Memory controller	This logic implements the required dual-ported controller, managing accesses from the eDMA engine as well as references from the internal peripheral bus. As noted earlier, in the event of simultaneous accesses, the eDMA engine is given priority and the peripheral transaction is stalled.
Memory array	TCD storage for each channel's transfer profile.

36.2.3 Features

The eDMA is a highly programmable data-transfer engine optimized to minimize any required intervention from the host processor. It is intended for use in applications where the data size to be transferred is statically known and not defined within the transferred data itself. The eDMA module features:

- All data movement via dual-address transfers: read from source, write to destination
  - Programmable source and destination addresses and transfer size
  - Support for enhanced addressing modes
- 32-channel implementation that performs complex data transfers with minimal intervention from a host processor
  - Internal data buffer, used as temporary storage to support 16- and 32-byte transfers
  - Connections to the crossbar switch for bus mastering the data movement
- Transfer control descriptor (TCD) organized to support two-deep, nested transfer operations
  - 32-byte TCD stored in local memory for each channel
  - An inner data transfer loop defined by a minor byte transfer count
  - An outer data transfer loop defined by a major iteration count
- Channel activation via one of three methods:
  - Explicit software initiation
  - Initiation via a channel-to-channel linking mechanism for continuous transfers
  - Peripheral-paced hardware requests, one per channel
- Fixed-priority and round-robin channel arbitration
- Channel completion reported via programmable interrupt requests
  - One interrupt per channel, which can be asserted at completion of major iteration count
  - Programmable error terminations per channel and logically summed together to form one error interrupt to the interrupt controller
- Programmable support for scatter/gather DMA processing

- Support for complex data structures
- Error detection and error correction

In the discussion of this module, *n* is used to reference the channel number.

36.3 Modes of operation

The eDMA operates in the following modes:

Table 36-3. Modes of operation

Mode	Description
Normal	In Normal mode, the eDMA transfers data between a source and a destination. The source and destination can be a memory block or an I/O block capable of operation with the eDMA. A service request initiates a transfer of a specific number of bytes (NBYTES) as specified in the transfer control descriptor (TCD). The minor loop is the sequence of read-write operations that transfers these NBYTES per service request. Each service request executes one iteration of the major loop, which transfers NBYTES of data.
Debug	DMA operation is configurable in Debug mode via the control register: • If CR[EDBG] is cleared, the DMA continues to operate. • If CR[EDBG] is set, the eDMA stops transferring data. If Debug mode is entered while a channel is active, the eDMA continues operation until the channel retires.
Wait	Before entering Wait mode, the DMA attempts to complete its current transfer. After the transfer completes, the device enters Wait mode.

36.4 Memory map/register definition

The eDMA's programming model is partitioned into two regions:

- The first region defines a number of registers providing control functions
- The second region corresponds to the local transfer control descriptor (TCD) memory

36.4.1 TCD memory

Each channel requires a 32-byte transfer control descriptor for defining the desired data movement operation. The channel descriptors are stored in the local memory in sequential order: channel 0, channel 1, ... channel 31. Each TCD*n* definition is presented as 11 registers of 16 or 32 bits.

36.4.2 TCD initialization

The initialization of the TCD memory is performed by the eDMA controller after reset. The initialization runs for 256 eDMA clock cycles. All fields in the TCD memory are initialized to 0. All application read or write accesses to the TCD are delayed until the initialization is finished. Prior to activating a channel, you must initialize its TCD with the appropriate transfer profile.

36.4.3 TCD structure

DMA Basics: TCD Structure
- One DMA engine has a number of channels to react to DMA requests
- Each channel has its own TCD

Word Offset	0 1 2 3	4 5 6 7	8 9 10 11	12 13 14 15	16 17 18 19	20 21 22 23	24 25 26 27	28 29 30 31

0x1008	NBYTES[1]							
0x1008	SMLOE[1] / DMLOE[1]	MLOFF or NBYTES[1]					NBYTES[1]	
0x100C	SLAST							
0x1010	DADDR							
0x1014	CITER.E_LINK	CITER or CITER.LINKCH	CITER		DOFF			
0x1018	DLAST_SGA							
0x101C	BITER.E_LINK	BITER or BITER.LINKCH	BITER		BWC	MAJOR LINKCH	DONE / ACTIVE / MAJOR.E_LINK / E_SG / D_REQ / INT_HALF / INT_MAJ / START	

[1] The fields implemented in Word 2 depend on whether EDMA_CR[EMLM] bit is set to 0 or 1.

36.4.4 Reserved memory and bit fields

- Reading reserved bits in a register returns the value of zero.
- Writes to reserved bits in a register are ignored.
- Reading or writing a reserved memory location generates a bus error.

NOTE

Accessing locations at offsets 38h and 3Ch will not result in a transfer error. Location 38h behaves as ROZ. Location 3Ch behaves as R/W.

36.4.5 Control Register (DMA_CR)

The CR defines the basic operating configuration of the DMA. The DMA arbitrates channel service requests in two groups of 16 channels each:

- Group 1 contains channels 31-16
- Group 0 contains channels 15-0

Arbitration within a group can be configured to use either a fixed-priority or a round-robin scheme. For fixed-priority arbitration, the highest priority channel requesting service is selected to execute. The channel priority registers assign the priorities; see the DCHPRIn registers. For round-robin arbitration, the channel priorities are ignored and channels within each group are cycled through (from high to low channel number) without regard to priority.

NOTE

For correct operation, writes to the CR register must be performed only when the DMA channels are inactive; that is, when TCDn_CSR[ACTIVE] bits are cleared.

The group priorities operate in a similar fashion. In group fixed priority arbitration mode, channel service requests in the highest priority group are executed first, where priority level 1 is the highest and priority level 0 is the lowest. The group priorities are assigned in the GRPnPRI fields of the DMA Control Register (CR). All group priorities must have unique values prior to any channel service requests occurring; otherwise, a configuration error will be reported. For group round robin arbitration, the group priorities are ignored and the groups are cycled through (from high to low group number) without regard to priority.

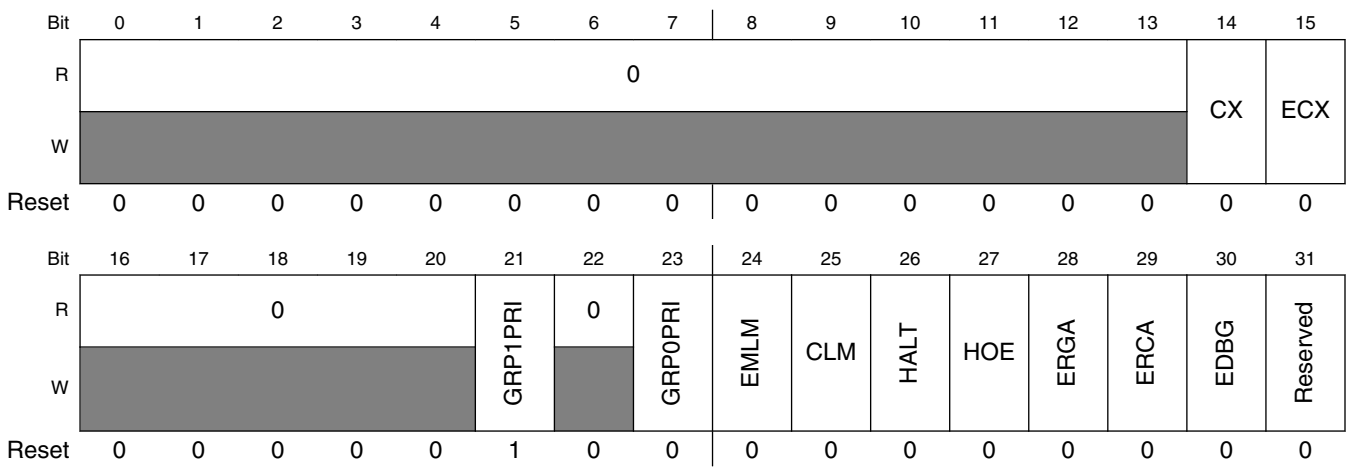
Minor loop offsets are address offset values added to the final source address (TCDn_SADDR) or destination address (TCDn_DADDR) upon minor loop completion. When minor loop offsets are enabled, the minor loop offset (MLOFF) is added to the final source address (TCDn_SADDR), to the final destination address (TCDn_DADDR), or to both prior to the addresses being written back into the TCD. If the major loop is

complete, the minor loop offset is ignored and the major loop address offsets (TCDn_SLAST and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

When minor loop mapping is enabled (EMLM is 1), TCDn word2 is redefined. A portion of TCDn word2 is used to specify multiple fields: a source enable bit (SMLOE) to specify the minor loop offset should be applied to the source address (TCDn_SADDR) upon minor loop completion, a destination enable bit (DMLOE) to specify the minor loop offset should be applied to the destination address (TCDn_DADDR) upon minor loop completion, and the sign extended minor loop offset value (MLOFF). The same offset value (MLOFF) is used for both source and destination minor loop offsets. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. When both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

When minor loop mapping is disabled (EMLM is 0), all 32 bits of TCDn word2 are assigned to the NBYTES field.

Address: 0h base + 0h offset = 0h



DMA_CR field descriptions

Field	Description
0–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 CX	Cancel Transfer 0 Normal operation 1 Cancel the remaining data transfer. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The CX bit clears itself after the cancel has been honored. This cancel retires the channel normally as if the minor loop was completed.
15 ECX	Error Cancel Transfer

Table continues on the next page...

DMA_CR field descriptions (continued)

Field	Description
	0 Normal operation 1 Cancel the remaining data transfer in the same fashion as the CX bit. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The ECX bit clears itself after the cancel is honored. In addition to cancelling the transfer, ECX treats the cancel as an error condition, thus updating the Error Status register (DMAx_ES) and generating an optional error interrupt.
16–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 GRP1PRI	Channel Group 1 Priority Group 1 priority level when fixed priority group arbitration is enabled.
22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 GRP0PRI	Channel Group 0 Priority Group 0 priority level when fixed priority group arbitration is enabled.
24 EMLM	Enable Minor Loop Mapping 0 Disabled. TCDn.word2 is defined as a 32-bit NBYTES field. 1 Enabled. TCDn.word2 is redefined to include individual enable fields, an offset field, and the NBYTES field. The individual enable fields allow the minor loop offset to be applied to the source address, the destination address, or both. The NBYTES field is reduced when either offset is enabled.
25 CLM	Continuous Link Mode **NOTE:** Do not use continuous link mode with a channel linking to itself if there is only one minor loop iteration per service request, e.g., if the channel's NBYTES value is the same as either the source or destination size. The same data transfer profile can be achieved by simply increasing the NBYTES value, which provides more efficient, faster processing. 0 A minor loop channel link made to itself goes through channel arbitration before being activated again. 1 A minor loop channel link made to itself does not go through channel arbitration before being activated again. Upon minor loop completion, the channel activates again if that channel has a minor loop channel link enabled and the link channel is itself. This effectively applies the minor loop offsets and restarts the next minor loop.
26 HALT	Halt DMA Operations 0 Normal operation 1 Stall the start of any new channels. Executing channels are allowed to complete. Channel execution resumes when this bit is cleared.
27 HOE	Halt On Error 0 Normal operation 1 Any error causes the HALT bit to set. Subsequently, all service requests are ignored until the HALT bit is cleared.
28 ERGA	Enable Round Robin Group Arbitration 0 Fixed priority arbitration is used for selection among the groups. 1 Round robin arbitration is used for selection among the groups.
29 ERCA	Enable Round Robin Channel Arbitration

Table continues on the next page...

DMA_CR field descriptions (continued)

Field	Description
	0 Fixed priority arbitration is used for channel selection within each group. 1 Round robin arbitration is used for channel selection within each group.
30 EDBG	Enable Debug 0 When in debug mode, the DMA continues to operate. 1 When in debug mode, the DMA stalls the start of a new channel. Executing channels are allowed to complete. Channel execution resumes when the system exits debug mode or the EDBG bit is cleared.
31 Reserved	This field is reserved. Reserved

36.4.6 Error Status Register (DMA_ES)

The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- A configuration error, that is:
  - An illegal setting in the transfer-control descriptor, or
  - An illegal priority register setting in fixed-arbitration
- An error termination to a bus master read or write cycle
- The UCE bit shows an uncorrectable error occurred while the device has ECC protection on the TCD SRAM
- A cancel transfer with error bit that will be set when a transfer is canceled via the corresponding cancel transfer control bit

See Fault reporting and handling for more details.

DMA_ES field descriptions

Field	Description
0 VLD	Logical OR of all ERR status bits

Table continues on the next page...

DMA_ES field descriptions (continued)

Field	Description
	0 No ERR bits are set. 1 At least one ERR bit is set indicating a valid error exists that has not been cleared.
1–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 UCE	Uncorrectable ECC error during channel execution. The UCE bit is set when an uncorrectable ECC error occurs on an access generated by the DMA only. If a CPU access to the TCD causes an uncorrectable ECC error, that access will receive a bus error response. **NOTE:** When the eDMA sees a RAM error on an IPS access (when the user is accessing a TCD), the error is reported as a bus abort. When the dma_engine (the execution engine is accessing a TCD) receives a RAM error, it is recorded in the Error Status register, DMA_ES[UCE], along with the channel number. 0 No uncorrectable ECC error 1 The last recorded error was an uncorrectable TCD RAM error
15 ECX	Transfer Canceled 0 No canceled transfers 1 The last recorded entry was a canceled transfer by the error cancel transfer input
16 GPE	Group Priority Error 0 No group priority error 1 The last recorded error was a configuration error among the group priorities. All group priorities are not unique.
17 CPE	Channel Priority Error 0 No channel priority error 1 The last recorded error was a configuration error in the channel priorities within a group. Channel priorities within a group are not unique.
18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–23 ERRCHN	Error Channel Number or Canceled Channel Number The channel number of the last recorded error, excluding GPE and CPE errors, or last recorded error canceled transfer.
24 SAE	Source Address Error 0 No source address configuration error. 1 The last recorded error was a configuration error detected in the TCDn_SADDR field. TCDn_SADDR is inconsistent with TCDn_ATTR[SSIZE].
25 SOE	Source Offset Error 0 No source offset configuration error 1 The last recorded error was a configuration error detected in the TCDn_SOFF field. TCDn_SOFF is inconsistent with TCDn_ATTR[SSIZE].
26 DAE	Destination Address Error

Table continues on the next page...

DMA_ES field descriptions (continued)

Field	Description
	0 No destination address configuration error 1 The last recorded error was a configuration error detected in the TCDn_DADDR field. TCDn_DADDR is inconsistent with TCDn_ATTR[DSIZE].
27 DOE	Destination Offset Error 0 No destination offset configuration error 1 The last recorded error was a configuration error detected in the TCDn_DOFF field. TCDn_DOFF is inconsistent with TCDn_ATTR[DSIZE].
28 NCE	NBYTES/CITER Configuration Error 0 No NBYTES/CITER configuration error 1 The last recorded error was a configuration error detected in the TCDn_NBYTES or TCDn_CITER fields. • TCDn_NBYTES is not a multiple of TCDn_ATTR[SSIZE] and TCDn_ATTR[DSIZE], or • TCDn_CITER[CITER] is equal to zero, or • TCDn_CITER[ELINK] is not equal to TCDn_BITER[ELINK]
29 SGE	Scatter/Gather Configuration Error 0 No scatter/gather configuration error 1 The last recorded error was a configuration error detected in the TCDn_DLASTSGA field. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCDn_CSR[ESG] is enabled. TCDn_DLASTSGA is not on a 32 byte boundary.
30 SBE	Source Bus Error 0 No source bus error 1 The last recorded error was a bus error on a source read
31 DBE	Destination Bus Error 0 No destination bus error 1 The last recorded error was a bus error on a destination write

36.4.7 Enable Request Register (DMA_ERQ)

The ERQ register provides a bit map for the 32 channels to enable the request signal for each channel. The state of any given channel enable is directly affected by writes to this register; it is also affected by writes to the SERQ and CERQ registers. These registers are provided so the request enable for a single channel can easily be modified without needing to perform a read-modify-write sequence to the ERQ.

DMA request input signals and this enable request flag must be asserted before a channel's hardware service request is accepted. The state of the DMA enable request flag does not affect a channel service request made explicitly through software or a linked channel request.

36.4.8 Enable Error Interrupt Register (DMA_EEI)

The EEI register provides a bit map for the 32 channels to enable the error interrupt signal for each channel. The state of any given channel's error interrupt enable is directly affected by writes to this register; it is also affected by writes to the SEEI and CEEI. These registers are provided so that the error interrupt enable for a single channel can easily be modified without the need to perform a read-modify-write sequence to the EEI register.

The DMA error indicator and the error interrupt enable flag must be asserted before an error interrupt request for a given channel is asserted to the interrupt controller.

36.4.9 Set Enable Request Register (DMA_SERQ)

The SERQ provides a simple memory-mapped mechanism to set a given bit in the ERQ to enable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQ to be set. Setting the SAER bit provides a global set function, forcing the entire contents of ERQ to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 18h offset = 18h

Bit	0	1	2	3	4	5	6	7
Read	0	0		0				
Write	NOP	SAER	0	SERQ				
Reset	0	0	0	0	0	0	0	0

DMA_SERQ field descriptions

Field	Description
0 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
1 SAER	Set All Enable Requests

Table continues on the next page...

DMA_SERQ field descriptions (continued)

Field	Description
	0 Set only the ERQ bit specified in the SERQ field 1 Set all bits in ERQ
2 Reserved	This field is reserved.
3–7 SERQ	Set Enable Request Sets the corresponding bit in ERQ.

36.4.10 Clear Enable Request Register (DMA_CERQ)

The CERQ provides a simple memory-mapped mechanism to clear a given bit in the ERQ to disable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQ to be cleared. Setting the CAER bit provides a global clear function, forcing the entire contents of the ERQ to be cleared, disabling all DMA request inputs. If NOP is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 19h offset = 19h

Bit	0	1	2	3	4	5	6	7
Read	0	0		0				
Write	NOP	CAER	0	CERQ				
Reset	0	0	0	0	0	0	0	0

DMA_CERQ field descriptions

Field	Description
0 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
1 CAER	Clear All Enable Requests 0 Clear only the ERQ bit specified in the CERQ field 1 Clear all bits in ERQ
2 Reserved	This field is reserved.
3–7 CERQ	Clear Enable Request Clears the corresponding bit in ERQ.

36.4.11 Set Enable Error Interrupt Register (DMA_SEEI)

The SEEI provides a simple memory-mapped mechanism to set a given bit in the EEI to enable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEI to be set. Setting the SAEE bit provides a global set function, forcing the entire EEI contents to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 1Ah offset = 1Ah

Bit	0	1	2	3	4	5	6	7
Read	0	0				0		
Write	NOP	SAEE	0			SEEI		
Reset	0	0	0	0	0	0	0	0

DMA_SEEI field descriptions

Field	Description
0 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
1 SAEE	Sets All Enable Error Interrupts 0 Set only the EEI bit specified in the SEEI field. 1 Sets all bits in EEI
2 Reserved	This field is reserved.
3–7 SEEI	Set Enable Error Interrupt Sets the corresponding bit in EEI

36.4.12 Clear Enable Error Interrupt Register (DMA_CEEI)

The CEEI provides a simple memory-mapped mechanism to clear a given bit in the EEI to disable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEI to be cleared. Setting the CAEE bit provides a global clear function, forcing the EEI contents to be cleared, disabling all DMA request inputs. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 1Bh offset = 1Bh

Bit	0	1	2	3	4	5	6	7
Read	0	0				0		
Write	NOP	CAEE	0			CEEI		
Reset	0	0	0	0	0	0	0	0

DMA_CEEI field descriptions

Field	Description
0 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
1 CAEE	Clear All Enable Error Interrupts 0 Clear only the EEI bit specified in the CEEI field 1 Clear all bits in EEI
2 Reserved	This field is reserved.
3–7 CEEI	Clear Enable Error Interrupt Clears the corresponding bit in EEI

36.4.13 Clear Interrupt Request Register (DMA_CINT)

The CINT provides a simple, memory-mapped mechanism to clear a given bit in the INT to disable the interrupt request for a given channel. The given value on a register write causes the corresponding bit in the INT to be cleared. Setting the CAIR bit provides a global clear function, forcing the entire contents of the INT to be cleared, disabling all DMA interrupt requests. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 1Ch offset = 1Ch

Bit	0	1	2	3	4	5	6	7
Read	0	0				0		
Write	NOP	CAIR	0			CINT		
Reset	0	0	0	0	0	0	0	0

DMA_CINT field descriptions

Field	Description
0 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
1 CAIR	Clear All Interrupt Requests 0 Clear only the INT bit specified in the CINT field 1 Clear all bits in INT
2 Reserved	This field is reserved.
3–7 CINT	Clear Interrupt Request Clears the corresponding bit in INT

36.4.14 Clear Error Register (DMA_CERR)

The CERR provides a simple memory-mapped mechanism to clear a given bit in the ERR to disable the error condition flag for a given channel. The given value on a register write causes the corresponding bit in the ERR to be cleared. Setting the CAEI bit provides a global clear function, forcing the ERR contents to be cleared, clearing all channel error indicators. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 1Dh offset = 1Dh

Bit	0	1	2	3	4	5	6	7
Read	0	0		0				
Write	NOP	CAEI	0	CERR				
Reset	0	0	0	0	0	0	0	0

DMA_CERR field descriptions

Field	Description
0 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
1 CAEI	Clear All Error Indicators 0 Clear only the ERR bit specified in the CERR field 1 Clear all bits in ERR
2 Reserved	This field is reserved.
3–7 CERR	Clear Error Indicator Clears the corresponding bit in ERR

36.4.15 Set START Bit Register (DMA_SSRT)

The SSRT provides a simple memory-mapped mechanism to set the START bit in the TCD of the given channel. The data value on a register write causes the START bit in the corresponding transfer control descriptor to be set. Setting the SAST bit provides a global set function, forcing all START bits to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 1Eh offset = 1Eh

Bit	0	1	2	3	4	5	6	7
Read	0	0				0		
Write	NOP	SAST	0			SSRT		
Reset	0	0	0	0	0	0	0	0

DMA_SSRT field descriptions

Field	Description
0 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
1 SAST	Set All START Bits (activates all channels) 0 Set only the TCDn_CSR[START] bit specified in the SSRT field 1 Set all bits in TCDn_CSR[START]
2 Reserved	This field is reserved.
3–7 SSRT	Set START Bit Sets the corresponding bit in TCDn_CSR[START]

36.4.16 Clear DONE Status Bit Register (DMA_CDNE)

The CDNE provides a simple memory-mapped mechanism to clear the DONE bit in the TCD of the given channel. The data value on a register write causes the DONE bit in the corresponding transfer control descriptor to be cleared. Setting the CADN bit provides a global clear function, forcing all DONE bits to be cleared. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: 0h base + 1Fh offset = 1Fh

Bit	0	1	2	3	4	5	6	7
Read	0	0		0				
Write	NOP	CADN	0	CDNE				
Reset	0	0	0	0	0	0	0	0

DMA_CDNE field descriptions

Field	Description
0 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
1 CADN	Clears All DONE Bits 0 Clears only the TCDn_CSR[DONE] bit specified in the CDNE field 1 Clears all bits in TCDn_CSR[DONE]
2 Reserved	This field is reserved.
3–7 CDNE	Clear DONE Bit Clears the corresponding bit in TCDn_CSR[DONE]

36.4.17 Interrupt Request Register (DMA_INT)

The INT register provides a bit map for the 32 channels signaling the presence of an interrupt request for each channel. Depending on the appropriate bit setting in the transfer-control descriptors, the eDMA engine generates an interrupt on data transfer completion. The outputs of this register are directly routed to the interrupt controller. During the interrupt-service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit, negating the interrupt request. Typically, a write to the CINT register in the interrupt service routine is used for this purpose.

The state of any given channel's interrupt request is directly affected by writes to this register; it is also affected by writes to the CINT register. On writes to INT, a 1 in any bit position clears the corresponding channel's interrupt request. A zero in any bit position has no affect on the corresponding channel's current interrupt status. The CINT register is provided so the interrupt request for a single channel can easily be cleared without the need to perform a read-modify-write sequence to the INT register.

Address: 0h base + 24h offset = 24h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	INT31	INT30	INT29	INT28	INT27	INT26	INT25	INT24	INT23	INT22	INT21	INT20	INT19	INT18	INT17	INT16

31 INT0	Interrupt Request 0 0 The interrupt request for corresponding channel is cleared 1 The interrupt request for corresponding channel is active

36.4.18 Error Register (DMA_ERR)

The ERR provides a bit map for the 32 channels, signaling the presence of an error for each channel. The eDMA engine signals the occurrence of an error condition by setting the appropriate bit in this register. The outputs of this register are enabled by the contents of the EEI, then logically summed across groups of 16 and 32 channels to form several group error interrupt requests, which are then routed to the interrupt controller. During the execution of the interrupt-service routine associated with any DMA errors, it is software's responsibility to clear the appropriate bit, negating the error-interrupt request. Typically, a write to the CERR in the interrupt-service routine is used for this purpose. The normal DMA channel completion indicators (setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request) are not affected when an error is detected.

