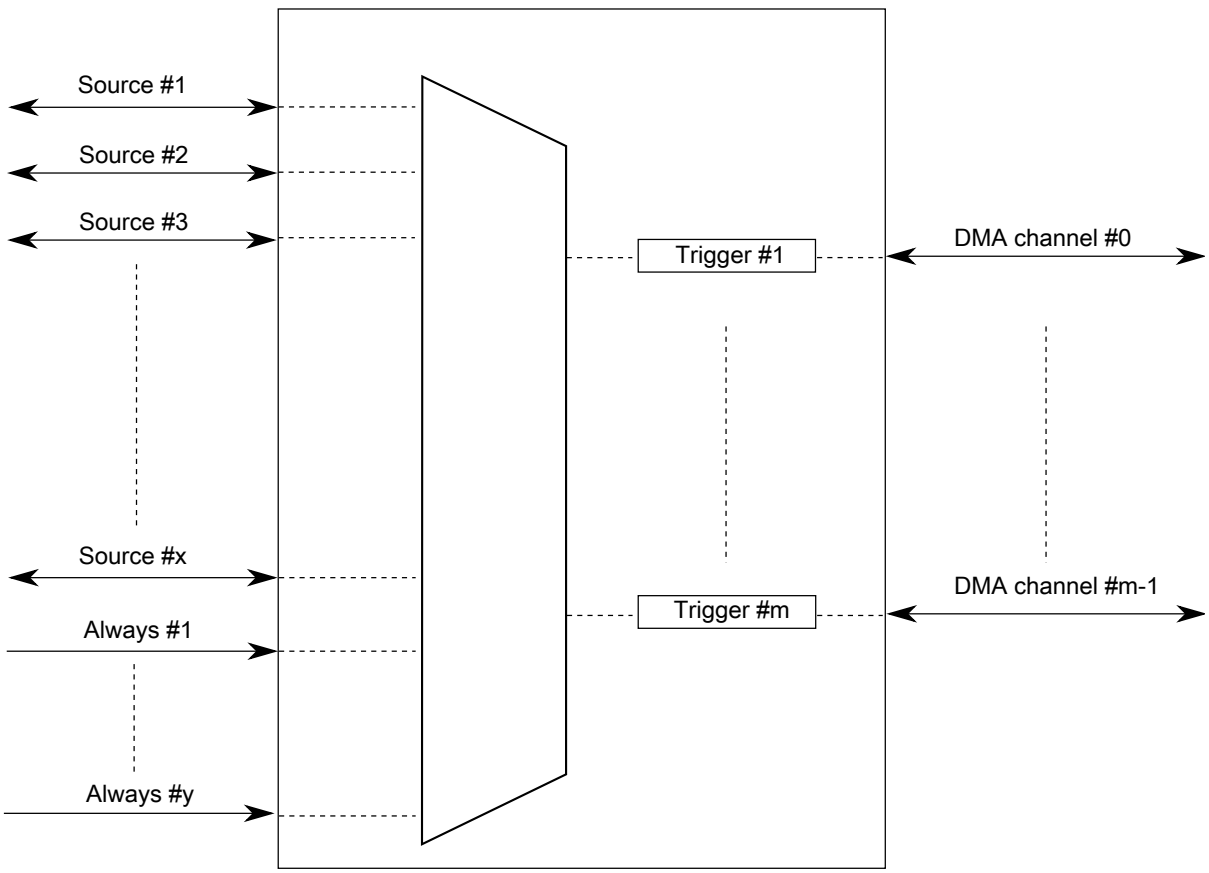

Figure 29-3. DMAMUX triggered channels

The DMA channel triggering capability allows the system to schedule regular DMA transfers, usually on the transmit side of certain peripherals, without the intervention of the processor. This trigger works by gating the request from the peripheral to the DMA until a trigger event has been seen. This is illustrated in the following figure.

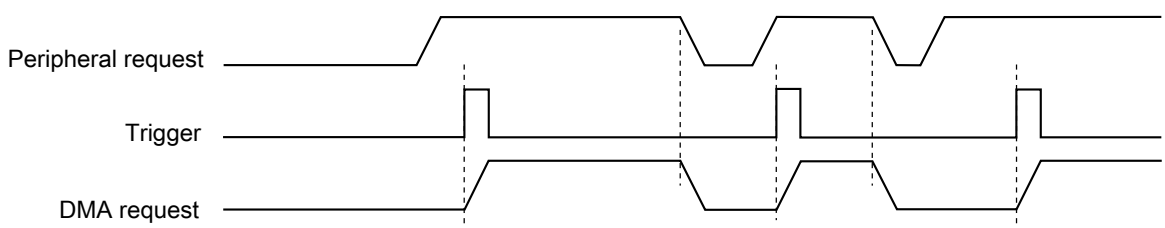

Figure 29-4. DMAMUX channel triggering: normal operation

After the DMA request has been serviced, the peripheral will negate its request, effectively resetting the gating mechanism until the peripheral reasserts its request and the next trigger event is seen. This means that if a trigger is seen, but the peripheral is not requesting a transfer, then that trigger will be ignored. This situation is illustrated in the following figure.

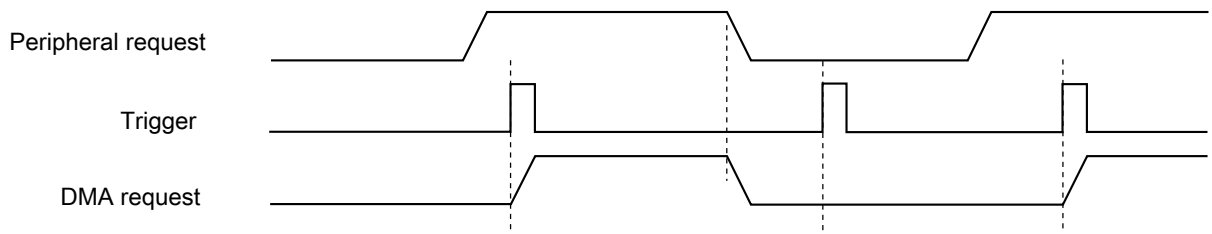

Figure 29-5. DMAMUX channel triggering: ignored trigger

This triggering capability may be used with any peripheral that supports DMA transfers, and is most useful for two types of situations:

- Periodically polling external devices on a particular bus

  As an example, the transmit side of an SPI is assigned to a DMA channel with a trigger, as described above. After it has been set up, the SPI will request DMA transfers, presumably from memory, as long as its transmit buffer is empty. By using a trigger on this channel, the SPI transfers can be automatically performed every 5 µs (as an example). On the receive side of the SPI, the SPI and DMA can be configured to transfer receive data into memory, effectively implementing a method to periodically read data from external devices and transfer the results into memory without processor intervention.

- Using the GPIO ports to drive or sample waveforms

  By configuring the DMA to transfer data to one or more GPIO ports, it is possible to create complex waveforms using tabular data stored in on-chip memory. Conversely, using the DMA to periodically transfer data from one or more GPIO ports, it is possible to sample complex waveforms and store the results in tabular form in on-chip memory.

A more detailed description of the capability of each trigger, including resolution, range of values, and so on, may be found in the periodic interrupt timer section.

29.5.2 DMA channels with no triggering capability

The other channels of the DMAMUX provide the normal routing functionality as described in Modes of operation.

29.5.3 Always-enabled DMA sources

In addition to the peripherals that can be used as DMA sources, there are six additional DMA sources that are always enabled. Unlike the peripheral DMA sources, where the peripheral controls the flow of data during DMA transfers, the sources that are always enabled provide no such "throttling" of the data transfers. These sources are most useful in the following cases:

- Performing DMA transfers to/from GPIO—Moving data from/to one or more GPIO pins, either unthrottled (that is, as fast as possible), or periodically (using the DMA triggering capability).
- Performing DMA transfers from memory to memory—Moving data from memory to memory, typically as fast as possible, sometimes with software activation.
- Performing DMA transfers from memory to the external bus, or vice-versa—Similar to memory to memory transfers, this is typically done as quickly as possible.
- Any DMA transfer that requires software activation—Any DMA transfer that should be explicitly started by software.

In cases where software should initiate the start of a DMA transfer, an always-enabled DMA source can be used to provide maximum flexibility. When activating a DMA channel via software, subsequent executions of the minor loop require that a new start event be sent. This can either be a new software activation, or a transfer request from the DMA channel MUX. The options for doing this are:

- Transfer all data in a single minor loop.

  By configuring the DMA to transfer all of the data in a single minor loop (that is, major loop counter = 1), no reactivation of the channel is necessary. The disadvantage to this option is the reduced granularity in determining the load that the DMA transfer will impose on the system. For this option, the DMA channel must be disabled in the DMA channel MUX.

- Use explicit software reactivation.

  In this option, the DMA is configured to transfer the data using both minor and major loops, but the processor is required to reactivate the channel by writing to the DMA registers *after every minor loop*. For this option, the DMA channel must be disabled in the DMA channel MUX.

- Use an always-enabled DMA source.

In this option, the DMA is configured to transfer the data using both minor and major loops, and the DMA channel MUX does the channel reactivation. For this option, the DMA channel should be enabled and pointing to an "always enabled" source. Note that the reactivation of the channel can be continuous (DMA triggering is disabled) or can use the DMA triggering capability. In this manner, it is possible to execute periodic transfers of packets of data from one source to another, without processor intervention.

29.6 Initialization/application information

This section provides instructions for initializing the DMA channel MUX.

29.6.1 Reset

The reset state of each individual bit is shown in Memory map/register definition. In summary, after reset, all channels are disabled and must be explicitly enabled before use.

29.6.2 Enabling and configuring sources

To enable a source with periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first 8 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Configure the corresponding timer.
5. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

NOTE

The following is an example. See the chip configuration details for the number of this device's DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1, with periodic triggering capability:

1. Write 0x00 to CHCFG1.

2. Configure channel 1 in the DMA, including enabling the channel.
3. Configure a timer for the desired trigger interval.
4. Write 0xC5 to CHCFG1.

The following code example illustrates steps 1 and 4 above:

```
void DMAMUX_Init(uint8_t DMA_CH, uint8_t DMAMUX_SOURCE)
{
    DMAMUX_0.CHCFG[DMA_CH].B.SOURCE = DMAMUX_SOURCE;
    DMAMUX_0.CHCFG[DMA_CH].B.ENBL   = 1;
    DMAMUX_0.CHCFG[DMA_CH].B.TRIG   = 1;
}
```

To enable a source, without periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first 8 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that CHCFG[ENBL] is set while CHCFG[TRIG] is cleared.

NOTE

The following is an example. See the chip configuration details for the number of this device's DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1, with no periodic triggering capability:

1. Write 0x00 to CHCFG1.
2. Configure channel 1 in the DMA, including enabling the channel.
3. Write 0x85 to CHCFG1.

The following code example illustrates steps 1 and 3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR     0x40021000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCFG0 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCFG1 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCFG2 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCFG3 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCFG4 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCFG5 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCFG6 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCFG7 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCFG8 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCFG9 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCFG10= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCFG11= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCFG12= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000C);
volatile unsigned char *CHCFG13= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000D);
```

```
volatile unsigned char *CHCFG14= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000E);
volatile unsigned char *CHCFG15= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000F);

In File main.c:
#include "registers.h"
:
:
*CHCFG1 = 0x00;
*CHCFG1 = 0x85;
```

To disable a source:

A particular DMA source may be disabled by not writing the corresponding source value into any of the CHCFG registers. Additionally, some module-specific configuration may be necessary. See the appropriate section for more details.

To switch the source of a DMA channel:

1. Disable the DMA channel in the DMA and reconfigure the channel for the new source.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] bits of the DMA channel.
3. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

To switch DMA channel 8 from source #5 transmit to source #7 transmit:

1. In the DMA configuration registers, disable DMA channel 8 and reconfigure it to handle the transfers to peripheral slot 7. This example assumes channel 8 doesn't have triggering capability.
2. Write 0x00 to CHCFG8.
3. Write 0x87 to CHCFG8. (In this example, setting CHCFG[TRIG] would have no effect due to the assumption that channel 8 does not support the periodic triggering functionality.)

The following code example illustrates steps 2 and 3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR     0x40021000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCFG0 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCFG1 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCFG2 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCFG3 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCFG4 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCFG5 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCFG6 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCFG7 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCFG8 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCFG9 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCFG10= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCFG11= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCFG12= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000C);
volatile unsigned char *CHCFG13= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000D);
volatile unsigned char *CHCFG14= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000E);
volatile unsigned char *CHCFG15= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000F);
```

```
In File main.c:
#include "registers.h"
:
:
*CHCFG8 = 0x00;
*CHCFG8 = 0x87;
```

Chapter 30
Platform Configuration Module (PCM)

30.1 Overview

The Platform Configuration Module contains miscellaneous configuration registers for the device. These configuration registers are related to the operation of the intelligent bus bridging gasket. The module is mapped to PBRIDGE on-platform slot 10 with a base address of 0xFC02_8000.

The register at offset 00h is present but serves no purpose. This register can be written and read, but its contents do not affect any functionality and no error is returned from accessing this register.

30.2 Memory map and register definition

The Platform Configuration Module contains miscellaneous configuration registers for the device. These configuration registers are related to the operation of the intelligent bus bridging gasket. The module is mapped to PBRIDGE on-platform slot 10 with a base address of 0xFC02_8000.

The register at offset 00h is present but serves no purpose. This register can be written and read, but its contents do not affect any functionality and no error is returned from accessing this register.

NOTE

PCM registers can only be accessed in supervisor mode.

PCM memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

31.1.1 AFE Filter Enable Register (MCB_AFE_FILTEN)

This register enables the AFE filter triggers. This register gets reset on every reset.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	RESERVED															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	RESERVED															GLOBAL_ FILTEN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

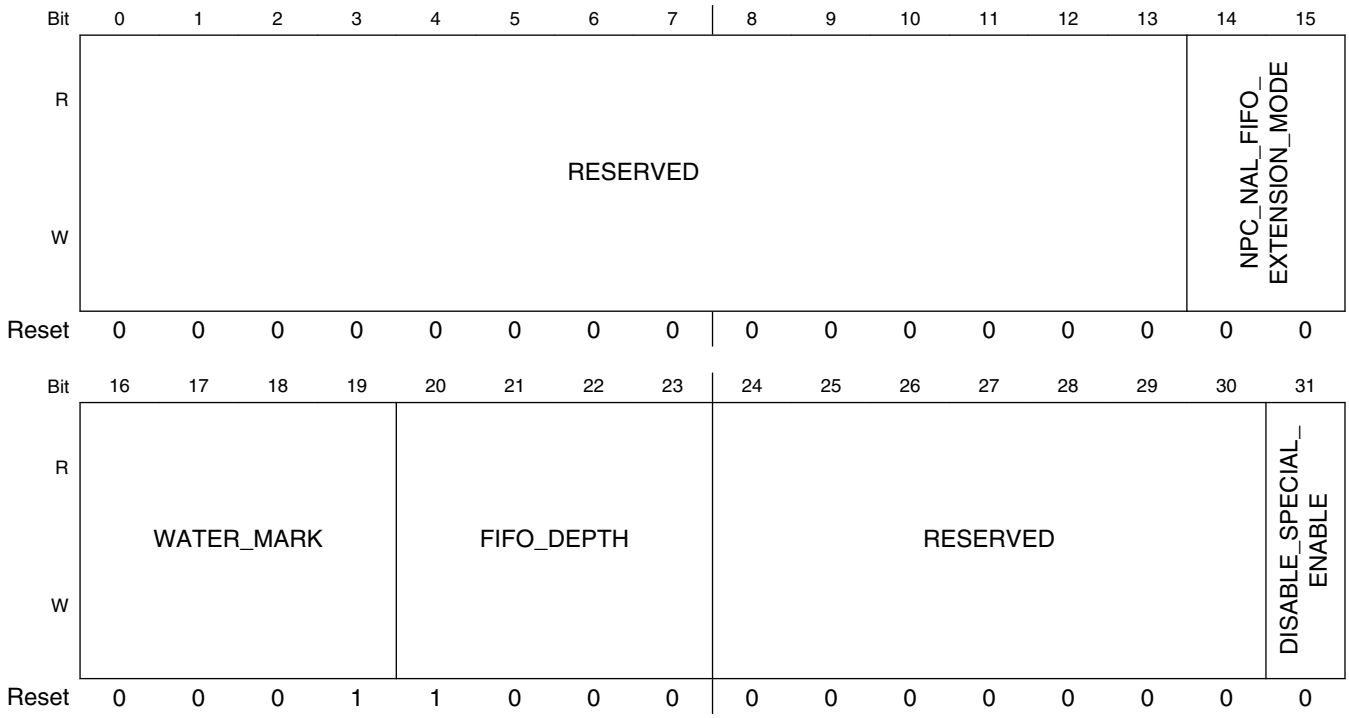
MCB_AFE_FILTEN field descriptions

Field	Description
0–30 RESERVED	This field is reserved.
31 GLOBAL_ FILTEN	Filter Enable 1 Filters are enabled once RFS is received 0 RFS is gated

31.1.2 NPC Special Enable Control (MCB_NPC_SPECIAL_ENABLE)

Enable/Disable special enable functionality. This register gets reset on every reset.

Address: 0h base + 8h offset = 8h



MCB_NPC_SPECIAL_ENABLE field descriptions

Field	Description
0–13 RESERVED	This field is reserved.
14–15 NPC_NAL_FIFO_EXTENSION_MODE	NPC NAL FIFO EXTENSION_MODE These bits are used to extend the fifo present between NPC and NAL from default 8 to 16. 00 Disable NAL_NPC Extended fifo mode 11 Enable NAL_NPC Extended fifo mode. Extends NAL existing fifo to make it 15 words deep. Set this bit prior to starting a NAL-NPC transaction. In this mode MCB_NPC_SPECIAL_ENABLE[WATER_MARK] should be configured to 4'b0101 or lower and MCB_NPC_SPECIAL_ENABLE[FIFO_DEPTH] should be programmed to 4'b1110
16–19 WATER_MARK	WATER MARK LEVEL NAL FIFO watermark level. This can be used to throttle trace from various nexus sources inside chip.
20–23 FIFO_DEPTH	NAL FIFO DEPTH Keep it always at 0x8 in default mode
24–30 RESERVED	RESERVED This field is reserved.

Table continues on the next page...

MCB_NPC_SPECIAL_ENABLE field descriptions (continued)

Field	Description
31 DISABLE_ SPECIAL_ ENABLE	Disable special enable fuinctionality of NPC auxilary ports Disables special enable functionality on NPC auxillary port related pads (such as MDOs, nex_ready_b, MCKO, EVTO, EVTI, MSEO) 0 Enable Special Enable functionality of NPC auxilary ports 1 Disable Special Enable fuinctionality of NPC auxilary ports

31.1.3 AFE LVD Mask (MCB_AFE_LVD_MASK)

This register gets reset on every reset.

Masks the eight LVDs from AFE. If not masked they act as source of destructive reset. By default the LVDs are masked.

NOTE

Before un-masking AFE LVD through the MCB register, the respective LVD status must be first polled from the relevant LVD status source. Only if LVD is in the released state should it be un-masked.

Address: 0h base + Ch offset = Ch

Chapter 32
Dual PLL Digital Interface (PLLDIG)

32.1 Introduction

The Dual PLL system composed of PLL0 and PLL1 analog blocks and the digital interface (PLLDIG). The two analog PLL blocks are cascaded, with the PHI1 output of PLL0 feeding the clock input of PLL1.

A key feature of the dual PLL architecture is the ability to drive peripherals from the PLL0 PHI output, which is non-modulated and independent of the core clock frequency. The core and platform clocks are driven by PLL1.

32.2 Block Diagram

Please refer to the “Clocking chapter” of this *Reference Manual* to see the block diagram.

32.3 Features

The Dual PLLDIG has the following features:

- Supports dual PLL in cascaded mode with PLL0 clock out as reference clock to PLL1.
- Reference clock pre-divider for finer frequency synthesis resolution.
- Reduced frequency divider for decreasing the PLL0/PLL1 output clock frequency without causing the PLLs to lose lock.
- Programmable frequency modulation on PLL1.
- Lock detect circuitry reports when the PLLs have achieved frequency lock, and continuously monitors lock status to report loss of lock conditions.
    - The loss of lock indication is sent to the FCCU via the system glue logic.

32.4 Modes of operation

The operating mode of the PLLs is determined by the value of PLL*n*CR[CLKCFG]. The various modes of operation for the PLL are:

- Bypass mode with reference, and both PLLs disabled
- Normal mode with reference, and either PLL0 or both PLLs enabled

NOTE

Mode changes are controlled by configuring the MC_ME Mode Configuration registers (MC_ME_<*mode*>_MC).

Bypass mode is defined as the mode where all clocks are driven by an external clock driving the EXTAL signal. Normal mode is defined as the mode where the clocks are driven by the PLLs. When using a crystal for the reference clock, reset should remain asserted until the oscillator has stabilized.

When PLL0:PHI1 is the source for PLL1, and PLL0 is powered down and working in bypass mode, PLL1 should be bypassed and powered down. PLL1 should be configured to work in normal mode only after PLL0 has achieved lock (for example, bypass with PLL0 running or PLL0 in normal mode, PLL*n*SR[LOCK] = 1).

32.4.1 Bypass mode with reference, both PLLs disabled

In this mode, the PLLs are bypassed and system and peripheral clocks (PLL clock outputs) are driven from the external clock reference. The user must supply a clock that is within the appropriate frequency range. This mode is indicated by PLL0CR[CLKCFG] = 00b and PLL1CR[CLKCFG] = 00b. This is also the default power up mode of the PLLs.

32.4.2 Normal mode with reference, PLL0 or both PLLs enabled

In normal mode, PLL0 receives an input clock from the reference which can be prescaled by the pre-divider. PLL0 multiplies the frequency to create the PLL0 output clock. The user must supply a crystal that is within the appropriate frequency range, the crystal manufacturer recommended external support circuitry and short signal route from the MCU to the crystal.

PLL0 generates a non-modulated clock which drives PLL0 PHI1. PLL1 can generate a frequency modulated clock or a non-modulated clock (for example, locked on a single frequency). The modulation rate, modulation depth, and modulation enable are programmed by configuring the PLLFM register.

NOTE

While powering down the PLLs and if PLL0:PHI1 is used as the source for PLL1, user must ensure that PLL1 is powered down first followed by powering down PLL0 for proper shut off.

Configuring the appropriate MC_ME_<*mode*>_MC register to start PLL1 should only be done after PLL0 has achieved lock.

32.5 Memory map and register definition

This section provides the memory map and detailed descriptions of all registers for configuring the PLLs. The table below shows the memory map. Addresses are given as offsets from the module base address. All registers can be accessed using 8-bit, 16-bit or 32-bit addressing.

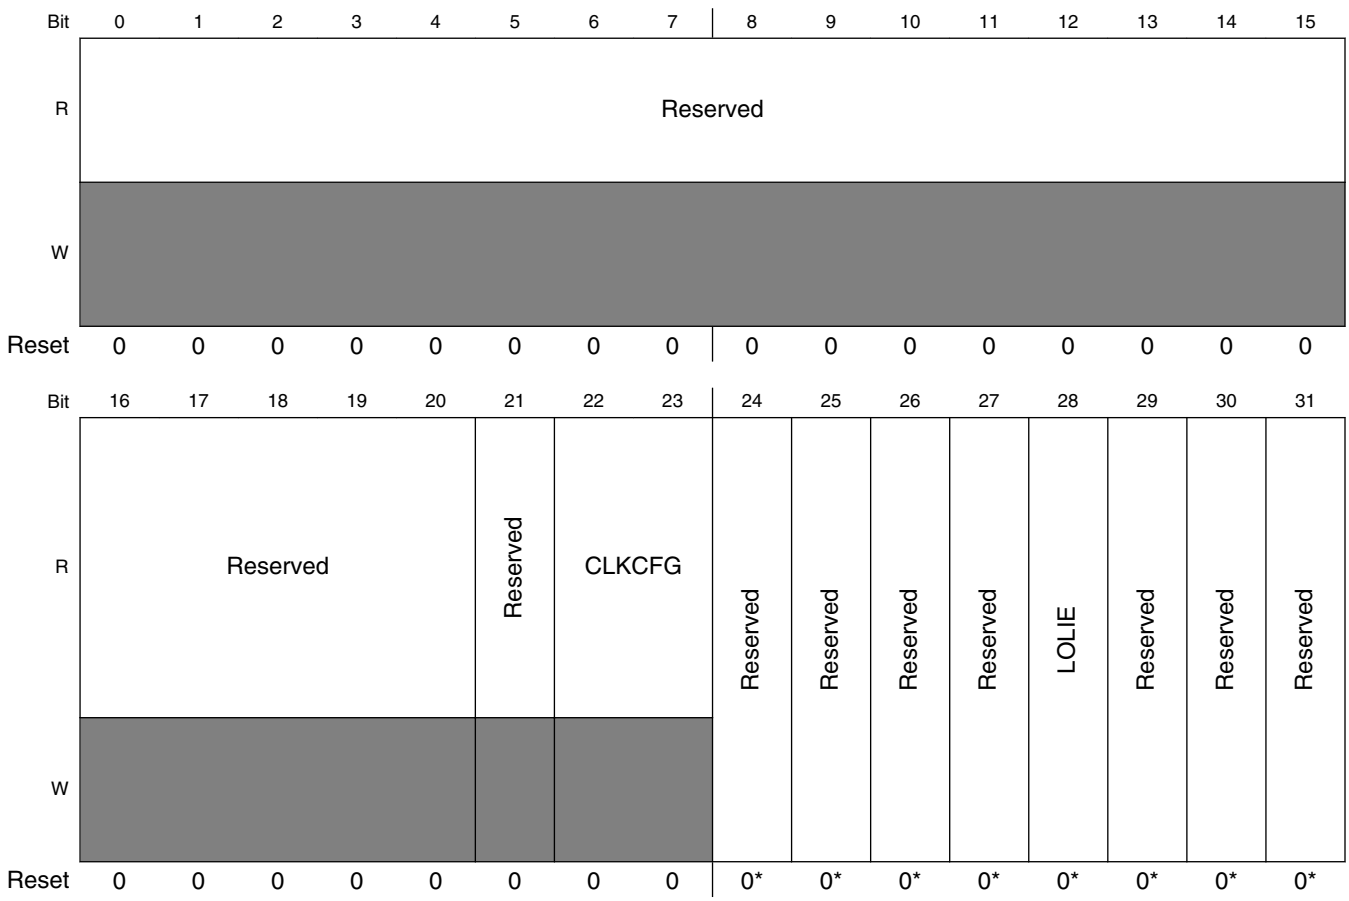
PLLDIG memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	PLLDIG PLL0 Control Register (PLLDIG_PLL0CR)	32	R/W	See section	32.5.1/1126
4	PLLDIG PLL0 Status Register (PLLDIG_PLL0SR)	32	R/W	See section	32.5.2/1128
8	PLLDIG PLL0 Divider Register (PLLDIG_PLL0DV)	32	R/W	See section	32.5.3/1130
20	PLLDIG PLL1 Control Register (PLLDIG_PLL1CR)	32	R/W	See section	32.5.4/1132
24	PLLDIG PLL1 Status Register (PLLDIG_PLL1SR)	32	R/W	See section	32.5.5/1134
28	PLLDIG PLL1 Divider Register (PLLDIG_PLL1DV)	32	R/W	See section	32.5.6/1135
2C	PLLDIG PLL1 Frequency Modulation Register (PLLDIG_PLL1FM)	32	R/W	0000_0000h	32.5.7/1137
30	PLLDIG PLL1 Fractional Divide Register (PLLDIG_PLL1FD)	32	R/W	0000_0000h	32.5.8/1139

32.5.1 PLLDIG PLL0 Control Register (PLLDIG_PLL0CR)

The PLL0CR is shown in the following table.

Address: 0h base + 0h offset = 0h



* Notes:
- This field can be written at any time, but writes are ignored. Read returns previously written value.
- LOLIE field: See the "Clocking" chapter for details on configuring this field.

PLLDIG_PLL0CR field descriptions

Field	Description
0–20 Reserved	This field is reserved.
21 Reserved	This field is reserved.
22–23 CLKCFG	Clock Configuration This field indicates the operational state of PLL.

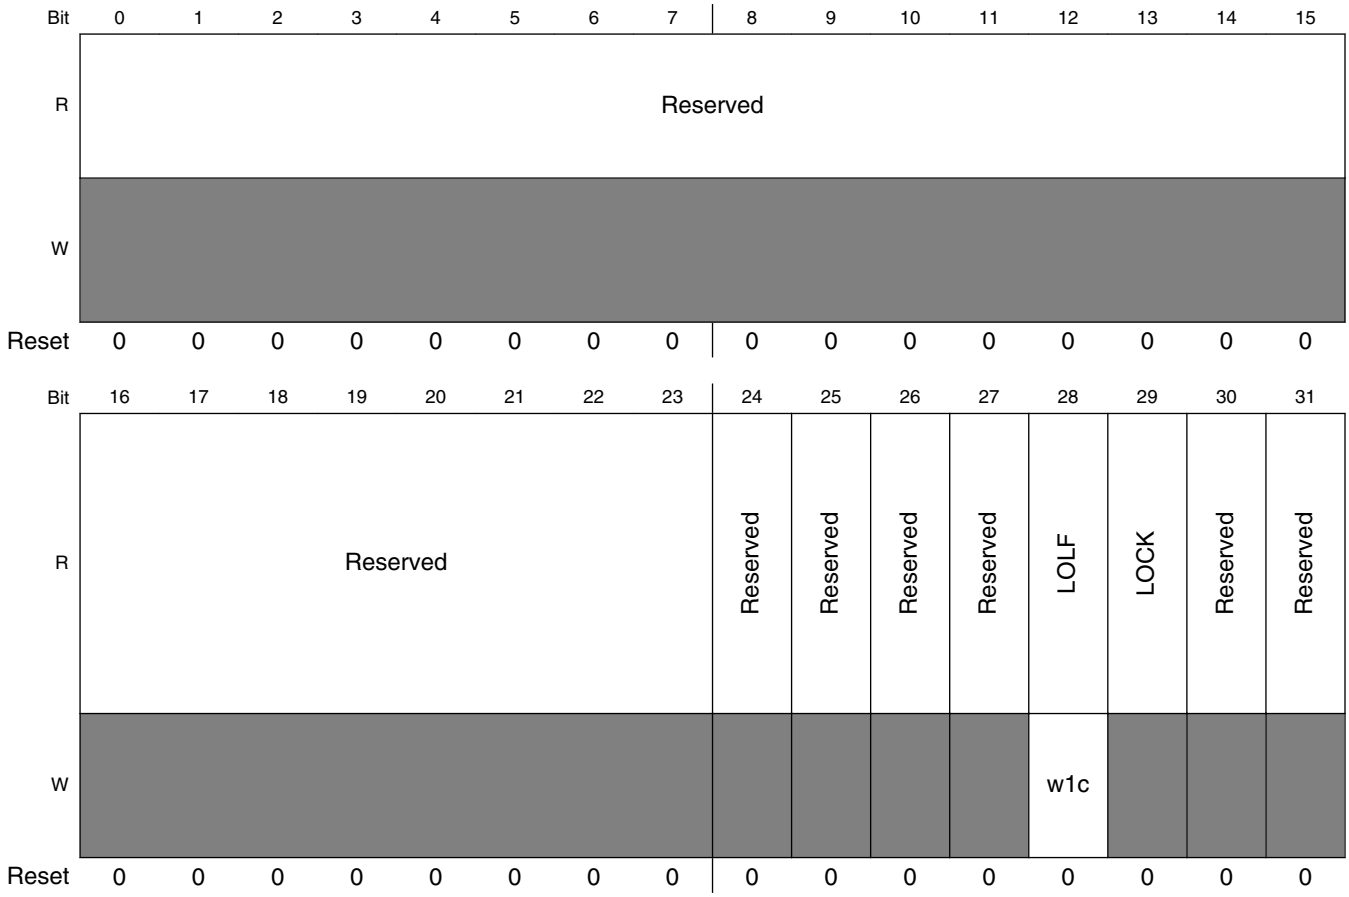
Table continues on the next page...

PLLDIG_PLL0CR field descriptions (continued)

Field	Description
	When PLLs are externally powered down the CLKCFG field changes to 00b. **NOTE:** In cascaded PLL configuration (PLL0 driving the reference clock for PLL1) the external power down signal for PLL1 must be removed only when PLL0 has locked, PLL0SR[LOCK] = 1. **NOTE:** CLKCFG can be written, but writes have no effect. Mode changes are implemented by writing to the appropriate MC_ME_< *mode* >_MC register (see the "Mode Entry Module (MC_ME)" chapter and Clock configuration for details). 00 Bypass mode with PLL off 01 Reserved 10 Reserved 11 Normal mode with PLL running.
24 Reserved	This field is reserved.
25 Reserved	This field is reserved.
26 Reserved	This field is reserved.
27 Reserved	This field is reserved.
28 LOLIE	Loss-of-lock interrupt enable. The LOLIE bit enables a loss-of-lock interrupt request when PLL0SR[LOLF] = 1. If PLL0SR[LOLF] = 0 or PLL0CR[LOLIE] = 0, the interrupt request is ignored. The interrupt request only occurs in normal mode, therefore LOLIE bit has no effect in bypass mode. 0 Ignore loss-of-lock. Interrupt not requested. 1 Enable interrupt request upon loss-of-lock.
29 Reserved	This field is reserved.
30 Reserved	This field is reserved.
31 Reserved	This field is reserved.

32.5.2 PLLDIG PLL0 Status Register (PLLDIG_PLL0SR)

Address: 0h base + 4h offset = 4h



PLLDIG_PLL0SR field descriptions

Field	Description
0–23 Reserved	This field is reserved.
24 Reserved	This field is reserved.
25 Reserved	This field is reserved.
26 Reserved	This field is reserved.
27 Reserved	This field is reserved.
28 LOLF	Loss-of-lock flag. This bit provides the interrupt request flag for the loss-of-lock condition. Software must write 1 to LOLF to clear it, writing 0 has no effect. This flag bit is sticky in the sense that if lock is reacquired, the bit will remain set until cleared by either writing 1 or asserting reset. LOLF is not asserted if the loss-of-lock

Table continues on the next page...

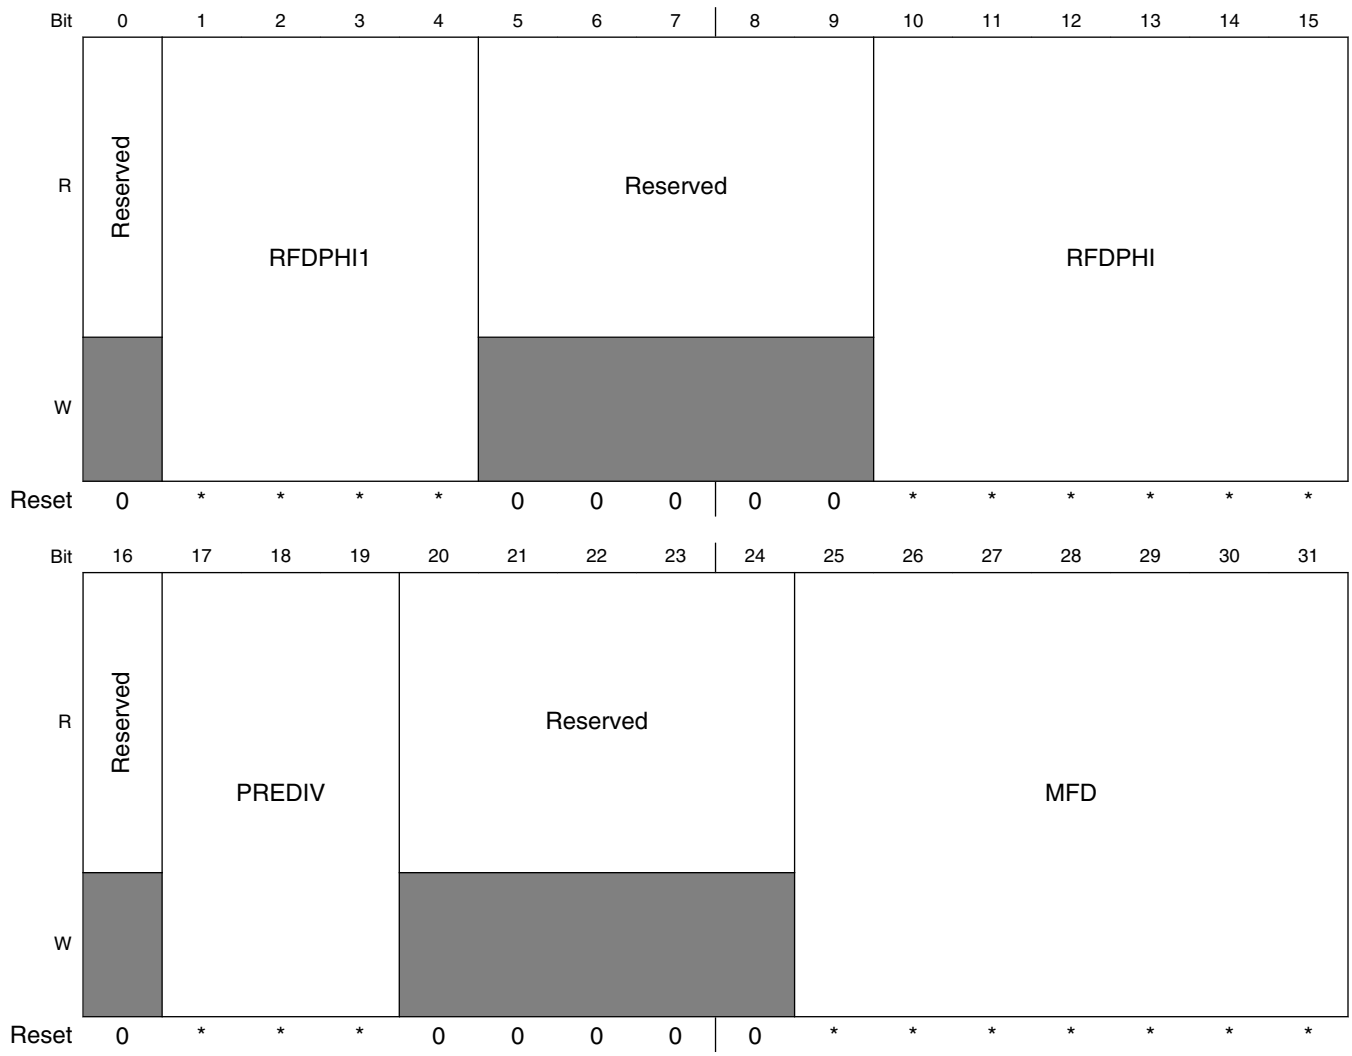
PLLDIG_PLL0SR field descriptions (continued)

Field	Description
	condition was detected while the PLL is in bypass mode, but changing from normal to bypass mode will not automatically clear the LOLF if it was previously asserted while the PLL was in normal mode. 0 No loss of lock detected. Interrupt service not requested. 1 Loss of lock detected. Interrupt service requested.
29 LOCK	Lock status bit. Indicates whether PLL has acquired lock. If operating in bypass mode, the LOCK bit will still operate normally (for example, assert when the PLL acquires lock or negate when it loses lock). 0 PLL is unlocked. 1 PLL is locked.
30 Reserved	This field is reserved.
31 Reserved	This field is reserved.

32.5.3 PLLDIG PLL0 Divider Register (PLLDIG_PLL0DV)

The PLL0DV register provides the PHI/PHI1 output clock reduced frequency divider (RFDPHI and RFDPHI1), pre-divider (PREDIV), and loop divider (MFD). If the PLL0DV fields are modified without powering down the PLL, the PLL will lose lock and generate either a reset or interrupt based on which is enabled.

Address: 0h base + 8h offset = 8h



* Notes:
- MFD field: See Clocking chapter for reset value
- PREDIV field: See Clocking chapter for reset value
- RFDPHI field: See Clocking chapter for reset value
- RFDPHI1 field: See Clocking chapter for reset value

PLLDIG_PLL0DV field descriptions

Field	Description
0 Reserved	This field is reserved.
1–4 RFDPHI1	PHI1 reduced frequency divider. This 4-bit field determines the VCO clock post divider for driving the PHI1 output clock. RFDPHI1 has a range of 4..15 (4h..Fh). All other values are reserved.
5–9 Reserved	This field is reserved.
10–15 RFDPHI	PHI reduced frequency divider. This 6-bit field determines the VCO clock post divider for driving the PHI output clock. RFDPHI has a range of 1..63 (1h..3Fh). All other values are reserved.
16 Reserved	This field is reserved.
17–19 PREDIV	Input clock predivider. This field controls the value of the divider on the input clock. The output of the predivider circuit generates the reference clock to the PLL analog loop. The PREDIV value 000b causes the input clock to be inhibited. 000 Clock inhibit 001 Divide by 1 010 Divide by 2 011 Divide by 3 100 Divide by 4 101 Divide by 5 110 Divide by 6 111 Divide by 7
20–24 Reserved	This field is reserved.
25–31 MFD	Loop multiplication factor divider. This field controls the value of the divider in the feedback loop. The value specified by the MFD bits establishes the multiplication factor applied to the reference frequency. Divider value = MFD, where MFD has the range 8...127 (8h...7Fh). All other values are reserved (see Clock configuration for details).

32.5.4 PLLDIG PLL1 Control Register (PLLDIG_PLL1CR)

The PLL1CR is shown in the following table. It contains the operational state of PLL1, and is used to enable/disable PLL specific interrupts.

Address: 0h base + 20h offset = 20h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	Reserved

* Notes:
- This field can be written at any time, but writes are ignored. Read returns previously written value.
- LOLIE field: Please refer to device "Clocking" chapter for details on configuring this field.

PLLDIG_PLL1CR field descriptions

Field	Description
0–20 Reserved	This field is reserved.
21 Reserved	This field is reserved.
22–23 CLKCFG	Clock Configuration

Table continues on the next page...

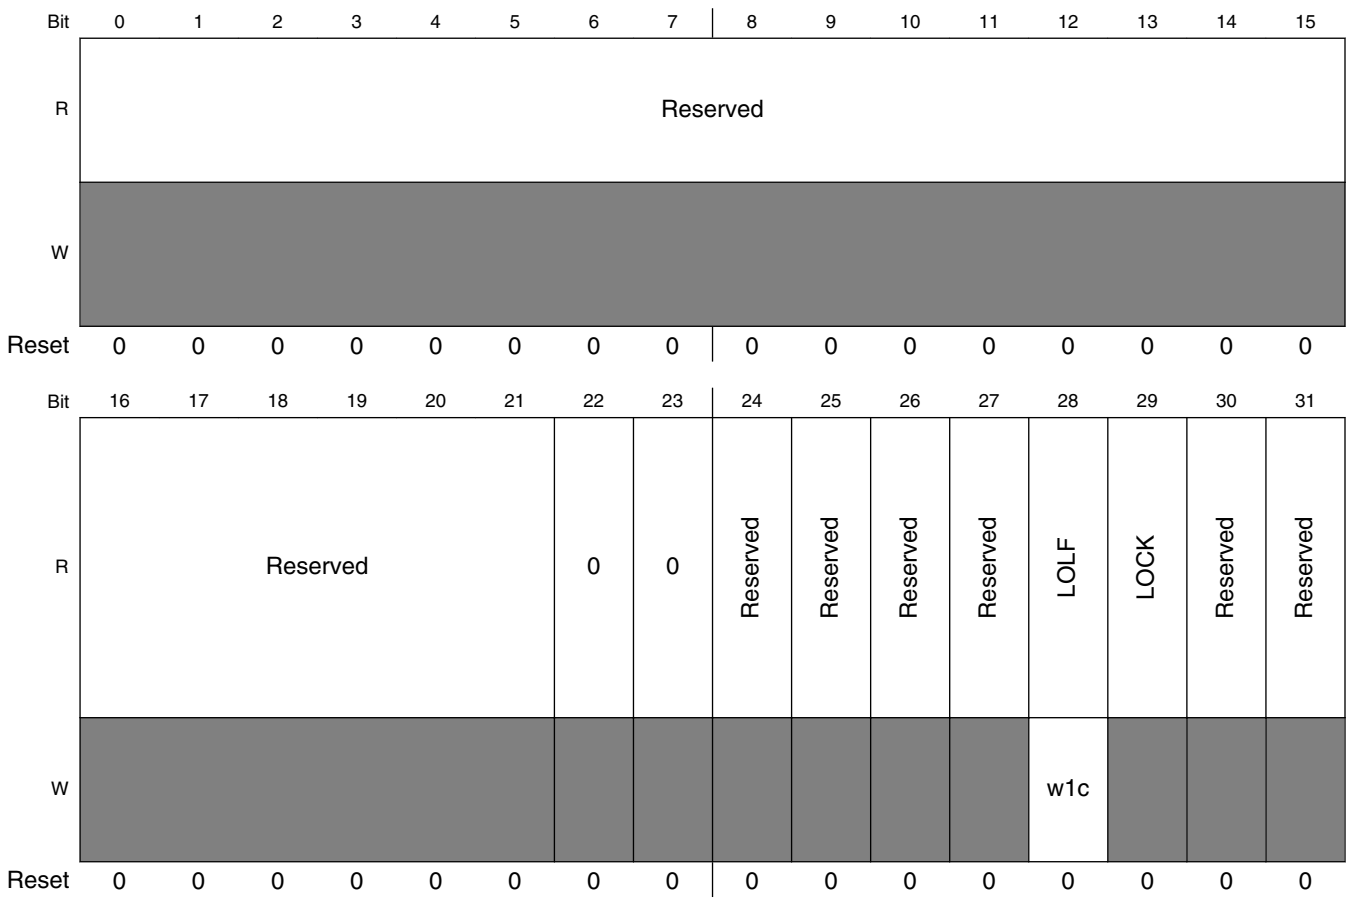
PLLDIG_PLL1CR field descriptions (continued)

Field	Description
	This field indicates the operational state of the PLL. When the PLLs are externally powered down the CLKCFG field changes to 00b. **NOTE:** In cascaded PLL configuration (PLL0 driving the reference clock for PLL1) the external power down signal for PLL1 must be removed only when PLL0 has locked, PLL0SR[LOCK] = 1. **NOTE:** CLKCFG can be written, but writes have no effect. Mode changes are implemented by writing to the appropriate MC_ME_< *mode* >_MC register (see the "Mode Entry Module (MC_ME)" chapter and Clock configuration for details). 00 Bypass mode with PLL off 01 Reserved 10 Reserved 11 Normal mode with PLL running.
24 Reserved	This field is reserved.
25 Reserved	This field is reserved.
26 Reserved	This field is reserved.
27 Reserved	This field is reserved.
28 LOLIE	Loss-of-lock interrupt enable. The LOLIE bit enables a loss-of-lock interrupt request when PLL1SR[LOLF] = 1. If PLL1SR[LOLF] = 0 or PLL1CR[LOLIE] = 0, the interrupt request is ignored. The interrupt request only occurs in normal mode, therefore LOLIE bit has no effect in bypass mode. 0 Ignore loss-of-lock. Interrupt not requested. 1 Enable interrupt request upon loss-of-lock.
29 Reserved	This field is reserved.
30 Reserved	This field is reserved.
31 Reserved	This field is reserved.