The contents of this register can also be polled because a non-zero value indicates the presence of a channel error regardless of the state of the EEI. The state of any given channel's error indicators is affected by writes to this register; it is also affected by writes to the CERR. On writes to the ERR, a one in any bit position clears the corresponding channel's error status. A zero in any bit position has no affect on the corresponding channel's current error status. The CERR is provided so the error indicator for a single channel can easily be cleared.

Address: 0h base + 2Ch offset = 2Ch

36.4.19 Hardware Request Status Register (DMA_HRS)

The HRS register provides a bit map for the DMA channels, signaling the presence of a hardware request for each channel. The hardware request status bits reflect the current state of the register and qualified (via the ERQ fields) DMA request signals as seen by the DMA's arbitration logic. This view into the hardware request signals may be used for debug purposes.

NOTE

These bits reflect the state of the request as seen by the arbitration logic. Therefore, this status is affected by the ERQ bits.

Address: 0h base + 34h offset = 34h

36.4.20 Channel n Priority Register (DMA_DCHPRI*n*)

When fixed-priority channel arbitration is enabled (CR[ERCA] = 0), the contents of these registers define the unique priorities associated with each channel within a group. The channel priorities are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, etc. Software must program the channel priorities with unique values; otherwise, a configuration error is reported. The range of the priority value is limited to the values of 0 through 15. When read, the GRPPRI bits of the DCHPRIn register reflect the current priority level of the group of channels in which the corresponding channel resides. GRPPRI bits are not affected by writes to the DCHPRIn registers. The group priority is assigned in the DMA control register.

Address: 0h base + 100h offset + (1d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7
Read	ECP	DPA	GRPPRI		CHPRI			
Write								
Reset	0	0	*	*	*	*	*	*

* Notes:
- CHPRI field: See bit field description.
- GRPPRI field: See bit field description.

DMA_DCHPRI*n* field descriptions

Field	Description
0 ECP	Enable Channel Preemption. 0 Channel n cannot be suspended by a higher priority channel's service request. 1 Channel n can be temporarily suspended by the service request of a higher priority channel.

Table continues on the next page...

DMA_DCHPRI*n* field descriptions (continued)

Field	Description
1 DPA	Disable Preempt Ability. 0 Channel n can suspend a lower priority channel. 1 Channel n cannot suspend any channel, regardless of channel priority.
2–3 GRPPRI	Channel n Current Group Priority Group priority assigned to this channel group when fixed-priority arbitration is enabled. This field is read-only; writes are ignored. **NOTE:** Reset value for the group and channel priority fields, GRPPRI and CHPRI, is equal to the corresponding channel number for each priority register, that is, DCHPRI31[GRPPRI] = 0b01 and DCHPRI31[CHPRI] equals 0b1111.
4–7 CHPRI	Channel n Arbitration Priority Channel priority when fixed-priority arbitration is enabled **NOTE:** Reset value for the group and channel priority fields, GRPPRI and CHPRI, is equal to the corresponding channel number for each priority register, that is, DCHPRI31[GRPPRI] = 0b01 and DCHPRI31[CHPRI] = 0b01111.

36.4.21 Channel n Master ID Register (DMA_DCHMID*n*)

The DMA master ID replication registers allow the DMA to use the same protection level and system bus ID of the master programming the DMA's TCD. When enabled, the DMA uses the master ID and protection level stored in the DCHMID register instead of the DMA's default values. When a master, for example, a core, programs a TCD, its master ID and protection level are captured when the TCDn.CSR control attributes are written. Although the scatter/gather operation can change the contents of TCDn_CSR, that operation does not affect the DCHMID *n* registers.

Address: 0h base + 140h offset + (1d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7
Read	EMI	PAL	0		MID			
Write								
Reset	0	0	0	0	0	0	0	0

DMA_DCHMID*n* field descriptions

Field	Description
0 EMI	Enable Master ID replication **NOTE:** If Master ID replication is disabled, the privileged protection level (supervisor mode) for DMA transfers is used.

Table continues on the next page...

DMA_DCHMID*n* field descriptions (continued)

Field	Description
	0 Master ID replication is disabled 1 Master ID replication is enabled
1 PAL	Privileged Access Level **NOTE:** The protection level captured in this register reflects the level used when writing the channel's control attributes; lower byte of TCDn.CSR. 0 User protection level for DMA transfers 1 Privileged protection level for DMA transfers
2–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–7 MID	Master ID DMA's master ID when channel n is active and master ID replication is enabled. **NOTE:** The master ID captured in this register reflects the ID used when writing the channel's control attributes; lower byte of TCDn.CSR.

36.4.22 TCD Source Address (DMA_TCD*n*_SADDR)

Address: 0h base + 1000h offset + (32d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	SADDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DMA_TCD*n*_SADDR field descriptions

Field	Description
0–31 SADDR	Source Address Memory address pointing to the source data.

36.4.23 TCD Transfer Attributes (DMA_TCD*n*_ATTR)

Address: 0h base + 1004h offset + (32d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	SMOD					SSIZE			DMOD					DSIZE		
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DMA_TCD*n*_ATTR field descriptions

Field	Description
0–4 SMOD	Source Address Modulo 0 Source address modulo feature is disabled ≠0 This value defines a specific address range specified to be the value after SADDR + SOFF calculation is performed on the original register value. Setting this field provides the ability to implement a circular data queue easily. For data queues requiring power-of-2 size bytes, the queue should start at a 0-modulo-size address and the SMOD field should be set to the appropriate value for the queue, freezing the desired number of upper address bits. The value programmed into this field specifies the number of lower address bits allowed to change. For a circular queue application, the SOFF is typically set to the transfer size to implement post-increment addressing with the SMOD function constraining the addresses to a 0-modulo-size range.
5–7 SSIZE	Source data transfer size **NOTE:** Using a Reserved value causes a configuration error. 000 8-bit 001 16-bit 010 32-bit 011 64-bit 100 Reserved 101 32-byte burst (4 beats of 64 bits) 110 Reserved 111 Reserved
8–12 DMOD	Destination Address Modulo See the SMOD definition
13–15 DSIZE	Destination data transfer size See the SSIZE definition

36.4.24 TCD Signed Source Address Offset (DMA_TCD*n*_SOFF)

Address: 0h base + 1006h offset + (32d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	SOFF															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DMA_TCD*n*_SOFF field descriptions

Field	Description
0–15 SOFF	Source address signed offset Sign-extended offset applied to the current source address to form the next-state value as each source read is completed.

36.4.25 TCD Minor Byte Count (Minor Loop Mapping Disabled) (DMA_TCD*n*_NBYTES_MLNO)

This register, or one of the next two registers (TCD_NBYTES_MLOFFNO, TCD_NBYTES_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is disabled (CR[EMLM] = 0)

If minor loop mapping is enabled, see the TCD_NBYTES_MLOFFNO and TCD_NBYTES_MLOFFYES register descriptions for the definition of TCD word 2.

Address: 0h base + 1008h offset + (32d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	NBYTES																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DMA_TCD*n*_NBYTES_MLNO field descriptions

Field	Description
0–31 NBYTES	Minor Byte Transfer Count Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed. **NOTE:** An NBYTES value of 0x0000_0000 is interpreted as a 4 GB transfer.

36.4.26 TCD Signed Minor Loop Offset (Minor Loop Mapping Enabled and Offset Disabled) (DMA_TCD*n*_NBYTES_MLOFFNO)

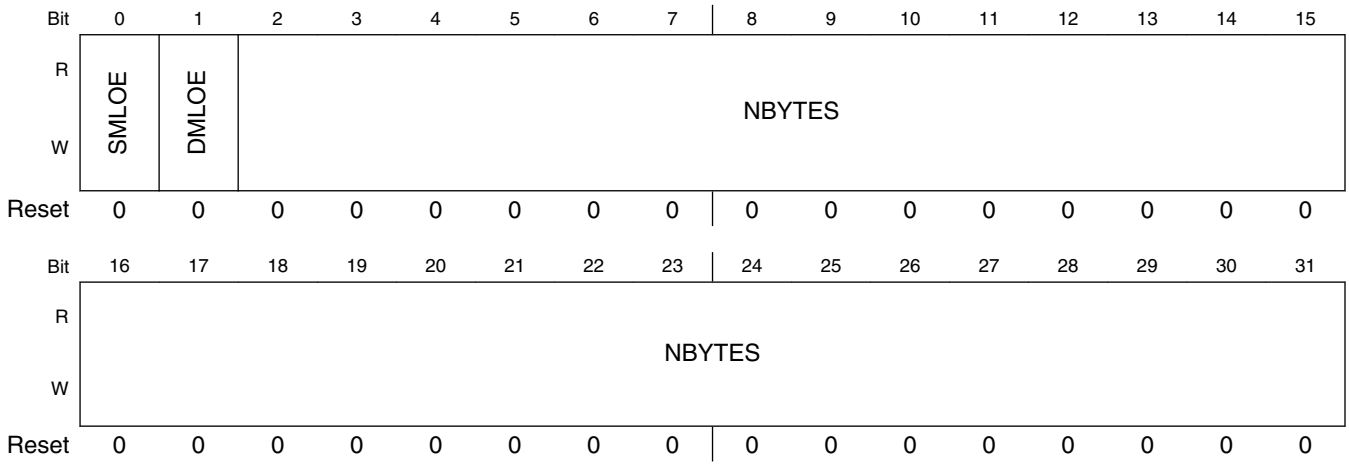
One of three registers (this register, TCD_NBYTES_MLNO, or TCD_NBYTES_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is enabled (CR[EMLM] = 1) and
- SMLOE = 0 and DMLOE = 0

If minor loop mapping is enabled and SMLOE or DMLOE is set, then refer to the TCD_NBYTES_MLOFFYES register description. If minor loop mapping is disabled, then refer to the TCD_NBYTES_MLNO register description.

Address: 0h base + 1008h offset + (32d × i), where i=0d to 31d



DMA_TCD*n*_NBYTES_MLOFFNO field descriptions

Field	Description
0 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0 The minor loop offset is not applied to the SADDR 1 The minor loop offset is applied to the SADDR
1 DMLOE	Destination Minor Loop Offset enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0 The minor loop offset is not applied to the DADDR 1 The minor loop offset is applied to the DADDR
2–31 NBYTES	Minor Byte Transfer Count Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed.

36.4.27 TCD Signed Minor Loop Offset (Minor Loop Mapping and Offset Enabled) (DMA_TCD*n*_NBYTES_MLOFFYES)

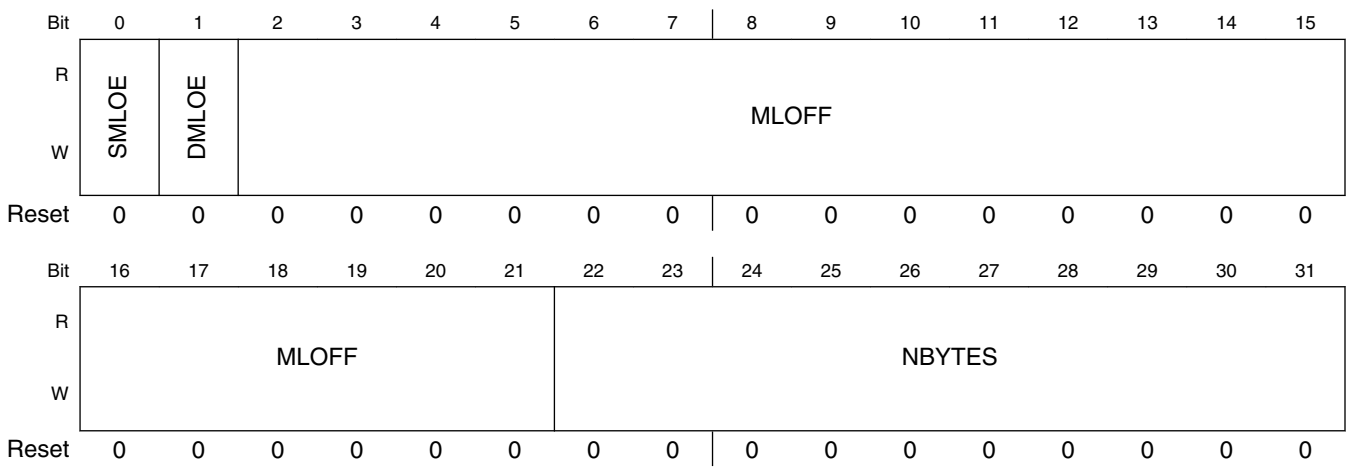
One of three registers (this register, TCD_NBYTES_MLNO, or TCD_NBYTES_MLOFFNO), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is enabled (CR[EMLM] = 1) and
- Minor loop offset is enabled (SMLOE or DMLOE = 1)

If minor loop mapping is enabled and SMLOE and DMLOE are cleared, then refer to the TCD_NBYTES_MLOFFNO register description. If minor loop mapping is disabled, then refer to the TCD_NBYTES_MLNO register description.

Address: 0h base + 1008h offset + (32d × i), where i=0d to 31d



DMA_TCD*n*_NBYTES_MLOFFYES field descriptions

Field	Description
0 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0 The minor loop offset is not applied to the SADDR 1 The minor loop offset is applied to the SADDR
1 DMLOE	Destination Minor Loop Offset enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0 The minor loop offset is not applied to the DADDR 1 The minor loop offset is applied to the DADDR

Table continues on the next page...

DMA_TCD*n*_NBYTES_MLOFFYES field descriptions (continued)

Field	Description
2–21 MLOFF	If SMLOE or DMLOE is set, this field represents a sign-extended offset applied to the source or destination address to form the next-state value after the minor loop completes.
22–31 NBYTES	Minor Byte Transfer Count Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed.

36.4.28 TCD Last Source Address Adjustment (DMA_TCD*n*_SLAST)

Address: 0h base + 100Ch offset + (32d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	SLAST																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DMA_TCD*n*_SLAST field descriptions

Field	Description
0–31 SLAST	Last Source Address Adjustment Adjustment value added to the source address at the completion of the major iteration count. This value can be applied to restore the source address to the initial value, or adjust the address to reference the next data structure. This register uses two's complement notation; the overflow bit is discarded.

36.4.29 TCD Destination Address (DMA_TCD*n*_DADDR)

Address: 0h base + 1010h offset + (32d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	DADDR

DMA_TCD*n*_DADDR field descriptions

Field	Description
0–31 DADDR	Destination Address Memory address pointing to the destination data.

36.4.30 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Enabled) (DMA_TCD*n*_CITER_ELINKYES)

If TCDn_CITER[ELINK] is set, the TCDn_CITER register is defined as follows.

Address: 0h base + 1014h offset + (32d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7
Read	ELINK	LINKCH						CITER
Write		0						
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read	CITER							
Write								
Reset	0	0	0	0	0	0	0	0

DMA_TCD*n*_CITER_ELINKYES field descriptions

Field	Description
0 ELINK	Enable channel-to-channel linking on minor-loop complete As the channel completes the minor loop, this flag enables linking to another channel, defined by the LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE:** This bit must be equal to the BITER[ELINK] bit; otherwise, a configuration error is reported. 0 The channel-to-channel linking is disabled 1 The channel-to-channel linking is enabled
1 Reserved	This field is reserved.
2–6 LINKCH	Minor Loop Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request to the channel defined by this field by setting that channel's TCDn_CSR[START] bit.
7–15 CITER	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the minor loop is completed and updated in the transfer control descriptor memory. After the major iteration count is exhausted, the channel performs a number of operations, for example, final source and destination address calculations, optionally generating an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field. **NOTE:** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. **NOTE:** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

36.4.31 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Disabled) (DMA_TCD*n*_CITER_ELINKNO)

If TCDn_CITER[ELINK] is cleared, the TCDn_CITER register is defined as follows.

Address: 0h base + 1014h offset + (32d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7
Read Write	ELINK	CITER						
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read Write	CITER							
Reset	0	0	0	0	0	0	0	0

DMA_TCD*n*_CITER_ELINKNO field descriptions

Field	Description
0 ELINK	Enable channel-to-channel linking on minor-loop complete As the channel completes the minor loop, this flag enables linking to another channel, defined by the LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE:** This bit must be equal to the BITER[ELINK] bit; otherwise, a configuration error is reported. 0 The channel-to-channel linking is disabled 1 The channel-to-channel linking is enabled
1–15 CITER	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the minor loop is completed and updated in the transfer control descriptor memory. After the major iteration count is exhausted, the channel performs a number of operations, for example, final source and destination address calculations, optionally generating an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field. **NOTE:** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. **NOTE:** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

36.4.32 TCD Signed Destination Address Offset (DMA_TCD*n*_DOFF)

Address: 0h base + 1016h offset + (32d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	DOFF															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DMA_TCD*n*_DOFF field descriptions

Field	Description
0–15 DOFF	Destination Address Signed Offset Sign-extended offset applied to the current destination address to form the next-state value as each destination write is completed.

36.4.33 TCD Last Destination Address Adjustment/Scatter Gather Address (DMA_TCD*n*_DLASTSGA)

Address: 0h base + 1018h offset + (32d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	DLASTSGA																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DMA_TCD*n*_DLASTSGA field descriptions

Field	Description
0–31 DLASTSGA	Destination last address adjustment or the memory address for the next transfer control descriptor to be loaded into this channel (scatter/gather). If (TCDn_CSR[ESG] = 0) then: • Adjustment value added to the destination address at the completion of the major iteration count. This value can apply to restore the destination address to the initial value or adjust the address to reference the next data structure. • This field uses two's complement notation for the final destination address adjustment. Otherwise: • This address points to the beginning of a 0-modulo-32-byte region containing the next transfer control descriptor to be loaded into this channel. This channel reload is performed as the major iteration count completes. The scatter/gather address must be 0-modulo-32-byte, otherwise a configuration error is reported.

36.4.34 TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Enabled) (DMA_TCD*n*_BITER_ELINKYES)

If the TCDn_BITER[ELINK] bit is set, the TCDn_BITER register is defined as follows.

Address: 0h base + 101Ch offset + (32d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7
Read Write	ELINK	0	LINKCH					BITER
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read Write	BITER							
Reset	0	0	0	0	0	0	0	0

DMA_TCD*n*_BITER_ELINKYES field descriptions

Field	Description
0 ELINK	Enables channel-to-channel linking on minor loop complete As the channel completes the minor loop, this flag enables the linking to another channel, defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. If channel linking disables, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE:** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. 0 The channel-to-channel linking is disabled 1 The channel-to-channel linking is enabled
1 Reserved	This field is reserved.
2–6 LINKCH	Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] bit. **NOTE:** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field.
7–15 BITER	Starting major iteration count As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be equal to the value in the CITER field. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. **NOTE:** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

36.4.35 TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Disabled) (DMA_TCD*n*_BITER_ELINKNO)

If the TCDn_BITER[ELINK] bit is cleared, the TCDn_BITER register is defined as follows.

Address: 0h base + 101Ch offset + (32d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7
Read Write	ELINK	BITER						
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read Write	BITER							
Reset	0	0	0	0	0	0	0	0

DMA_TCD*n*_BITER_ELINKNO field descriptions

Field	Description
0 ELINK	Enables channel-to-channel linking on minor loop complete As the channel completes the minor loop, this flag enables the linking to another channel, defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. If channel linking is disabled, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE:** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. 0 The channel-to-channel linking is disabled 1 The channel-to-channel linking is enabled
1–15 BITER	Starting Major Iteration Count As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be equal to the value in the CITER field. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. **NOTE:** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field is reloaded into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

36.4.36 TCD Control and Status (DMA_TCD*n*_CSR)

Address: 0h base + 101Eh offset + (32d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7
Read	BWC			MAJORLINKCH				
Write			0

Write								
Reset	0	0	0	0	0	0	0	0

DMA_TCD*n*_CSR field descriptions

Field	Description
0–1 BWC	Bandwidth Control Throttles the amount of bus bandwidth consumed by the eDMA. Generally, as the eDMA processes the minor loop, it continuously generates read/write sequences until the minor count is exhausted. This field forces the eDMA to stall after the completion of each read/write access to control the bus request bandwidth seen by the crossbar switch. **NOTE:** If the source and destination sizes are equal, this field is ignored between the first and second transfers and after the last write of each minor loop. This behavior is a side effect of reducing start-up latency. 00 No eDMA engine stalls. 01 Enable eDMA master high-priority elevation (HPE) mode. No eDMA engine stalls. 10 eDMA engine stalls for 4 cycles after each R/W. 11 eDMA engine stalls for 8 cycles after each R/W.
2 Reserved	This field is reserved.
3–7 MAJORLINKCH	Major Loop Link Channel Number If (MAJORELINK = 0) then: • No channel-to-channel linking, or chaining, is performed after the major loop counter is exhausted. Otherwise: • After the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] bit.
8 DONE	Channel Done This flag indicates the eDMA has completed the major loop. The eDMA engine sets it as the CITER count reaches zero. The software clears it, or the hardware when the channel is activated. **NOTE:** This bit must be cleared to write the MAJORELINK or ESG bits.
9 ACTIVE	Channel Active

Table continues on the next page...

DMA_TCD*n*_CSR field descriptions (continued)

Field	Description
	This flag signals the channel is currently in execution. It is set when channel service begins, and is cleared by the eDMA as the minor loop completes or when any error condition is detected.
10 MAJORELINK	Enable channel-to-channel linking on major loop complete As the channel completes the major loop, this flag enables the linking to another channel, defined by MAJORLINKCH. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. **NOTE:** To support the dynamic linking coherency model, this field is forced to zero when written to while the TCDn_CSR[DONE] bit is set. 0 The channel-to-channel linking is disabled. 1 The channel-to-channel linking is enabled.
11 ESG	Enable Scatter/Gather Processing As the channel completes the major loop, this flag enables scatter/gather processing in the current channel. If enabled, the eDMA engine uses DLASTSGA as a memory pointer to a 0-modulo-32 address containing a 32-byte data structure loaded as the transfer control descriptor into the local memory. **NOTE:** To support the dynamic scatter/gather coherency model, this field is forced to zero when written to while the TCDn_CSR[DONE] bit is set. 0 The current channel's TCD is normal format. 1 The current channel's TCD specifies a scatter gather format. The DLASTSGA field provides a memory pointer to the next TCD to be loaded into this channel after the major loop completes its execution.
12 DREQ	Disable Request If this flag is set, the eDMA hardware automatically clears the corresponding ERQ bit when the current major iteration count reaches zero. 0 The channel's ERQ bit is not affected. 1 The channel's ERQ bit is cleared when the major loop is complete.
13 INTHALF	Enable an interrupt when major counter is half complete. If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT register when the current major iteration count reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER == (BITER >> 1)). This halfway point interrupt request is provided to support double-buffered, also known as ping-pong, schemes or other types of data movement where the processor needs an early indication of the transfer's progress. **NOTE:** If BITER = 1, do not use INTHALF. Use INTMAJOR instead. 0 The half-point interrupt is disabled. 1 The half-point interrupt is enabled.
14 INTMAJOR	Enable an interrupt when major iteration count completes. If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT when the current major iteration count reaches zero. 0 The end-of-major loop interrupt is disabled. 1 The end-of-major loop interrupt is enabled.
15 START	Channel Start

Table continues on the next page...

DMA_TCD*n*_CSR field descriptions (continued)

Field	Description
	If this flag is set, the channel is requesting service. The eDMA hardware automatically clears this flag after the channel begins execution. 0 The channel is not explicitly started. 1 The channel is explicitly started via a software initiated service request.

36.5 Functional description

The operation of the eDMA is described in the following subsections.

36.5.1 eDMA basic data flow

The basic flow of a data transfer can be partitioned into three segments.