32.5.5 PLLDIG PLL1 Status Register (PLLDIG_PLL1SR)

PLL1SR contains status flags showing the current state of the PLL.

Address: 0h base + 24h offset = 24h



PLLDIG_PLL1SR field descriptions

Field	Description
0–21 Reserved	This field is reserved.
22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 Reserved	This field is reserved.
25 Reserved	This field is reserved.

Table continues on the next page...

PLLDIG_PLL1SR field descriptions (continued)

Field	Description
26 Reserved	This field is reserved.
27 Reserved	This field is reserved.
28 LOLF	Loss-of-lock flag. This bit provides the interrupt request flag for the loss-of-lock condition. Software must write 1 to LOLF to clear it, writing 0 has no effect. This flag bit is sticky in the sense that if lock is reacquired, the bit will remain set until cleared by either writing 1 or asserting reset. LOLF is not asserted if the loss-of-lock condition was detected while the PLL is in bypass mode, but changing from normal to bypass mode will not automatically clear the LOLF if it was previously asserted while the PLL was in normal mode. 0 No loss of lock detected. Interrupt service not requested. 1 Loss of lock detected. Interrupt service requested.
29 LOCK	Lock status bit. Indicates whether PLL has acquired lock. If operating in bypass mode, the LOCK bit will still operate normally (for example, assert when the PLL acquires lock or negate when it loses lock). 0 PLL is unlocked. 1 PLL is locked.
30 Reserved	This field is reserved.
31 Reserved	This field is reserved.

32.5.6 PLLDIG PLL1 Divider Register (PLLDIG_PLL1DV)

The PLL1DV register provides the PHI output clock reduced frequency divider (RFDPHI) and loop divider (MFD). If the PLL1DV fields are modified without powering down the PLL, the PLL will lose lock and generate either a reset or interrupt based on which is enabled.

Address: 0h base + 28h offset = 28h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

* Notes:

- MFD field: See Clocking chapter for reset value
- RFDPHI field: See Clocking chapter for reset value

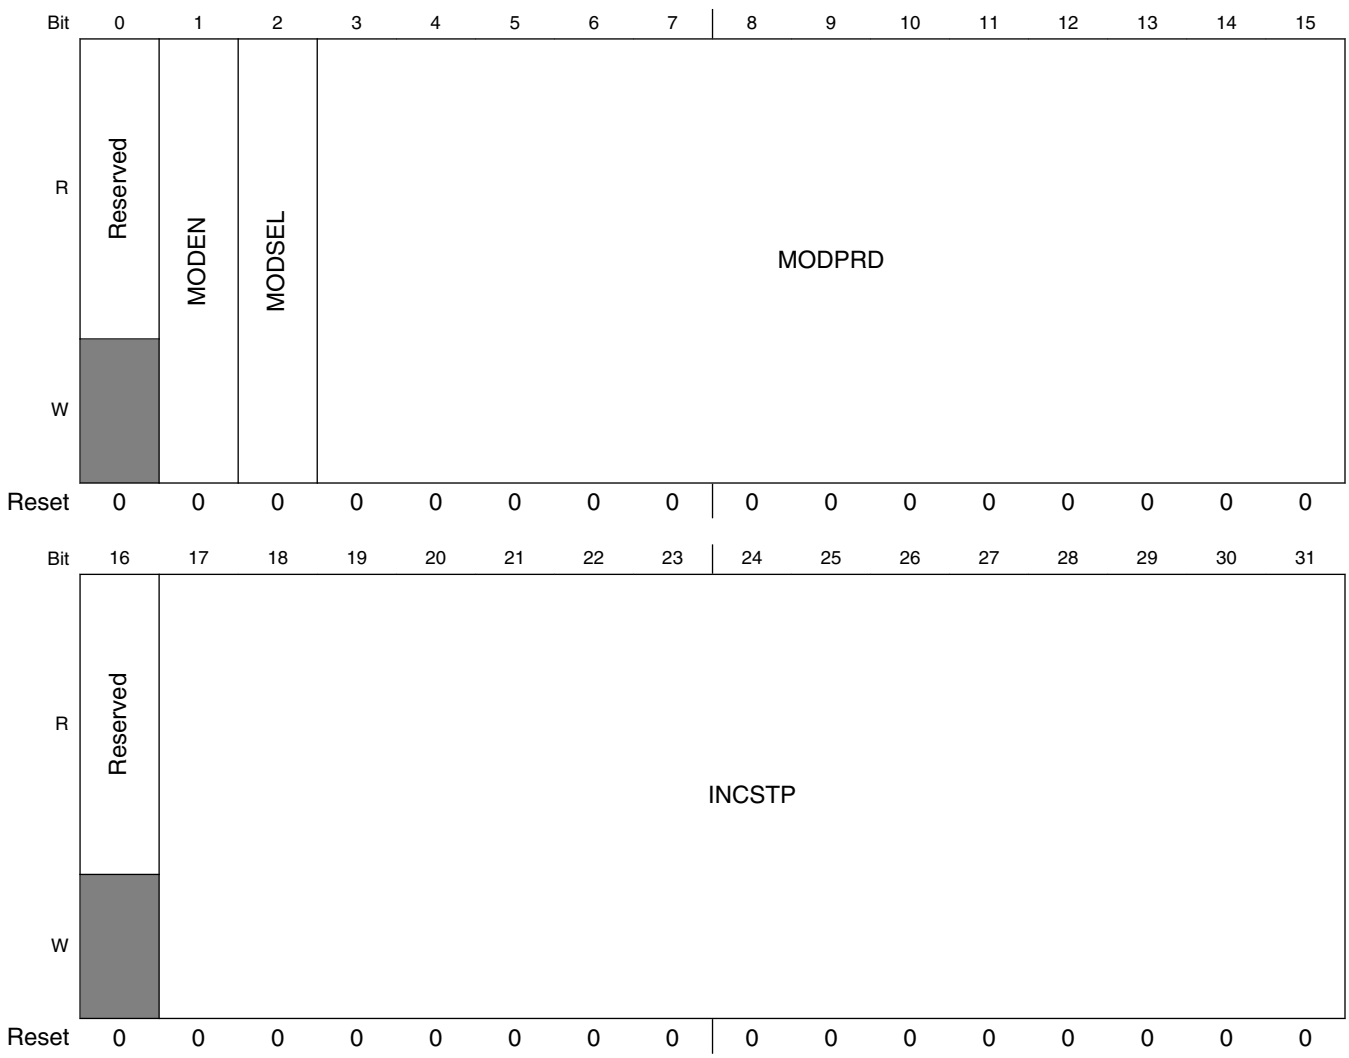
PLLDIG_PLL1DV field descriptions

Field	Description
0–9 Reserved	This field is reserved.
10–15 RFDPHI	PHI reduced frequency divider. This 6-bit field determines the VCO clock post divider for driving the PHI output clock. RFDPHI has a range of 1..63 (1h..3Fh). All other values are reserved.
16–20 Reserved	This field is reserved.
21–24 Reserved	This field is reserved.
25–31 MFD	Loop multiplication factor divider. This field controls the value of the divider in the feedback loop. The value specified by the MFD bits establishes the multiplication factor applied to the reference frequency. Divider value = MFD, where MFD has the range 16...34 (10h...22h). All other values are reserved.

32.5.7 PLLDIG PLL1 Frequency Modulation Register (PLLDIG_PLL1FM)

The PLL1FM register controls enables frequency modulation, and provides controls for modulation mode selection, modulation depth and modulation rate. This register should be written when PLL1CR[CLKCFG] = 00b (PLL1 powered down). The PLL would then be required to be power cycled to regain normal functionality.

Address: 0h base + 2Ch offset = 2Ch



PLLDIG_PLL1FM field descriptions

Field	Description
0 Reserved	This field is reserved.

Table continues on the next page...

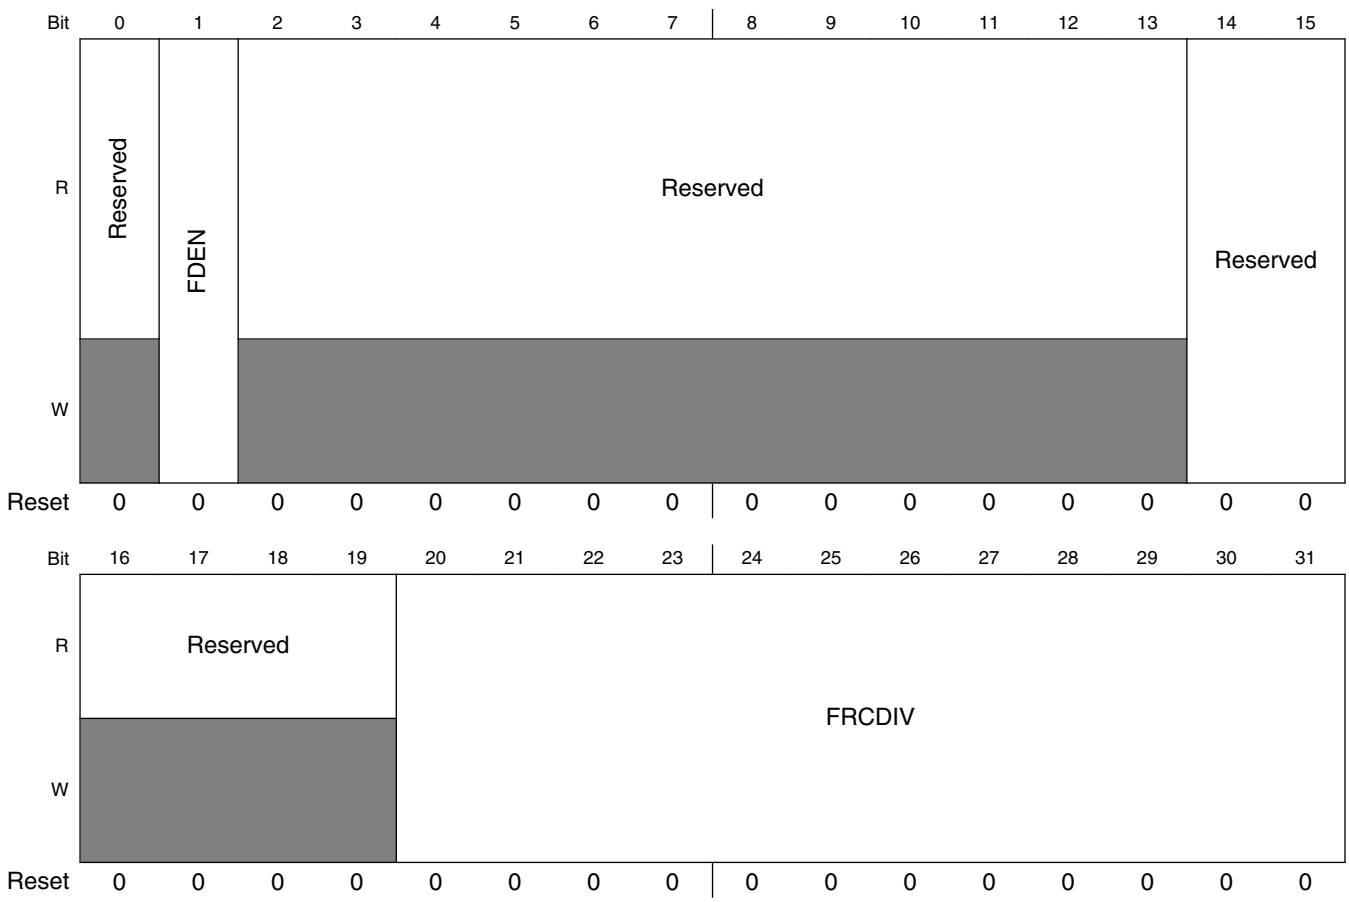
PLLDIG_PLL1FM field descriptions (continued)

Field	Description
1 MODEN	Modulation enable. This bit enables the frequency modulation. 0 Frequency modulation disabled. 1 Frequency modulation enabled.
2 MODSEL	Modulation selection. This bit selects whether modulation is centered around the nominal frequency or spread below the nominal frequency. 0 Centre Spread Modulation - Modulation centred around nominal frequency. 1 Down Spread Modulation - Modulation spread below nominal frequency.
3–15 MODPRD	Modulation period. MODPRD is the modulation period variable derived from the formulas shown in Frequency modulation.
16 Reserved	This field is reserved.
17–31 INCSTP	Increment step. This field is the INCSTP variable derived from the formulas shown in Frequency modulation.

32.5.8 PLLDIG PLL1 Fractional Divide Register (PLLDIG_PLL1FD)

The PLL1FD register provides the enable and fractional divide factor for the loop divider. This register should be written when PLL1CR[CLKCFG] = 00b (PLL1 powered down). Changing the values of FDEN once the PLL is running, and has locked, can result in the PLL losing its lock. The PLL would then require power cycling to regain normal functionality.

Address: 0h base + 30h offset = 30h



PLLDIG_PLL1FD field descriptions

Field	Description
0 Reserved	This field is reserved.
1 FDEN	Fractional Divide Enable This bit enables the fractional divider in the loop divider for PLL1.

Table continues on the next page...

PLLDIG_PLL1FD field descriptions (continued)

Field	Description
	0 Fractional divide disabled. 1 Fractional divide enabled.
2–13 Reserved	This field is reserved.
14–15 Reserved	Reserved. This field is reserved. **Important:** This field must be written 00b.
16–19 Reserved	This field is reserved.
20–31 FRCDIV	Fractional divide input. When the fractional divide is disabled, the VCO clock frequency is the product of the input clock and the loop divide factor (MFD). When fractional divide is enabled, the mean VCO clock frequency is given by the equation in the section Clock configuration.

32.6 Functional description

This section explains the operation and configuration of the Dual PLLDIG module.

32.6.1 Input clock frequency

PLL0 and PLL1 are designed to operate over an input clock frequency range. The operating ranges for the PLLs are discussed in detail in the *Data Sheet*.

32.6.2 Clock configuration

The relationship between input and output frequency is determined by programming the PLL0DV, PLL1DV, and PLL1FD registers, and calculated according to the following equations:

$$f_{pll0\_phi} = f_{pll0\_ref} \times \left(\frac{PLL0DV[MFD]}{PLL0DV[PREDIV] \times PLL0DV[RFDPHI]} \right)$$

Equation 1. PLL0 PHI Output Frequency

$$f_{pll0\_phi1} = f_{pll0\_ref} \times \left(\frac{PLL0DV[MFD]}{PLL0DV[PREDIV] \times PLL0DV[RFDPHI1]} \right)$$

Equation 2. PLL0 PHI1 Output Frequency

$$f_{pll1\_phi} = f_{pll1\_ref} \times \left(\frac{PLL1DV[MFD] + \frac{PLL1FD[FRCDIV]}{2^{12}} + \frac{1}{2^{13}}}{2 \times PLL1DV[RFDPHI]} \right)$$

Equation 3. PLL1 PHI Output Frequency (PLLDIG_PLL1FD[FDEN] = 1b)

$$f_{pll1\_phi} = f_{pll1\_ref} \times \left(\frac{PLL1DV[MFD]}{2 \times PLL1DV[RFDPHI]} \right)$$

Equation 4. PLL1 PHI Output Frequency (PLLDIG_PLL1FD[FDEN] = 0b)

The relationship between the VCO frequency (f_{VCO}) and the output frequency of the PLLs is determined by the configuration of the PLL1DV, PLL1FD, and PLL0DV registers, according to the following equations:

$$f_{pll0\_VCO} = f_{pll0\_ref} \times \left(\frac{PLL0DV[MFD] \times 2}{PLL0DV[PREDIV]} \right)$$

Equation 5. PLL0 VCO Frequency

$$f_{pll1\_VCO} = f_{pll1\_ref} \times \left(PLL1DV[MFD] + \frac{PLL1FD[FRCDIV]}{2^{12}} + \frac{1}{2^{13}} \right)$$

Equation 6. PLL1 VCO Frequency (PLLDIG_PLL1FD[FDEN] = 1b)

$$f_{pll1\_VCO} = f_{pll1\_ref} \times PLL1DV[MFD]$$

Equation 7. PLL1 VCO Frequency (PLLDIG_PLL1FD[FDEN] = 0b)

NOTE

f_{pll0_phi1} is the reference clock generated by PLL0 for PLL1

When programming the PLLs, user software must not violate the maximum system clock frequency or max/min VCO frequency specification of PLL0 and PLL1. Furthermore, the PLL0DV[PREDIV] value must not be set to any value that causes the input frequency to the phase detector of analog PLL blocks to go below the prescribed ranges.

The lock signal and PLL*n*SR[LOCK] flag are immediately negated if the fields of the PLL*n*DV registers are changed without powering down the analog PLLs.

When any of these events occur, an internal timer is initialized to count 64 cycles of the PLL input clock. During this period (64 cycles and a few extra clock cycles for synchronization, for example, 64 to 72 cycles), the PLL*n*SR[LOCK] flag is held negated. After the timer expires, the PLL*n*SR[LOCK] flag reflects the value coming from the PLL lock detection circuitry.

Note

The PLL must be powered down and powered up by configuring, then executing, a mode change in the MC_ME_<*mode*>_MC before PLL0DV[PREDIV], PLL0DV[MFD], PLL1DV[MFD], or the input clocks are modified.

The recommended procedure to program the PLLs and engage normal mode is shown in Initialization information.

Coming out of reset, PLL1 and PLL0 are off and in bypass mode. The recommended procedure to program the PLLs and engage normal mode is described in the 'Clocking' chapter.

32.6.3 Frequency modulation

Frequency modulation uses a triangular profile as shown in Figure 32-1. The modulation frequency and depth are controlled using PLL1FM[MODPRD] and PLL1FM[INCSTP].

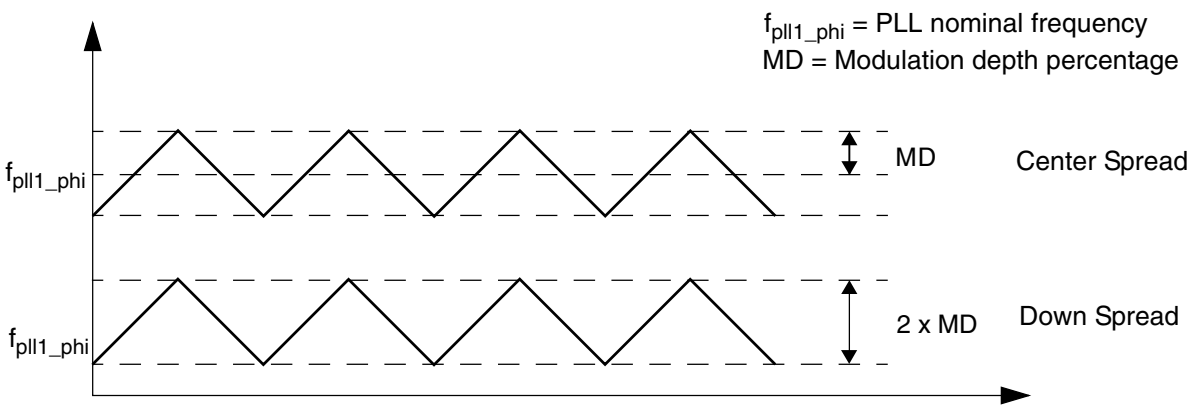


Figure 32-1. Triangular frequency modulation

NOTE

The device maximum operating frequency includes the frequency modulation. If center modulation is used, the f_{sys} must be below f_{max} by MD percentage such that $f_{max} = f_{sys} \times (1 + (MD\% / 100))$.

The following equations define how to calculate PLL1FM[MODPRD] and PLL1FM[INCSTP] based on the output frequency of the feedback divider (f_{ref}), the modulation frequency (f_{mod}) and the modulation depth percentage (MD).

$$PLL1FM[MODPRD] = round\left(\frac{f_{pll1\_ref}}{4 \times f_{mod}}\right)$$

Equation 8. PLL1FM[MODPRD] Calculation

The equation to determine PLL1FM[INCSTP] is shown in Equation 9 on page 1143.

$$PLL1FM[INCSTP] = round\left(\frac{(2^{15}-1) \times MD \times PLL1DV[MFD]}{100 \times 5 \times PLL1FM[MODPRD]}\right)$$

Equation 9. PLL1FM[INCSTP] Calculation

PLL1FM[MODPRD] and PLL1FM[INCSTP] are subject to the following restriction:

$$(PLL1FM[MODPRD] \times PLL1FM[INCSTP]) < 2^{15}$$

Equation 10. PLL1FM[MODPRD] and PLL1FM[INCSTP] Restriction

Because of the above rounding operations, the effective modulation depth applied to the FMPLL is shown in Equation 11 on page 1143.

$$ModulationDepth = round\left(\frac{PLL1FM[MODPRD] \times PLLIFM[INCSTP] \times 100 \times 5}{(2^{15} - 1) \times PLL1DV[MFD]}\right)$$

Equation 11. Modulation Depth

FM parameters should only be changed, and FM enabled, after PLL0 has obtained lock. The sequence for reprogramming the FM is:

1. Power down PLL1 by writing MC_ME_<*mode*>_MC[PLL1ON] = 0, followed by a mode change.
2. Write a mode change to MC_ME_<*mode*>_MC[PLL1ON].
3. Program the PLL1FM while PLL1 is powered down.
4. Power up the PLL1 by writing MC_ME_<*mode*>_MC[PLL1ON] = 1, followed by a mode change.
5. Write a mode change to MC_ME_<*mode*>_MC[PLL1ON].

32.7 Maximum lock time

This describes the maximum lock time of the PLL across process, supply voltages, and junction temperature. Maximum lock time is for the condition when the operating mode of the PLL has changed from power-down to Normal mode, input control bits are stable, and supplies (analog and digital) have attained levels shown in the *Data Sheet*. It is also the time in which the PLLs regain lock after a loss of lock event, assuming all inputs are stable and supplies are within specifications.

32.8 Initialization information

Coming out of reset PLL0 and PLL1 are disabled per the DRUN mode configuration register, MC_ME_DRUN_MC. The Dual PLLDIG initialization procedure is described in the "Clocking" chapter.

NOTE

See the "Mode Entry Module (MC_ME)" chapter in this *Reference Manual* more details.

Chapter 33
Clock Monitor Unit (CMU)

33.1 Introduction

The Clock Monitor Unit (CMU), also referred to as Clock Quality Checker or Clock Fault Detector, serves three purposes:

- Measures the frequency of clock source CLKMT0_RMN with CLKMN0_RMT as the reference clock
- Monitors CLKMN0_RMT frequency with CLKMT0_RMN as reference clock
- Monitors CLKMN1 frequency with CLKMT0_RMN as reference clock and detects if the monitored clock frequency leaves an upper or lower frequency boundary

NOTE

See the "Clocking" chapter for chip-specific sources used by the CMU.

One of the tasks is to supervise the integrity of the various clock sources on the chip, for example CLKMN0_RMT or CLKMN1. If the monitored clock frequency is less than the reference clock, or it violates an upper or lower frequency boundary, the CMU detects and reports this event.

The CMU can monitor CLKMN0_RMT, which must have a frequency higher than that of CLKMT0_RMN divided by the factor shown in CMU_CSR[RCDIV], and reports this event. The CMU can also monitor CLKMN1 and generate an event if CLKMN1 is greater than a high frequency boundary or less than a low frequency boundary. The upper and lower frequency boundaries are defined by the CMU High Frequency Reference Register (CMU_HFREFR) and CMU Low Frequency Reference Register (CMU_LFREFR).

The second task of the CMU is to provide a frequency meter, which allows measuring the frequency of a clock source against a reference clock. This is useful to allow the calibration of the metered clocks (such as CLKMT0_RMN), as well as to be able to correct/calculate the time deviation of a counter that is clocked by the metered clocks.

NOTE

See the "Clocking" chapter for the number of CMU instances on this chip.

33.1.1 Main features

- CLKMT0_RMN frequency measurement with CLKMN0_RMT as reference clock.
- CLKMN0_RMT monitoring with respect to CLKMT0_RMN ÷ $2^{CSR[RCDIV]}$ clock.
- Upper or lower frequency boundary monitoring of CLKMN1 with respect to CLKMT0_RMN ÷ 4.
- Event generation for various failures detected inside monitoring unit.

33.2 Block diagram

The block diagram of the CMU module(s) is shown in the “Clocking" chapter of this Reference Manual.

33.3 Signals

The table below describes the signals on the boundary of the CMU (in alphabetical order).

Table 33-1. Signal description

Signal	I/O	Description
CLKMN0_RMT	I	Monitored Clock Signal 0/Metered Clock Signal Reference — Receives a clock signal that the CMU compares to a specified low-limit frequency to determine whether the frequency of the clock signal is greater than the specified limit. Also provides a reference clock signal for all metered clock signals.
CLKMN1	I	Monitored Clock Signal 1 — Receives a clock signal that the CMU compares to specified low-limit and high-limit frequencies to determine whether the frequency of the clock signal is between the specified limits.
CLKMT0_RMN	I	Metered Clock Signal 0/Monitored Clock Signal Reference — Receives a clock signal that the CMU measures against a reference clock frequency. Also provides a reference clock signal for all monitored clock signals.

NOTE

See the "Clocking" chapter for device specific clock sources of each CMU.

33.4 Register description and memory map

This section describes in address order all the CMU registers. Each description includes a standard register diagram with an associated figure number. The CMU memory map is listed in the following table.

NOTE

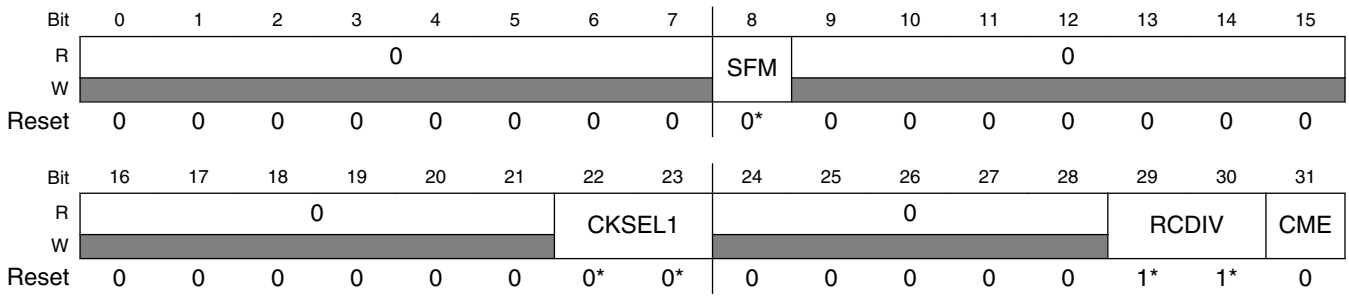
See "Clocking" chapter for register and field availability details.

CMU memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	CMU Control Status Register (CMU_CSR)	32	R/W	See section	33.4.1/1148
4	CMU Frequency Display Register (CMU_FDR)	32	R	0000_0000h	33.4.2/1149
8	CMU High Frequency Reference Register CLKMN1 (CMU_HFREFR)	32	R/W	0000_0FFFh	33.4.3/1150
C	CMU Low Frequency Reference Register CLKMN1 (CMU_LFREFR)	32	R/W	0000_0000h	33.4.4/1150
10	CMU Interrupt Status Register (CMU_ISR)	32	w1c	See section	33.4.5/1151
18	CMU Measurement Duration Register (CMU_MDR)	32	R/W	0000_0000h	33.4.6/1153

33.4.1 CMU Control Status Register (CMU_CSR)

Address: 0h base + 0h offset = 0h



* Notes:
- RCDIV field: Not all CMU blocks will utilize this feature. See the “Clocking” chapter for CMU implementation details.
- CKSEL1 field: Not all CMU blocks will utilize this feature. See the “Clocking” chapter for CMU implementation details.
- SFM field: Not all CMU blocks will utilize this feature. See the “Clocking” chapter for CMU implementation details.

CMU_CSR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 SFM	Start frequency measure. The software can only set this bit to start a clock frequency measure. It is reset by hardware when the measure is ready in the CMU_FDR. **NOTE:** MDR[MD] must be written before enabling frequency measurement (CSR[SFM] = 1). Do not write MDR[MD] while CSR[SFM] = 1. 0 Frequency measurement is completed or not yet started 1 Frequency measurement is not completed
9–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–23 CKSEL1	Frequency measure clock selection bit. CKSEL1 selects the clock to be measured by the frequency meter. This only affects CMU instances that utilizes clock metering. Not all CMU blocks will utilize this feature. See the “Clocking” chapter for device specific CMU implementation details. 00 CLKMT0_RMN is selected 01 Reserved 10 Reserved 11 CLKMT0_RMN is selected
24–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

CMU_CSR field descriptions (continued)

Field	Description
29–30 RCDIV	CLKMT0_RMN division factor. These bits specify the CLKMT0_RMN division factor. The output clock frequency is $f_{CLKMT0\_RMN} \div 2^{CMU\_CSR[RCDIV]}$. This output clock is used as reference clock to compare with CLKMN0_RMT for crystal clock monitor feature. **NOTE:** Ensure clock source for CLKMN0_RMT is off before writing CMU_CSR[RCDIV]. 00 CLKMT0_RMN ÷ 1 (No division) 01 CLKMT0_RMN ÷ 2 10 CLKMT0_RMN ÷ 4 11 CLKMT0_RMN ÷ 8
31 CME	CLKMN1 monitor enable. 0 CLKMN1 monitor is disabled 1 CLKMN1 monitor is enabled

33.4.2 CMU Frequency Display Register (CMU_FDR)

The CMU_FDR is used to determine the measured frequency of:

- CLKMT0_RMN

with respect to the reference clock CLKMN0_RMT.

NOTE

The CMU_FDR should be read only when CMU_CSR[SFM] = 0.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

CMU_FDR field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–31 FD	Measured frequency bits. This register displays the measured frequency (f_{sel}) with respect to the reference clock (f_{CLKMN0_RMT}). The measured value is given by the following formula: $f_{sel} = (f_{CLKMN0\_RMT} \times CMU\_MDR[MD]) \div CMU\_FDR[FD]$

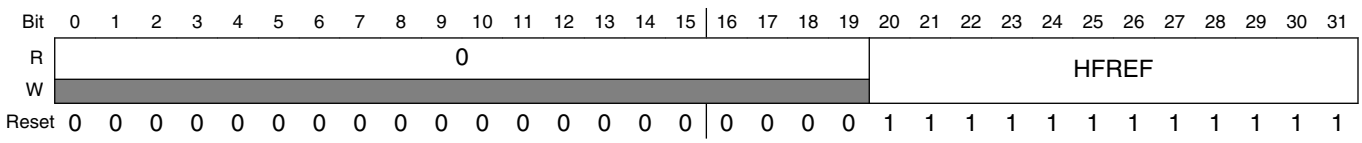
33.4.3 CMU High Frequency Reference Register CLKMN1 (CMU_HFREFR)

The HFREFR is configured for the high frequency reference that the CMU will use for comparing against the monitored clock. The figure and table below show the CMU_HFREFR register.

NOTE

For correct synchronization of CMU_HFREFR write data, the user must ensure that a time interval of 10 peripheral bus clock cycles + 40 CLKMT0_RMN clock cycles elapses before attempting subsequent writes to the same register.

Address: 0h base + 8h offset = 8h



CMU_HFREFR field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 HFREF	High Frequency reference value. These bits determine the high reference value for the CLKMN1 frequency. The reference value is given by: (HFREF ÷ 16) × (f_{CLKMT0_RMN} ÷ 4).

33.4.4 CMU Low Frequency Reference Register CLKMN1 (CMU_LFREFR)

The LFREFR is configured for the low frequency reference that the CMU will use for comparing against the monitored clock. The figure and table below show the CMU_LFREFR register.

NOTE

For correct synchronization of CMU_LFREFR write data, the user must ensure that a time interval of 10 peripheral bus clock cycles + 40 CLKMT0_RMN clock cycles elapses before attempting subsequent writes to the same register.

Address: 0h base + Ch offset = Ch

Bit	0–19	20–31
R	0	LFREF
W		
Reset	0	0

CMU_LFREFR field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 LFREF	Low Frequency reference value. These bits determine the low reference value for the CLKMN1 frequency. The reference value is given by: (LFREF ÷ 16) × (f_{CLKMT0_RMN} ÷ 4).

33.4.5 CMU Interrupt Status Register (CMU_ISR)

NOTE

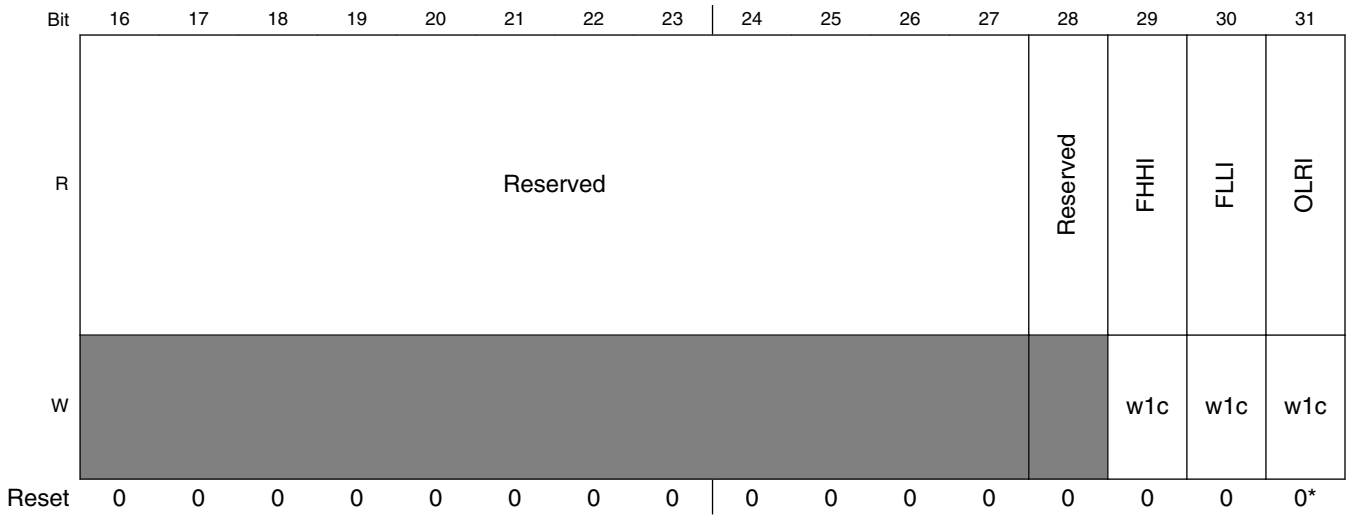
All flags in the CMU_ISR are set asynchronously. This register must be read only after a CMU event is triggered. Otherwise, a read access on this register may fetch an incorrect value (see "Clocking" chapter for interrupt operation) .

NOTE

Before entering low-power stop modes, all clock frequency measurements in the CMU should be disabled. Failing to do so may result in ISR flags being spuriously set.

Address: 0h base + 10h offset = 10h

Bit	0–7	8–15
R	Reserved	
W		
Reset	0	0



* Notes:

- OLRI field: Not all CMU blocks will utilize this feature. See the "Clocking" chapter for specific CMU implementation details.

CMU_ISR field descriptions

Field	Description
0–27 Reserved	This field is reserved.
28 Reserved	This field is reserved. **NOTE:** This bit will show indeterministic behavior if the clock monitored by the CMU is not enabled .
29 FHHI	CLKMN1 frequency higher than high reference event status. This bit is set by hardware when CLKMN1 frequency becomes higher than the high frequency reference value determined by CMU_HFREFR[HFREF] and CLKMN1 is 'ON' as signaled by the MC_ME. It can be cleared by software by writing '1'. 0 No FHH event 1 FHH event occurred
30 FLLI	CLKMN1 frequency less than low reference event status. This bit is set by hardware when CLKMN1 frequency becomes lower than the low frequency reference value determined by CMU_LFREFR[LFREF], and CLKMN1 is 'ON' as signaled by the MC_ME. Software clears this field by writing a '1'. **NOTE:** This bit will show indeterministic behavior if the clock monitored by the CMU is not enabled . 0 No FLL event 1 FLL event occurred
31 OLRI	Oscillator frequency less than $f_{CLKMT0_RMN} \div 2^{CMU_CSR[RCDIV]}$event status. This bit is set by hardware when the f_{CLKMN0_RMT} is less than $f_{CLKMT0_RMN} \div 2^{CMU_CSR[RCDIV]}$frequency and CLKMN0_RMT is 'ON' as signaled by the MC_ME. It can be cleared by software by writing '1'. **NOTE:** While entering STOP mode, OLRI may be triggered due to stoppage of XOSC. To avoid this, disable the XOSC before entering STOP mode.

Table continues on the next page...

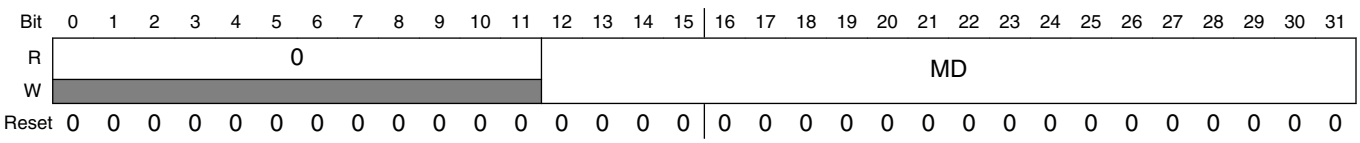
33.4.6 CMU Measurement Duration Register (CMU_MDR)

Address: 0h base + 18h offset = 18h



CMU_MDR field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–31 MD	Measurement duration bits This field displays the measurement duration in terms of selected clock (CLKMT0_RMN) cycles. This value is loaded in the frequency meter down-counter. The down-counter starts counting when CMU_CSR [SFM] = 1. **NOTE:** Only values that do not cause a CMU_FDR[FD] overflow shall be written to CMU_MDR[MD]. There is no internal status of a CMU_FDR[FD] overflow.

33.5 Functional description

33.5.1 Frequency meter

The purpose of the frequency meter is to evaluate the deviation from the nominal metered source (such as CLKMT0_RMN) frequencies. This in turn allows either recalibration of these clocks or other timing corrections. Programming of the CMU_CSR[CKSEL1] field is used to select one of the metered clocks from a multiplexer that drives a simple Frequency Meter (see the CMU Block Diagram in the "Clocking" chapter). The reference clock for the Frequency Meter is the CLKMN0_RMT signal. The measurement starts when CMU_CSR[SFM] = 1. The measurement duration is given by the contents of CMU_MDR[MD] in terms of number of clock cycles of the selected metered clock. The CMU_CSR[SFM] bit is cleared by hardware once the frequency measurement is

complete and the count is loaded in CMU_FDR[FD]. The frequency of the selected clock (f_{sel}) can be derived from the value loaded in the CMU_FDR[FD] as shown in the following equation:

$$f_{sel} = \left(f_{CLKMNO\_RMT} \times MDR[MD]\right) / \ FDR[FD]$$

33.5.2 CLKMN0_RMT supervisor

If frequency of CLKMN0_RMT is smaller than the frequency of CLKMT0_RMN ÷ $2^{CMU\_CSR[RCDIV]}$ and CLKMN0_RMT is 'ON' as signaled by the MC_ME, then:

- The CMU writes 1 to CMU_ISR[OLRI].
- The CMU asserts the OLR signal.

Note

f_{CLKMN0_RMT} must be greater than $f_{CLKMT0\_RMN} \div 2^{CMU\_CSR[RCDIV]}$ by at least 0.5 MHz in order to guarantee correct f_{CLKMN0_RMT} monitoring.

33.5.3 CLKMN1 supervisor

The frequency of CLKMN1(f_{CLKMN1}) can be monitored by programming CMU_CSR[CME] = 1. CLKMN1 monitoring starts as soon as CMU_CSR[CME] = 1. This monitor can be disabled at any time by programming CMU_CSR[CME] = 0.

If f_{CLKMN1} is greater than the reference value determined by fields CMU_HFREFR[HFREF] and CLKMN1 is 'ON' as signaled by the MC_ME, then:

- The CMU writes 1 to CMU_ISR[FHHI].
- The CMU asserts the FHH signal.

If f_{CLKMN1} is less than a reference value determined by the bits CMU_LFREFR[LFREF] and the CLKMN1 is 'ON' as signaled by the MC_ME, then:

- The CMU writes 1 to CMU_ISR[FLLI].
- The CMU asserts the FLL signal.

Note

An example of determining the $HFREF_{Actual}$ is as follows. Assume a f_{CLKMT0_RMN} = 16 MHz with a accuracy of +/-5% (see *Data Sheet* for actual value). In order to monitor a f_{CLKMN1} = 200 MHz, the ideal $HFREF_{Ideal}$ = 800. The actual HFREF value will be 842 when the accuracy is taken into consideration ($HFREF_{Actual}$ = ($HFREF_{Ideal}$ ÷ 0.95). The actual LFREF value will be 762 when accuracy is taken into consideration ($LFREF_{Actual}$ = $LFREF_{Ideal}$ ÷ 1.05).

Chapter 34
Clock Generation Module (MC_CGM)

34.1 Introduction

34.1.1 Overview

The clock generation module (MC_CGM) generates reference clocks for all the chip blocks. The MC_CGM selects one of the system clock sources to supply the system clock. The MC_ME controls the system clock selection (see the MC_ME chapter for more details). A set of MC_CGM registers controls the clock dividers which are used for divided system and peripheral clock generation. The memory spaces of system and peripheral clock sources which have addressable memory spaces are accessed through the MC_CGM memory space.

The following figure shows the MC_CGM block diagram.

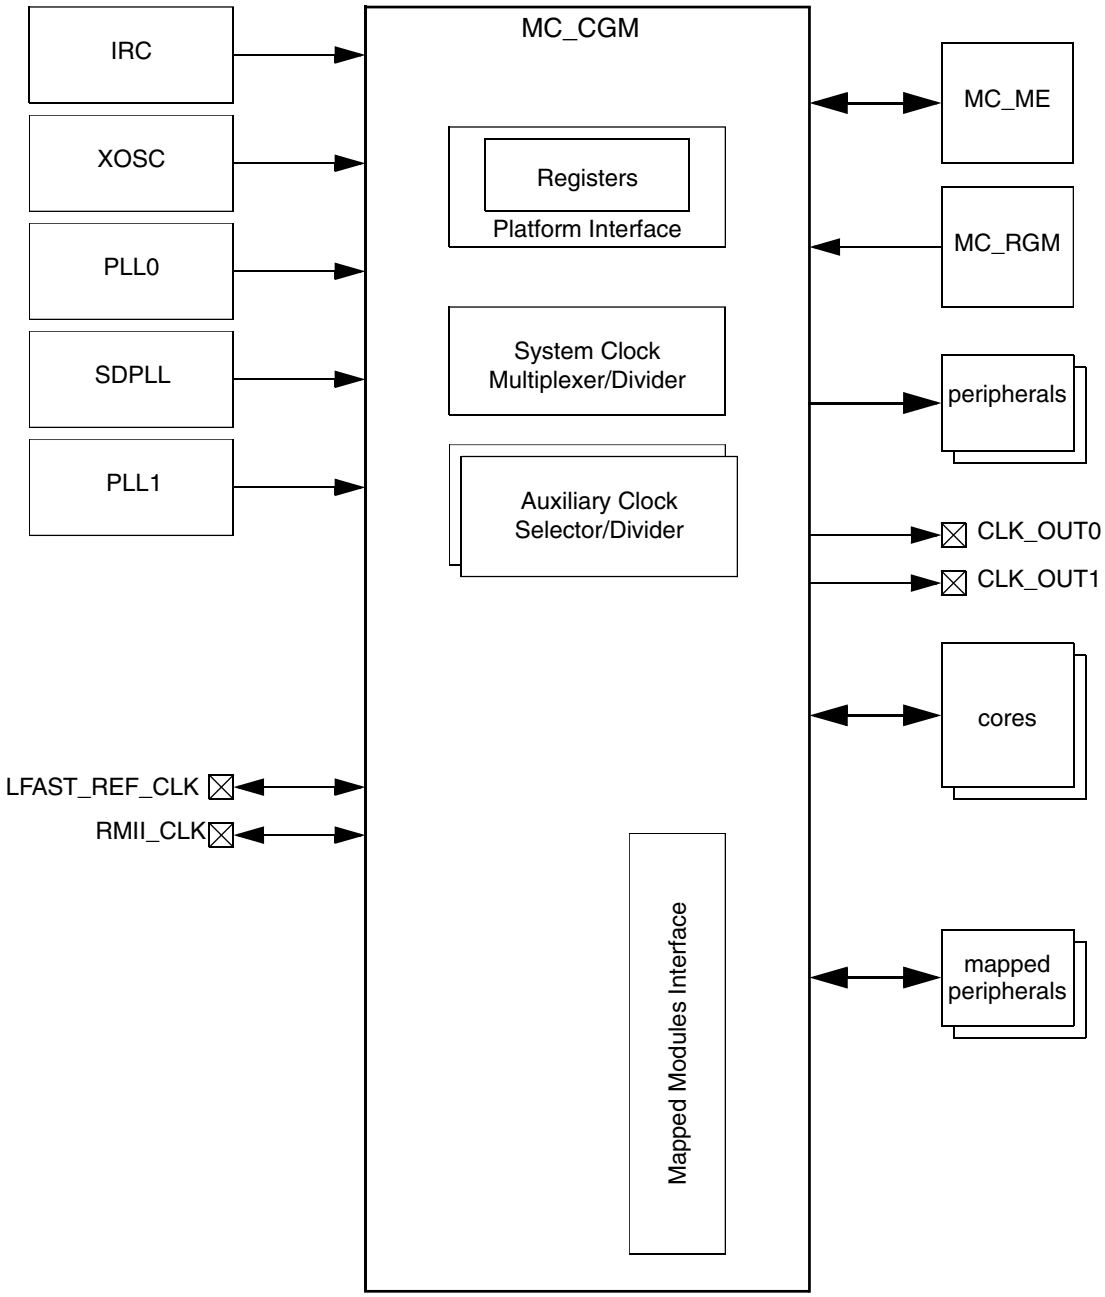


Figure 34-1. MC_CGM block diagram

34.1.2 Features

The MC_CGM includes the following features:

- generates system and peripheral clocks
- selects and enables/disables the system clock supply from system clock sources according to MC_ME control
- performs progressive system clock frequency change depending on MC_ME mode configuration

- contains a set of registers to control clock dividers for divided clock generation
- supports multiple clock sources and maps their address spaces to its memory map
- guarantees glitch-less clock transitions when changing the system clock selection
- supports 8, 16, and 32-bit wide read/write accesses

34.2 External signal description

The MC_CGM delivers output clocks to the CLK_OUT0 and CLK_OUT1 pins for off-chip use and/or observation.