As shown in the following diagram, the first segment involves the channel activation:

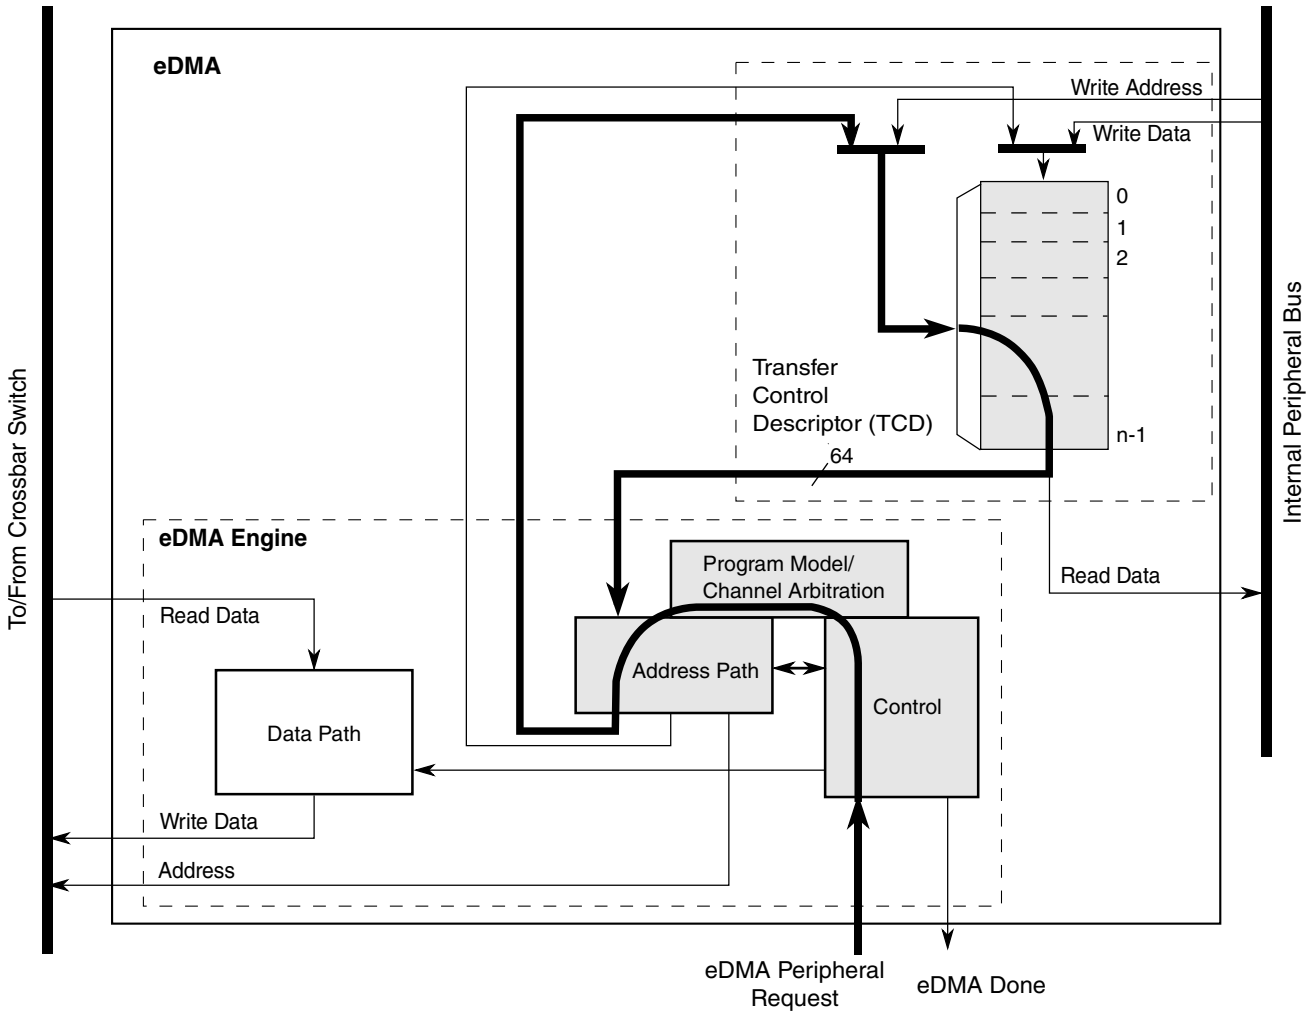

Figure 36-3. eDMA operation, part 1

This example uses the assertion of the eDMA peripheral request signal to request service for channel *n*. Channel activation via software and the TCD*n*_CSR[START] bit follows the same basic flow as peripheral requests. The eDMA request input signal is registered internally and then routed through the eDMA engine: first through the control module, then into the program model and channel arbitration. In the next cycle, the channel arbitration performs, using the fixed-priority or round-robin algorithm. After arbitration is complete, the activated channel number is sent through the address path and converted into the required address to access the local memory for TCD*n*. Next, the TCD memory is accessed and the required descriptor read from the local memory and loaded into the eDMA engine address path channel x or y registers. The TCD memory is 64 bits wide to minimize the time needed to fetch the activated channel descriptor and load it into the address path channel x or y registers.

The following diagram illustrates the second part of the basic data flow:

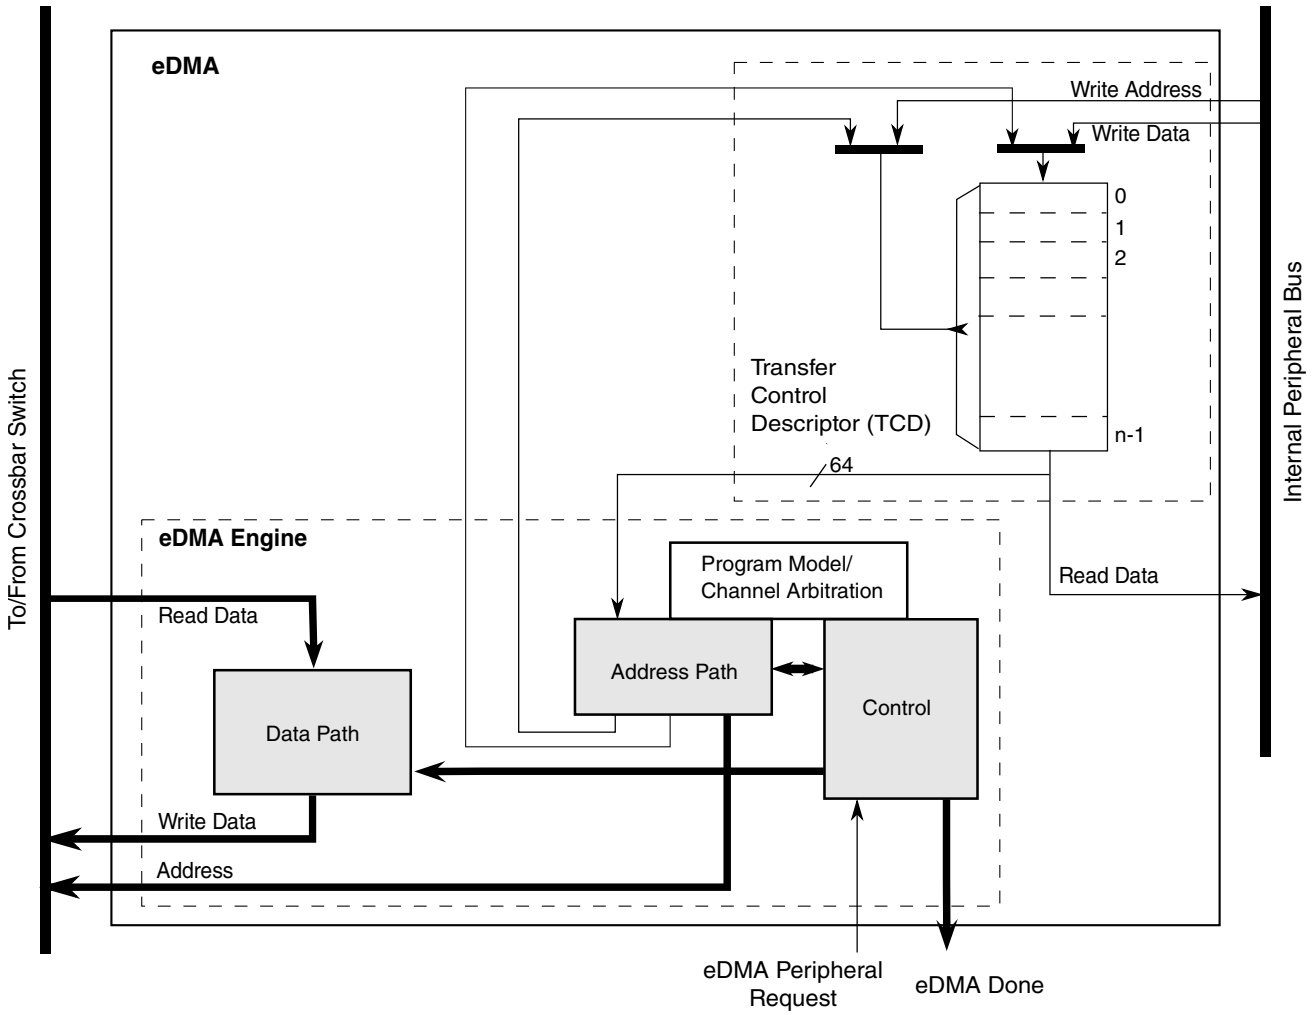

Figure 36-4. eDMA operation, part 2

The modules associated with the data transfer (address path, data path, and control) sequence through the required source reads and destination writes to perform the actual data movement. The source reads are initiated and the fetched data is temporarily stored in the data path block until it is gated onto the internal bus during the destination write. This source read/destination write processing continues until the minor byte count has transferred.

After the minor byte count has moved, the final phase of the basic data flow is performed. In this segment, the address path logic performs the required updates to certain fields in the appropriate TCD, for example, SADDR, DADDR, CITER. If the major iteration count is exhausted, additional operations are performed. These include the final address adjustments and reloading of the BITER field into the CITER. Assertion of an optional interrupt request also occurs at this time, as does a possible fetch of a new TCD from memory using the scatter/gather address pointer included in the descriptor (if scatter/gather is enabled). The updates to the TCD memory and the assertion of an interrupt request are shown in the following diagram.

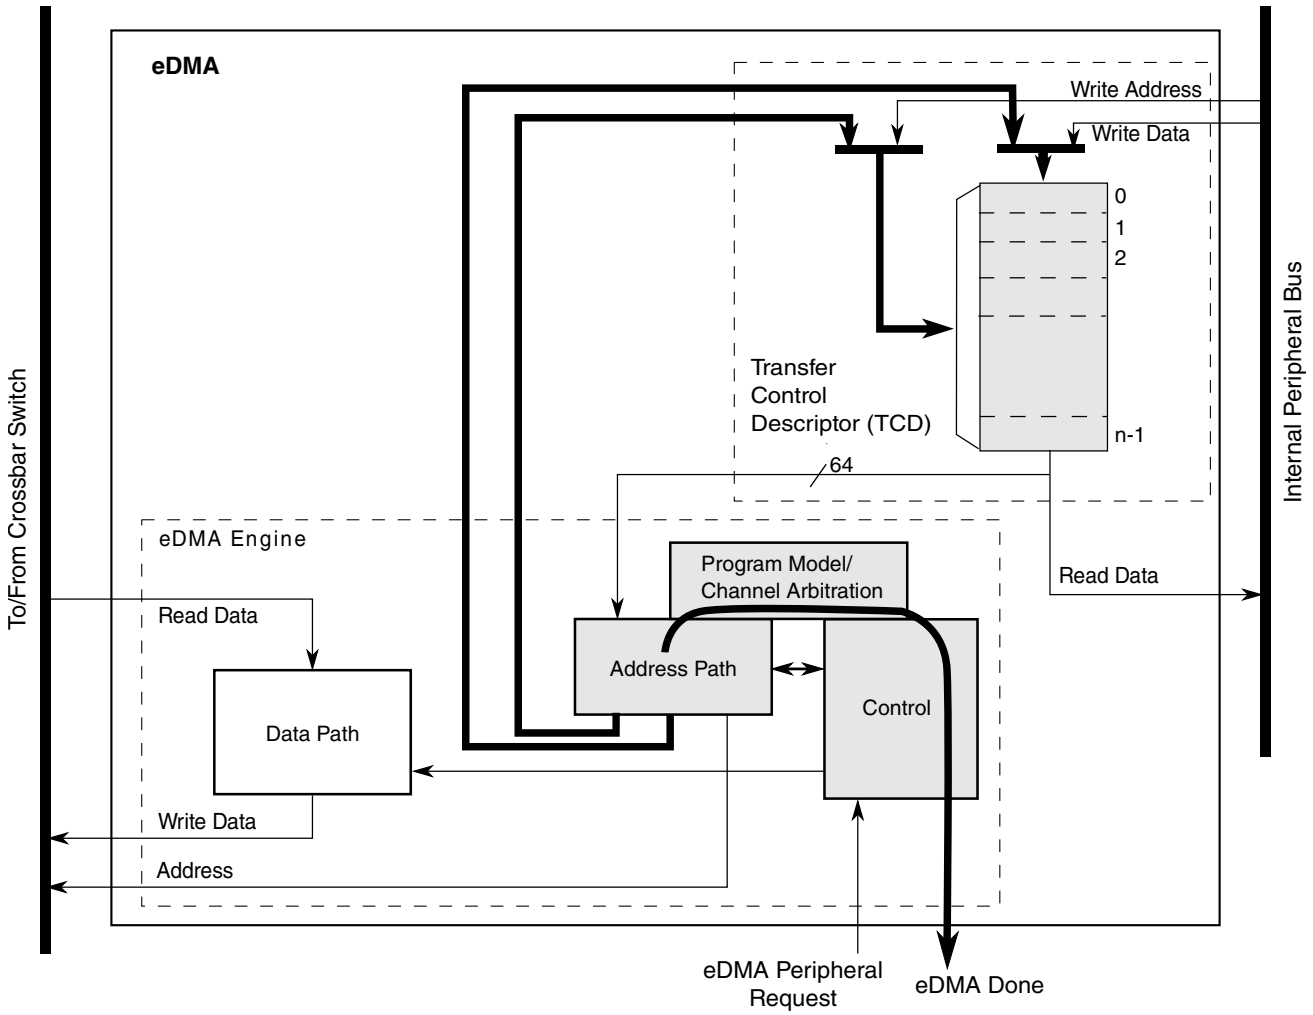

Figure 36-5. eDMA operation, part 3

36.5.2 Fault reporting and handling

Channel errors are reported in the Error Status register (DMAx_ES) and can be caused by:

- A configuration error, which is an illegal setting in the transfer-control descriptor or an illegal priority register setting in Fixed-Arbitration mode
- An uncorrectable ECC error, or
- An error termination to a bus master read or write cycle

A configuration error is reported when the starting source or destination address, source or destination offsets, minor loop byte count, or the transfer size represent an inconsistent state. Each of these possible causes are detailed below:

- The addresses and offsets must be aligned on 0-modulo-transfer-size boundaries.

- The minor loop byte count must be a multiple of the source and destination transfer sizes.
- All source reads and destination writes must be configured to the natural boundary of the programmed transfer size respectively.
- In fixed arbitration mode, a configuration error is caused by any two channel priorities being equal. All channel priority levels must be unique when fixed arbitration mode is enabled.

NOTE

When two channels have the same priority, a channel priority error exists and will be reported in the Error Status register. However, the channel number will not be reported in the Error Status register. When all of the channel priorities within a group are not unique, the channel number selected by arbitration is undetermined.

To aid in Channel Priority Error (CPE) debug, set the Halt On Error bit in the DMA's Control Register. If all of the channel priorities within a group are not unique, the DMA will be halted after the CPE error is recorded. The DMA will remain halted and will not process any channel service requests. Once all of the channel priorities are set to unique numbers, the DMA may be enabled again by clearing the Halt bit.

- If a scatter/gather operation is enabled upon channel completion, a configuration error is reported if the scatter/gather address (DLAST_SGA) is not aligned on a 32-byte boundary.
- If minor loop channel linking is enabled upon channel completion, a configuration error is reported when the link is attempted if the TCDn_CITER[E_LINK] bit does not equal the TCDn_BITER[E_LINK] bit.

If enabled, all configuration error conditions, except the scatter/gather and minor-loop link errors, report as the channel activates and asserts an error interrupt request. A scatter/gather configuration error is reported when the scatter/gather operation begins at major loop completion when properly enabled. A minor loop channel link configuration error is reported when the link operation is serviced at minor loop completion.

If a system bus read or write is terminated with an error, the data transfer is stopped and the appropriate bus error flag set. In this case, the state of the channel's transfer control descriptor is updated by the eDMA engine with the current source address, destination address, and current iteration count at the point of the fault. When a system bus error

occurs, the channel terminates after the next transfer. Due to pipeline effect, the next transfer is already in progress when the bus error is received by the eDMA. If a bus error occurs on the last read prior to beginning the write sequence, the write executes using the data captured during the bus error. If a bus error occurs on the last write prior to switching to the next read sequence, the read sequence executes before the channel terminates due to the destination bus error.

If an uncorrectable ECC error occurs during a peripheral bus access, the access is terminated with a bus error. The occurrence of an uncorrectable ECC error during an eDMA engine read causes the eDMA engine to stop the active channel immediately. The ECC error and channel number are recorded in the eDMA's Error Status register.

A transfer may be cancelled by software with the CR[CX] bit. When a cancel transfer request is recognized, the DMA engine stops processing the channel. The current read-write sequence is allowed to finish. If the cancel occurs on the last read-write sequence of a major or minor loop, the cancel request is discarded and the channel retires normally.

The error cancel transfer is the same as a cancel transfer except the Error Status register (DMAx_ES) is updated with the cancelled channel number and ECX is set. The TCD of a cancelled channel contains the source and destination addresses of the last transfer saved in the TCD. If the channel needs to be restarted, you must re-initialize the TCD because the aforementioned fields no longer represent the original parameters. When a transfer is cancelled by the error cancel transfer mechanism, the channel number is loaded into DMA_ES[ERRCHN] and ECX and VLD are set. In addition, an error interrupt may be generated if enabled.

NOTE

The cancel transfer request allows the user to stop a large data transfer in the event the full data transfer is no longer needed. The cancel transfer bit does not abort the channel. It simply stops the transferring of data and then retires the channel through its normal shutdown sequence. The application software must handle the context of the cancel. If an interrupt is desired (or not), then the interrupt should be enabled (or disabled) before the cancel request. The application software must clean up the transfer control descriptor since the full transfer did not occur.

The occurrence of any error causes the eDMA engine to stop normal processing of the active channel immediately (it goes to its error processing states and the transaction to the system bus still has pipeline effect), and the appropriate channel bit in the eDMA error register is asserted. At the same time, the details of the error condition are loaded into the Error Status register (DMAx_ES). The major loop complete indicators, setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request,

are not affected when an error is detected. After the error status has been updated, the eDMA engine continues operating by servicing the next appropriate channel. A channel that experiences an error condition is not automatically disabled. If a channel is terminated by an error and then issues another service request before the error is fixed, that channel executes and terminates with the same error condition.

36.5.3 Channel preemption

Channel preemption is enabled on a per-channel basis by setting the DCHPRIn[ECP] bit. Channel preemption allows the executing channel's data transfers to temporarily suspend in favor of starting a higher priority channel. After the preempting channel has completed all its minor loop data transfers, the preempted channel is restored and resumes execution. After the restored channel completes one read/write sequence, it is again eligible for preemption. If any higher priority channel is requesting service, the restored channel is suspended and the higher priority channel is serviced. Nested preemption, that is, attempting to preempt a preempting channel, is not supported. After a preempting channel begins execution, it cannot be preempted. Preemption is available only when fixed arbitration is selected.

A channel's ability to preempt another channel can be disabled by setting DCHPRIn[DPA]. When a channel's preempt ability is disabled, that channel cannot suspend a lower priority channel's data transfer, regardless of the lower priority channel's ECP setting. This allows for a pool of low priority, large data-moving channels to be defined. These low priority channels can be configured to not preempt each other, thus preventing a low priority channel from consuming the preempt slot normally available to a true, high priority channel.

36.6 Initialization/application information

The following sections discuss initialization of the eDMA and programming considerations.

36.6.1 eDMA initialization

To initialize the eDMA:

1. Write to the CR if a configuration other than the default is desired.

2. Write the channel priority levels to the DCHPRI*n* registers if a configuration other than the default is desired.
3. Enable error interrupts in the EEI register if so desired.
4. Write the 32-byte TCD for each channel that may request service.
5. Enable any hardware service requests via the ERQ register.
6. Request channel service via either:
   - Software: setting the TCD*n*_CSR[START]
   - Hardware: slave device asserting its eDMA peripheral request signal

After any channel requests service, a channel is selected for execution based on the arbitration and priority levels written into the programmer's model. The eDMA engine reads the entire TCD, including the TCD control and status fields, as shown in the following table, for the selected channel into its internal address path module.

As the TCD is read, the first transfer is initiated on the internal bus, unless a configuration error is detected. Transfers from the source, as defined by TCD*n*_SADDR, to the destination, as defined by TCD*n*_DADDR, continue until the number of bytes specified by TCD*n*_NBYTES are transferred.

When the transfer is complete, the eDMA engine's local TCD*n*_SADDR, TCD*n*_DADDR, and TCD*n*_CITER are written back to the main TCD memory and any minor loop channel linking is performed, if enabled. If the major loop is exhausted, further post processing executes, such as interrupts, major loop channel linking, and scatter/gather operations, if enabled.

Table 36-4. TCD Control and Status fields

TCD*n*_CSR field name	Description
START	Control bit to start channel explicitly when using a software initiated DMA service (Automatically cleared by hardware)
ACTIVE	Status bit indicating the channel is currently in execution
DONE	Status bit indicating major loop completion (cleared by software when using a software initiated DMA service)
D_REQ	Control bit to disable DMA request at end of major loop completion when using a hardware initiated DMA service
BWC	Control bits for throttling bandwidth control of a channel
E_SG	Control bit to enable scatter-gather feature
INT_HALF	Control bit to enable interrupt when major loop is half complete
INT_MAJ	Control bit to enable interrupt when major loop completes

The following figure shows how each DMA request initiates one minor-loop transfer, or iteration, without CPU intervention. DMA arbitration can occur after each minor loop, and one level of minor loop DMA preemption is allowed. The number of minor loops in a major loop is specified by the beginning iteration count (BITER).

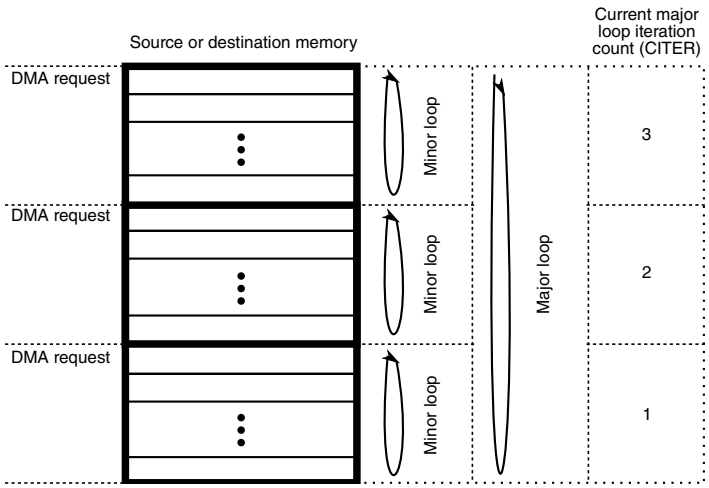

Figure 36-6. Example of multiple loop iterations

The following figure lists the memory array terms and how the TCD settings interrelate.

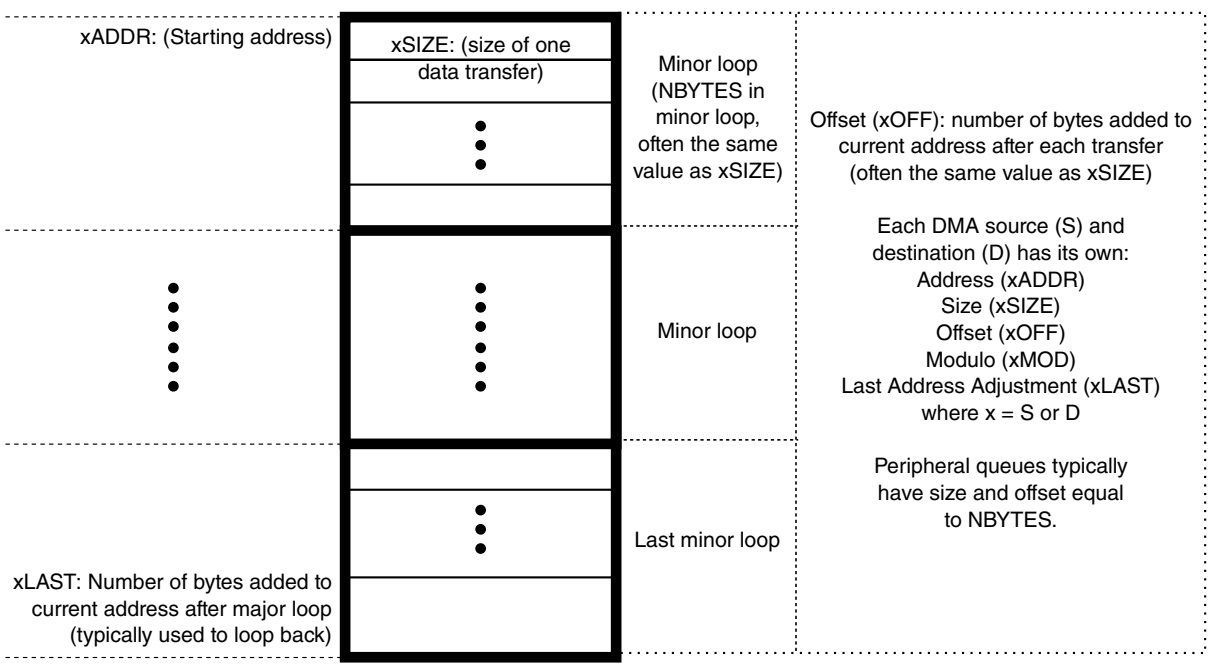

Figure 36-7. Memory array terms

36.6.2 Programming errors

The eDMA performs various tests on the transfer control descriptor to verify consistency in the descriptor data. Most programming errors are reported on a per channel basis with the exception of channel priority error (ES[CPE]).