The LFAST_Ref pin can be either driven by the MC_CGM or used as an input to source the LFAST_CLK.

The RMII_CLK pin can be either driven by the MC_CGM or used as an input to source the ENET_CLK and ENET_TIME_CLK.

34.3 Memory mapped registers

The bytes are ordered according to big endian. For example, the **CGM_PCS_DIVC1** register **RATE** bits may be accessed as a word at address offset 0x0704, as a half-word at address offset 0x0706, or as a byte at address offset 0x0707.

NOTE

Any access to unused registers as well as write accesses to read-only registers will

- not change register content
- cause a transfer error

Any access to offsets 0x80Ch, 0x82Ch, 0x9E8h will not return transfer error.

NOTE

Do not write on reserved fields of registers

NOTE

The following registers are also writable in user mode

- CGM_PCS_DIVSn
- CGM_PCS_DIVEn

- CGM_PCS_DIVCn
- CGM_PCS_SDUR

NOTE

Accessing following registers in user mode does not have any effect

- CGM_SC_DIV_RC
- CGM_DIV_UPD_TYPE
- CGM_DIV_UPD_TRIG
- CGM_DIV_UPD_STAT

NOTE

The following registers are reset to their default values during a POR event only:

- CGM_PCS_SDUR
- CGM_PCS_DIVC1
- CGM_PCS_DIVS1
- CGM_PCS_DIVE1
- CGM_PCS_DIVC2
- CGM_PCS_DIVS2
- CGM_PCS_DIVE2
- CGM_PCS_DIVC4
- CGM_PCS_DIVS4
- CGM_PCS_DIVE4
- CGM_AC0_SC
- CGM_AC1_SC
- CGM_AC2_SC
- CGM_AC3_SC
- CGM_AC4_SC
- CGM_AC7_SC
- CGM_AC8_SC
- CGM_AC10_SC
- CGM_AC11_SC
- CGM_AC12_SC
- CGM_AC13_SC

34.3.1 PCS Switch Duration Register (CGM_PCS_SDUR)

This register contains the progressive system clock switching duration for each step. See Progressive System Clock Switching for details on how to set this value.

Address: 0h base + 700h offset = 700h

Bit	0	1	2	3	4	5	6	7
Read Write	SDUR							
Reset	0	0	0	0	0	0	0	0

CGM_PCS_SDUR field descriptions

Field	Description
0–7 SDUR	**Switch Duration** — This value defines the duration of one PCS clock switch step in terms of IRC_CLK cycles.

34.3.2 PCS Divider Change Register 1 (CGM_PCS_DIVC1)

This register defines the rate of frequency change and initial change value for the progressive system clock switching when switching the system clock source to or from the XOSC_CLK on ramp-up and ramp-down, respectively. See Progressive System Clock Switching for details on how to set these values.

NOTE

Byte write accesses are not allowed for the INIT field of this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

Address: 0h base + 704h offset = 704h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	INIT																0								RATE							
W																																
Reset	0	0	0	0	0	0	1	1	1	1	1	0	0	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CGM_PCS_DIVC1 field descriptions

Field	Description
0–15 INIT	**Divider Change Initial Value** — This is initial change value of the clock divider for the clock ramp-up phase when switching to the XOSC_CLK.
16–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 RATE	**Divider Change Rate** — This value controls the change value of the clock divider for the clock ramp-up and ramp-down phase when switching to/from the XOSC_CLK.

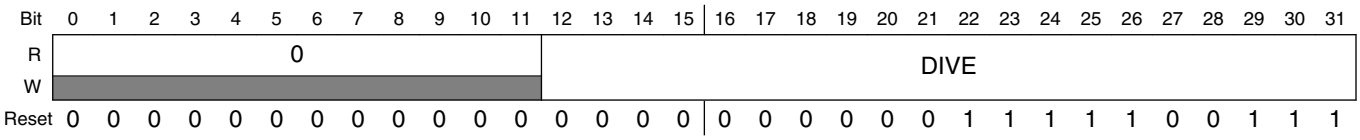
34.3.3 PCS Divider End Register 1 (CGM_PCS_DIVE1)

This register defines the final division value for the progressive system clock switching when switching the system clock source from the XOSC_CLK on ramp-down. See Progressive System Clock Switching for details on how to set this value.

NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

Address: 0h base + 708h offset = 708h



CGM_PCS_DIVE1 field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–31 DIVE	**Divider End Value** — This is the clock divider end value for the clock ramp-down phase when switching from the XOSC_CLK.

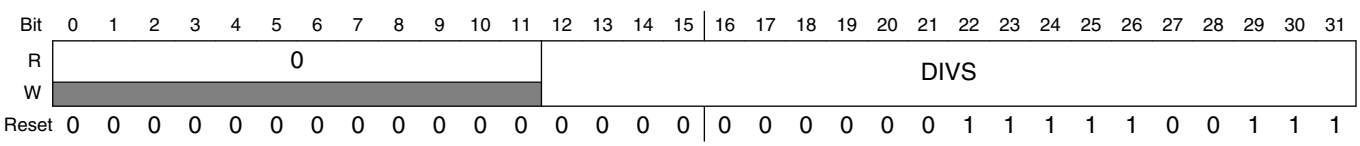
34.3.4 PCS Divider Start Register 1 (CGM_PCS_DIVS1)

This register defines the initial division value for the progressive system clock switching when switching the system clock source to the XOSC_CLK on ramp-up. Register *n* corresponds to system clock source *n*. See Progressive System Clock Switching for details on how to set these values.

NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

Address: 0h base + 70Ch offset = 70Ch



CGM_PCS_DIVS1 field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–31 DIVS	**Divider Start Value** — This is the start value of the clock divider for the clock ramp-up phase when switching to the XOSC_CLK.

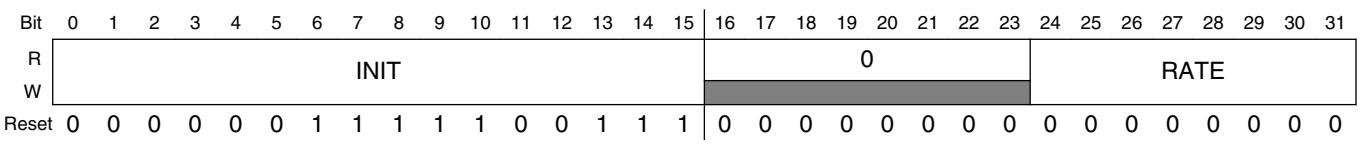
34.3.5 PCS Divider Change Register 2 (CGM_PCS_DIVC2)

This register defines the rate of frequency change and initial change value for the progressive system clock switching when switching the system clock source to or from the PLL0_PHI_CLK on ramp-up and ramp-down, respectively. See Progressive System Clock Switching for details on how to set these values.

NOTE

Byte write accesses are not allowed for the INIT field of this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

Address: 0h base + 710h offset = 710h



CGM_PCS_DIVC2 field descriptions

Field	Description
0–15 INIT	**Divider Change Initial Value** — This is initial change value of the clock divider for the clock ramp-up phase when switching to the PLL0_PHI_CLK.
16–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 RATE	**Divider Change Rate** — This value controls the change value of the clock divider for the clock ramp-up and ramp-down phase when switching to/from the PLL0_PHI_CLK.

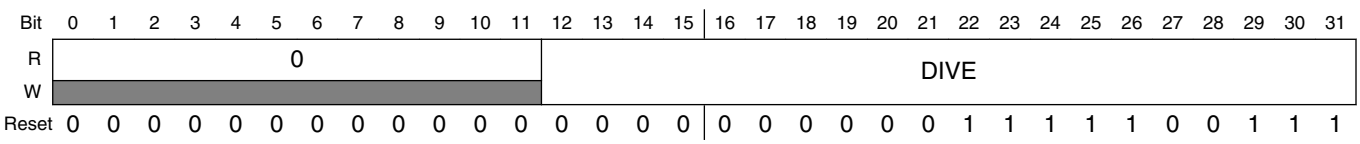
34.3.6 PCS Divider End Register 2 (CGM_PCS_DIVE2)

This register defines the final division value for the progressive system clock switching when switching the system clock source from the PLL0_PHI_CLK on ramp-down. See Progressive System Clock Switching for details on how to set this value.

NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

Address: 0h base + 714h offset = 714h



CGM_PCS_DIVE2 field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–31 DIVE	**Divider End Value** — This is the clock divider end value for the clock ramp-down phase when switching from the PLL0_PHI_CLK.

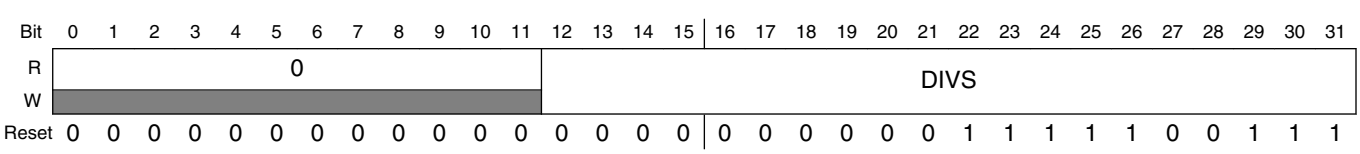
34.3.7 PCS Divider Start Register 2 (CGM_PCS_DIVS2)

This register defines the initial division value for the progressive system clock switching when switching the system clock source to the PLL0_PHI_CLK on ramp-up. See Progressive System Clock Switching for details on how to set this value.

NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

Address: 0h base + 718h offset = 718h



CGM_PCS_DIVS2 field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–31 DIVS	**Divider Start Value** — This is the start value of the clock divider for the clock ramp-up phase when switching to the PLL0_PHI_CLK.

34.3.8 PCS Divider Change Register 4 (CGM_PCS_DIVC4)

This register defines the rate of frequency change and initial change value for the progressive system clock switching when switching the system clock source to or from the PLL1_PHI_CLK on ramp-up and ramp-down, respectively. See Progressive System Clock Switching for details on how to set these values.

NOTE

Byte write accesses are not allowed for the INIT field of this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

Address: 0h base + 728h offset = 728h

CGM_PCS_DIVS4 field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–31 DIVS	**Divider Start Value** — This is the start value of the clock divider for the clock ramp-up phase when switching to the PLL1_PHI_CLK.

34.3.11 System Clock Divider Ratio Change Register (CGM_SC_DIV_RC)

This register selects whether the system clock divider ratios will change from the current configuration to the configuration in the next update. If the value of SYS_DIV_RATIO_CHNG is ‘1’ at the time of a write to the CGM_DIV_UPD_TRIG register and a pre-loaded system clock divider update is pending, the crossbar is halted while the system clock divider update takes place. If the value of SYS_DIV_RATIO_CHNG is ‘0’, the crossbar switch is not halted. This register has no effect if the system clock divider update is configured in the CGM_DIV_UPD_TYPE register to be immediate.

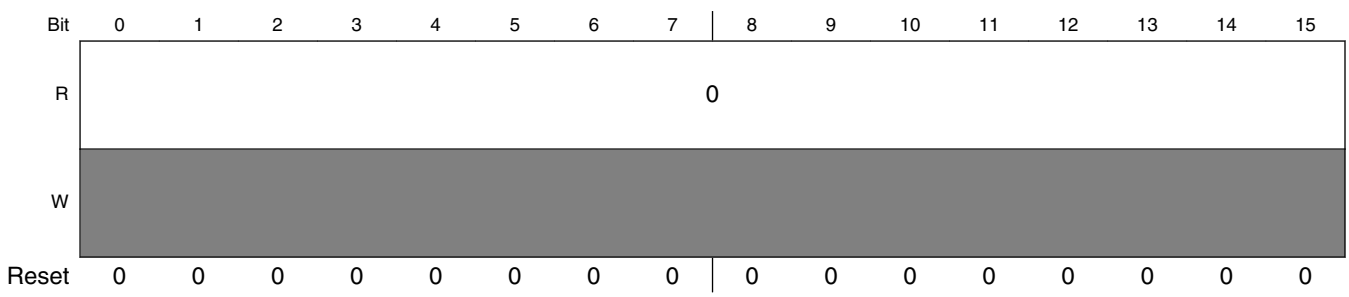
An example of a divider ratio not changing is divider 0 changes from divide by 1 to divide by 2, and divider 1 changes from divide by 2 to divide by 4. The ratio is 1:2 in both configurations.

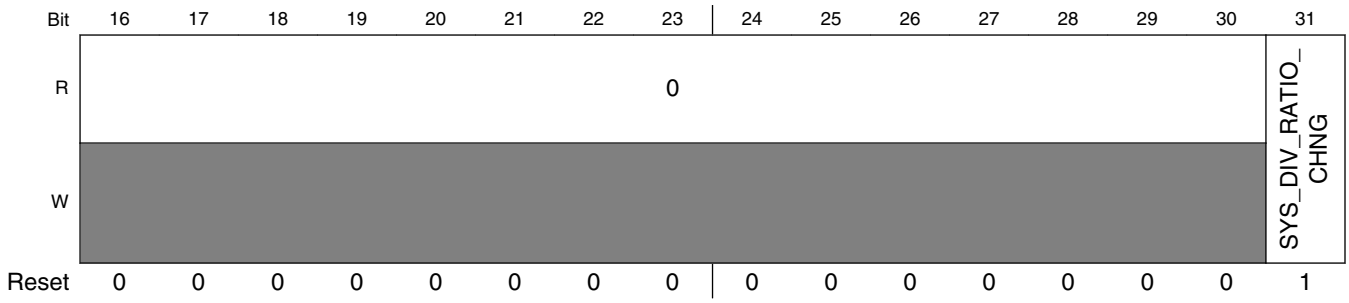
An example of a divider ratio changing is divider 0 changes from divide by 1 to divide by 2, and divider 1 changes from divide by 2 to divide by 6. The ratio changes from 1:2 to 1:3.

The value of SYS_DIV_RATIO_CHNG is returned to ‘1’ automatically on each write to the CGM_DIV_UPD_TRIG register.

Software must never write a ‘0’ to the SYS_DIV_RATIO_CHNG bit if the system clock divider ratios change from the current configuration to the next configuration. This can potentially cause errors in the crossbar which lead to lost data.

Address: 0h base + 7D0h offset = 7D0h





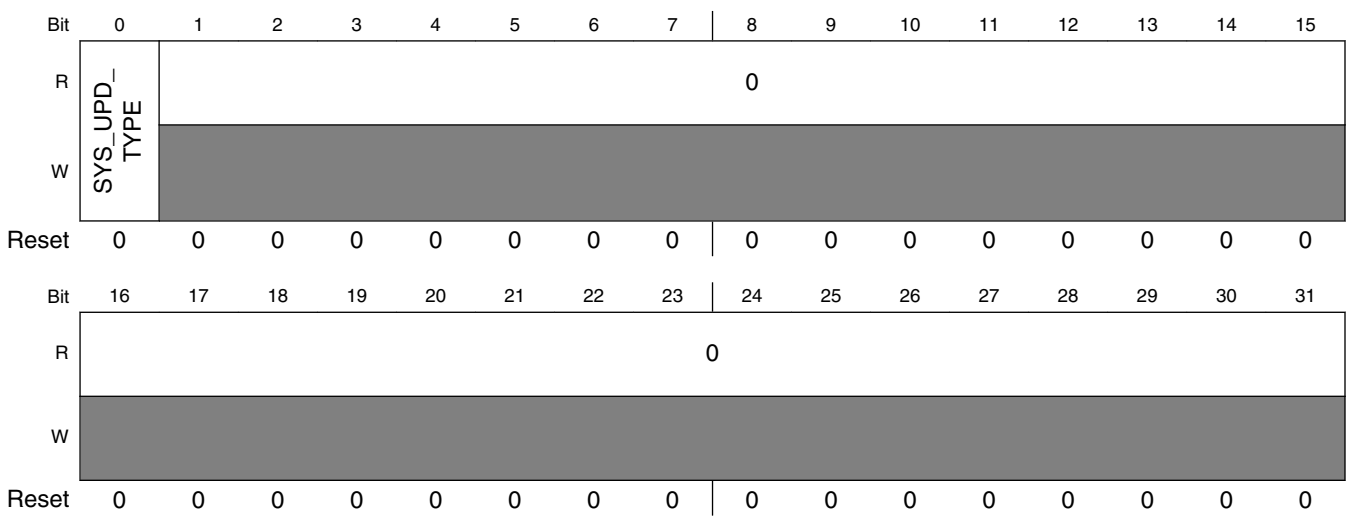
CGM_SC_DIV_RC field descriptions

Field	Description
0–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 SYS_DIV_RATIO_CHNG	System Clock Divider Ratio Change 0 the system clock divider ratios will not change with the next system clock divider configuration update 1 the system clock divider ratios will change with the next system clock divider configuration update

34.3.12 Divider Update Type Register (CGM_DIV_UPD_TYPE)

This register selects whether the dividers associated with a clock are updated immediately on writing to the corresponding divider configuration register or only on writing to the divider update trigger register CGM_DIV_UPD_TRIG, after which the pre-loaded configuration in the divider configuration registers wil take effect.

Address: 0h base + 7D4h offset = 7D4h



CGM_DIV_UPD_TYPE field descriptions

Field	Description
0 SYS_UPD_TYPE	System Clock Divider Update Type

Table continues on the next page...

CGM_DIV_UPD_TYPE field descriptions (continued)

Field	Description
	0 The configuration for each system clock divider is updated immediately on writing to the corersponding CGM_SC_DCi register 1 The configuration for each system clock divider is preloaded on writing to the corersponding CGM_SC_DCi register, and the pre-loaded configurations of all the system clock dividers are updated on writing to the CGM_DIV_UPD_TRIG register
1–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

34.3.13 Divider Update Trigger Register (CGM_DIV_UPD_TRIG)

Address: 0h base + 7D8h offset = 7D8h

12–14 SWTRG	**Switch Trigger cause** — This value indicates the cause for the latest clock source switch. 000 reserved 001 switch after request from MC_ME succeeded 010 switch after request from MC_ME failed due inactive target clock 011 switch after request from MC_ME failed due inactive current clock 100 switch to IRC_CLK due to SAFE mode request or reset succeeded 101 switch to IRC_CLK due to SAFE mode request or reset succeeded, but current clock source was inactive 110 reserved 111 reserved **NOTE:** The reset value of SWTRG may reflect 001 instead of 100, if offline Self test has been executed.
15 SWIP	**Switch In Progress** 0 clock source switching has completed 1 clock source switching is in progress
16–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

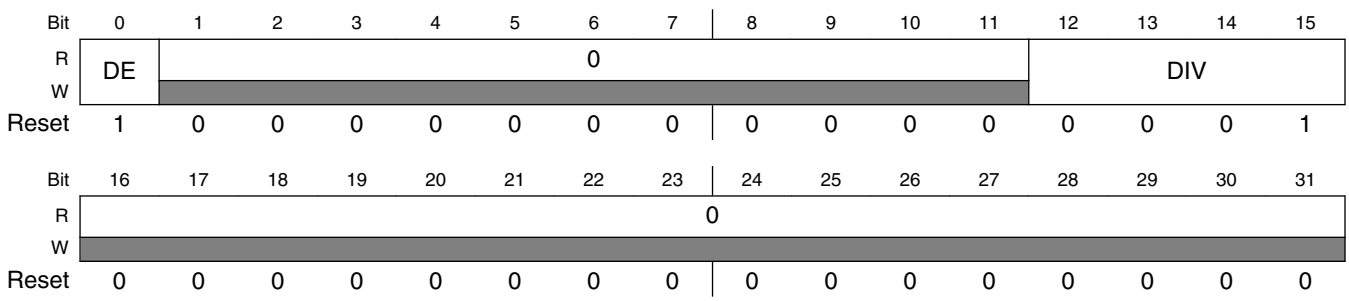
34.3.16 System Clock Divider 0 Configuration Register (CGM_SC_DC0)

This register controls system clock divider 0. See System Clock Divider Synchronization for details on division value limitations.

NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

Address: 0h base + 7E8h offset = 7E8h



CGM_SC_DC0 field descriptions

Field	Description
0 DE	**Divider 1 Enable** — This divider is always enabled. Therefore, this bit is read-only and always returns a value of '1'.
1–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 DIV	**Divider 1 Division Value** — The resultant SYS_CLK will have a period 'DIV + 1' times that of the system clock. If DE is set to '0' (divider 1 is disabled), any write access to the DIV field is ignored and the SYS_CLK remains disabled.
16–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

34.3.17 System Clock Divider 1 Configuration Register (CGM_SC_DC1)

This register controls system clock divider 1. See System Clock Divider Synchronization for details on division value limitations.

NOTE

Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception, however the value will not be loaded with the new value.

Address: 0h base + 7ECh offset = 7ECh

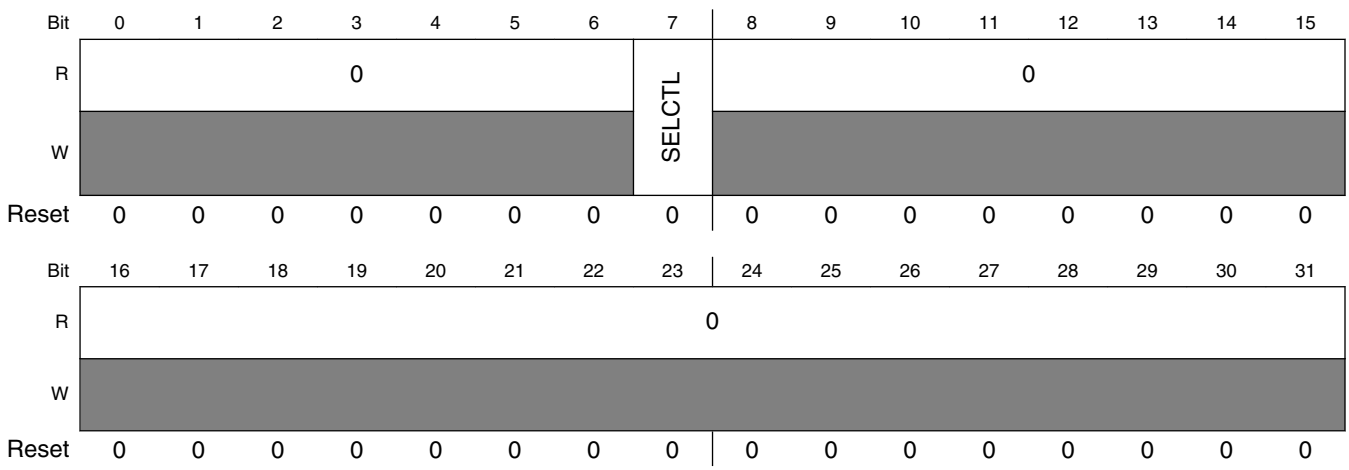
CGM_AC2_DC0 field descriptions (continued)

Field	Description
1–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–15 DIV	**Divider Division Value** — The resultant CAN0_CLK will have a period 'DIV + 1' times that of the auxiliary clock 2. If DE is set to '0' (divider 0 is disabled), any write access to the DIV field is ignored and the CAN0_CLK remains disabled.
16–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

34.3.32 Auxiliary Clock 3 Select Control Register (CGM_AC3_SC)

This register is used to select the current clock source for the PLL0 reference clock.