For all error types other than group or channel priority errors, the channel number causing the error is recorded in the Error Status register (DMAx_ES). If the error source is not removed before the next activation of the problem channel, the error is detected and recorded again.

Channel priority errors are identified within a group once that group has been selected as the active group. For example:

1. The eDMA is configured for fixed group and fixed channel arbitration modes.
2. Group 1 is the highest priority and all channels are unique in that group.
3. Group 0 is the next highest priority and has two channels with the same priority level.
4. If Group 1 has any service requests, those requests will be executed.
5. After all of Group 1 requests have completed, Group 0 will be the next active group.
6. If Group 0 has a service request, then an undefined channel in Group 0 will be selected and a channel priority error will occur.
7. This repeats until the all of Group 0 requests have been removed or a higher priority Group 1 request comes in.

In this sequence, for item 2, the eDMA acknowledge lines will assert only if the selected channel is requesting service via the eDMA peripheral request signal. If interrupts are enabled for all channels, the user will get an error interrupt, but the channel number for the ERR register and the error interrupt request line may be wrong because they reflect the selected channel. A group priority error is global and any request in any group will cause a group priority error.

If priority levels are not unique, when any channel requests service, a channel priority error is reported. The highest channel/group priority with an active request is selected, but the lowest numbered channel with that priority is selected by arbitration and executed by the eDMA engine. The hardware service request handshake signals, error interrupts, and error reporting is associated with the selected channel.

36.6.3 Arbitration mode considerations

This section discusses arbitration considerations for the eDMA.

36.6.3.1 Fixed group arbitration, Fixed channel arbitration

In this mode, the channel service request from the highest priority channel in the highest priority group is selected to execute. If the eDMA is programmed so that the channels within one group use "fixed" priorities, and that group is assigned the highest "fixed" priority of all groups, that group can take all the bandwidth of the eDMA controller. That is, no other groups will be serviced if there is always at least one DMA request pending on a channel in the highest priority group when the controller arbitrates the next DMA request. The advantage of this scenario is that latency can be small for channels that need to be serviced quickly. Preemption is available in this scenario only.

36.6.3.2 Fixed group arbitration, Round-robin channel arbitration

The highest priority group with a request will be serviced. Lower priority groups will be serviced if no pending requests exist in the higher priority groups.

Within each group, channels are serviced starting with the highest channel number and rotating through to the lowest channel number without regard to the channel priority levels assigned within the group.

This scenario could cause the same bandwidth consumption problem as indicated in Fixed group arbitration, Fixed channel arbitration, but all the channels in the highest priority group will be serviced. Service latency will be short on the highest priority group, but could potentially be very much longer as the group priority decreases.

36.6.4 Performing DMA transfers

This section presents examples on how to perform DMA transfers with the eDMA.

36.6.4.1 Single request

To perform a simple transfer of n bytes of data with one activation, set the major loop to one (TCD*n*_CITER = TCD*n*_BITER = 1). The data transfer begins after the channel service request is acknowledged and the channel is selected to execute. After the transfer is complete, the TCD*n*_CSR[DONE] bit is set and an interrupt generates if properly enabled.

For example, the following TCD entry is configured to transfer 16 bytes of data. The eDMA is programmed for one iteration of the major loop transferring 16 bytes per iteration. The source memory has a byte wide memory port located at 0x1000. The destination memory has a 32-bit port located at 0x2000. The address offsets are programmed in increments to match the transfer size: one byte for the source and four bytes for the destination. The final source and destination addresses are adjusted to return to their beginning values.

```
TCDn_CITER = TCDn_BITER = 1
TCDn_NBYTES = 16
TCDn_SADDR = 0x1000
TCDn_SOFF = 1
TCDn_ATTR[SSIZE] = 0
TCDn_SLAST = -16
TCDn_DADDR = 0x2000
TCDn_DOFF = 4
TCDn_ATTR[DSIZE] = 2
TCDn_DLAST_SGA= -16
TCDn_CSR[INT_MAJ] = 1
TCDn_CSR[START] = 1 (Should be written last after all other fields have been initialized)
All other TCDn fields = 0
```

This generates the following event sequence:

1. User write to the TCD*n*_CSR[START] bit requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: TCD*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, TCD*n*_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:
    a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
    b. Write 32-bits to location 0x2000 → first iteration of the minor loop.
    c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.

d. Write 32-bits to location 0x2004 → second iteration of the minor loop.

e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.

f. Write 32-bits to location 0x2008 → third iteration of the minor loop.

g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.

h. Write 32-bits to location 0x200C → last iteration of the minor loop → major loop complete.

6. The eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 1 (TCD*n*_BITER).
7. The eDMA engine writes: TCD*n*_CSR[ACTIVE] = 0, TCD*n*_CSR[DONE] = 1, INT[*n*] = 1.
8. The channel retires and the eDMA goes idle or services the next channel.

36.6.4.2 Multiple requests

The following example transfers 32 bytes via two hardware requests, but is otherwise the same as the previous example. The only fields that change are the major loop iteration count and the final address offsets. The eDMA is programmed for two iterations of the major loop transferring 16 bytes per iteration. After the channel's hardware requests are enabled in the ERQ register, the slave device initiates channel service requests.

```
TCDn_CITER = TCDn_BITER = 2
TCDn_SLAST = -32
TCDn_DLAST_SGA = -32
```

This would generate the following sequence of events:

1. First hardware, that is, eDMA peripheral, request for channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: TCD*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, TCD*n*_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD*n* data from local memory to internal register file.
5. The source to destination transfers are executed as follows:

   a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.

b. Write 32-bits to location 0x2000 → first iteration of the minor loop.

c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.

d. Write 32-bits to location 0x2004 → second iteration of the minor loop.

e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.

f. Write 32-bits to location 0x2008 → third iteration of the minor loop.

g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.

h. Write 32-bits to location 0x200C → last iteration of the minor loop.

6. eDMA engine writes: TCD*n*_SADDR = 0x1010, TCD*n*_DADDR = 0x2010, TCD*n*_CITER = 1.
7. eDMA engine writes: TCD*n*_CSR[ACTIVE] = 0.
8. The channel retires → one iteration of the major loop. The eDMA goes idle or services the next channel.
9. Second hardware, that is, eDMA peripheral, requests channel service.
10. The channel is selected by arbitration for servicing.
11. eDMA engine writes: TCD*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, TCD*n*_CSR[ACTIVE] = 1.
12. eDMA engine reads: channel TCD data from local memory to internal register file.
13. The source to destination transfers are executed as follows:

a. Read byte from location 0x1010, read byte from location 0x1011, read byte from 0x1012, read byte from 0x1013.

b. Write 32-bits to location 0x2010 → first iteration of the minor loop.

c. Read byte from location 0x1014, read byte from location 0x1015, read byte from 0x1016, read byte from 0x1017.

d. Write 32-bits to location 0x2014 → second iteration of the minor loop.

e. Read byte from location 0x1018, read byte from location 0x1019, read byte from 0x101A, read byte from 0x101B.

f. Write 32-bits to location 0x2018 → third iteration of the minor loop.

g. Read byte from location 0x101C, read byte from location 0x101D, read byte from 0x101E, read byte from 0x101F.

h. Write 32-bits to location 0x201C → last iteration of the minor loop → major loop complete.

14. eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 2 (TCD*n*_BITER).

15. eDMA engine writes: TCD*n*_CSR[ACTIVE] = 0, TCD*n*_CSR[DONE] = 1, INT[n] = 1.

16. The channel retires → major loop complete. The eDMA goes idle or services the next channel.

36.6.4.3 Using the modulo feature

The modulo feature of the eDMA provides the ability to implement a circular data queue in which the size of the queue is a power of 2. MOD is a 5-bit field for the source and destination in the TCD, and it specifies which lower address bits increment from their original value after the address+offset calculation. All upper address bits remain the same as in the original value. A setting of 0 for this field disables the modulo feature.

The following table shows how the transfer addresses are specified based on the setting of the MOD field. Here a circular buffer is created where the address wraps to the original value while the 28 upper address bits (0x1234567*x*) retain their original value. In this example the source address is set to 0x12345670, the offset is set to 4 bytes and the MOD field is set to 4, allowing for a 2^4 byte (16-byte) size queue.

Table 36-5. Modulo example

Transfer Number	Address
1	0x12345670
2	0x12345674
3	0x12345678
4	0x1234567C
5	0x12345670
6	0x12345674

36.6.5 Monitoring transfer descriptor status

This section discusses how to monitor eDMA status.

36.6.5.1 Testing for minor loop completion

There are two methods to test for minor loop completion when using software initiated service requests. The first is to read the TCD*n*_CITER field and test for a change. Another method may be extracted from the sequence shown below. The second method is to test the TCD*n*_CSR[START] bit and the TCD*n*_CSR[ACTIVE] bit. The minor-loop-complete condition is indicated by both bits reading zero after the TCD*n*_CSR[START] was set. Polling the TCD*n*_CSR[ACTIVE] bit may be inconclusive, because the active status may be missed if the channel execution is short in duration.

The TCD status bits execute the following sequence for a software activated channel:

Stage	TCD*n*_CSR bits			State
	START	ACTIVE	DONE	
1	1	0	0	Channel service request via software
2	0	1	0	Channel is executing
3a	0	0	0	Channel has completed the minor loop and is idle
3b	0	0	1	Channel has completed the major loop and is idle

The best method to test for minor-loop completion when using hardware, that is, peripheral, initiated service requests is to read the TCD*n*_CITER field and test for a change. The hardware request and acknowledge handshake signals are not visible in the programmer's model.

The TCD status bits execute the following sequence for a hardware-activated channel:

Stage	TCD*n*_CSR bits			State
	START	ACTIVE	DONE	
1	0	0	0	Channel service request via hardware (peripheral request asserted)
2	0	1	0	Channel is executing
3a	0	0	0	Channel has completed the minor loop and is idle
3b	0	0	1	Channel has completed the major loop and is idle

For both activation types, the major-loop-complete status is explicitly indicated via the TCD*n*_CSR[DONE] bit.

The TCD*n*_CSR[START] bit is cleared automatically when the channel begins execution regardless of how the channel activates.

36.6.5.2 Reading the transfer descriptors of active channels

The eDMA reads back the true TCD*n*_SADDR, TCD*n*_DADDR, and TCD*n*_NBYTES values if read while a channel executes. The true values of the SADDR, DADDR, and NBYTES are the values the eDMA engine currently uses in its internal register file and not the values in the TCD local memory for that channel. The addresses, SADDR and DADDR, and NBYTES, which decrement to zero as the transfer progresses, can give an indication of the progress of the transfer. All other values are read back from the TCD local memory.

36.6.5.3 Checking channel preemption status

Preemption is available only when fixed arbitration is selected for both group and channel arbitration modes. A preemptive situation is one in which a preempt-enabled channel runs and a higher priority request becomes active. When the eDMA engine is not operating in fixed group, fixed channel arbitration mode, the determination of the actively running relative priority outstanding requests become undefined. Channel and/or group priorities are treated as equal, that is, constantly rotating, when Round-Robin Arbitration mode is selected.

The TCD*n*_CSR[ACTIVE] bit for the preempted channel remains asserted throughout the preemption. The preempted channel is temporarily suspended while the preempting channel executes one major loop iteration. If two TCD*n*_CSR[ACTIVE] bits are set simultaneously in the global TCD map, a higher priority channel is actively preempting a lower priority channel.

36.6.6 Channel Linking

Channel linking (or chaining) is a mechanism where one channel sets the TCD*n*_CSR[START] bit of another channel (or itself), therefore initiating a service request for that channel. When properly enabled, the EDMA engine automatically performs this operation at the major or minor loop completion.

The minor loop channel linking occurs at the completion of the minor loop (or one iteration of the major loop). The TCD*n*_CITER[E_LINK] field determines whether a minor loop link is requested. When enabled, the channel link is made after each iteration of the major loop except for the last. When the major loop is exhausted, only the major loop channel link fields are used to determine if a channel link should be made. For example, the initial fields of:

```
TCDn_CITER[E_LINK] = 1
TCDn_CITER[LINKCH] = 0xC
```

```
TCDn_CITER[CITER] value = 0x4
TCDn_CSR[MAJOR_E_LINK] = 1
TCDn_CSR[MAJOR_LINKCH] = 0x7
```

executes as:

1. Minor loop done → set TCD12_CSR[START] bit
2. Minor loop done → set TCD12_CSR[START] bit
3. Minor loop done → set TCD12_CSR[START] bit
4. Minor loop done, major loop done→ set TCD7_CSR[START] bit

When minor loop linking is enabled (TCD*n*_CITER[E_LINK] = 1), the TCD*n*_CITER[CITER] field uses a nine bit vector to form the current iteration count. When minor loop linking is disabled (TCD*n*_CITER[E_LINK] = 0), the TCD*n*_CITER[CITER] field uses a 15-bit vector to form the current iteration count. The bits associated with the TCD*n*_CITER[LINKCH] field are concatenated onto the CITER value to increase the range of the CITER.

Note

The TCD*n*_CITER[E_LINK] bit and the TCD*n*_BITER[E_LINK] bit must equal or a configuration error is reported. The CITER and BITER vector widths must be equal to calculate the major loop, half-way done interrupt point.

The following table summarizes how a DMA channel can link to another DMA channel, i.e, use another channel's TCD, at the end of a loop.

Table 36-6. Channel Linking Parameters

Desired Link Behavior	TCD Control Field Name	Description
Link at end of Minor Loop	CITER[E_LINK]	Enable channel-to-channel linking on minor loop completion (current iteration)
	CITER[LINKCH]	Link channel number when linking at end of minor loop (current iteration)
Link at end of Major Loop	CSR[MAJOR_E_LINK]	Enable channel-to-channel linking on major loop completion
	CSR[MAJOR_LINKCH]	Link channel number when linking at end of major loop

36.6.7 Dynamic programming

This section provides recommended methods to change the programming model during channel execution.

36.6.7.1 Dynamically changing the channel priority

The following two options are recommended for dynamically changing channel priority levels:

1. Switch to Round-Robin Channel Arbitration mode, change the channel priorities, then switch back to Fixed Arbitration mode,
2. Disable all the channels, change the channel priorities, then enable the appropriate channels.

36.6.7.2 Dynamic channel linking

Dynamic channel linking is the process of setting the TCD.major.e_link bit during channel execution (see the diagram in TCD structure). This bit is read from the TCD local memory at the end of channel execution, thus allowing the user to enable the feature during channel execution.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic channel link by enabling the TCD.major.e_link bit at the same time the eDMA engine is retiring the channel. The TCD.major.e_link would be set in the programmer's model, but it would be unclear whether the actual link was made before the channel retired.

The following coherency model is recommended when executing a dynamic channel link request.

1. Write 1 to the TCD.major.e_link bit.
2. Read back the TCD.major.e_link bit.
3. Test the TCD.major.e_link request status:
   - If TCD.major.e_link = 1, the dynamic link attempt was successful.
   - If TCD.major.e_link = 0, the attempted dynamic link did not succeed (the channel was already retiring).

For this request, the TCD local memory controller forces the TCD.major.e_link bit to zero on any writes to a channel's TCD.word7 after that channel's TCD.done bit is set, indicating the major loop is complete.

NOTE

The user must clear the TCD.done bit before writing the TCD.major.e_link bit. The TCD.done bit is cleared

automatically by the eDMA engine after a channel begins execution.

36.6.7.3 Dynamic scatter/gather

Scatter/gather is the process of automatically loading a new TCD into a channel. It allows a DMA channel to use multiple TCDs; this enables a DMA channel to scatter the DMA data to multiple destinations or gather it from multiple sources.When scatter/gather is enabled and the channel has finished its major loop, a new TCD is fetched from system memory and loaded into that channel's descriptor location in eDMA programmer's model, thus replacing the current descriptor.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic scatter/gather operation by enabling the TCD.e_sg bit at the same time the eDMA engine is retiring the channel. The TCD.e_sg would be set in the programmer's model, but it would be unclear whether the actual scatter/gather request was honored before the channel retired.

Two methods for this coherency model are shown in the following subsections. Method 1 has the advantage of reading the major.linkch field and the e_sg bit with a single read. For both dynamic channel linking and scatter/gather requests, the TCD local memory controller forces the TCD.major.e_link and TCD.e_sg bits to zero on any writes to a channel's TCD.word7 if that channel's TCD.done bit is set indicating the major loop is complete.

NOTE

The user must clear the TCD.done bit before writing the TCD.major.e_link or TCD.e_sg bits. The TCD.done bit is cleared automatically by the eDMA engine after a channel begins execution.

36.6.7.3.1 Method 1 (channel not using major loop channel linking)

For a channel not using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request.

When the TCD.major.e_link bit is zero, the TCD.major.linkch field is not used by the eDMA. In this case, the TCD.major.linkch bits may be used for other purposes. This method uses the TCD.major.linkch field as a TCD indentification (ID).

1. When the descriptors are built, write a unique TCD ID in the TCD.major.linkch field for each TCD associated with a channel using dynamic scatter/gather.
2. Write 1b to the TCD.d_req bit.

   Should a dynamic scatter/gather attempt fail, setting the TCD.d_req bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a dlast final offest value.

3. Write the TCD.dlast_sga field with the scatter/gather address.
4. Write 1b to the TCD.e_sg bit.
5. Read back the 16 bit TCD control/status field.
6. Test the TCD.e_sg request status and TCD.major.linkch value:

   If e_sg = 1b, the dynamic link attempt was successful.

   If e_sg = 0b and the major.linkch (ID) did not change, the attempted dynamic link did not succeed (the channel was already retiring).

   If e_sg = 0b and the major.linkch (ID) changed, the dynamic link attempt was successful (the new TCD's e_sg value cleared the e_sg bit).

36.6.7.3.2 Method 2 (channel using major loop channel linking)

For a channel using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request. This method uses the TCD.dlast_sga field as a TCD indentification (ID).

1. Write 1b to the TCD.d_req bit.

   Should a dynamic scatter/gather attempt fail, setting the d_req bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a dlast final offest value.

2. Write theTCD.dlast_sga field with the scatter/gather address.
3. Write 1b to the TCD.e_sg bit.
4. Read back the TCD.e_sg bit.

5. Test the TCD.e_sg request status:

   If e_sg = 1b, the dynamic link attempt was successful.

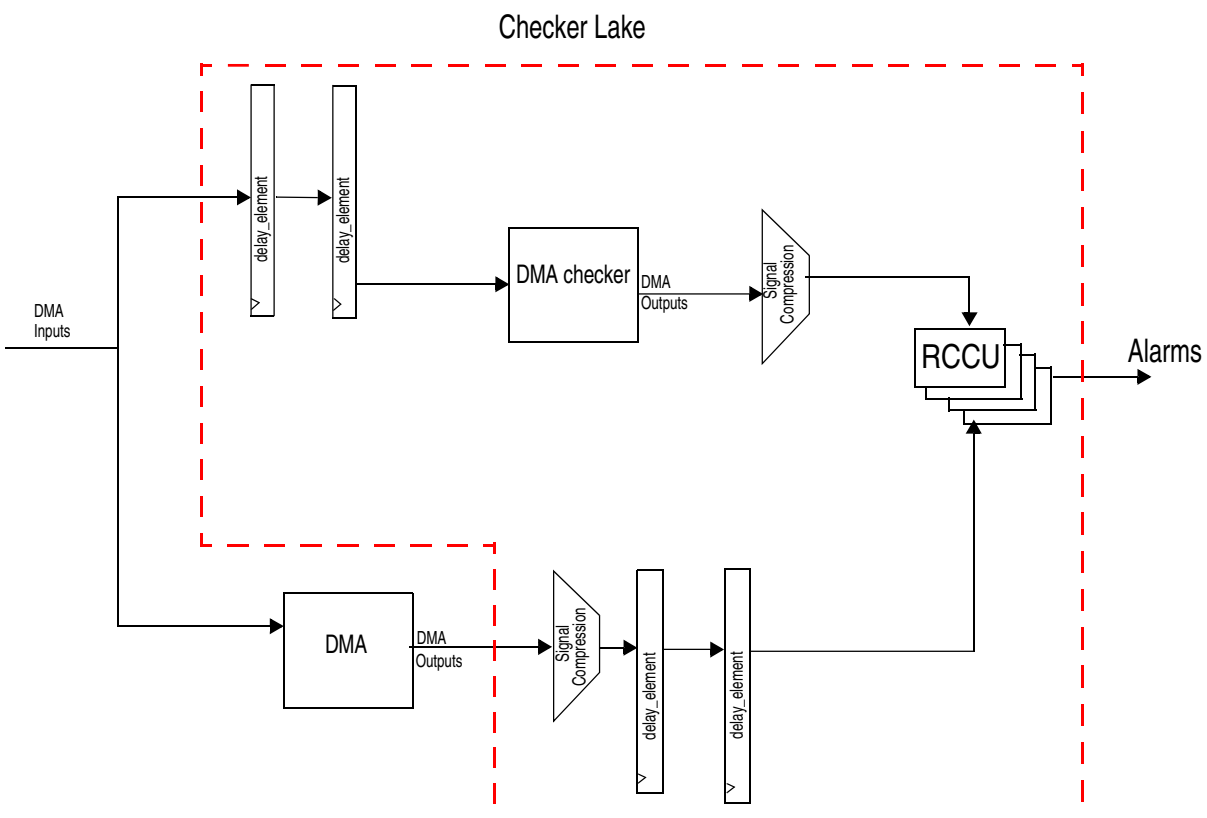
   If e_sg = 0b, read the 32 bit TCD dlast_sga field.

   If e_sg = 0b and the dlast_sga did not change, the attempted dynamic link did not succeed (the channel was already retiring).

   If e_sg = 0b and the dlast_sga changed, the dynamic link attempt was successful (the new TCD's e_sg value cleared the e_sg bit).

36.6.8 Lockstep

This chip contains an eDMA Checker which, when enabled, operates in Lockstep mode with the primary eDMA, executing the exact same transfer profiles. The eDMA Checker checks to ensure the primary eDMA is operating correctly. A block diagram is shown below.



36.6.8.1 Initialization

To prevent the eDMA Checker from generating a false comparison error after power-on-reset, the eDMA's data output buffer must be initialized prior to enabling the Checker. To initialize the eDMA data output buffer, the eDMA must perform a one or more 64-bit data transfers using any data value.

36.6.8.2 Errors

To handle source-address errors (SAE), perform the following steps.

1. Fix the addressing error.
2. Clear the error bit in Error Register (DMA_ERR).
3. Start the channel in a normal fashion.

NOTE

Error Status Register (DMA_ES) is read-only; the bits cannot be cleared. It saves the last recorded error. The VLD bit shows the user whether any error bits in the Error Register are set, thus indicating an error occurred that hasn't been cleared.

Chapter 37
Quad-ported RAM controller (PRAMC)

37.1 Introduction

This section provides an overview of the quad-ported Platform RAM Controller. The RAM controller acts as an interface between the system bus (AHB-Lite 2.v6) and multiple banks of integrated system RAM, enabling simultaneous SRAM accesses by multiple bus masters.

Internally the quad-ported RAM controller provides an independently-configurable RAM controller for each associated bank of SRAM. One of the internal RAM controllers supports the use of its associated SRAM as overlay SRAM. See the chip-specific information for details.

Figure 37-1 illustrates the quad-port RAM controller in the context of a typical SoC platform architecture. The RAM controller supports four 64-bit primary AHB interfaces, each to a separate system crossbar switch slave port, a backdoor AHB port to the on-chip flash controller, and a 64-bit RAM array interface to each associated bank of on-chip SRAM.

The primary AHB ports provide a connection to the platform crossbar for direct RAM access from the various system crossbar masters. The backdoor AHB port provides a connection from the flash controller to facilitate calibration overlay access.

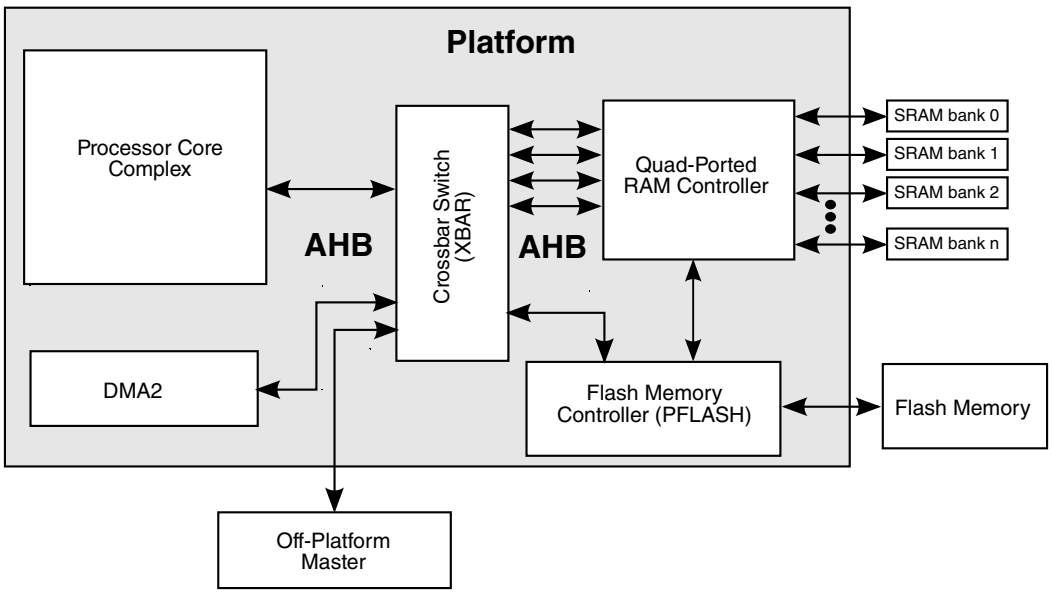


Figure 37-1. Simplified platform block diagram

The following list summarizes the key features of the RAM controller:

- End-to-End ECC (e2eECC) support
- System bus supports 64-bit data + 8-bit ECC AHB interfaces
- Array interfaces support a 64-bit data + 8-bit ECC interface
- Late-write support via 64-bit data + 8-bit ECC storage buffer to support single-cycle write accesses
- Configurable read access timing (zero or one wait-state programmable) allowing use in large range of frequency targets
- Read-modify-write operation to support array write size less than a double word

NOTE

1. Read-modify-write operations are performed for writes of less than 64-bits and writes not aligned with the 64-bit segments for which ECC check bits are calculated. The read-modify-write operations are necessary to preserve the integrity of the End-to_end ECC (e2eECC) check bits. See e2eECC considerations on less-than-64-bit write transactions for a detailed explanation.
2. The RAM controller supports parallel read-modify-write operations only to separate SRAM banks.

The address path of the RAM controller contains a mux that chooses among the addresses presented on the system bus for a read request, either the address from the temporary holding register or the address from the late-write buffer. The temporary holding register contains the address which was presented during the AHB address phase of the write

request. The request is stalled from being presented to the RAM by one cycle in order to present simultaneously the address and associated write data, which is not valid until the AHB data phase. The late-write buffer holds write requests which are delayed to facilitate single-cycle response on the system bus.

The read data path contains a mux that chooses the source of the read data to be presented on the system bus on a read request. In the event that a read request matches the contents of the late-write buffer, a RAM access is not required and the late-write buffer contents are selected onto the read data bus. Otherwise, the read data is a result of a RAM access. Along with the read and write data, the corresponding ECC codewords traverse the entire data path of the RAM controller, including the late-write storage buffer, to support end-to-end ECC (e2eECC) coverage.

The write data path contains the mux that chooses the source of the write data as well as the control logic for generating read-modify-write operations on writes that are less than 64 bits in size. A write operation can be performed to empty the contents of the late-write buffer. In the case of back-to-back writes, the write may be forced to bypass the late-write buffer and instead be stored directly, precisely in the RAM.

37.2 SRAM controller memory map and register definition

The quad-ported RAM controller module provides an IPS programming model mapped to a standard 16 KB on-platform peripheral slot. The programming model can only be referenced using a 32-bit (word) access. Attempted references using different access sizes or to undefined (reserved) addresses generate an IPS error termination.

NOTE

1. Due to the structure of the quad-ported RAM controller, there are other programming considerations that are discussed in the PRAM_XBAR section of the Embedded Memories chapter.
2. Attempted updates to the PRAMC programming model while a PRAMC operation is in progress will result in non-deterministic behavior. Software must be architected to avoid this scenario by ensuring that PRAMC configuration changes are made only during system boot or when only one master is enabled. In multi-core devices, update the PRAMC configuration only when one core is active and no other masters, e.g., DMA or communications modules, are enabled. Move any instruction execution or memory

references outside the system RAM while updating the PRAMC configuration, e.g., to the core local memory space.

PRAMC memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Platform RAM Configuration Register 1 (PRAMC_PRCR1)	32	R/W	0000_0100h	37.2.1/1342

37.3 Functional description

This section describes the functions of the RAM controller.

37.3.1 Read and Write operations

The RAM controller processes read and write requests to on-chip RAM and provides a register interface for access to performance tuning functions.

NOTE

The RAM controller register interface is accessible only in supervisor mode. Accesses in user mode return a transfer error.

37.3.1.1 Reads

Read transfers, of any size, can be configured to complete with a zero or one additional wait state response on the system bus.

37.3.1.2 Optional read wait-state

The RAM controller can be optionally programmed to register RAM read data prior to returning it on the system bus. Setting the PRCRx[FT_DIS] field inserts a register in the read data path for use when operating the controller at high frequencies. The state of PRCRx[FT_DIS] field has no effect on writes.

A random, initial access will take 2 clock cycles (2T) to complete if PRCRx[FT_DIS]=0, and a WRAP4 burst will have an access time of 2-2-2-2. A random, initial access will take 3 clock cycles (3T) to complete if PRCRx[FT_DIS]=1, and a WRAP4 burst will have an access time of 3-2-2-2.

NOTE

The number of cycles taken for a RAM access can vary ±1 clock cycle depending on the RAM speed relative to the PRAMC controller clock frequency. If system RAM is running at the same frequency as the PRAMC controller, a random initial access takes 2 clock cycles. If system RAM is running at a slower frequency, a random initial access may take 3 clock cycles. Subsequent burst beats take either 1 or 2 cycles

depending on RAM speed relative to the PRAMC controller clock frequency.

37.3.1.3 Writes

This section discusses various write operations of the RAM controller.

37.3.1.3.1 64-bit writes

Aligned 64-bit writes execute in a single AHB data phase cycle, allowing for zero wait states on back-to-back writes of these sizes. If, during the data phase of a write, a read is requested on the AHB, the write is registered in the late-write buffer, allowing the read to take place without a wait state. The valid buffered or late-write data is stored on the next available array address phase.

Back to back 64-bit writes execute slightly differently whereby the first write bypasses the late-write buffer. Rather, the write data is stored directly to the array in the same cycle in which it is valid on the AHB.

37.3.1.3.2 Less than 64-bit writes

Writes of size less than 64 bits incur a read-modify-write action as a consequence of the ECC coding scheme's 64-bit granularity. In the case of a read-modify-write action, the RAM controller performs SEC/DED on the read data. The write data is merged into the appropriate byte lanes along with the potentially corrected read data. A new codeword is generated based on the newly formed doubleword. The newly formed doubleword and its associated checkbits are subsequently written to the RAM. Figure 37-2 provides details on the read-modify-write datapath.

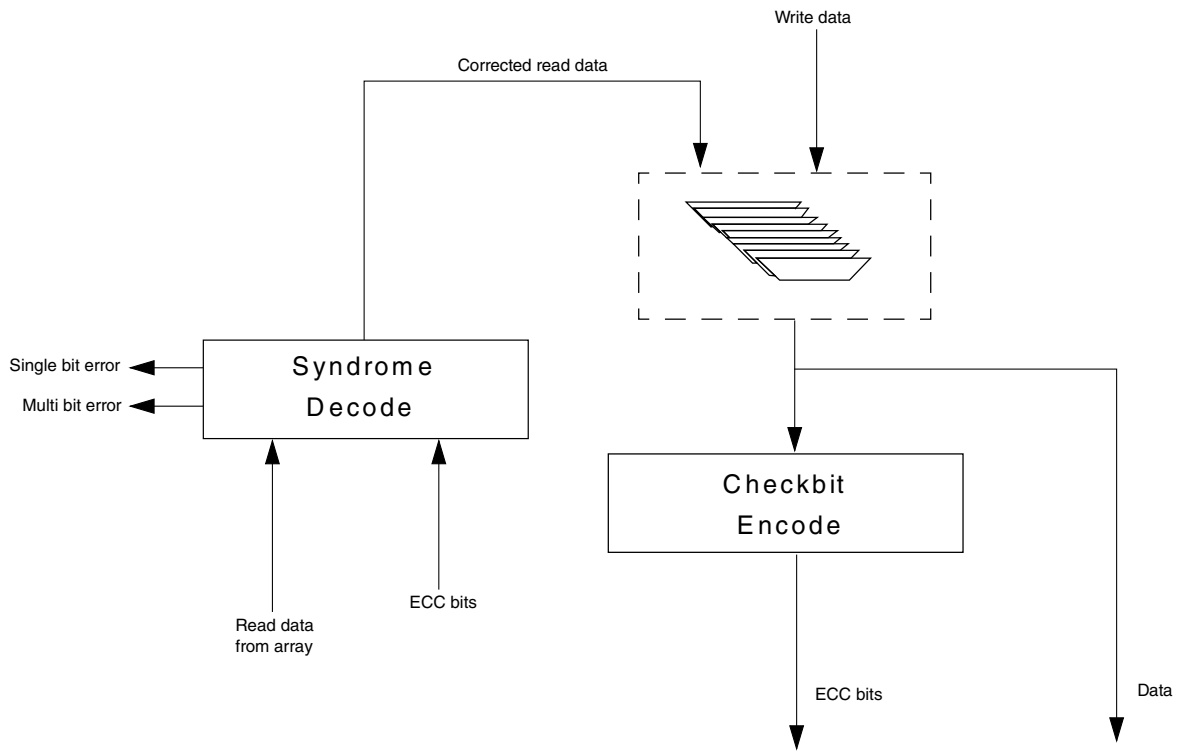

Figure 37-2. Read-modify-write datapath

On a read-modify-write operation, the array read data is registered after it is decoded and before it is merged with the AHB write data. Therefore, writes of size less than 64 bits require the insertion of one wait state before the data phase can be completed.

37.3.1.3.3 Unaligned writes

The RAM controller is compliant with the AMBA-AHB2.v6 Extensions specification with regard to byte strobes. The size of the transfer is sufficient to cover all bytes being written and covers more bytes in the case of an unaligned transfer. The address of the transfer is rounded down to the nearest boundary of the size of the transaction.

NOTE

Unaligned writes always generate read-modify-write operations in the RAM controller in order to preserve the validity of the ECC codeword.

37.4 Initialization/application information

It is essential that each memory address be written to a known value before it is read, to initialize the ECC. This includes reads generated from the read-modify-write operation which occurs when a write transfer of less than 64 bits or an unaligned write is requested. Without writing an address to a known value first, a read from this address will most likely generate an uncorrectable ECC event.

One possibility for initializing PRAMC memory space is to use a stored 64-bit word instruction such as Store Multiple Word (e_stmw) in Power Architecture VLE.

37.5 Reliability considerations

This section discusses reliability considerations of the RAM controller.

37.5.1 Hsiao ECC algorithm

The e2eECC scheme implements a single-error correction, double-error detection (SECDED) code using the so-called Hsiao odd-weight column criteria. These codes are named for M.Y. Hsiao, an IBM researcher who published extensively in the early 1970s on SECDED codes better suited for implementation in protecting (mainframe) computer memories than traditional Hamming codes.

The Hsiao codes are Hamming distance 4 implementations which provide the SECDED capabilities. The minimum odd-weight constraints defined by Hsiao are relatively simple in the resulting implementation of the parity check H matrix which defines the association between the data (and address) bits and the checkbits. They are:

1. There are no all-zeroes columns.
2. Every column is distinct.
3. Every column contains an odd number of ones, and hence is "odd weight".

In defining the H-matrix for this family of devices, these requirements from Hsiao were applied. Additionally, there are a variety of ECC codeword requirements associated with specific functional requirements associated with the system RAM that further dictated the specific column definitions. In any case, the resulting ECC is organized based on 64 data bits plus 29 address bits (the upper bits of the 32-bit address field minus the 3 bits which select the byte within the 64-bit (8-byte) data field.

The basic H-matrix for this (101, 93) code (93 is the total number of data bits, 101 is the total number of data bits (93) plus 8 checkbits) is shown in the following table. A '*' in the table indicates the corresponding data or address bit is XOR'ed to form the final checkbit value on the left. For 64-bit data writes, the table sections corresponding to D[63:32], D[31:0], and A[31:3] are logically summed (output of each table section is XOR'ed) together to the final value driven on the hwchkbit[7:0] outputs. Note that this table uses *the AHB bit numbering convention where bit[0] is the least significant bit*.

Table 37-1. RAM controller basic H-matrix definition

1. Bit numbering is AHB convention: bit 0 is LSB. D[7:0] corresponds to byte at address 0. D[63:56] corresponds to byte at address 7.

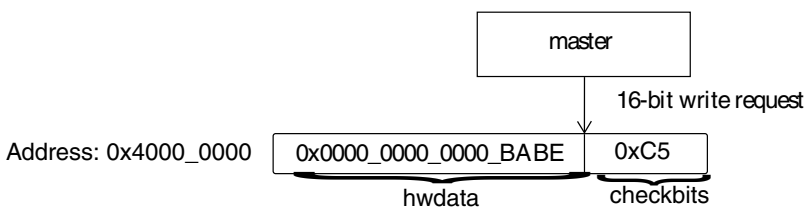
2. Bit numbering is AHB convention: bit 0 is LSB. D[7:0] corresponds to byte at address 0. D[63:56] corresponds to byte at address 7.

37.5.1.1 e2eECC considerations on less-than-64-bit write transactions

Recall writes of size less than 64-bit incur a read-modify-write action as a consequence of the ECC coding scheme 64-bit granularity. In the case of a read-modify-write action, the RAM controller performs SEC/DED on the read data. The RAM controller uses the following checkbit manipulation technique to ensure any faults in the PRAMC control logic associated with performing the read-modify-write action will ultimately be detectable by e2eECC:

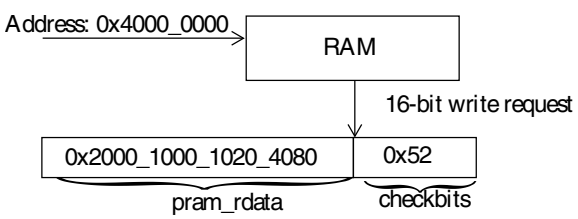
- On an 8-, 16-, or 32-bit write request, the write data is presented by the master on the AHB bus in the correct byte lanes, with the non-pertinent byte lanes zeroed out, and the associated checkbit is based on this "zero-padded" write data.

  Consider the following example whereby the master presents a 16-bit write request at address 0x40000000:

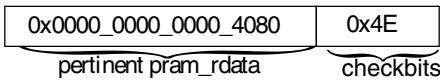


- The RAM controller detects that the request is a less-than-64-bit write request and initiates a read to address 0x40000000. An ECC check and potential single-bit correction is performed on the data returned from the RAM. In addition, the ECC event is reported to the Memory Error Management Unit (MEMU).

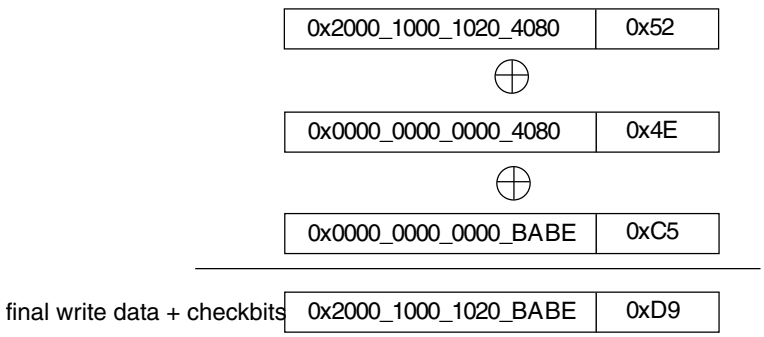
  If a non-correctable ECC event is detected, the AHB request is terminated with error on the system bus. In addition, the ECC event is reported to the MEMU.



- The RAM controller isolates the pertinent byte lanes of the read data by zero-padding the non-pertinent byte lanes and calculating the checkbit contribution associated with the read data in the byte lanes to be updated as a result of the write request.



- Merge the non-pertinent read data bytes with the write data in the appropriate byte lanes. Take the checkbit value that was stored in the RAM and remove the checkbit contribution associated with the read data in the byte lanes to be updated. Then introduce the checkbits associated with the write data. The result is ultimately a checkbit value associated with the complete 64-bit data to be written to the array.



This technique calculates the ultimate checkbit value on a read-modify-write transaction through a series of data manipulations, taking care to avoid discarding the original checkbits provided by the requesting master, such that faults in the crossbar (XBAR) and RAM controller datapath and control logic are covered by e2eECC.

Malfunction of the ECC logic described above may result in the corruption of the SEC/DED event reporting.

37.5.2 Transaction monitor

The integrity of the address and data on a system RAM transaction is covered by e2eECC check performed by the requesting master. Fault detection coverage of the address path and control within the RAM controller is handled by a transaction monitor which verifies the integrity of the transactions between the RAM controller and the RAM array. The transaction monitor verifies RAM transactions initiated to service the following types of transactions:

- Direct system bus read or write request
- Read followed by write to fulfill a read-modify write transaction
- Write transaction to empty the late-write buffer

The function of the transaction monitor relies on a feedback path between the RAM controller and RAM array, wherein the RAM provides latched address and control feedback outputs as an indication of received inputs when a RAM access is initiated.

This feedback information is used by the RAM controller transaction monitor to verify the expected transaction. If a mismatch is detected, indicating a failure in the address generation or control logic within the RAM controller or the transmission path between the RAM controller and RAM array, the event is forwarded to the Fault Collection and Control Unit (FCCU).

Since writes to the RAM can be buffered, the transaction monitor also tracks the contents of the late-write buffer. When the late-write buffer is emptied, outputs from the RAM are evaluated against the expected contents of the late-write buffer as tracked by the transaction monitor.

As a countermeasure against false misses to the late-write buffer on reads, the transaction monitor also verifies the expected source of data returned on a read as supplied either from the RAM or from the late-write buffer.

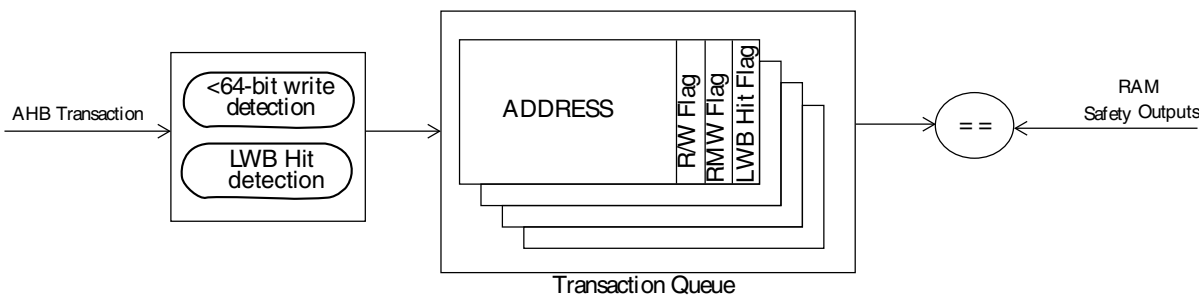


Figure 37-3. RAM controller transaction monitor block diagram

Chapter 38
Flash memory controller

38.1 Introduction

The flash memory controller has these functions:

- It acts as an interface between the system bus (AHB-Lite 2.v6) and the flash memory array.
- It serves as the interface to on-chip System RAM that can be used as overlay RAM.

The flash memory controller supports three 64-bit AHB buses and a 256-bit read data interface from each flash memory array. Each AHB port contains a 4-entry, 2-way set-associative mini-cache as well as an associated controller that prefetches sequential lines of data from the flash arrays into the mini-cache. This buffer mechanism serves to deliver flash read data with zero-wait state response on lines that reside in the cache. AHB requests that miss the cache generate the needed flash array access and are forwarded to the AHB upon completion. Each mini-cache entry is 256 bits in size, matching the flash array page size and providing 256 bytes of total buffered storage. Along with the read and write data, the corresponding ECC codewords traverse the entire datapath of the flash memory controller, including the mini-cache, to support end-to-end ECC (e2eECC) coverage.

38.2 Features

The following list summarizes the key features of the flash memory controller:

- Three 64-bit AHB interface (p0, p1, p2) allowing simultaneous access to dedicated prefetch mini-cache per slave port.
- 256-bit read data bus + 64-bit write data bus
- Configurable read buffering and line prefetching support via 4-entry, 2-way set-associative mini-cache plus prefetch controller per AHB port to provide single-cycle "buffer hit" read response.

- Configurable access control based on read/write and AHB master ID attributes.
- Configurable access timing (wait-state programmable) allowing use in a wide range of frequency targets.
- Optional address pipelining capability to maximize throughput.
- Support for reporting of single- and multi-bit flash ECC events on a 64-bit doubleword boundary.
- Configurable overlay remapping of logical flash accesses to on-chip system RAM

38.3 Block diagrams

Figure 38-1 illustrates the connections of the flash memory controller and flash memory array within the chip.

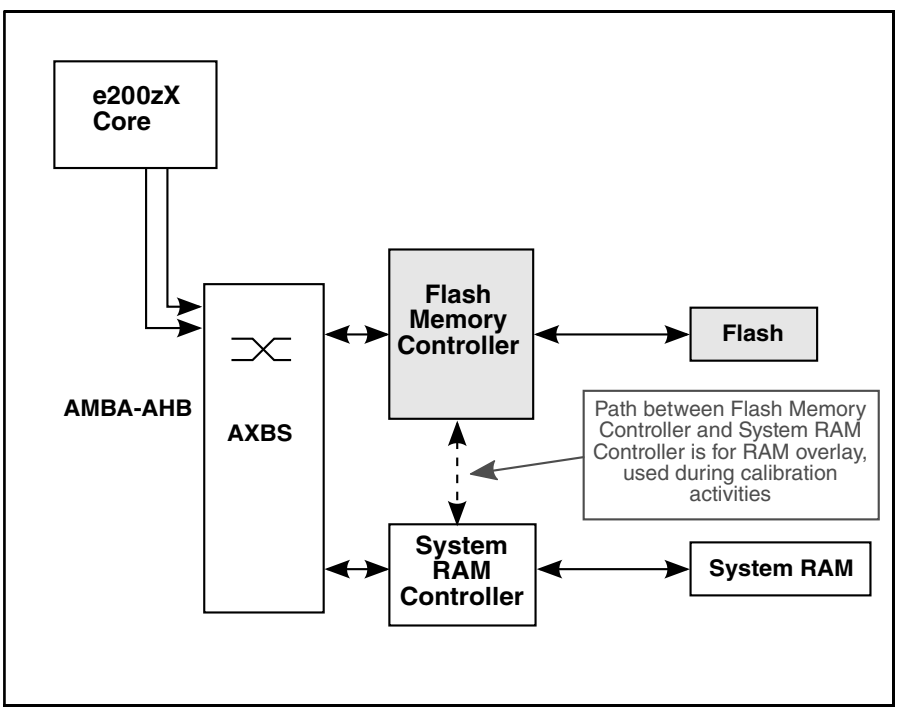

Figure 38-1. Platform-centric simple block diagram with flash memory controller

38.4 Flash memory controller memory map

The flash memory controller module provides an IPS programming model mapped to a standard 16 KB on-platform peripheral slot. The programming model consists of flash memory access configuration and overlay remapping configuration.

The programming model can only be referenced using a 32-bit (word) access. Attempted references using different access sizes or to undefined (reserved) addresses or in user mode generates an IPS error termination. The flash controller allows access to the programming model by all system bus masters.

The programming model can only be accessed in supervisor mode.

A write to any flash memory controller register, when executed concurrently with a flash memory access, will result in non-deterministic behavior and may include lockup of the flash memory controller. There is no idle indicator for the flash controller, so software must be architected to prevent any possible conflicts. The following recommendations will help.