Address: 0h base + 860h offset = 860h



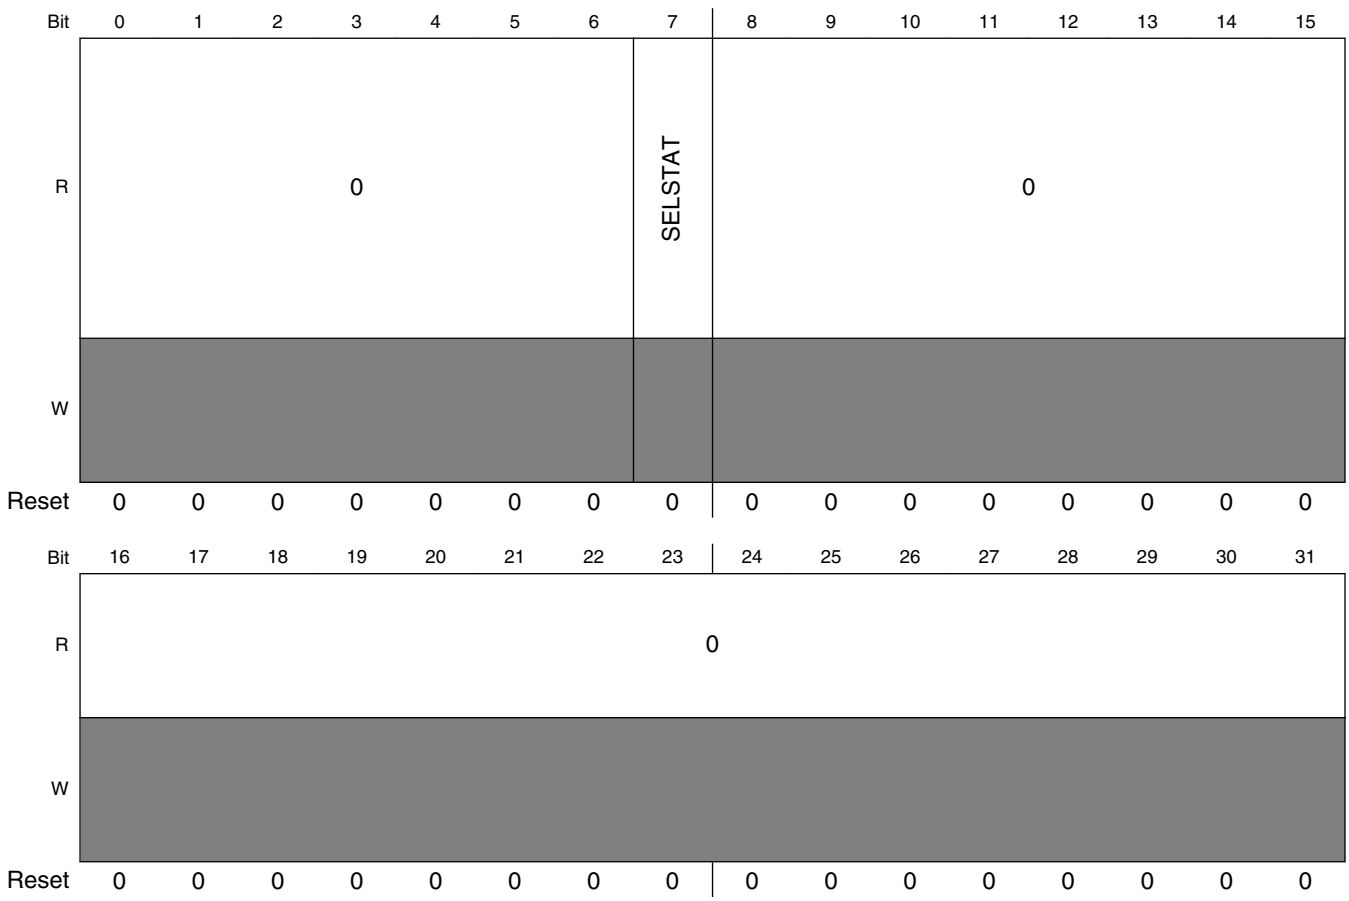
CGM_AC3_SC field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 SELCTL	**Auxiliary Clock 3 Source Selection Control** — This value selects the current source for auxiliary clock 3. 0 IRC_CLK 1 XOSC_CLK
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

34.3.33 Auxiliary Clock 3 Select Status Register (CGM_AC3_SS)

This register provides the current auxiliary clock 3 source selection.

Address: 0h base + 864h offset = 864h



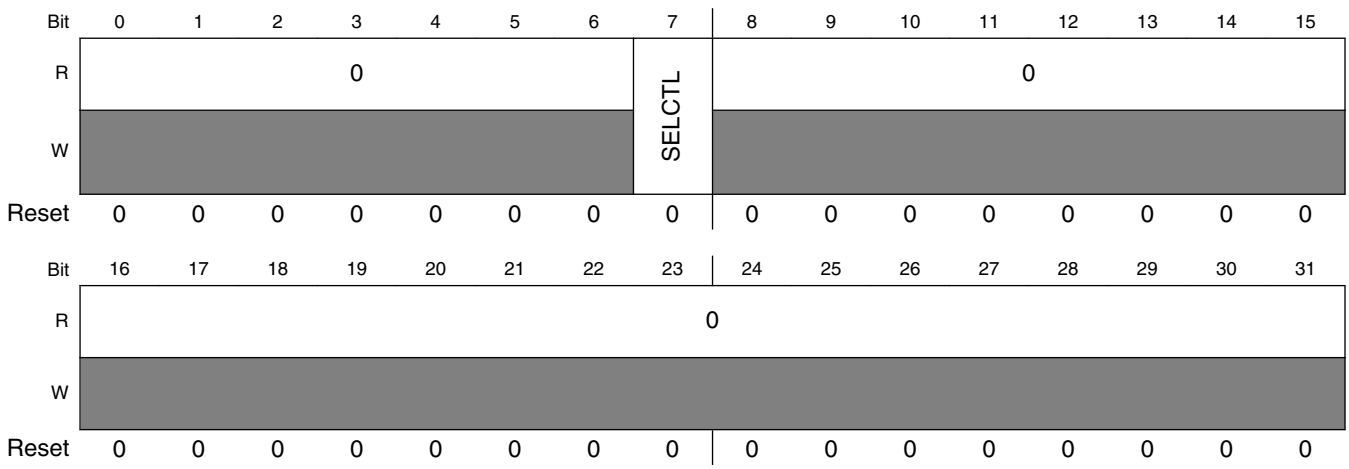
CGM_AC3_SS field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 SELSTAT	**Auxiliary Clock 3 Source Selection Status** — This value indicates the current source for auxiliary clock 3. 0 IRC_CLK 1 XOSC_CLK
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

34.3.34 Auxiliary Clock 4 Select Control Register (CGM_AC4_SC)

This register is used to select the current clock source for the PLL1 reference clock.

Address: 0h base + 880h offset = 880h



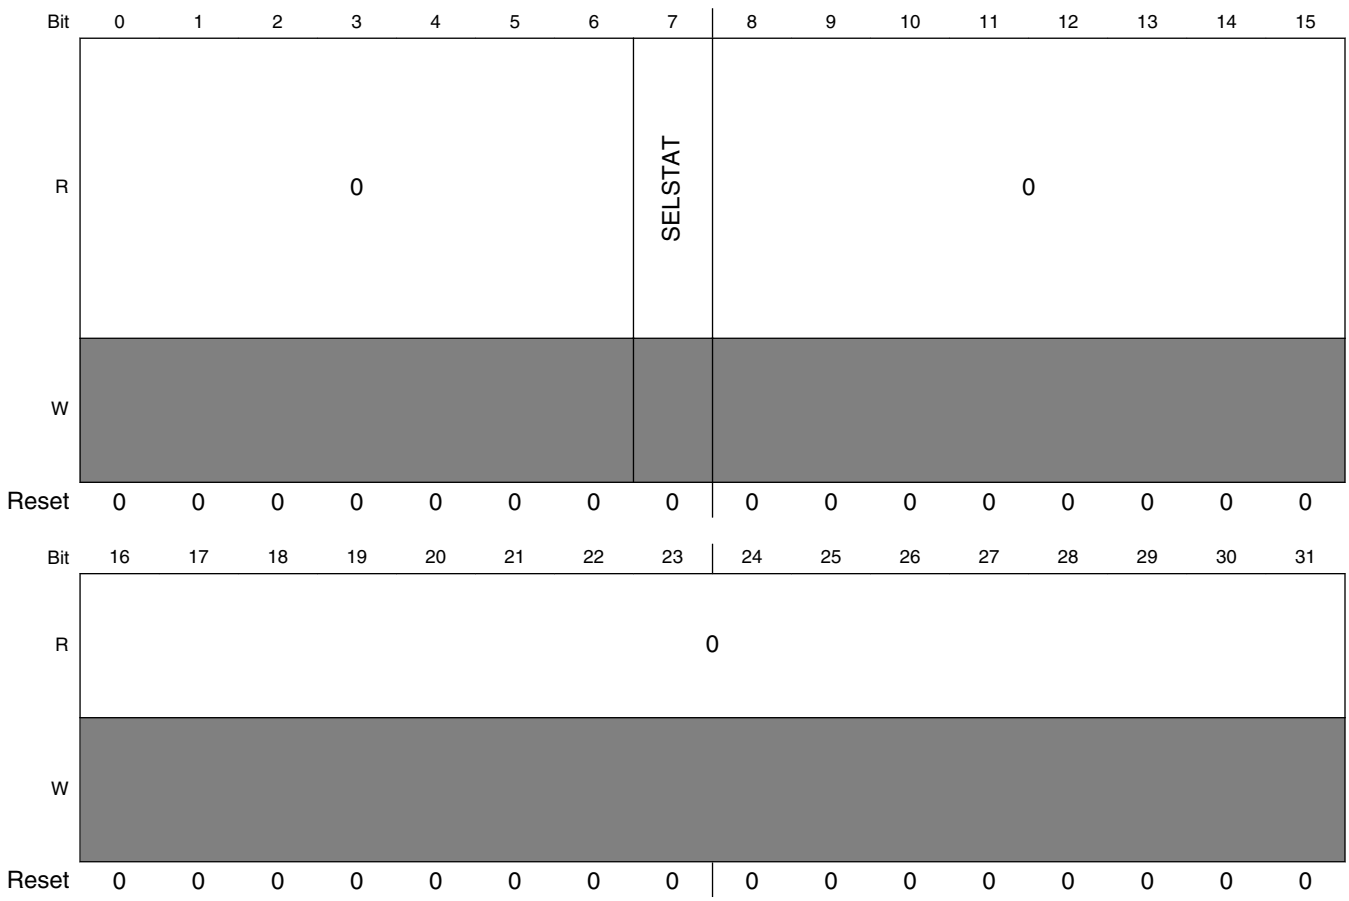
CGM_AC4_SC field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 SELCTL	**Auxiliary Clock 4 Source Selection Control** — This value selects the current source for auxiliary clock 4. 0 PLL0_PHI1_CLK 1 XOSC_CLK
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

34.3.35 Auxiliary Clock 4 Select Status Register (CGM_AC4_SS)

This register provides the current auxiliary clock 4 source selection.

Address: 0h base + 884h offset = 884h



CGM_AC4_SS field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 SELSTAT	**Auxiliary Clock 4 Source Selection Status** — This value indicates the current source for auxiliary clock 4. 0 PLL0_PHI1_CLK 1 XOSC_CLK
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

34.3.36 Auxiliary Clock 7 Select Control Register (CGM_AC7_SC)

This register is used to select the current clock source for the following clock.

- divided by auxiliary clock 7 divider 0: SPT_CLK

Address: 0h base + 8E0h offset = 8E0h

34.4 Functional Description

34.4.1 System Clock Generation

The following figure shows the block diagram of the system clock generation logic. The MC_ME provides the system clock select and switch mask (see MC_ME chapter for more details), and the MC_RGM provides the safe clock request (see MC_RGM chapter for more details). The safe clock request forces the selector to select the IRC_CLK as the system clock and to ignore the system clock select.

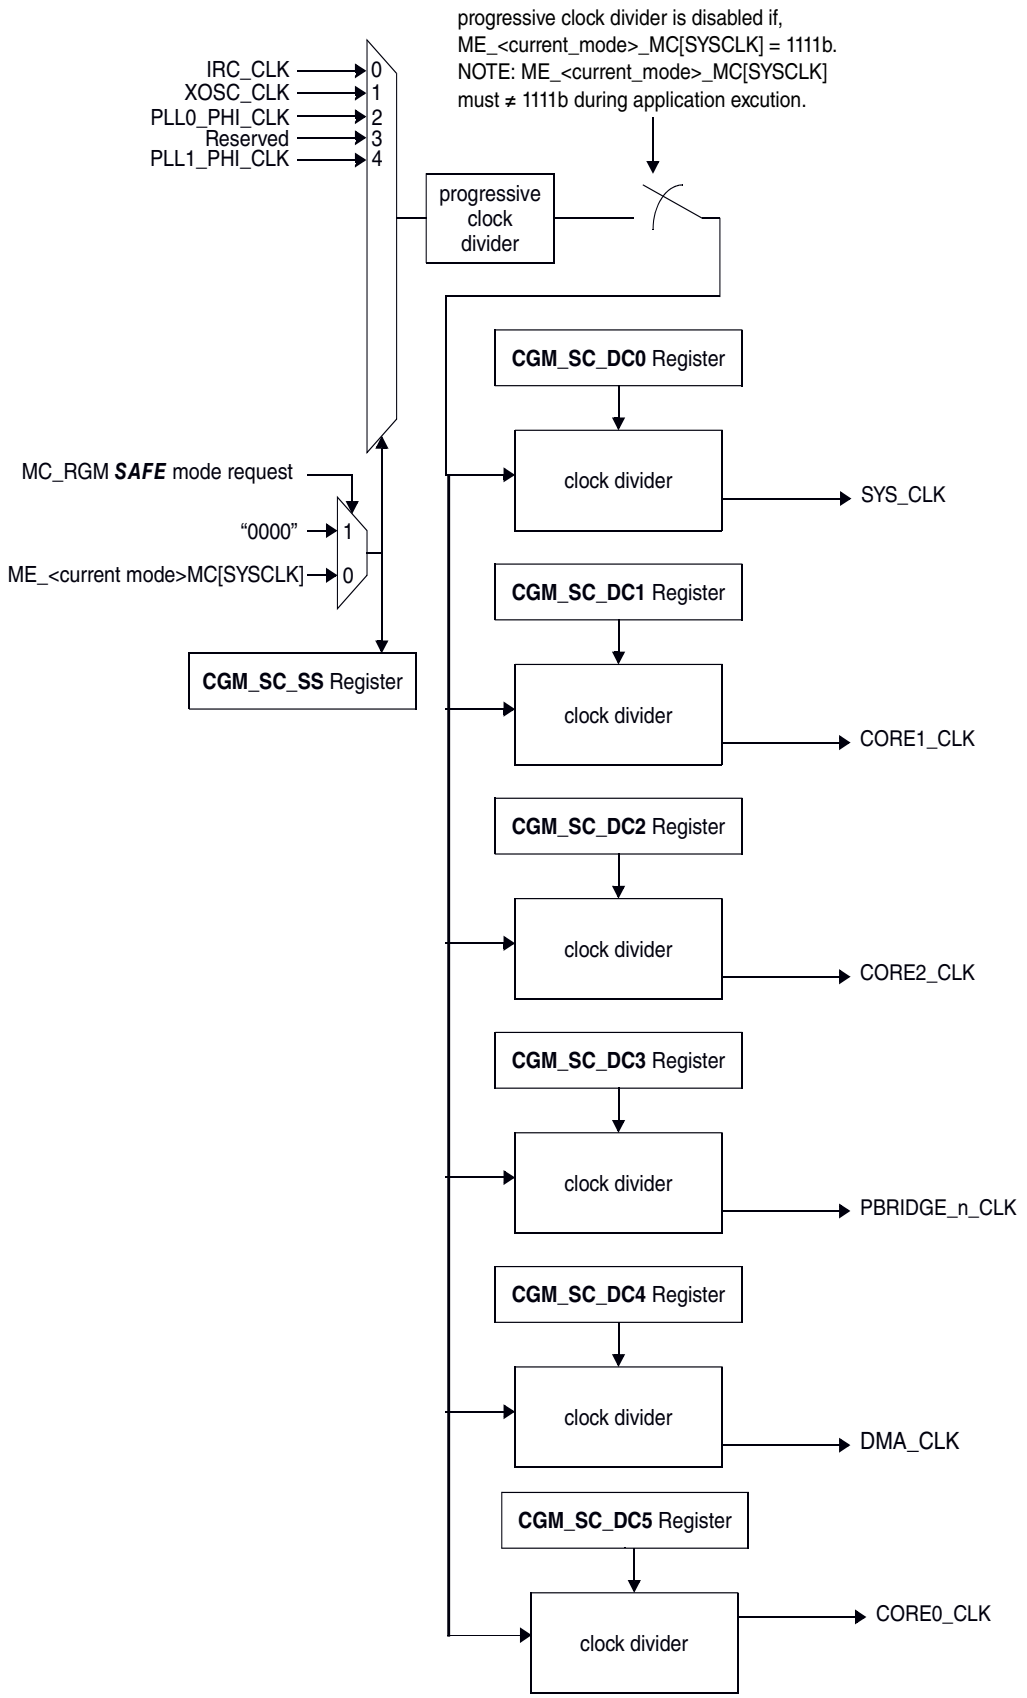

Figure 34-2. MC_CGM System Clock Generation Overview

34.4.1.1 System Clock Source Selection

During normal operation, the system clock selection is controlled

- on a ***SAFE*** mode or reset event, by the MC_RGM
- otherwise, by the MC_ME

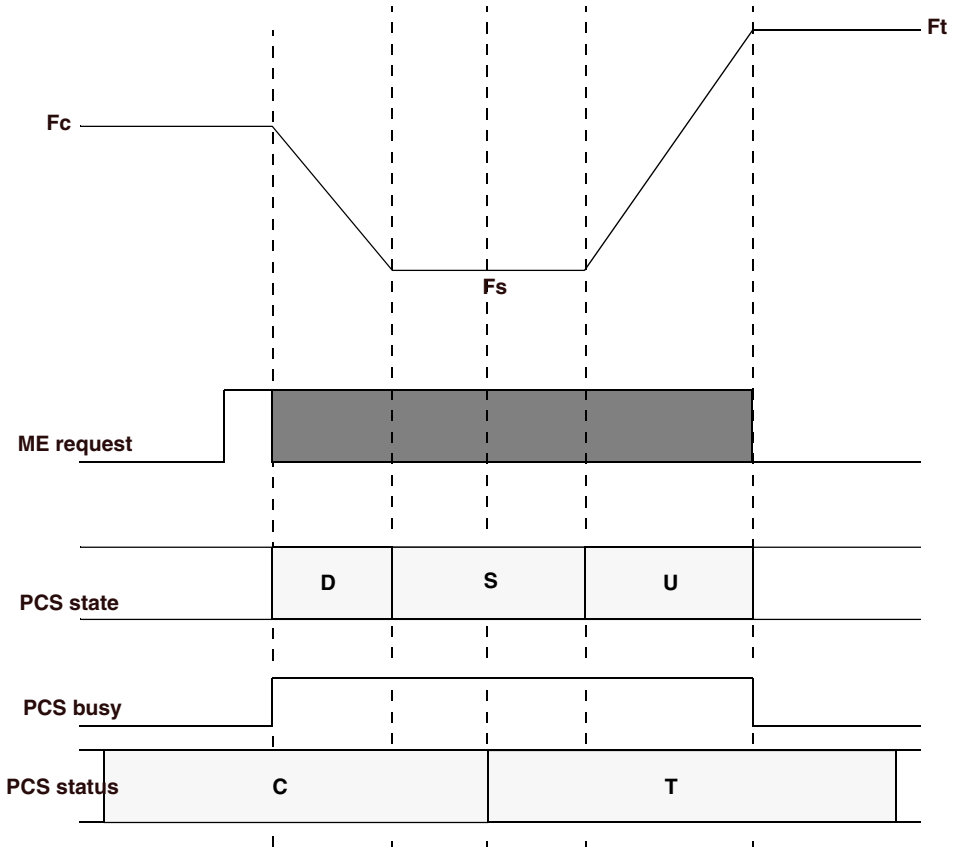
34.4.1.2 Progressive System Clock Switching

Progressive clock switching (PCS) is an option which simplifies the load changes when transitioning between modes by first going to a lower frequency, of the 16 MHz IRC, and then ramping the frequency with the new clock source selected.

The diagram below shows the frequency change in a device using PCS when the system moves from Fc to Ft. The current clock or Fc is gradually divided using the PCS configuration registers to reach 16 MHz which is the safe clock freq (Fs). Once the current clock frequency comes down to Fs, a clock switch to IRC is made. At this point all the peripherals and cores are switched on/off to match the target configuration of the MC_ME registers. Then the clock is switched from IRC to the target clock with dividers configured such that the target clock is running at 16 MHz (Fs). After that the dividers are changed to get a gradual ramp up to the target frequency(Ft), at this point, the PCS divider is dividing the target clock by 1.

NOTE

PCS configuration should not be done if some communication peripherals e.g., FlexCAN, LinFlex which are required to be working in a seamless manner during mode transition.



Note:
C: Current clock, T: Target clock, D: Clock Ramp down, S: Safe clock, U: Clock Ramp up

Figure 34-3. Progressive System Clock Switching

Based on the power level values of the current and target modes, the MC_ME requests the MC_CGM to ramp the system clock frequency down and/or up. During ramp-down, the rate of the frequency change is based on the CGM_PCS_SDUR, CGM_PCS_DIVCn, and CGM_PCS_DIVEn registers, where n corresponds to the current system clock source selection. During ramp-up, the rate of the frequency change is based on the CGM_PCS_SDUR, CGM_PCS_DIVCn, and CGM_PCS_DIVSn registers, where n corresponds to the target system clock source selection.

34.4.1.2.1 Generic Clock Change Requirements

For a maximum allowed change of the frequency (f_{chg}) and for a given source clock frequency f_{src} (current or target clock source), the maximum allowed frequency change rate a_{max} is given in the following equation.

$$a_{max} = \frac{f_{chg}}{f_{src}}$$

Figure 34-4. Equation 1

34.4.1.2.2 Configuration of CGM_PCS_SDUR

The switch duration field **CGM_PCS_SDUR[SDUR]** defines the duration of one system clock switch step in terms of IRC_CLK. After the expiration of this time, the module changes the clock divider value which changes the frequency of the system clock.

34.4.1.2.3 Configuration of CGM_PCS_DIVC*n*[RATE]

For a given maximum allowed frequency change rate a_{max} the value d to be programmed into the **PCS_DIVC*n*[RATE]**register is given in the following figure.

Table 34-1. MC_CGM CGM_PCS_DIVC*n*[RATE] values

a_{max}	d = CGM_PCS_DIVC*n*[RATE]
0.05	12
0.10	48
0.15	112
0.20	184

34.4.1.2.4 Generic Clock Change Properties

The number *k* of required steps to reach or leave the divided system clock with frequency f_{div} from the source clock with frequency f_{src} is given in the following equation.

$$k = \left\lceil 0.5 + \sqrt{0.25 - \frac{2\left(1 - \frac{f_{src}}{16MHz}\right)}{d/1000}} \right\rceil$$

Figure 34-5. Equation 2

34.4.1.2.5 Clock Ramp-Down

The clock ramp-down starts with the divider value 1 and with the given divider increment value **PCD_DIVC*n*[RATE]** and ends with the given divider value **PCS_DIVE*n*[DIVE]**.

The divider end value for clock ramp-down is given in the following equation.

$$\text{PCS\_DIVEn[DIVE]} = \frac{f_{src}}{16MHz} \times 1000 - 1$$

Figure 34-6. Equation 3

Where f_{curr} is the frequency of the currently selected system clock source.

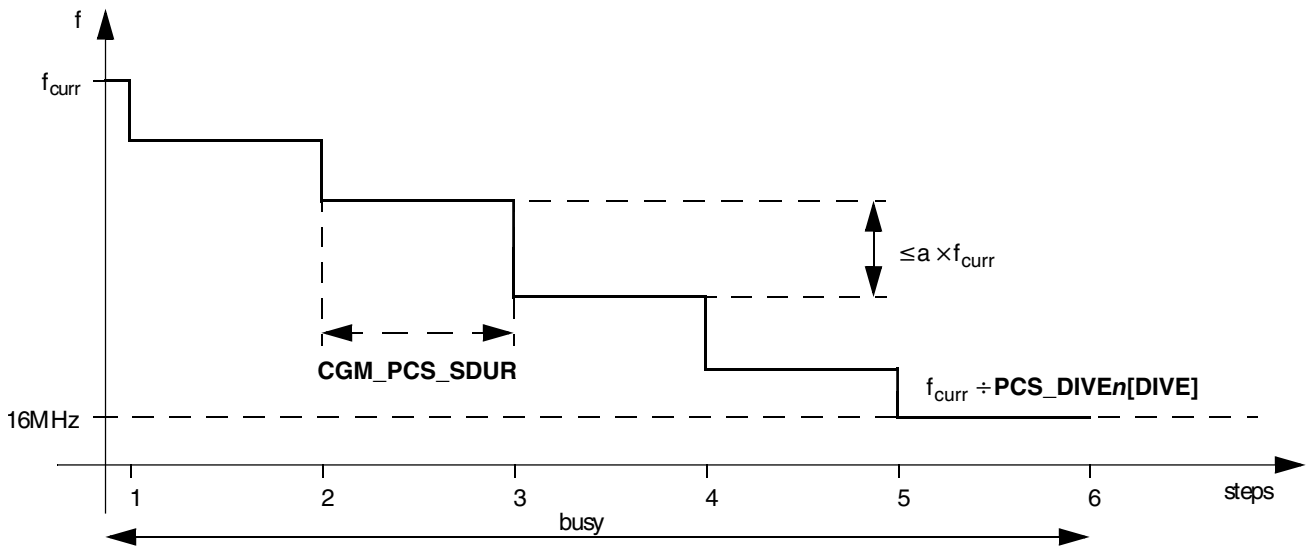


Figure 34-7. MC_CGM System Clock Ramp-Down Timing (k = 6 example)

34.4.1.2.6 Clock Ramp-Up

The clock ramp-up starts with the given divider value **PCS_DIVS*n*[DIVS]** and with the given divider decrement value **PCD_DIVC*n*[INIT]** and ends with the divider value 1.

The initial divider change start value **PCS_DIVC*n*[INIT]** for system clock ramp-up is given in Figure 34-8.

$$\text{PCS\_DIVCn[INIT]} = d \times k$$

Figure 34-8. Equation 4

Where *k* is calculated from Figure 34-5 using the target system clock source frequency f_{targ}. The divider start value for clock ramp-up is given in Figure 34-9.

$$\text{PCS\_DIVSn[DIVS]} = d\,\frac{k\,(k+1)}{2} + 999$$

Figure 34-9. Equation 5

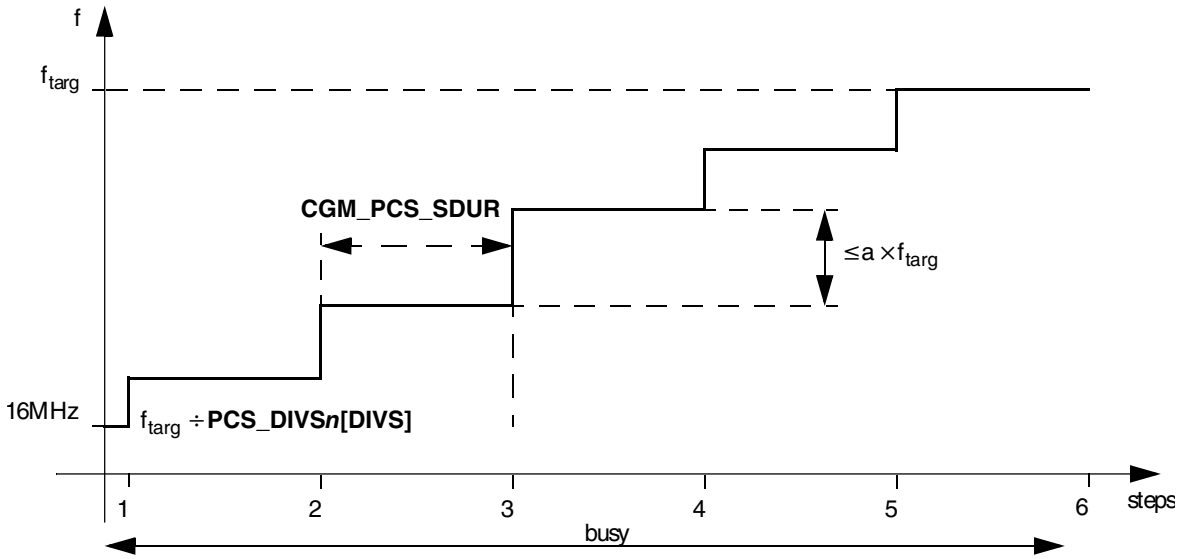

Figure 34-10. MC_CGM System Clock Ramp-Up Timing (k = 6 example)

34.4.1.3 System Clock Disable

During the TEST mode, the system clock can be disabled by the MC_ME.

34.4.1.4 System Clock Divider Synchronization

The system clock dividers are synchronized to each other such that the rising edges of the lower frequency clocks are aligned with those of the higher frequency clocks. This, however, imposes limitations on the division factors which can be used. In order for the synchronization to work properly, each division factor must be selected such that its value is an integer multiple of each division factor that has a lower value.

Warning

Configuring the system clock dividers incorrectly will cause the divided clocks to become unsynchronized. This may lead to lost communication between the clock domains and/or the inability to further change the system clock divider division factors without first disabling them or performing a reset.

34.4.1.4.1 Example 1: Correct System Clock Divider Configuration

Table 34-2. MC_CGM Example System Clock Division Values Compatible with Divider Synchronization

Divider	Division Factor	Register Value
0	1	**CGM_SC_DC0[DIV]** =0

Table continues on the next page...

Table 34-2. MC_CGM Example System Clock Division Values Compatible with Divider Synchronization (continued)

Divider	Division Factor	Register Value
1	2	**CGM_SC_DC1[DIV]** = 1
2	6	**CGM_SC_DC2[DIV]** = 5

In this case, system clock divider 1 has a division factor greater than that of system clock divider 0. Since 2 is an integer multiple of 1, its configration is correct. Also, system clock divider 3 has a division factor that is greater than those of both system clock dividers 0 and 1. Since 6 is an integer multiple of 1 and 6 is an integer multiple of 2, its configuration is also correct.

34.4.1.4.2 Example 2: Incorrect System Clock Divider Configuration

Table 34-3. MC_CGM Example System Clock Division Values Incompatible with Divider Synchronization

Divider	Division Factor	Register Value
0	1	**CGM_SC_DC0[DIV]** = 0
1	4	**CGM_SC_DC1[DIV]** = 3
2	6	**CGM_SC_DC2[DIV]** = 5

In this case, system clock divider 1 has a division factor greater than that of system clock divider 0. Since 4 is an integer multiple of 1, its configration is correct. Also, system clock divider 3 has a division factor that is greater than those of both system clock dividers 0 and 1. Since 6 is not an integer multiple of 4, its configuration is incorrect.

34.4.2 Auxiliary Clock Generation

The following figures show the block diagrams of the generation logic for the various auxiliary clocks. See the following sections for auxiliary clock selection control:

- Auxiliary Clock 0 Select Control Register (CGM_AC0_SC)
- Auxiliary Clock 1 Select Control Register (CGM_AC1_SC)
- Auxiliary Clock 2 Select Control Register (CGM_AC2_SC)
- Auxiliary Clock 3 Select Control Register (CGM_AC3_SC)
- Auxiliary Clock 4 Select Control Register (CGM_AC4_SC)
- Auxiliary Clock 7 Select Control Register (CGM_AC7_SC)
- Auxiliary Clock 8 Select Control Register (CGM_AC8_SC)
- Auxiliary Clock 10 Select Control Register (CGM_AC10_SC)
- Auxiliary Clock 11 Select Control Register (CGM_AC11_SC)

- Auxiliary Clock 12 Select Control Register (CGM_AC12_SC)
- Auxiliary Clock 13 Select Control Register (CGM_AC13_SC)

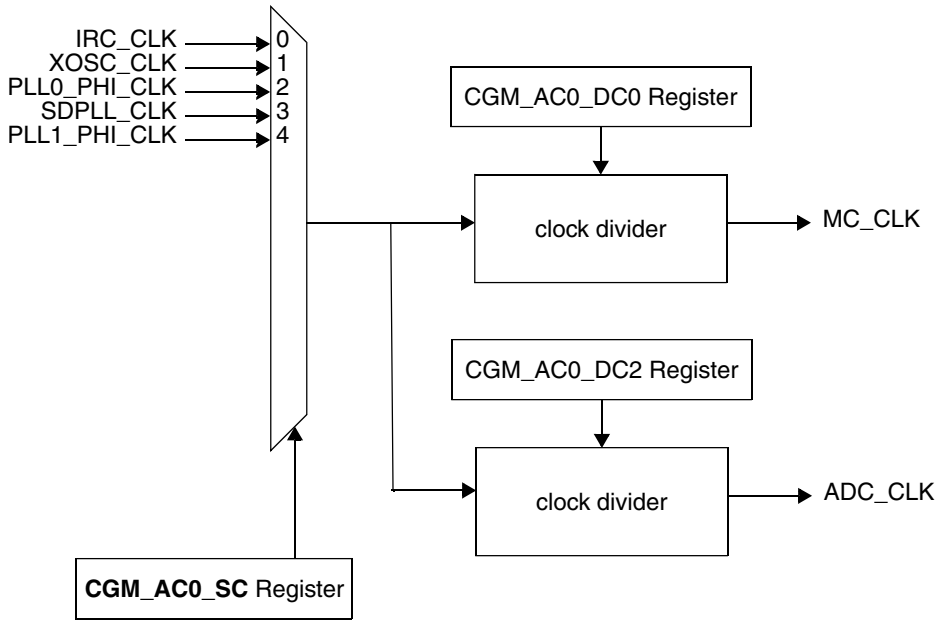

Figure 34-11. MC_CGM Auxiliary Clock 0 Generation Overview

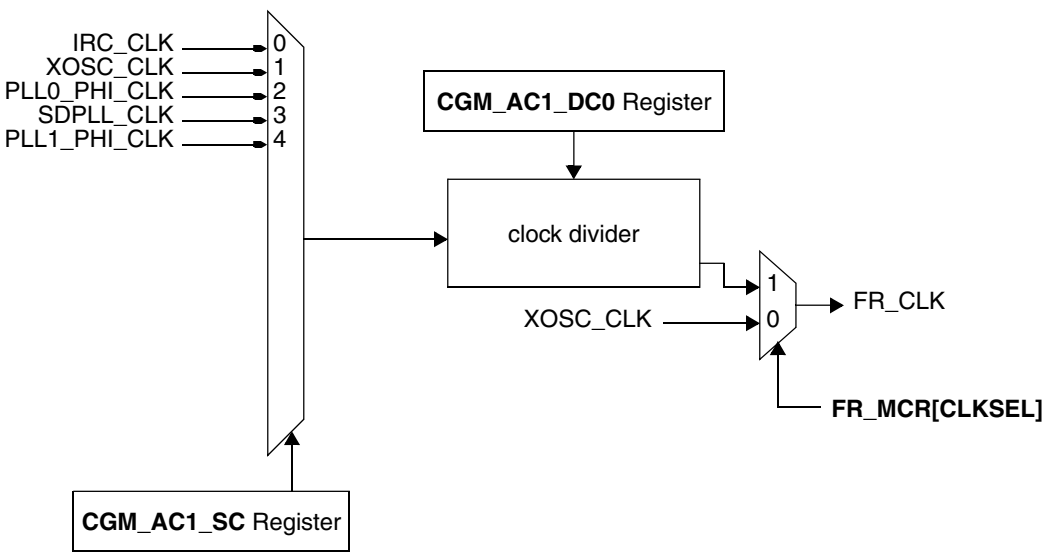

Figure 34-12. MC_CGM Auxiliary Clock 1 Generation Overview

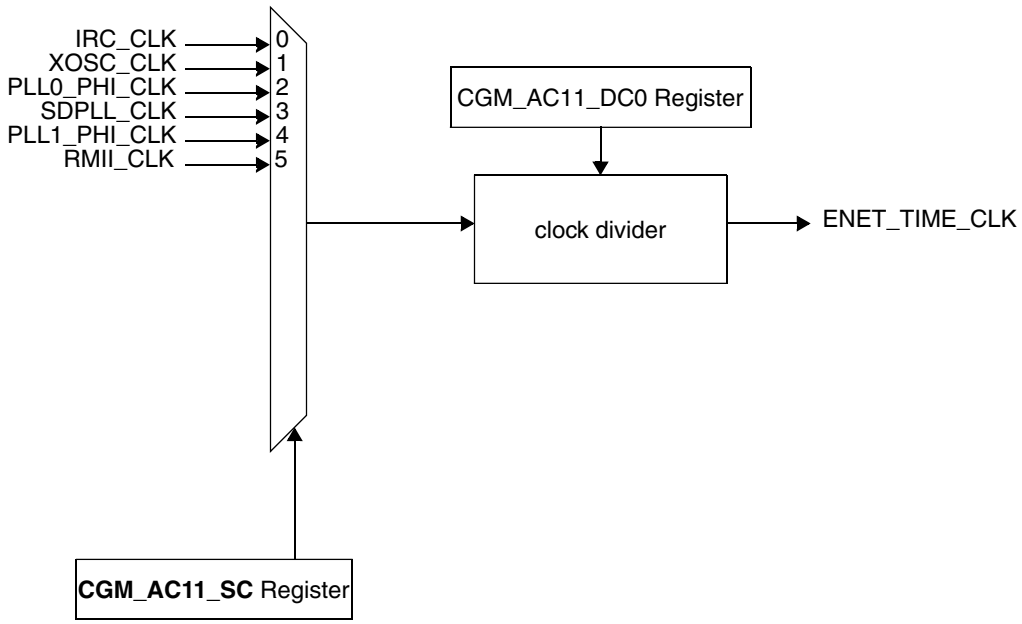

Figure 34-19. MC_CGM Auxiliary Clock 11 Generation Overview

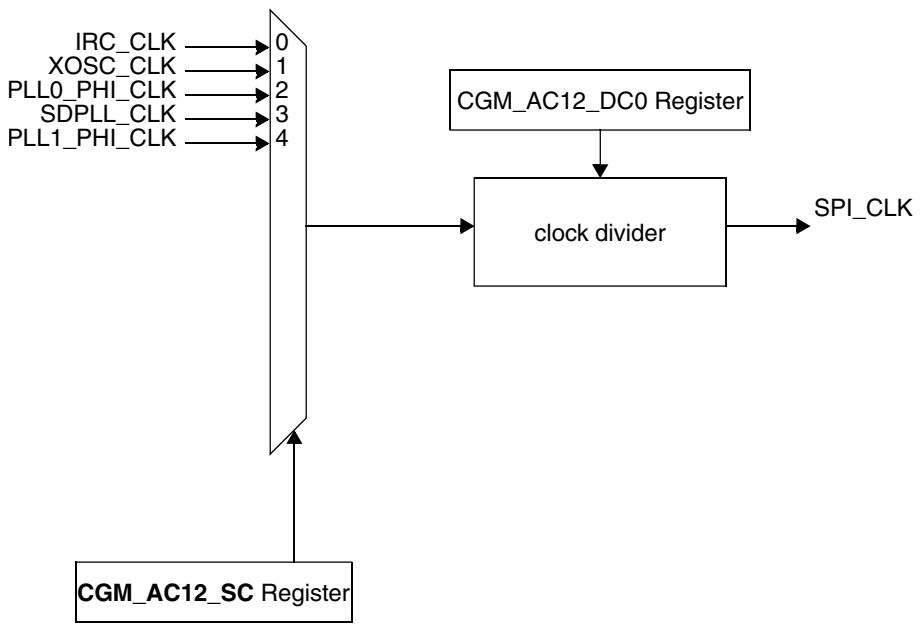

Figure 34-20. MC_CGM Auxiliary Clock 12 Generation Overview

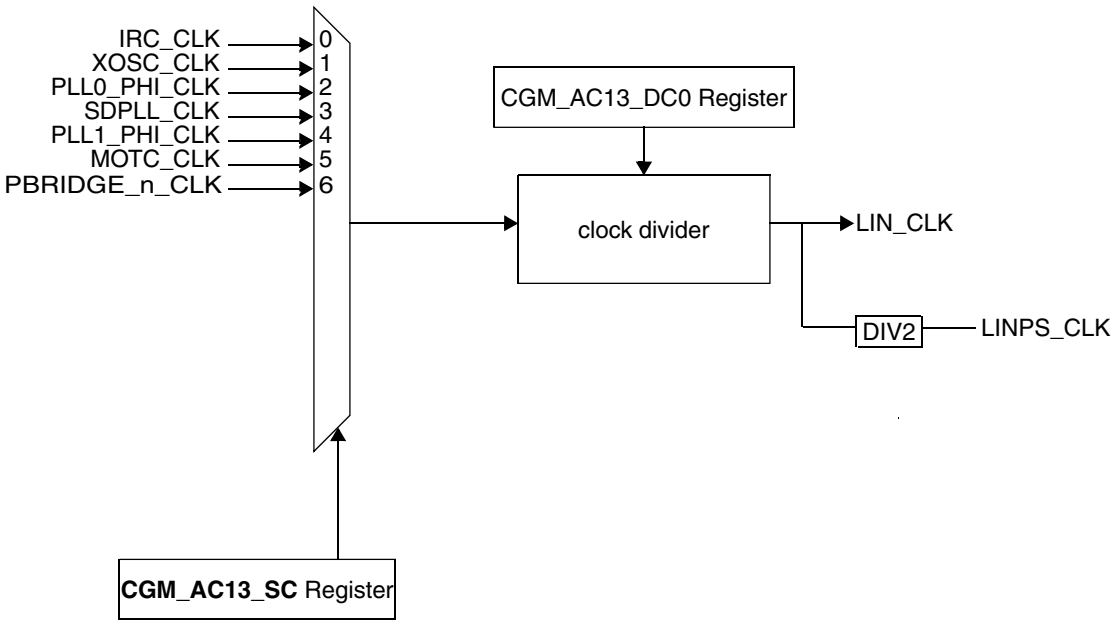

Figure 34-21. MC_CGM Auxiliary Clock 13 Generation Overview

NOTE

The selection mux is not glitch-less. Therefore, the auxiliary clock must be disabled in the MC_CGM before the time of selection until a 'safe' time (few clock cycles) afterwards in order to guarantee that no glitches are propagated.

34.4.3 Dividers Functional Description

Dividers are used for the generation of divided system and peripheral clocks. The MC_CGM has the following control registers for built-in dividers:

- System Clock Divider 0 Configuration Register (CGM_SC_DC0)
- System Clock Divider 1 Configuration Register (CGM_SC_DC1)
- System Clock Divider 2 Configuration Register (CGM_SC_DC2)
- System Clock Divider 3 Configuration Register (CGM_SC_DC3)
- System Clock Divider 4 Configuration Register (CGM_SC_DC4)
- System Clock Divider 5 Configuration Register (CGM_SC_DC5)
- Auxiliary Clock 0 Divider 0 Configuration Register (CGM_AC0_DC0)
- Auxiliary Clock 0 Divider 2 Configuration Register (CGM_AC0_DC2)
- Auxiliary Clock 1 Divider 0 Configuration Register (CGM_AC1_DC0)

- Auxiliary Clock 2 Divider 0 Configuration Register (CGM_AC2_DC0)
- Auxiliary Clock 7 Divider 0 Configuration Register (CGM_AC7_DC0)
- Auxiliary Clock 8 Divider 0 Configuration Register (CGM_AC8_DC0)
- Auxiliary Clock 9 Divider 0 Configuration Register (CGM_AC9_DC0)
- Auxiliary Clock 10 Divider 0 Configuration Register (CGM_AC10_DC0)
- Auxiliary Clock 11 Divider 0 Configuration Register (CGM_AC11_DC0)
- Auxiliary Clock 12 Divider 0 Configuration Register (CGM_AC12_DC0)
- Auxiliary Clock 13 Divider 0 Configuration Register (CGM_AC13_DC0)
- Auxiliary Clock 14 Divider 0 Configuration Register (CGM_AC14_DC0)

The reset value of all counters is ‘1’. If a divider has its DE bit in the respective configuration register set to ‘0’ (the divider is disabled), any value in its DIV field is ignored.