- For multi-core devices, start only one core and execute initialization code to completion before starting the remaining cores.
- If flash must be reconfigured during application code execution, temporarily move all required code and data to system RAM before any writes to flash memory controller registers.
- If application software functionality includes invalidating a port read buffer, the recommended method for invalidating a port read buffer is:
  a. Unlock the buffer's enable field by setting the PFLASH_PFCR3[BFEN_LK] field to '0'
  b. Disable the buffer by setting it's associated enable field (PFLASH_PFCR1[Pn_BFEN]) to '0'
  c. If needed, enable the buffer by setting it's associated enable field (PFLASH_PFCR1[Pn_BFEN]) to '1'

The above method requires updating flash memory controller registers, so software must ensure that no flash accesses are issued concurrently with any of the steps. In cases where that cannot be guaranteed, there is a workaround but its use is not generally recommended because it relies on a hardware side effect instead of the flash memory controller's built-in functions intended for invalidating port read buffers. The workaround is to issue an interlock write without an accompanying program or erase operation—an interlock write, without an accompanying program or erase, does not change any flash content.

NOTE

1. If this workaround is implemented in application code, note that an interlock write invalidates only the buffers associated with the system bus port on which the interlock write was issued.
2. See the flash memory chapter for the steps to issue an interlock write.

3. See the flash memory controller's chip-specific information for any restrictions on the interlock write data size.

Field	Description
0 P0_M15PFE	Port0 Master 15 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 15. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
1 P0_M14PFE	Port0 Master 14 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 14. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
2 P0_M13PFE	Port0 Master 13 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 13. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
3 P0_M12PFE	Port0 Master 12 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 12. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
4 P0_M11PFE	Port0 Master 11 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 11. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
5 P0_M10PFE	Port0 Master 10 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 10. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
6 P0_M9PFE	Port0 Master 9 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 9. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
7 P0_M8PFE	Port0 Master 8 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 8. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
8 P0_M7PFE	Port0 Master 7 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 7. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
9 P0_M6PFE	Port0 Master 6 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 6. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
10 P0_M5PFE	Port0 Master 5 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 5. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master

Table continues on the next page...

PFLASH_PFCR1 field descriptions (continued)

Field	Description
11 P0_M4PFE	Port0 Master 4 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 4. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
12 P0_M3PFE	Port0 Master 3 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 3. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
13 P0_M2PFE	Port0 Master 2 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 2. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
14 P0_M1PFE	Port0 Master 1 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 1. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
15 P0_M0PFE	Port0 Master 0 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 0. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
16–18 APC	Address Pipeline Control. This field controls the number of cycles that a subsequent flash read from the opposite AHB port can be initiated prior to the previous read data being valid. This field applies to the configuration of Port0 and Port1. For valid RWSC and APC combinations please refer to the device data sheet. **NOTE:** 1. A value of '1' in the most significant bit causes the flash controller to function in retrograde/ legacy mode, in which there is no pipelining between the sampling of flash read data and the presentation of the next address for flash lookup. 2. Flash operation is not guaranteed for RWSC/APC combinations other than those specified in the data sheet. 000 Pipelined access to the flash disabled. 001 A pipelined access can be initiated 1 cycle before the previous data is valid 010 A pipelined access can be initiated 2 cycles before the previous data is valid 011 A pipelined access can be initiated 3 cycles before the previous data is valid 1xx Pipelined access to the flash is disabled and one wait state is inserted before a subsequent access can be initiated
19–23 RWSC	Read Wait State Control. This field controls the number of wait-states to be added to the best-case flash array access time for reads. The best-case flash array access time for reads is one cycle. This field must be set to a value corresponding to the operating frequency of the flash memory controller and the actual read access time of the flash memory controller. For valid RWSC and APC combinations please refer to the device data sheet. **NOTE:** 1. Higher operating frequencies require non-zero settings for this field for proper flash operation. 2. Flash operation is not guaranteed for RWSC/APC combinations other than those specified in the device data sheet. This field applies to the configuration of Port0, Port1, and Port2. 00000 No additional wait-states are added

Table continues on the next page...

PFLASH_PFCR1 field descriptions (continued)

Field	Description
	00001 One additional wait-state is added ... 11111 Thirty-one additional wait-states are added
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 P0_DPFEN	Port0 Data Prefetch Enable. This field enables or disables prefetching initiated by a data read access. 0 No prefetching is triggered by a data read access 1 Prefetching may be triggered by any data read access
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 P0_IPFEN	Port0 Instruction Prefetch Enable. This bit enables or disables prefetching initiated by an instruction read access. 0 No prefetching is triggered by an instruction read access 1 Prefetching may be triggered by any instruction read access
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–30 P0_PFLIM	Port0 PFlash Prefetch Limit. This field controls the prefetch algorithm used by the prefetch controller. This field defines a limit on the maximum number of sequential prefetches which will be attempted between buffer misses. In all situations when enabled, only a single prefetch is initiated on each buffer miss or hit. 00 No prefetching or buffering is performed. 01 The referenced line is prefetched on a buffer miss, that is, prefetch on miss. 10 The referenced line is prefetched on a buffer miss, or the next sequential line is prefetched on a buffer hit (if not already present), that is, prefetch on miss or hit. 11 The referenced line is prefetched on a buffer miss, or the next sequential line is prefetched on a buffer hit (if not already present), that is, prefetch on miss or hit.
31 P0_BFEN	Port0 PFlash Line Read Buffers Enable. This bit enables or disables line read buffer hits. It is also used to invalidate the buffers. This bit can only be updated while PFCR3[BFEN_LK]=0. 0 The line read buffers are disabled from satisfying read requests, and all buffer valid bits are cleared. 1 The line read buffers are enabled to satisfy read requests on hits. Buffer valid bits may be set when the buffers are successfully filled.

38.4.2 Platform Flash Configuration Register 2 (PFLASH_PFCR2)

The PFlash Configuration Register 2 (PFCR2) controls the operation of Port1 of the PFLASH_C55FM flash memory controller.

NOTE

See the chip-specific platform flash controller information for details about the masters.

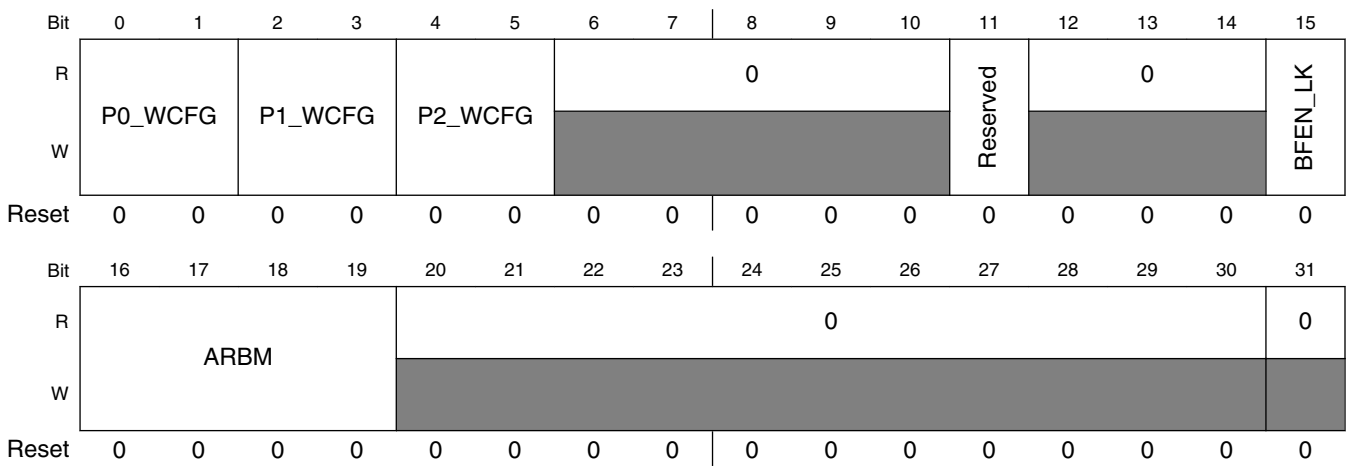
29–30 P1_PFLIM	Port1 PFlash Prefetch Limit. This field controls the prefetch algorithm used by the prefetch controller. This field defines a limit on the maximum number of sequential prefetches which will be attempted between buffer misses. In all situations when enabled, only a single prefetch is initiated on each buffer miss or hit. 00 No prefetching or buffering is performed. 01 The referenced line is prefetched on a buffer miss, that is, prefetch on miss. 10 The referenced line is prefetched on a buffer miss, or the next sequential line is prefetched on a buffer hit (if not already present), that is, prefetch on miss or hit. 11 The referenced line is prefetched on a buffer miss, or the next sequential line is prefetched on a buffer hit (if not already present), that is, prefetch on miss or hit
31 P1_BFEN	Port1 PFlash Line Read Buffers Enable. This bit enables or disables line read buffer hits. It is also used to invalidate the buffers. This bit can only be updated while PFCR3[BFEN_LK]=0. 0 The line read buffers are disabled from satisfying read requests, and all buffer valid bits are cleared. 1 The line read buffers are enabled to satisfy read requests on hits. Buffer valid bits may be set when the buffers are successfully filled.

38.4.3 Platform Flash Configuration Register 3 (PFLASH_PFCR3)

Address: 0h base + 8h offset = 8h



PFLASH_PFCR3 field descriptions

Field	Description
0–1 P0_WCFG	Port0 Way Configuration. This field controls the configuration of the line buffers for a given set across two ways in the controller cache. The indexed set can be organized as a "pool" of available resources, or with a fixed partition between instruction and data buffers.

Table continues on the next page...

PFLASH_PFCR3 field descriptions (continued)

Field	Description
	In all cases, when a buffer miss occurs, the flash page is assigned a location within the controller cache. Within the indexed set, the way is selected using a least-recently-used replacement policy, and the entry is then marked as most-recently-used for that set. If the flash access is for the next-sequential line (prefetch), the buffer is not marked as most-recently-used until the given address produces a buffer hit. This field is initialized by hardware reset. 00 Both buffers in an indexed set are available for any flash access, that is, there is no partitioning of the buffers based on the access type. 01 Reserved 10 The buffers in an indexed set are partitioned into two groups with way 0 allocated for instruction fetches and way 1 for data accesses. 11 Reserved
2–3 P1_WCFG	Port1 Way Configuration. This field controls the configuration of the line buffers for a given set across two ways in the controller cache. The indexed set can be organized as a "pool" of available resources, or with a fixed partition between instruction and data buffers. In all cases, when a buffer miss occurs, the flash page is assigned a location within the controller cache. Within the indexed set, the way is selected using a least-recently-used replacement policy, and the entry is then marked as most-recently-used for that set. If the flash access is for the next-sequential line (prefetch), the buffer is not marked as most-recently-used until the given address produces a buffer hit. This field is initialized by hardware reset. 00 Both buffers are available for any flash access, that is, there is no partitioning of the buffers based on the access type. 01 Reserved 10 The buffers are partitioned into two groups with way 0 allocated for instruction fetches and way 1 for data accesses. 11 Reserved
4–5 P2_WCFG	Port2 Line Buffer Configuration. This field controls the configuration of the line buffers for a given set across both ways in the controller cache. The indexed set can be organized as a “pool” of available resources, or with a fixed partition between instruction and data buffers. In all cases, when a buffer miss occurs, the flash page is assigned a location within the controller cache. Within the indexed set, the way is selected using a least-recently-used replacement policy, and the entry is then marked as most-recently-used for that set. If the flash access is for the next-sequential line (prefetch), the buffer is not marked as most-recently-used until the given address produces a buffer hit. This field is initialized by hardware reset. 00 Both buffers are available for any flash access, that is, there is no partitioning of the buffers based on the access type. 01 Reserved 10 The buffers are partitioned into two groups with buffer 0 allocated for instruction fetches and buffer 1 for data accesses. 11 Reserved
6–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 Reserved	This field is reserved.
12–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

PFLASH_PFCR3 field descriptions (continued)

Field	Description
15 BFEN_LK	BFEN Lock. This field controls access to the PFCRm[Pn_BFEN] fields, which enable or disable line read buffer hits and are also used to invalidate the buffers. After this field is set to 1, it can be cleared to 0 only by a system reset. 0 PFCRm[Pn_BFEN] fields are R/W. 1 PFCRm[Pn_BFEN] fields are Read-only.
16–19 ARBM	Arbitration Mode. This 4-bit field controls the arbitration of concurrent flash access requests from the three AHB ports of the flash memory controller. In both fixed priority or round-robin modes, write requests are prioritized higher than read requests, and read requests are prioritized higher than speculative prefetch requests whenever multiple ports issue concurrent requests. This field is initialized by hardware reset. **NOTE:** Specifying a reserved value in this field causes it to default to round-robin arbitration. 0000 Fixed priority arbitration with AHB p0>p1>p2 0001 Fixed priority arbitration with AHB p0>p2>p1 0010 Fixed priority arbitration with AHB p2>p0>p1 0011 Fixed priority arbitration with AHB p2>p1>p0 0100 Fixed priority arbitration with AHB p1>p0>p2 0101 Fixed priority arbitration with AHB p1>p2>p0 0110 Reserved 0111 Reserved 1000 Reserved 1001 Reserved 1010 Reserved 1011 Reserved 1100 Reserved 1101 Reserved 1110 Reserved 1111 Round-robin arbitration

PFLASH_PFAPR field descriptions

Field	Description
0–1 M0AP	Master 0 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
2–3 M1AP	Master 1 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
4–5 M2AP	Master 2 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
6–7 M3AP	Master 3 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
8–9 M4AP	Master 4 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
10–11 M5AP	Master 5 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master

38.4.5 Platform Flash Remap Control Register (PFLASH_PFCRCR)

The PFCRCR is used to globally enable/disable the calibration remap function.

CAUTION

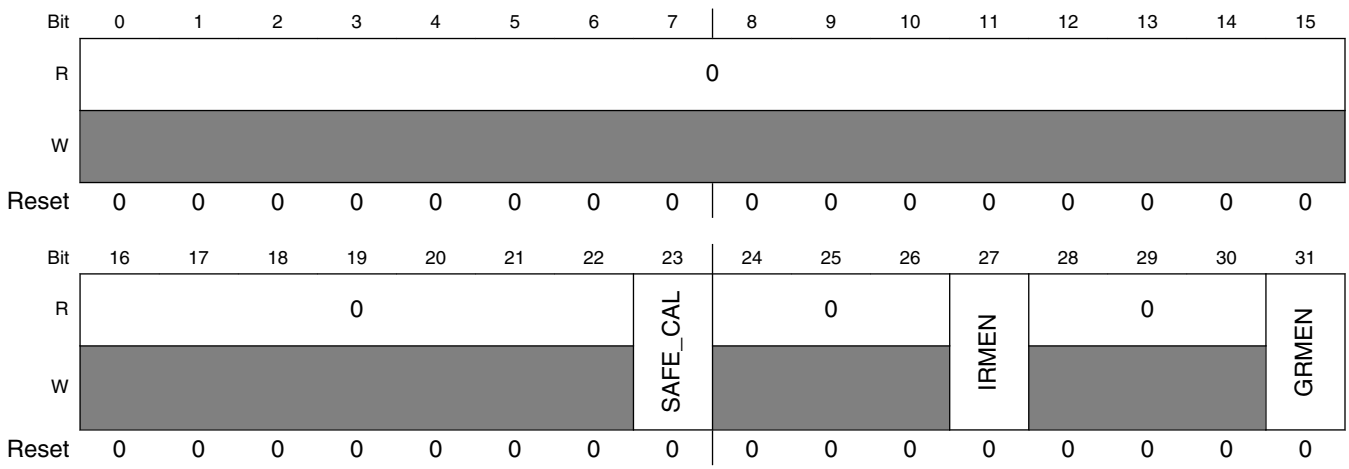
Overlay remap functions, when used with line read buffers enabled (PFLASH_PFCRx[BFy_EN] field(s)='1') have a potential to cause data coherency issues, i.e., prefetched data in a line read buffer can become out-of-sync with data contained at the associated flash address range. To prevent this issue, always clear the flash controller line read buffers prior to enabling any remap region.

To clear the flash controller line read buffers, issue an interlock write command to a valid flash memory address. There will not be an actual flash program operation performed, but the flash controller mini-cache will be cleared as a side effect of

executing the command. The interlock write must be issued from a core having appropriate access to flash. The sequence is as follows:

1. Set the C55FMC_MCR[PGM] field to '1'
2. Issue a 64-bit write to a valid flash address on a 64-bit boundary, i.e., the least significant 5 bits of the address are '0'
3. Clear C55FMC_MCR[PGM]

Address: 0h base + 10h offset = 10h



PFLASH_PFCRCR field descriptions

Field	Description
0–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 SAFE_CAL	Safe Calibration. This bit facilitates the use of safety-critical calibration data. When this bit is enabled, the flash memory controller is configured to perform redundancy checking on the calibration remap function and reduce the total number of potential calibration regions from 8 to 4. This field is initialized by hardware reset. 1 Established calibration overlay regions are considered safety-critical. 0 Established calibration overlay regions are not considered safety-critical.
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 IRMEN	Instruction Remap. This bit enables calibration remapping evaluation on instruction fetches. When PFCRCR[GRMEN] is disabled, this bit is ignored. This field is initialized by hardware reset. 0 Calibration remap evaluation is performed on any incoming data fetch requests only. 1 Calibration remap evaluation is performed on all incoming flash access requests - data and instruction fetches.
28–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Field	Description
31 GRMEN	Global Remap Enable. This bit globally enables or disables the calibration remapping evaluation on system flash accesses. This field is initialized by hardware reset. 0 Calibration remap evaluation is not performed on any incoming system flash access requests. 1 Calibration remap evaluation is performed on all incoming system flash access requests.

38.4.6 Platform Flash Remap Descriptor Enable Register (PFLASH_PFCRDE)

The PFlash Calibration Remap Descriptor Enable Register (PFCRDE) is used to enable or disable up to 8 calibration remap descriptors. Note there is also a global remap enable (PFCRCR[GRMEN]) that also must be asserted in conjunction with the individual CRDnEN flags to enable a given remap descriptor.

Address: 0h base + 14h offset = 14h

Table continues on the next page...

PFLASH_PFCR4 field descriptions (continued)

Field	Description
	0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
14 P2_M1PFE	Port2 Master 1 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 1. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
15 P2_M0PFE	Port2 Master 0 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 0. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
16–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 P2_DPFEN	Port2 Data Prefetch Enable. This field enables or disables prefetching initiated by a data read access. 0 No prefetching is triggered by a data read access 1 Prefetching may be triggered by any data read access
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 P2_IPFEN	Port2 Instruction Prefetch Enable. This bit enables or disables prefetching initiated by an instruction read access. 0 No prefetching is triggered by an instruction read access 1 Prefetching may be triggered by any instruction read access
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–30 P2_PFLIM	Port2 PFlash Prefetch Limit. This field controls the prefetch algorithm used by the prefetch controller. This field defines a limit on the maximum number of sequential prefetches which will be attempted between buffer misses. In all situations when enabled, only a single prefetch is initiated on each buffer miss or hit. 00 No prefetching or buffering is performed. 01 The referenced line is prefetched on a buffer miss, that is, prefetch on miss. 10 The referenced line is prefetched on a buffer miss, or the next sequential line is prefetched on a buffer hit (if not already present), that is, prefetch on miss or hit. 11 The referenced line is prefetched on a buffer miss, or the next sequential line is prefetched on a buffer hit (if not already present), that is, prefetch on miss or hit
31 P2_BFEN	PFlash Line Read Buffers Enable. This bit enables or disables line read buffer hits. It is also used to invalidate the buffers. This bit can only be updated while PFCR3[BFEN_LK]=0. 0 The line read buffers are disabled from satisfying read requests, and all buffer valid bits are cleared. 1 The line read buffers are enabled to satisfy read requests on hits. Buffer valid bits may be set when the buffers are successfully filled.

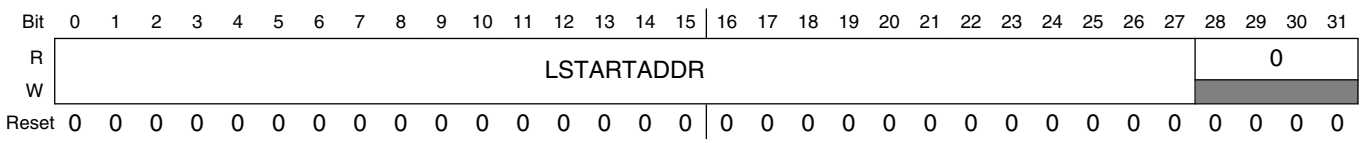
38.4.8 Platform Flash Calibration Region Descriptor n Word0 (PFLASH_PFCRD*n*_Word0)

Each 96-bit (12-byte) region descriptor specifies an overlay region where a flash access can be remapped during calibration and debug. The calibration remap descriptors are organized sequentially as 128-bit (16-byte) structures in the Platform Flash Controller's programming model. Each of the three 32-bit words that define a single calibration region are detailed in the subsequent sections; the fourth word is unused.

The first word of the flash memory controller overlay region descriptor defines the 0-modulo-size logical start (byte) address of the calibration remap region. It is software's responsibility to guarantee the low-order bits of the address, as defined by the remap descriptor size, are zeroed to enable the remap descriptor hit logic to function correctly.

The hardware performs basic checks on the validity of the logical start address when this word is written; if a non-supported logical start address is defined, the register write is terminated with an error and the register left unchanged and the valid bit cleared. Successful writes to this word also clear the calibration remap descriptor's valid bit.

Address: 0h base + 100h offset + (16d × i), where i=0d to 7d



PFLASH_PFCRD*n*_Word0 field descriptions

Field	Description
0–27 LSTARTADDR	Logical Start Address. This field defines the most significant bits of the 0-modulo-size logical start address of the overlay remap region. It corresponds to the logical system address which maps to the flash memory space. Any write to PFCRDn.Word{0,1,2} clears the corresponding PFCRDE[CRDnEN] bit, leaving the calibration remap descriptor invalid.
28–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

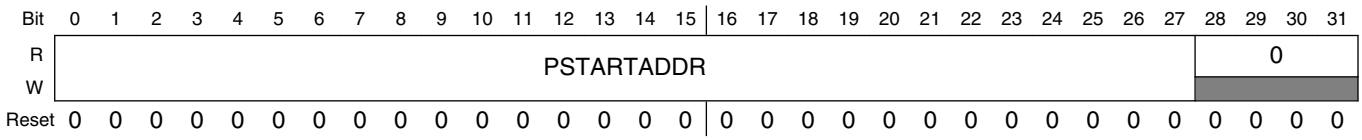
38.4.9 Platform Flash Calibration Region Descriptor n Word1 (PFLASH_PFCRD*n*_Word1)

The second word of the flash memory controller calibration region descriptor defines the 0-modulo-size byte physical start (byte) address of the calibration remap region.

The contents of this word define the targeted destination overlay memory. It is software's responsibility to guarantee the low-order bits of the address, as defined by the remap descriptor size, are zeroed to enable the remap descriptor hit logic to function correctly.

Attempted writes to this register with illegal values, as defined by the sizes and locations of the overlay memories, are terminated with an error and clear the valid bit. Successful writes to this word also clear the calibration remap descriptor's valid bit.

Address: 0h base + 104h offset + (16d × i), where i=0d to 7d



PFLASH_PFCRD*n*_Word1 field descriptions

Field	Description
0–27 PSTARTADDR	Calibration Remap Descriptor *n* Physical Start Address - This field defines the most significant bits of the 0-modulo-size physical start byte address of the calibration remap descriptor. This address corresponds to the physical address which maps to the destination calibration overlay memory. Any write to PFCRDn.Word{0,1,2} clears the corresponding PFCRDE[CRDnEN] bit, leaving the calibration remap descriptor invalid.
28–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

38.4.10 Platform Flash Calibration Region Descriptor n Word2 (PFLASH_PFCRD*n*_Word2)

The third word of the calibration region descriptor defines a per-master calibration remap enable and the remap region size. For cacheable spaces being remapped, the minimum region size is 32 bytes to match the flash page and cache line sizes. Writes to this word clear the calibration remap descriptor's valid bit.

Address: 0h base + 108h offset + (16d × i), where i=0d to 7d

38.5 Functional description

The flash memory controller interfaces between:

- The AHB system bus ports
- Flash memory array
- System RAM

For accesses targeting the flash array, the flash memory controller generates read and write enables, block selects, array address, write size and write data as inputs to the flash array. The flash memory controller captures read data from the flash array and drives it onto the AHB system bus. Up to four pages of data (256-bit page size) may be buffered in each of two ways of the flash memory controller mini-cache. Lines may be prefetched in advance of being requested, allowing single-cycle (zero AHB wait-states) read data responses on buffer hits.

Several prefetch control algorithms are available for controlling line read buffer fills. Prefetch triggering may be restricted to instruction accesses only, data accesses only, or may be unrestricted. Prefetch triggering may also be controlled on a per-master basis.

Buffers may also be selectively enabled or disabled for allocation by instruction and data prefetch.

Access protections may be applied on a per-master basis for both reads and writes to support security and privilege mechanisms.

38.5.1 Basic interface protocol

Read accesses are terminated under control of the appropriate wait state settings. Thus, the access time of the operation is determined by the setting of the PFCR1[RWSC] field. Access timing can be varied to account for the operating conditions of the SoC (frequency, voltage, temp) by appropriately setting the PFCR1[RWSC] field.