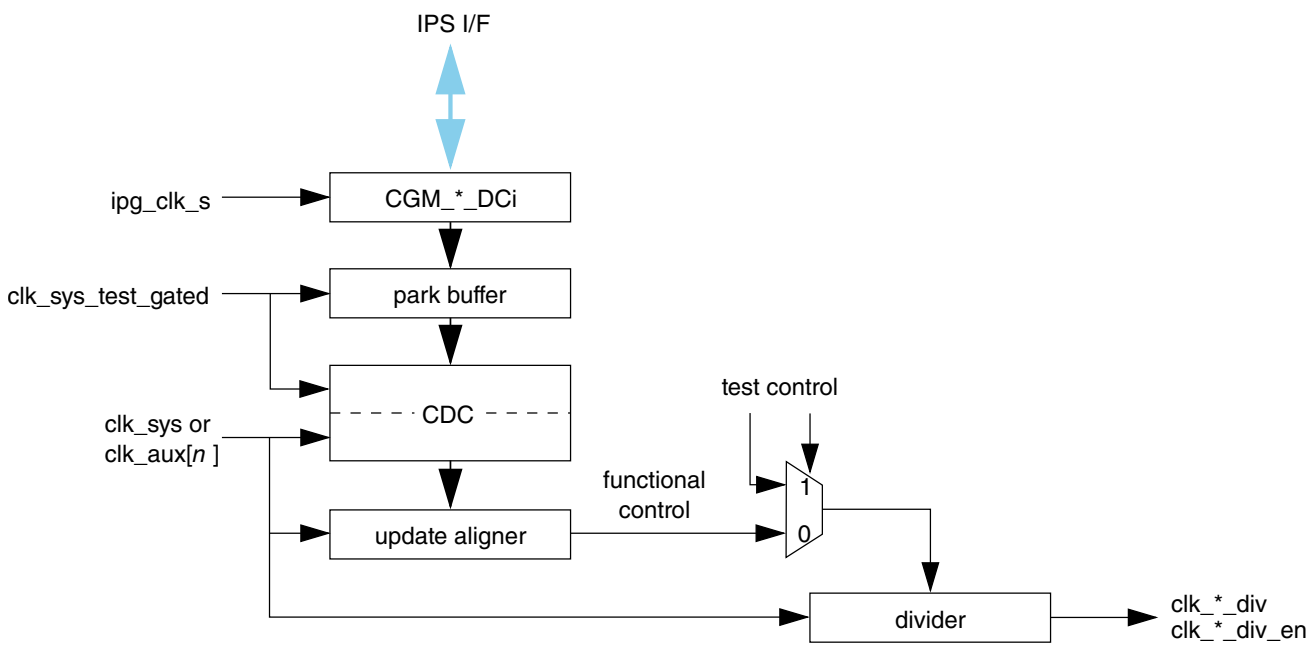

Figure 34-22. MC_CGM General Divider Structure Overview

34.4.3.1 Fractional Divider Details

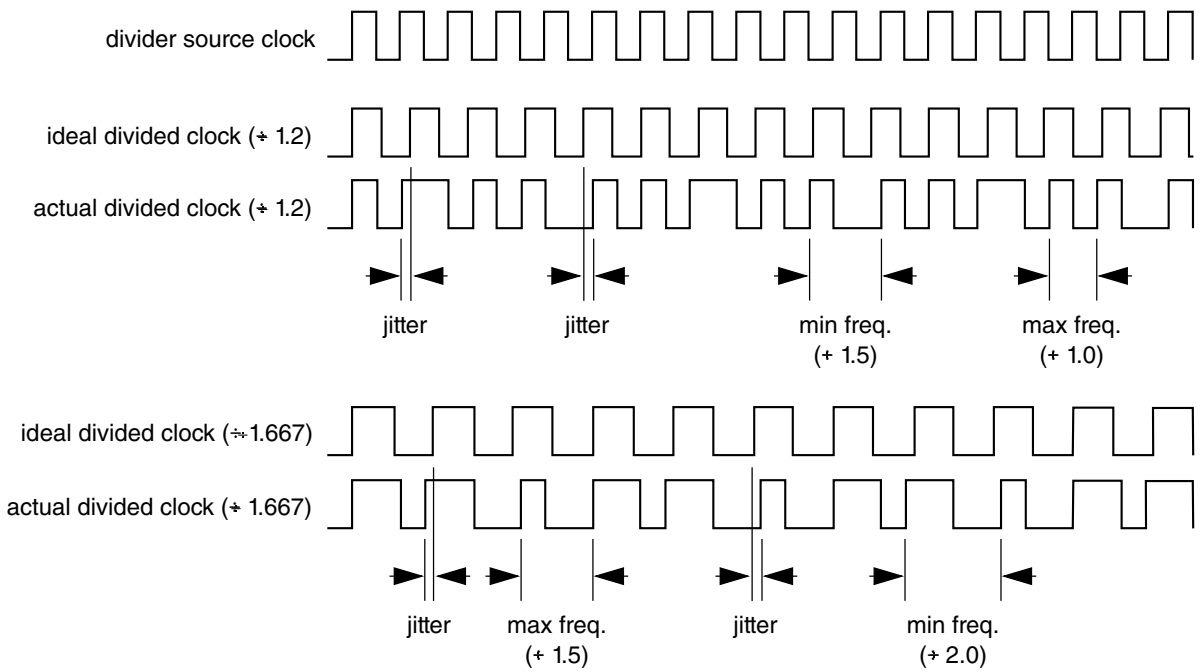

Figure 34-23. MC_CGM Fractional Clock Division Examples

For division factors of *x*.0, where $x > 0$, the fractional divider does not introduce any additional jitter to that of the clock source, neither on the rising edge nor on the falling edge, and the duty cycle = 50%.

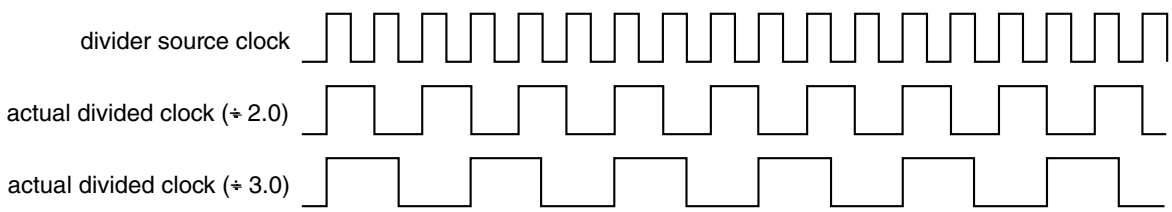

Figure 34-24. MC_CGM Fractional Clock Division Examples (x.0 division factor case)

For division factors of *x*.5, where $x > 0$, the fractional divider does not introduce any additional jitter to that of the clock source, neither on the rising edge nor on the falling edge, and the duty cycle is a constant value > 50%.

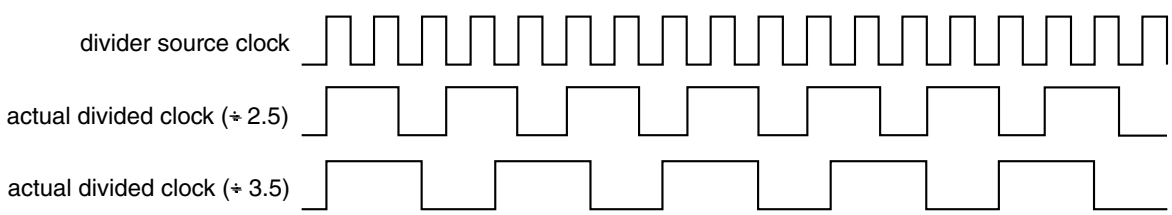

Figure 34-25. MC_CGM Fractional Clock Division Examples (x.5 division factor case)

34.4.3.2 Divider Update Synchronization

For the system clock all the associated dividers of the punch-out and 50% duty cycle types are synchronized to each other such that the rising edges of the lower frequency clocks are aligned with those of the higher frequency clocks. This, however, imposes limitations on the division factors which can be used. In order for the synchronization to work properly, each division factor must be selected such that its value is an integer multiple of each division factor that has a lower value.

Table 34-4 shows an example of a correct divider configuration.

Table 34-4. MC_CGM Example Clock Division Values Compatible with Divider Synchronization

Divider	Division Factor	Register Value
0	1	CGM_xC_DC0[DIV] = 0
1	2	CGM_xC_DC1[DIV] = 1
2	6	CGM_xC_DC2[DIV] = 5

In this case, clock divider 1 has a division factor greater than that of clock divider 0. Since 2 is an integer multiple of 1, its configuration is correct. Also, clock divider 3 has a division factor that is greater than those of both clock dividers 0 and 1. Since 6 is an integer multiple of 1 and 6 is an integer multiple of 2, its configuration is also correct.

Table 34-5 shows an example of an incorrect divider configuration.

Table 34-5. MC_CGM Example Clock Division Values Compatible with Divider Synchronization

Divider	Division Factor	Register Value
0	1	CGM_xC_DC0[DIV] = 0
1	4	CGM_xC_DC1[DIV] = 3
2	6	CGM_xC_DC2[DIV] = 5

In this case, clock divider 1 has a division factor greater than that of clock divider 0. Since 2 is an integer multiple of 1, its configuration is correct. Also, clock divider 3 has a division factor that is greater than those of both clock dividers 0 and 1. Since 6 is an integer multiple of 1 and 6 is an integer multiple of 2, its configuration is also correct.

WARNING

Configuring the clock dividers incorrectly will cause the divided clocks to become unsynchronized. This may lead to lost communication between the clock domains and/or the inability to further change the clock divider division factors without first disabling them or performing a reset.

34.4.3.3 Divider Update Triggering

There are two methods for updating the dividers associated with the system clock and each auxiliary clock: immediate and register triggered. Which method is used for which set of dividers is controlled by the DIV_UPD_TYPE register.

Regardless of which method is selected for a given group of dividers, once an update of one of the dividers of that group has been triggered, the associated bit in the UPD_STAT register is set. this bit is then cleared when all the dividers of that group have completed the update process and are running with the current configuration.

34.4.3.3.1 Immediate Divider Update

If a divider group has been configured to be updated immediately (i.e., the corresponding DIV_UPD_TYPE register bit = ‘0’), the configuration of a divider in that group will be applied immediately on the write to that divider's configuration register. The actual update will take some time to actually reach the divider output due to the clock domain crossing and edge alignment mechanisms.

34.4.3.3.2 Software-Triggered Divider Update

If a divider group has been configured to be updated via a software trigger (i.e., the corresponding DIV_UPD_TYPE register bit = ‘1’), the configuration of a divider in that group will not be applied immediately on the write to that divider's configuration register. Instead, the configuration in the corresponding configuration register will be applied only when software writes any value to the DIV_UPD_TRIG register. The actual update will take some time to actually reach the divider output due to the clock domain crossing and edge alignment mechanisms.

The following software programming steps may be used for updating the system clock dividers:

1. Configure the SC_DC***n*** registers as desired and aligned with the target system clock source frequency making sure that the dividers are configured consistently as described in Divider Update Synchronization.
2. Set the DIV_UPD_TYPE.SYS_UPD_TYPE field as ’1’ to enable the update via a software trigger
3. Optional Step: If the divider ratios are not changing with respect to the previous configuration, the SC_DIV_RC.SYS_DIV_RATIO_CHNG field may be reset to 0 to disable the crossbar halt handshake mechanism

4. Write any non-zero value to the DIV_UPD_TRIG register to trigger the divider update.
5. Poll the status register DIV_UPD_STAT.SYS_UPD_STAT field to check when the divider update completes.

NOTE

In order to ensure a clean clock divider configuration update, software must check that all ongoing updates have already completed (i.e., all relevant bits in the DIV_UPD_STAT register are ‘0’) before triggering a new update via the DIV_UPD_TRIG register

Chapter 35
IRCOSC Digital Interface

35.1 Introduction

The Internal RC Oscillator Digital Interface (IRCOSC) controls the internal 16 MHz RC oscillator system. This oscillator system includes the main internal RC oscillator (MRC), as well as an internal temperature sensor and an internal voltage regulator used to compensate external variations in temperature and voltage. It also provides access to trimming information used for safety implementations.

35.2 Functional description

The IRCOSC provides a high frequency (f_{MRC}) clock with a nominal frequency of 16 MHz. After deassertion of reset, the output clock is available after a short time (see the Data Sheet for timing details) which is required for stabilization. The IRCOSC status is updated in the MC_ME_GS[S_IRC] field (see the "Mode Entry Module MC_ME" chapter).

The IRCOSC output frequency can be trimmed by configuring IRCOSC_CTL[USER_TRIM[4:0]]. The USER_TRIM bits can be programmed to modify internal capacitor/resistor values to match output clock frequency with δf_{var_SW}, as defined in the Data Sheet.

35.3 Memory map and register definition

IRCOSC memory map

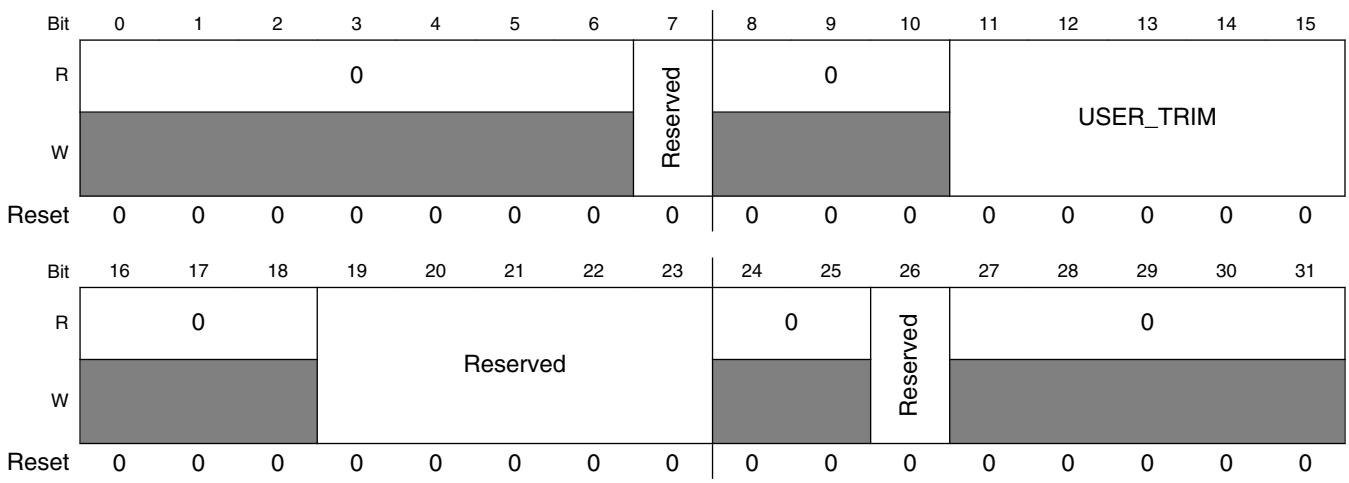
Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	IRCOSC Control Register (IRCOSC_CTL)	32	R/W	See section	35.3.1/1232

35.3.1 IRCOSC Control Register (IRCOSC_CTL)

The IRCOSC_CTL contains user programmable parameters.

IRCOSC_CTL is writable only in supervisor mode.

Address: 0h base + 0h offset = 0h



IRCOSC_CTL field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 Reserved	This field is reserved. This bit can be written with any value, but writes are ignored. A read returns last written value.
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–15 USER_TRIM	User trimming bits with respect to nominal factory frequency The MSB of the USER_TRIM bits is used to determine whether the frequency will be increased or decreased. If MSB = 0 then a change in USER_TRIM[3:0] will decrease the frequency, and likewise, if MSB = 1 then a change in USER_TRIM[3:0] will increase the frequency. Frequency trimming calculation shows how RCOSC_CTL[USER_TRIM] field is used to trim the IRCOSC frequency.
16–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

IRCOSC_CTL field descriptions (continued)

Field	Description
19–23 Reserved	This field is reserved. This field can be written at any time, but writes have no effect. Reads return the previously written value.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 Reserved	This field is reserved. This field may sometimes have the value of 1, and can be cleared by writing a 1 to this bit. However, this field has no effect on the IRCOSC or chip behavior.
27–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

35.3.2 Frequency trimming calculation

Table 35-1. IRCOSC_CTL[USER_TRIM] frequency trimming calculation

USER_TRIM[4:0] value	Frequency
....	....
10011	$f + (3 \times \delta f_{TRIM})$
10010	$f + (2 \times \delta f_{TRIM})$
10001	$f + \delta f_{TRIM}$
10000	f
00000	f
00001	$f - \delta f_{TRIM}$
00010	$f - (2 \times \delta f_{TRIM})$
00011	$f - (3 \times \delta f_{TRIM})$
....	....

NOTE

See the data sheet for δf_{TRIM} value and min/max frequency variations.

Chapter 36
Enhanced Direct Memory Access (eDMA)

36.1 DMA Controller configuration

Due to the strict architecture of the RAM controller, the DMA_DCHMIDn register should not be used to replicate Core_1 or Core_2 accesses to the SRAM from the DMA. Doing so results in an error that is reflected in the DMA_ES register.

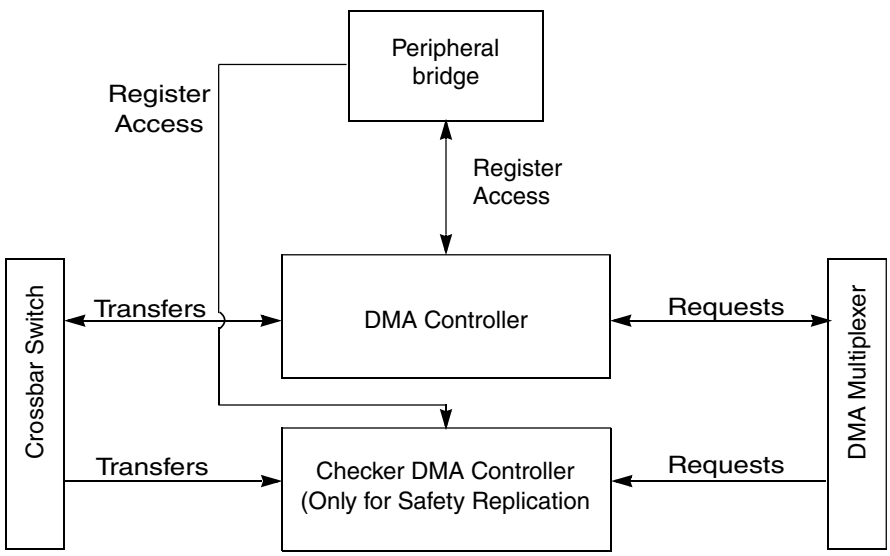


Figure 36-1. DMA controller configuration

36.2 Introduction

The enhanced direct memory access (eDMA) controller is a second-generation module capable of performing complex data transfers with minimal intervention from a host processor. The hardware microarchitecture includes:

- A DMA engine that performs:

- Source address and destination address calculations
- Data-movement operations

• Local memory containing transfer control descriptors for each of the 32 channels

36.2.1 eDMA system block diagram

Figure 36-2 illustrates the components of the eDMA system, including the eDMA module ("engine").

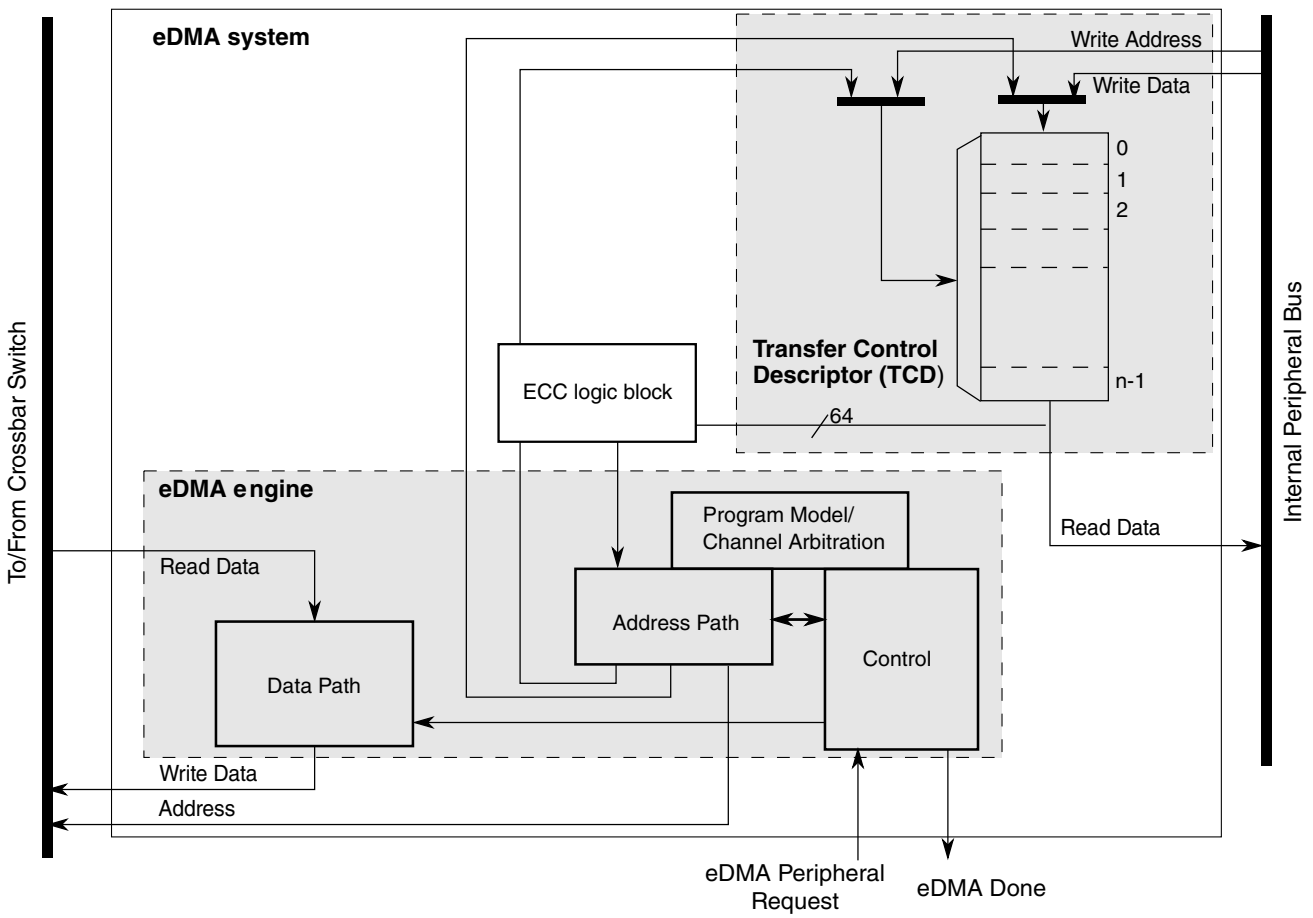

Figure 36-2. eDMA system block diagram

36.2.2 Block parts

The eDMA module is partitioned into two major modules: the eDMA engine and the transfer-control descriptor local memory.

The eDMA engine is further partitioned into four submodules:

Table 36-1. eDMA engine submodules

Submodule	Function
Address path	This block implements registered versions of two channel transfer control descriptors, channel x and channel y, and manages all master bus-address calculations. All the channels provide the same functionality. This structure allows data transfers associated with one channel to be preempted after the completion of a read/write sequence if a higher priority channel activation is asserted while the first channel is active. After a channel is activated, it runs until the minor loop is completed, unless preempted by a higher priority channel. This provides a mechanism (enabled by DCHPRI*n*[ECP]) where a large data move operation can be preempted to minimize the time another channel is blocked from execution. When any channel is selected to execute, the contents of its TCD are read from local memory and loaded into the address path channel x registers for a normal start and into channel y registers for a preemption start. After the minor loop completes execution, the address path hardware writes the new values for the TCD*n*_{SADDR, DADDR, CITER} back to local memory. If the major iteration count is exhausted, additional processing is performed, including the final address pointer updates, reloading the TCD*n*_CITER field, and a possible fetch of the next TCD*n* from memory as part of a scatter/gather operation.
Data path	This block implements the bus master read/write datapath. It includes a data buffer and the necessary multiplex logic to support any required data alignment. The internal read data bus is the primary input, and the internal write data bus is the primary output. The address and data path modules directly support the 2-stage pipelined internal bus. The address path module represents the 1st stage of the bus pipeline (address phase), while the data path module implements the 2nd stage of the pipeline (data phase).
Program model/channel arbitration	This block implements the first section of the eDMA programming model as well as the channel arbitration logic. The programming model registers are connected to the internal peripheral bus. The eDMA peripheral request inputs and interrupt request outputs are also connected to this block (via control logic).
Control	This block provides all the control functions for the eDMA engine. For data transfers where the source and destination sizes are equal, the eDMA engine performs a series of source read/ destination write operations until the number of bytes specified in the minor loop byte count has moved. For descriptors where the sizes are not equal, multiple accesses of the smaller size data are required for each reference of the larger size. As an example, if the source size references 16-bit data and the destination is 32-bit data, two reads are performed, then one 32-bit write.

The transfer-control descriptor local memory is further partitioned into:

Table 36-2. Transfer control descriptor memory

Submodule	Description