38.5.2 Access protections

On-chip Flash memory accesses are subject to restrictions based on chip security implementation and/or requirements based on functional restrictions of the flash memory, e.g., a read access to a flash block while it is currently being written is not allowed. When a prohibited access is attempted, a system bus error termination results.

The flash memory controller may invoke a system bus error termination in the following scenarios:

- Attempted access by an AHB master whose corresponding read access control or write access control settings do not allow the access, thus causing a protection violation. See Platform Flash Access Protection Register (PFLASH_PFAPR) for more detail. In this case the flash memory controller does not initiate the requested flash array access.
- The flash returns an error response on an attempted access to a partition that is unavailable. (see Flash error response operation or Embedded Flash Memory).
- Attempted access by an AHB master to a reserved region in the flash memory map.

The flash array may also signal an error response to terminate a requested access due to improper sequencing during program/erase operations, improper sequencing during array integrity testing. When an error response is received the flash memory controller does not update or validate a page read buffer. An error response may be signaled on a read or interlock write operation. For more information on the specifics related to signaling of flash errors, including flash ECC events, array integrity testing and read-while-write events, refer to the flash memory chapter.

38.5.2.1 PFAPR - Platform Flash Access Protection Register (PFAPR)

The flash memory controller provides programmable, configurable access protections for both read and write cycles on a per-master basis via the PFlash Access Protection Register (PFAPR). It allows restriction of read and write requests on a per-master basis. This functionality is described in Platform Flash Access Protection Register (PFLASH_PFAPR). Detection of a protection violation results in an error response from the flash memory controller on the AHB transfer.

38.5.3 Security Module Alternate Programming Interface

The secure flash space is independently controlled for each of the following regions:

- 16 KB CSE2 flash block0 at address range 00A0_0000h - 00A0_3FFFh
- 16 KB CSE2 flash block1 at address range 00A0_4000h - 00A0_7FFFh

38.5.4 Access pipelining

Accesses to the flash array may be pipelined by driving a subsequent access address and control signals while waiting for the current access to complete. Pipelined access requests are always run to completion and are not aborted by the flash memory controller. Flash access pipelining allows for improved performance by reducing the access latency seen by the AHB master. Access pipelining may be applied only to read cycles targeting the flash array. Address pipelining is enabled by setting the PFCR1[APC] field.

Access pipelining is only supported for normal flash access and is not supported for calibration overlay RAM fetches. On calibration reads, the setting of PFCR1[APC] is ignored.

NOTE

Not all combinations of PFCR1[APC] (Address Pipeline Control) and PFCR1[RWSC] (Read Wait State Control) settings are recommended or supported. Please refer to the device data sheet for guidance.

38.5.5 Line read buffers and prefetch operation

The AHB ports of the flash memory controller each contain a two-way set-associative mini cache, where each way contains four page buffers which are used to hold data read from the flash arrays. Each 256-bit buffer operates independently, and is filled using a single array access. The buffers are used for both prefetch and normal demand fetches.

Prefetch triggering is controllable on a per-master and access-type basis (see Platform Flash Configuration Register 1 (PFLASH_PFCR1)). Bus masters may be enabled or disabled from triggering prefetches, and triggering may be further restricted based on whether a read access is for instruction or data. A read access by the flash memory controller may trigger a prefetch to the next sequential line of array data on the cycle following the request. The access address is incremented by 32-bytes, and a subsequent flash access is initiated. A flash array prefetch is initiated if the data is not already resident in a line read buffer. Prefetched data is always loaded into the least-recently-used buffer.

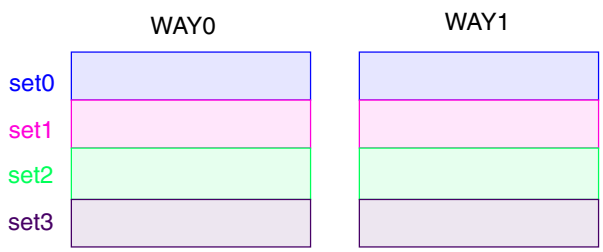

Figure 38-2. Flash memory controller 4-entry, 2-way mini-cache organization

Once the candidate line buffer has been selected, the flash array is accessed and read data loaded into the buffer. If the buffer load was in response to a miss, the buffer which was loaded is immediately marked as most-recently-used. If the buffer load was in response to a speculative fetch to the next-sequential line address after a buffer hit, *the recently-used status is not changed*. Rather, it is marked as most-recently-used only after a subsequent buffer hit.

This policy maximizes performance based on reference patterns of flash accesses and allows for prefetched data to remain valid when non-prefetch enabled bus masters are granted flash access.

Several algorithms are available for prefetch control which trade off performance for power. They are described in Platform Flash Configuration Register 1 (PFLASH_PFCR1). More aggressive prefetching may increase power due to the number of potentially discarded prefetches, but may increase performance by lowering average read latency.

For prefetching to occur, all of the following must apply:

1. PFCR{1,2,4}[P{0,1,2}_BFEN] must be set to ‘1’,

2. PFCR{1,2,4}[P{0,1,2}_PFLIM] must be non-zero, and
3. Either PFCR{1,2,4}[P{0,1,2}_IPFEN] or PFCR{1,2,4}[P{0,1,2}_DPFEN] must be asserted.

Refer to Platform Flash Configuration Register 1 (PFLASH_PFCR1) for a description of these controls.

38.5.6 Instruction/Data prefetch triggering

Port0 prefetch triggering may be enabled for instruction reads via the PFCR1[IPFEN] control field, while Port0 prefetching for data reads is enabled via the PFCR1[DPFEN] control field. Additionally, the PFCR1[PFLIM] must also be set to enable prefetching on Port0. Refer to Platform Flash Configuration Register 1 (PFLASH_PFCR1) for a description of these controls. Prefetches are never triggered by write cycles.

Port1 prefetch triggering may be enabled for instruction reads via the PFCR2[IPFEN] control field, while Port1 prefetching for data reads is enabled via the PFCR2[DPFEN] control field. Additionally, the PFCR2[PFLIM] must also be set to enable prefetching on Port1. Refer to Platform Flash Configuration Register 2 (PFLASH_PFCR2) for a description of these controls. Prefetches are never triggered by write cycles.

Port2 prefetch triggering may be enabled for instruction reads via the PFCR4[IPFEN] control field, while Port2 prefetching for data reads is enabled via the PFCR4[DPFEN] control field. Additionally, the PFCR4[PFLIM] must also be set to enable prefetching on Port2. Refer to the Platform Flash Configuration Register 4 (PFCR4) section for a description of these controls. Prefetches are never triggered by write cycles.

38.5.7 Per-Master prefetch triggering

Prefetch triggering may be controlled for individual bus masters. Refer to Platform Flash Configuration Register 1 (PFLASH_PFCR1) for a description of these controls.

38.5.8 Buffer allocation

Allocation of the line read buffers is controlled via the PFCR3 control register, specifically the line buffer configuration ({P0,P1,P2}_WCFG) field. Refer to Platform Flash Configuration Register 3 (PFLASH_PFCR3). The buffers can be organized as a "pool" of available resources (with both ways within a given set) or with a fixed partition between ways allocated to instruction or data accesses. For the fixed partitions, way 0 is allocated for instruction fetches and way 1 for data accesses.

38.5.9 PFlash calibration remap support

The flash memory controller supports calibration development by providing a remapping function to route flash accesses to on-chip System RAM that can be used as overlay RAM.

The overlay function supports the following features:

- Can be mapped over internal flash memory
  - Allows calibration of constant data without requirement for additional external RAMs and calibration memory interfaces
- Protected with error detection and correction mechanism
- Accesses to all overlay RAMs can achieve the same timing as accesses to internal flash
  - Timing for calibration accesses to overlay RAM is only guaranteed if RWSC is set sufficiently high to cover the intrinsic burst access incurred when fetching a full page of calibration data
- Support for up to 32 distinct calibration remap regions.
- Protection against accidental enable and reconfiguration of calibration remap function :
  - Two stage mechanism to enable remap, using both global and individual calibration region descriptor enable bits
  - Optional configuration of calibration region descriptors as redundant pairs, allowing detection of accidental region reconfiguration.
- Support for overlay remapping to unique calibration regions on a per-master basis.

The calibration remap function supports the following overlay targets:

- A portion of the system RAM can be used for overlay.

38.5.9.1 PFlash calibration remap to RAM

The overlay RAM is selected based on the translated physical address.

The translated physical address defines the destination memory. Table 38-1 shows the base addresses for the calibration data memories as defined by the system memory map.

Table 38-1. Calibration data memory base addresses

Calibration Memory	Base Address	Possible Access Sources
Flash Arrays	0x0{8,9,A}--_----	P0, P1
System RAM	0x40{0,1}-_----	P0, P1

The system RAM connection from the calibration remap logic is implemented via a private 64-bit connection to the platform RAM controller.

Accesses to the flash arrays always use the logical, non-remapped system address. Calibration data store references to the system RAM always use the physical, non-remapped system address. Conversely, calibration data load references can be accessed using a translated physical address or, if provided by the requesting master, the physical, non-remapped system address.

The read data interface of system RAM is 64 bits wide , whereas the flash read data interface is 256 bits wide. As a result, a remapped calibration load access initiates a four-beat burst sequence to mimic the throughput of a single flash access. There is a direct relationship between the operating frequency range and the required number of wait states to correctly sample flash read data. By contrast, a remapped calibration load access has a fixed, intrinsic 4-beat latency. Therefore, in order for an initial, random calibration load access to mimic the flash access time, PFCR1[RWSC] read wait state setting must be programmed to a value which sufficiently covers the intrinsic access time to complete a four-beat burst sequence from the slowest available overlay target at the specified device operating frequency. Expressed mathematically:

$$(\mathrm{RWSC}+2) \geq \left(\frac{\mathrm{IntrinsicFlashAccessTime}}{\mathrm{OperatingFrequencyClockPeriod}}+2\right) \geq (\mathrm{OverlayRAMTransferBurstLatency})$$

Equation 12. Access time

Notice the overall latency on a random, initial flash access that does not hit in the prefetch mini-buffer incurs an additional cycle latency beyond the intrinsic flash access time. This cycle accounts for pipeline stalls incurred by the flash controller state machine. The formula above is based on specified intrinsic flash access times of the C55FMC array at 150 °C. Calibration data that is loaded in the flash controller's mini-cache is returned with single-cycle latency.

The memory-mapped calibration remap (region) descriptor (CRD*n*) registers define the required address translation. Each calibration remap descriptor includes the logical base address, the translated physical base address and a region size (plus other control bits). The calibration remap evaluation is initiated when the flash controller is presented with a flash access request from any system bus master to a location in the mirrored flash address space. Conversely, references using the associated non-mirrored flash system address are not evaluated for calibration remapping.

The address translation mechanism requires the logical and physical base addresses of the region be aligned on 0-modulo-size boundaries.

The region size is decoded to create the appropriate address bit enables which are then applied to the registered logical flash address. An equality comparator then compares the adjusted logical flash address against the logical address from the calibration remap

descriptor to determine the region "hit". The hit determination is further qualified based on the bus master number that initiated the flash access. At the same time, the logical flash address and the physical address defined in the calibration remap descriptor are merged to form the translated address to be used in the event of a calibration region hit. Aside from the individual instantiations of the calibration remap descriptors, this logic examines all the descriptor hit indicators to select the appropriate translated address.

In the absence of a region "hit" data is returned from the flash at the provided logical address.

It should be noted in the event of *overlapping remap regions*, the calibration remap descriptor with the largest number is used for the address translation, that is, if a logical flash address hits in multiple descriptors, say CRDx and CRDy, the translated address from CRDy is used, given y > x.

In general, the calibration remap logic operates only on flash *data* accesses. However, flash instruction references can optionally remapped while in debug modes of operation to support the use of software breakpoints when PFCRC[IRMEN] is set.

38.5.10 Reliability considerations

This section summarizes mechanism to enhance the reliability of flash by correcting and detecting faults.

38.5.10.1 e2eECC End-to-End ECC

38.5.10.1.1 e2eECC and flash accesses

There are multiple complications associated with the use of the standard e2eECC algorithm with flash memory. The basic issues involve: the default state of a flash block that is erased (all ones) and the fact that programming an erased flash involves changing the state of memory bit from a logical 1 to a logical 0. These factors require that the system level e2eECC must be modified on references to the flash memory in three ways.

First, the all-ones codeword, since it reflects the state of an erased flash location, is treated as a valid error free encoding; in particular, it is required that the checkbits associated with the all all-ones value and the all zeroes data value are required to be the same with a checkbit value of 0xFF. Second, since an erased flash block generates an all-ones data for all locations, the address field cannot be included in the ECC code used by the flash. The flash array implements special address re-encoding logic based on the decoded array address to protect against address faults. Third, there are additional ECC

implications associated with the flash memory and its support for EEPROM emulation. Lastly, there are ECC implications associated with the storage and retrieval of overlaid calibration data.

In summary, the basic operation of an NVM bit cell impacts the e2eECC algorithm used in the flash memory in multiple ways. The required ECC adjustments are handled by the platform flash controller before data is written to the flash array(s) or applied to read data accessed from the array(s). These adjustments are two-fold. Consider a flash write during a programming event:

1. Remove the address field from the ECC codeword by XOR'ing the address calculation of the H-matrix from the checkbits.
2. Invert the resulting 8-bit ECC checkbit vector. This step is required to support the all-ones erased state.

On a flash read operation, a similar but "reversed" set of steps are performed as the data is driven into the system bus interconnect:

1. Invert the 8-bit ECC checkbit vector read from the flash.
2. Factor the address field into the ECC checkbits by XOR'ing the address calculation of the H-matrix.

Consider the following flash ECC example. Let the flash block containing address 0x00345678 be erased. The following is the sequence of operations:

1. Read address 0x00345678. Flash array returns fl_rdata = 0xFFFFFFFF_FFFFFFFF, fl_cdata = 0xFF. The flash memory controller calculates the addr_chkbit = 0xC4 using the H-matrix; it inverts the fl_cdata vector to 0x00 and factors in the addr_chkbit = 0xC4 to produce the following valid e2eECC codeword:

   addr = 0x00345678, rdata = 0xFFFFFFFF_FFFFFFFF, rchkbit = 0xC4 (0x00 ^ 0xC4)

2. Program address 0x00345678 with data = 0xBABEFACE_DEADBEEF. The initiating bus master calculates the e2eECC codeword as:

   addr = 0x00345678, wdata = 0xBABEFACE_DEADBEEF, wchkbit = 0xE3

   Before performing the interlock write to the flash array, the flash memory controller adjusts the chkbit value as fl_wchkbit = 0xD8 (0xE3 ^ 0xff ^ 0xC4) by toggling the original write checkbits and then factoring in the addr_ecc. Accordingly, the codeword stored in the flash array is:

   fl_data = 0xBABEFACE_DEADBEEF, fl_checkbit = 0xD8

3. Read address 0x00345678. The flash array returns the stored codeword, fl_rdata = 0xBABEFACE_DEADBEEF, fl_rchkbit = 0xD8. The flash memory controller

inverts the checkbit vector and factors in the address checkbits (0xD8 ^ 0xFF ^ 0xC4) to produce:

addr = 0x00345678, rdata = 0xBABEFACE_DEADBEEF, rchkbit = 0xE3

This read codeword matches the original e2eECC codeword generated by the write.

Malfunction of the ECC logic described above may result in the corruption of the SEC/DED event reporting. The flash memory controller performs EDC after ECC check on all flash transactions. If a mismatch is detected, indicating a failure in the ECC logic, the event is reported to the device fault collection module.

38.5.10.2 Flash address generation check

Fault detection coverage of the address and data are handled by ECC performed within the flash and e2eECC performed at the master. Fault detection coverage of the address path and control within the flash memory controller rely on a feedback path between the flash controller and flash. Recall on a requested access to flash, the flash memory controller must decode the system AHB bus signals to generate the corresponding flash interface signals to invoke a flash lookup. In addition to providing the requested read data, the flash also provides output sidebands reflecting the encoded address and block selects used to perform the actual row lookup.

This sideband information is used by the flash memory controller to verify the expected transaction. If a mismatch is detected, indicating a failure in the address generation or control logic within the flash memory controller or the transmission path between the flash memory controller and flash array, the event is forwarded to the device fault collection module and the corresponding buffer is invalidated.

38.5.10.2.1 Overlay RAM feedback check

The integrity of the address and data on an overlay RAM transaction is covered by e2eECC check performed by the requesting master. Fault detection coverage of the address path and control within the flash memory controller is handled by a transaction monitor which verifies the integrity of the transactions between the flash memory controller and the on-chip overlay RAM. The function of the transaction monitor relies on a feedback path between the flash memory controller and the on-chip overlay RAM, wherein the RAM provides latched address and control feedback outputs as an indication of received inputs when a RAM access is initiated. This feedback information is used by the flash memory controller transaction monitor to verify the expected transaction. If a mismatch is detected, indicating a failure in the address generation or control logic within

the flash memory controller or the transmission path between the flash memory controller and on-chip overlay RAM array, the event is forwarded to the Fault Collection and Control Unit (FCCU).

38.5.10.2.2 Reliability considerations on overlay accesses

Because calibration write accesses are always presented with the physical, non-remapped system address, the write data checkbits presented by the master are calculated based on the physical overlay RAM system address. On a subsequent overlay read, the ECC checkbits must be manipulated to replace the physical overlay RAM address contribution with the logical flash address contribution. This is required to satisfy the e2eECC check at the originating master.

In addition, the flash memory controller can be configured to treat calibration RAM space as a safety-critical component. By programming PFCRCR[SAFE_CAL]=1, the flash memory controller treats the set of available calibration region descriptors as a replicated pair, with each set containing half the total number of available calibration region descriptors.

If there are 32 calibration region descriptors, CRD0 – CRD31, and PFCRCR[SAFE_CAL]=1, the flash memory controller treats CRD0 – CRD15 and CRD16 – 32 as replicated sets of 16 calibration region descriptors, where:

- CRD0 and CRD16 are configured identically
- CRD1 and CRD17 are configured identically
- CRD2 and CRD18 are configured identically
- ...
- and CRD15 and CRD31 are configured identically

Expressed more generally, the contents of CRD[n] must be identical to the contents of CRD[(N/2) + n], where N is the total number of region descriptors and $0 \le n \le (N/2) - 1$.

Note

It is the user's responsibility to establish redundant calibration region descriptors by programming the associated pairs of CRDs.

Incoming flash read requests are compared simultaneously against the calibration regions defined in CRD0 to CRD[(N/2) – 1] and the calibration regions defined in CRD[N/2] to CRD[N – 1]. Due to the enabled redundancy, the parallel overlay remap hardware structures should evaluate to symmetric results. If a mismatch is detected, the event is reported to the FCCU and calibration remapping is not performed. Instead, data is returned from the flash.

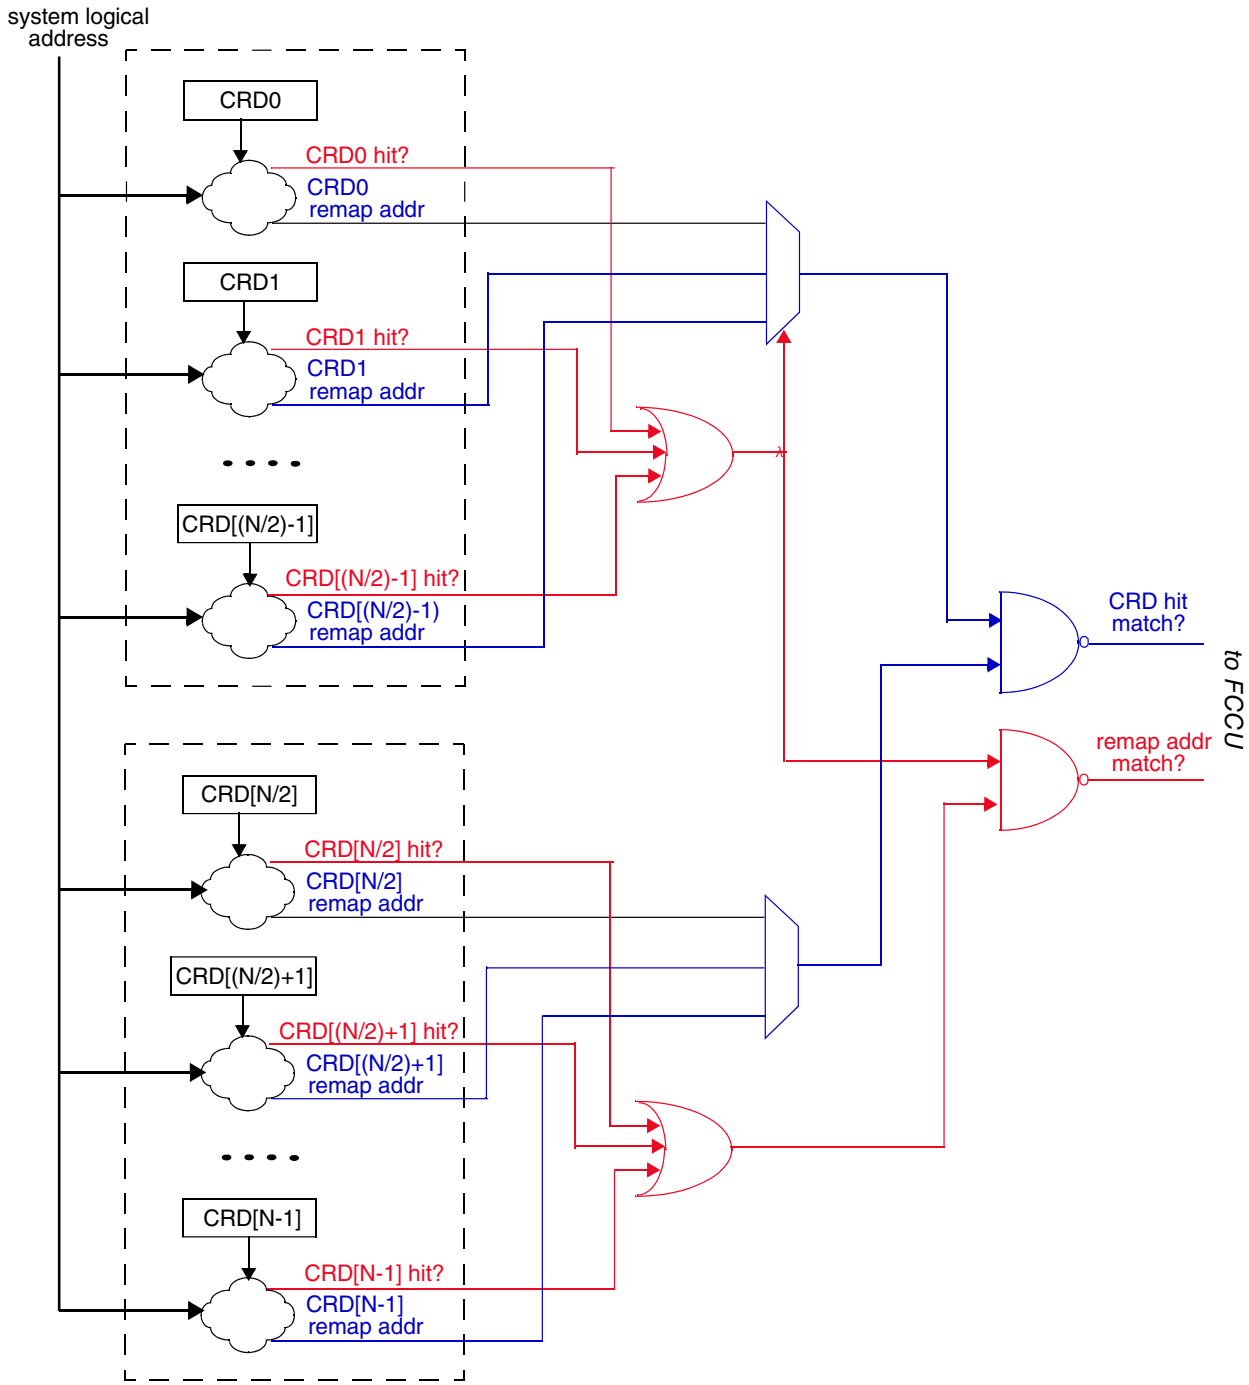

Figure 38-3. Safety-critical calibration remap datapath with redundancy

38.5.11 ECC on data flash accesses

For single-bit correction events, the corrected data and checkbits are returned to the requesting master, and the single-bit correction event is reported to the MEMU.

In the event of a non-correctable error detection, a fixed, illegal opcode value (1555_1555h) is returned to the requesting master along with the associated ECC checkbits as determined by the requesting address and the non-correctable error event is reported to the MEMU.

NOTE

EEPROM should be avoided for storage of executable code.

38.5.12 Array integrity considerations

During an array integrity sequence, the flash memory array ignores any incoming read requests. When a flash array integrity check is in progress, the flash memory controller terminates all flash access requests with an error. More specifically, it aborts the incoming flash access requests and terminates the system bus transfer with an error.

Chapter 39
Embedded Flash Memory (c55fmc)

39.1 Introduction

The primary function of the embedded flash memory is to serve as electrically programmable and erasable non-volatile memory (NVM) that may be used for instruction or data storage.

The following figure shows the top-level diagram and functional organization of the flash memory unit.

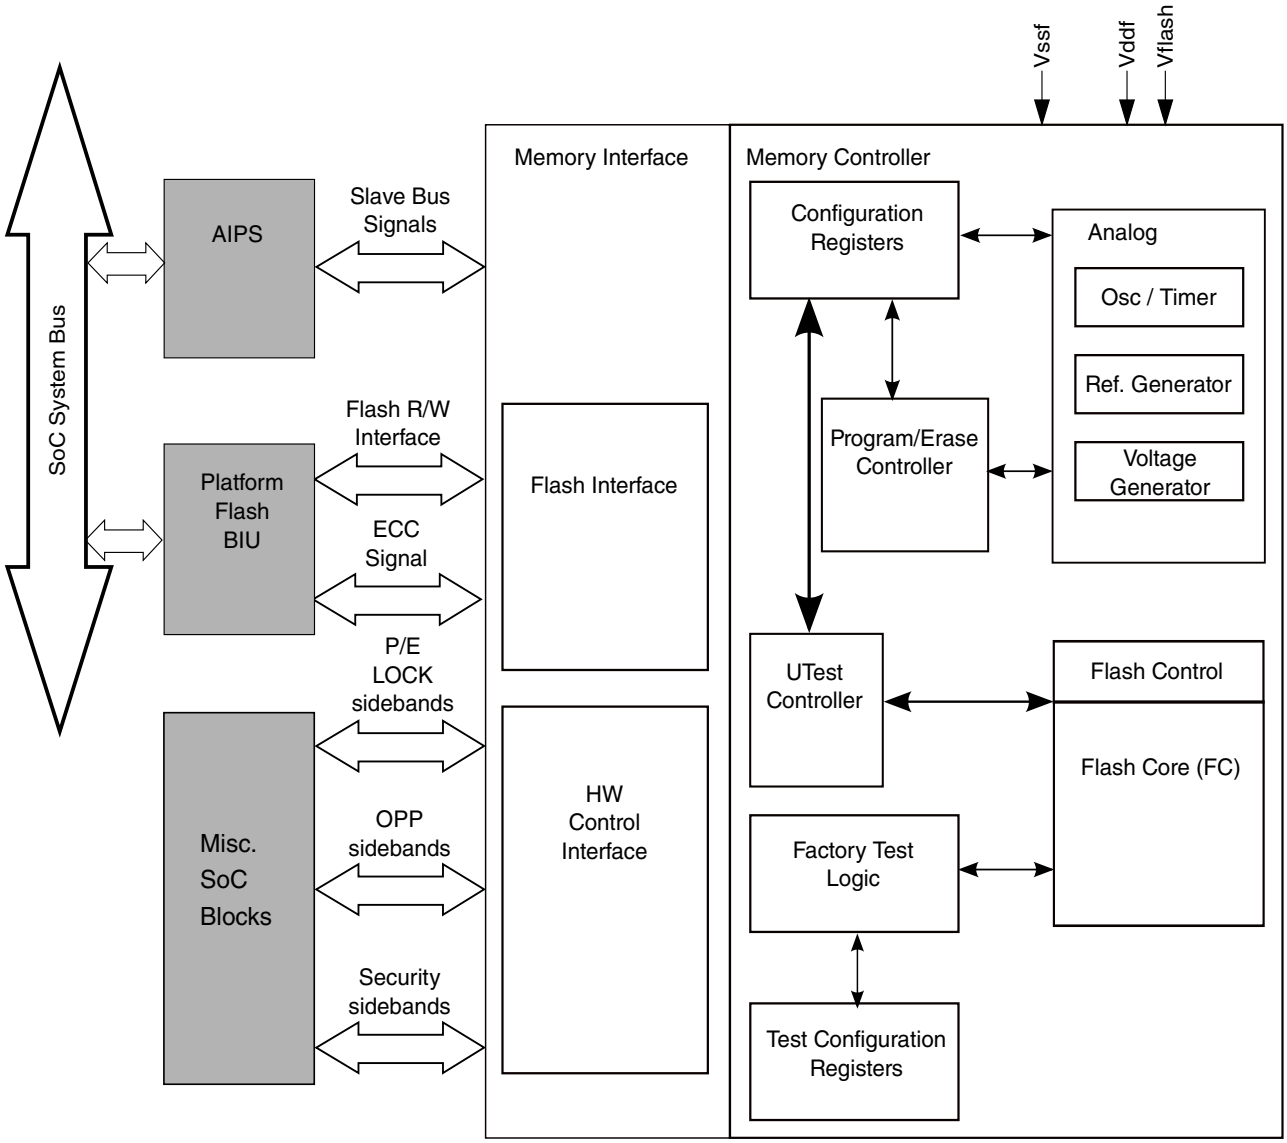

Figure 39-1. c55fmc block diagram

39.1.1 Overview

The embedded flash memory is addressable by word (32 bits) or double word (64 bits) for program operation, and page (256 bits) for read operation. Multiple word or double-word writes may be done to the flash memory to fill up the program page buffer (256 bits), enabling page programming (256 bits, requiring 4 double-word writes) and quad-page programming (1024 bits, requiring 16 double-word writes). Flash memory reads always return 256 bits, although read page buffering may be performed by the Bus Interface Unit (BIU).

For more details on the embedded flash memory architecture and features, see Functional Description.

39.1.2 Features

The embedded flash memory includes these distinct features:

- Test information stored in a dedicated nonvolatile block (referred to as the UTest block)
- OTP space made available in the UTest block
- Read page size of 256 bits (8 words)
- ECC with single-bit correction, double-bit detection (all 1's valid)
- Quad Page programming (64-bit granularity)
- Software programmable block program/erase restriction control
- Erasing of selected block(s)
- Independent programming of the UTest NVM block
- Embedded hardware program and erase algorithms
- Support for reading while writing when the accesses are to different partitions
- Erase suspend, program suspend, and erase-suspended program
- UTest mode (user-accessible test modes) including Array Integrity and Margin Read
- Triple Voted Flops for flash functions requiring high reliability, e.g., internal trimming, redundancy, and mode control

39.1.3 Modes of operation

Following is a brief description of the embedded flash memory operating modes.

- *User mode* is the default operating mode of the embedded flash memory. In this mode, it is possible to read and write registers, read and interlock write the memory array, program the memory array, and erase the memory array. In this mode program and erase operations are initiated by doing array and register writes, and are controlled by an internal state machine.
- *UTest mode* is a tiered test mode strategy in which a portion of the factory test modes are made available. This mode is protected but accessible.

39.2 UTest NVM block

The UTest NVM block may be enabled by the BIU. When the UTest NVM space is enabled, all operations are mapped to the UTest NVM block. User-mode programming of the UTest NVM block is enabled only when MCR[PEAS] is high. The UTest NVM block is an OTP block (assuming Test Mode Disable Seal is written) - thus erase is not allowed.

The UTest NVM block supports RWW, and is grouped with the blocks in partition 0.

The UTest NVM block may be locked against program by using the lock registers.

Programming of the UTest NVM space has restrictions that are similar to those of the main space in terms of how ECC is calculated. Only one program operation is allowed per 64-bit ECC segment.

The UTest NVM block contains specified data that is needed for embedded flash memory or SoC features.

39.3 Test mode disable seal

Also included in the UTest NVM block is a mechanism to disable factory entry into Test mode. Extreme care must be taken when using this feature, as blocks that are selected to be protected in this method will not be able to have possible failures analyzed by factory failure analysts. Once sealed, the UTest block becomes OTP (Erase Locked, and Over Program Protection enabled). The UTest Block also is not accessible in Test mode.

Protection of this sort prevents all high-voltage operations to the flash executed by the internal state-machine, as well as reads through this state machine, and reads through the Array Integrity state machine when using Test mode interfaces.

UTest operations Margin Read and Array Integrity are also protected by preventing MISR updates on blocks selected for protection, although reads will still be done and single bit corrections and double bit detections will be logged. Protection through other interfaces is protected by normal User mode protection mechanisms, and are device-specific.

The method to disable factory entry into Test mode is to first program the Test Mode Disable Seal location to be 0x2D3C_4B5A. Once the next reset is asserted, Test mode will be disabled.

It is possible to create a password to enable factory entry into test mode. This can be programmed into the Test Mode Disable Override Passcode. The passcode may not be 0x0000_0000, 0xFFFF_FFFF, or 0x5555_5555. These are all invalid passcodes and will not be accepted to override. If it is desired by the customer that override never be possible, one of the three invalid passcodes should be put into this location. Passcode may be entered to authenticate entry (if enabled) by doing a 32-bit register write to register address 0x90. The UTest NVM block is always protected even if the Test Mode Disable Seal password is written. UTest operations Margin Read and Array Integrity are always protected even if the Test Mode Disable Seal password is written.

Only blocks selected in the Test Mode Disable Block Select field(s) are controlled by the Test Mode Disable feature. Thus it is possible for customers to selectively pick blocks that have this type of protection, and will not be eligible for factory failure analysis. Bits programmed to 0 in the Test Mode Disable Block Select field(s) will designate blocks that are controlled by the Test Mode Disable feature. If either Test Mode Disable Block Select - 0 or Test Mode Disable Block Select - 1 have a 0 programmed, that block will be protected. In order to provide two opportunities to select blocks for the Test Mode Disable, two regions are available, Test Mode Disable Block Select - 0 and Test Mode Disable Block Select - 1. The bit of these two regions are logically ANDed, to define which blocks are effectively selected for the Test Mode Disable feature. The Block Select field is organized as follows, and aligns with how blocks are defined in the LOCK registers.

Table 39-1. Test mode disable block select

Block	Bits used to select blocks
Low Block Disable	Data[13:0]
Unused	Data[15:14]
Mid Block Disable	Data[31:16]
High Block Disable	Data[47:32]
256K Block Disable	Data[95:48]

39.4 Memory map and register definition

The embedded flash memory map consists of a flash memory array (which includes main array space and UTest NVM space) and a region of registers associated with the programming model that enable flash memory array operation and modification.

The address space consists of 16 KB, 32 KB, 64 KB, and 256 KB blocks.

39.4.1 Module Configuration Register (C55FMC_MCR)

NOTE

1. A number of Module Configuration Register (MCR) bits are locked against write by other bits. These locks are discussed in relationship to each bit in this section. Simultaneously writing bits which lock each other out is also discussed in Functional Description.
2. See Functional Description for information about simultaneous MCR writes, and priority levels.

Address: 0h base + 0h offset = 0h

C55FMC_MCR field descriptions

Field	Description
0 RVE	Read Voltage Error RVE provides information on previous reads monitoring the read pump voltage. If the read voltage is detected to be out of range, this bit is set to indicate that previous reads requested may have been

Table continues on the next page...

C55FMC_MCR field descriptions (continued)

Field	Description
	corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring without voltage issues 1 A previous read may have been corrupted due to read voltage being out of range
1 RRE	Read Reference Error RRE provides information on previous reads monitoring the read reference. If the read reference is detected to be out of range, this bit is set to indicate that previous reads requested may have been corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring without reference issues 1 A previous read may have been corrupted due to read reference being out of range
2 AEE	Address Encode Error AEE provides information on previous reads monitoring the address encode feature. On every read request to the flash, the incoming address is compared to an encoded address (row, column, and block) coming back from the memory array using the read data sense amplifier timing. If these two values do not match (zero selected, multiple selected, wrong selected), or the timing is incorrect, an address encode error will be recorded. If an address encode mismatch is detected, this bit is set to indicate that previous reads requested may have been corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring without address encode mismatches 1 A previous read may be corrupted based on address encode mismatch
3 EEE	ECC after ECC Error EEE provides information on previous reads monitoring the ECC after ECC feature. On every read request to the flash, ECC is recalculated serially, and if there is a mismatch between the ECC calculations (taking into account corrections or detections) a late error will be reported. If an ECC after ECC mismatch is detected, this bit is set to indicate that previous reads requested may have been corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring without ECC after ECC mismatches 1 A previous read may be corrupted based on ECC calculation errors
4–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 EER	ECC Event Error This bit provides information on previous reads. If a double bit detection occurred, the EER bit is set to a '1'. This bit must then be cleared, or a reset must occur before it returns to a 0 state. This bit may not be set by software. In the event of a single bit detection and correction, this bit is not set. If EER is not set, or remains 0, this indicates that all previous reads (from the last reset, or clearing of EER) are correct. Since this bit is an error flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring normally. 1 An ECC Error occurred during a previous read.
17 RWE	Read-While-Write Event Error This bit provides information on previous read-while-write (RWW) reads. If an RWW error occurs, this bit is set to 1. The bit must then be cleared, or a reset must occur before it returns to a 0 state. This bit may not be written to a 1. If RWE is not set, or remains 0, this indicates that all previous RWW reads (from the last

Table continues on the next page...

C55FMC_MCR field descriptions (continued)

Field	Description
	reset, or clearing of RWE) are correct. Since this bit is an error flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring normally. 1 A read-while-write error occurred during a previous read.
18 SBC	Single Bit Correction SBC provides information on previous reads, if the SBCE is set. If a single bit correction occurred, the SBC bit is set to a 1. This bit must then be cleared, or a reset must occur before this bit returns to a 0 state. If SBC is not set, or remains 0, this indicates that all previous reads (from the last reset, or clearing of SBC) did not require a correction. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring without corrections. 1 A Single Bit Correction occurred during a previous read.
19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 PEAS	Program Access Space PEAS indicates which space is valid for program or erase operations — either main array space or UTest NVM space. It should be noted that if the flash is sealed, and the Test Mode Disable Seal is programmed, erase is not allowed on the UTest NVM space. PEAS = 0 indicates the main address space is active for all program or erase operations. PEAS = 1 indicates the UTest NVM address space is active for program or erase (if applicable) operations. The value in PEAS is captured and held when the UTest NVM block is enabled with the first interlock write done for program operations(and erase operations if the flash is unsealed). The value of PEAS is retained between sampling events (in other words, subsequent first interlock writes). The value in PEAS may be changed during erase-suspended program, and reverts back to its original state once the erase-suspended program is completed. PEAS is read only. 0 UTest NVM address space is disabled for program/erase and main address space enabled. 1 UTest NVM address space is enabled for program/erase and main address space disabled.
21 DONE	State Machine Status DONE indicates whether the embedded flash memory is performing a high voltage operation. DONE is set to a 1 on termination of the embedded flash memory reset. DONE is read only. DONE is set to a 1 at the end of program and erase high voltage sequences. **NOTE:** This bit transitions from a 0 to 1 during reset and remains at 1 after reset. 0 Flash memory is executing a high voltage operation. 1 Flash memory is not executing a high voltage operation.
22 PEG	Program/Erase Good The PEG bit indicates the completion status of the last flash memory program or erase sequence for which high voltage operations were initiated. The value of PEG is updated automatically during the program and erase high voltage operations. Aborting a program/erase high voltage operation causes PEG to be cleared, indicating the sequence failed. PEG is set to a 1 when the embedded flash memory is reset. PEG is read only. The value of PEG is valid only when PGM = 1 or ERS = 1 and after DONE transitions from 0 to 1 due to an abort or the completion of a program/erase operation. PEG is valid until PGM/ERS makes a 1 to 0 transition or EHV makes a 0 to 1 transition. The value in PEG is not valid after a 0 to 1 transition of DONE caused by PSUS or ESUS being set to logic 1. If PGM and ERS are both 1 when DONE makes a qualifying 0 to 1 transition the value of PEG indicates the completion status of the PGM sequence. This happens in an erase-suspended program operation.

Table continues on the next page...

C55FMC_MCR field descriptions (continued)

Field	Description
	PEG will be 0 if an Erase-Suspended Program is attempted to a block that has been selected for Erase. PEG will also be 0 in the event of an error in the interlock write for program only. An error in the interlock write occurs when the ECC value provided to the flash memory does not match the ECC calculated within the flash memory. In the event of this, high voltage will not be applied to the array, and PEG will indicate a failed program. **NOTE:** 1. If program or erase operations are attempted on blocks that are locked, the response from embedded flash memory is PEG = 1, indicating that the operation was successful, and the contents of the block are properly protected from the program or erase operation. PEG = 1 is also true if an abort occurs during an HV request to a locked block. 2. If a program operation is attempted to a location marked as OTP, the response from the embedded flash memory is PEG = 0, indicating that the operation was not allowed, and the value interlocked was not programmed, since the desired doubleword was already programmed with a previous program operation. 0 Program or erase operation failed. 1 Program or erase operation successful.
23 PECIE	Program/Erase Complete Interrupt Enable PECIE provides a mechanism to trigger an interrupt request upon the assertion of the DONE flag due to a high voltage event (program or erase) finishing (normal, abort, suspend). If PECIE is written while not in a high voltage event, the interrupt will not immediately trigger, but will trigger after the next high voltage event is completed. 0 An interrupt request will not be generated when the DONE flag is set. 1 An interrupt request will be generated when the DONE flag is set.
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 PGM	Program PGM is used to set up embedded flash memory for a program operation. A 0 to 1 transition of PGM initiates a program sequence. A 1 to 0 transition of PGM ends the program sequence. PGM can be set only under one of the following conditions: • User mode read (ERS is low and UTE is low) • Erase suspend (ERS and ESUS are 1) with EHV low PGM can be cleared only when PSUS and EHV are low and DONE is high. PGM is cleared on reset. 0 Flash memory is not executing a program sequence. 1 Flash memory is executing a program sequence.
28 PSUS	Program Suspend PSUS is used to indicate the embedded flash memory is in program suspend or in the process of entering a suspend state. The embedded flash memory is in program suspend when PSUS = 1 and DONE = 1. PSUS can be set high only when PGM and EHV are high. A 0 to 1 transition of PSUS starts the sequence which sets DONE and places the embedded flash memory in program suspend. The embedded flash memory enters suspend within Tpsus of this transition. PSUS can be cleared only when DONE and EHV are high. A 1 to 0 transition of PSUS with EHV = 1 starts the sequence which clears DONE and returns the embedded flash memory to program. The embedded flash memory cannot exit program suspend and clear DONE while EHV is low. PSUS is cleared on reset. 0 Program sequence is not suspended. 1 Program sequence is suspended.

Table continues on the next page...

C55FMC_MCR field descriptions (continued)

Field	Description
29 ERS	Erase ERS is used to set up embedded flash memory for an erase operation. A 0 to 1 transition of ERS initiates an erase sequence. A 1 to 0 transition of ERS ends the erase sequence. ERS can only be set in user mode read (PGM is low and UTE is low). ERS can be cleared only when ESUS and EHV are low and DONE is high. ERS is cleared on reset. 0 Flash memory is not executing an erase sequence. 1 Flash memory is executing an erase sequence.
30 ESUS	Erase Suspend ESUS is used to indicate that the embedded flash memory is in erase suspend or in the process of entering a suspend state. The embedded flash memory is in erase suspend when ESUS = 1 and DONE = 1. ESUS can be set high only when ERS and EHV are high and PGM is low. A 0 to 1 transition of ESUS starts the sequence which sets DONE and places the flash memory in erase suspend. The embedded flash memory enters suspend within Tesus of this transition. ESUS can be cleared only when DONE and EHV are high and PGM is low. A 1 to 0 transition of ESUS with EHV = 1 starts the sequence which clears DONE and returns the embedded flash memory to erase. The embedded flash memory cannot exit erase suspend and clear DONE while EHV is low. ESUS is cleared on reset. 0 Erase sequence is not suspended. 1 Erase sequence is suspended.
31 EHV	Enable High Voltage The EHV bit enables the embedded flash memory for a high voltage program/erase operation. EHV is cleared on reset. EHV must be set after an interlock write to start a program/erase sequence. EHV may be set, initiating a program/erase, after an interlock under one of the following conditions: • Erase (ERS = 1, ESUS = 0) • Program (ERS = 0, ESUS = 0, PGM = 1, PSUS = 0) • Erase-suspended program (ERS = 1, ESUS = 1, PGM = 1, PSUS = 0) If a program operation is to be initiated while an erase is suspended, EHV must be cleared while in erase suspend before setting PGM. In normal operation, a 1 to 0 transition of EHV with DONE high, PSUS low, and ESUS low terminates the current program/erase high-voltage operation. In an erase-suspended program operation, a 1 to 0 transition of EHV with DONE high, ESUS high, PGM high, ERS high, and PSUS low terminates the program that is the current high voltage operation. When an operation is aborted, there is a 1 to 0 transition of EHV with DONE low and the suspend bit for the current program/erase sequence low. An abort causes the value of PEG to be cleared, indicating a failed program/erase; address locations being operated on by the aborted operation contain indeterminate data after an abort. EHV may not be written to a 1 after an abort is requested (EHV being cleared) and before DONE transitions high. A suspended operation cannot be aborted. EHV may be written during suspend. EHV must be high for the embedded flash memory to exit suspend. EHV may not be written after a suspend bit is set high and before DONE transitions high. EHV may not be set low after the current suspend bit is set low and before DONE transitions low. **NOTE:** Aborting a high voltage operation leaves FC addresses in an indeterminate data state. This may be recovered by executing an erase on the affected blocks. 0 Flash memory is not enabled to perform a high voltage operation. 1 Flash memory is enabled to perform a high voltage operation.

39.4.2 Extended Module Configuration Register (C55FMC_MCRE)

NOTE

The reset value of this register is set at the factory and varies among devices. See the chip-specific C55FMC information for details.

C55FMC_MCRE field descriptions

Field	Description
0 HT	High Temperature Enabled. HT provides configuration information of the module. If the flash is tuned for high temperature operation (165 °C) at reduced performance (slower read at 165 °C and less and slower program and erase at 150 °C or less), and limited features at this temperature (no margin reads), the HT status bit will be a 1. Default is 150 °C as maximum operating temperature, and the HT status bit will be a 0. HT is read only. 0 150 °C maximum operating temperature. **NOTE:** 165 °C operating temperature maximum is not supported on this device. 1 Reserved
1–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–7 n256K	Number of 256 KB blocks. The value of this field is dependent upon the size of the embedded flash memory. This field is read only. 00000 Zero 256 KB blocks. 00001 Two 256 KB blocks (512 KB total). 00010 Four 256 KB blocks (1 MB total). 00011 Six 256 KB blocks (1.5 MB total). 00100 Eight 256 KB blocks (2 MB total).

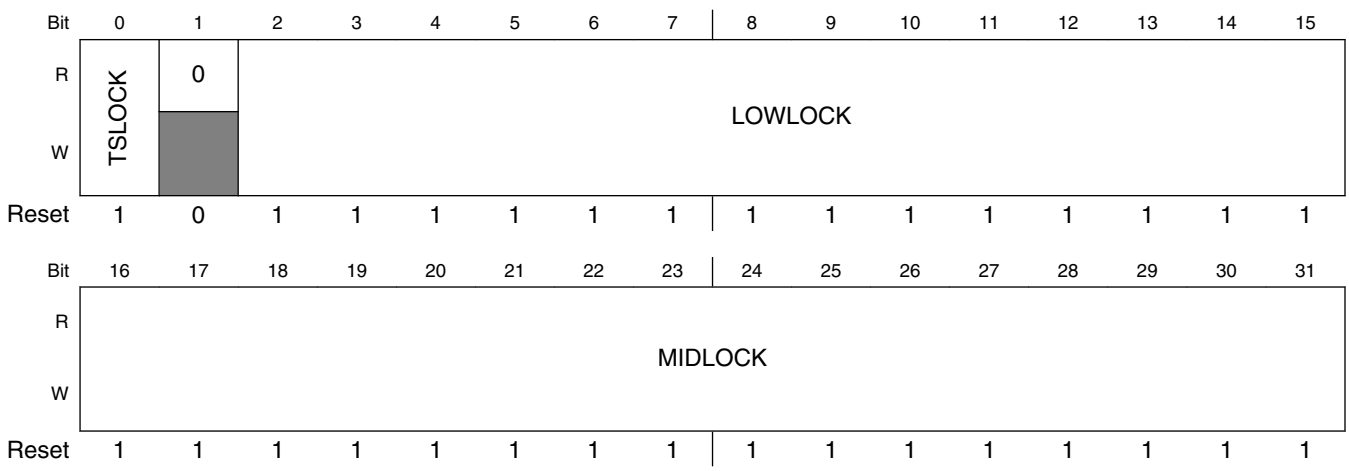
39.4.3 Lock 0 register (C55FMC_LOCK0)

The Lock 0 (LOCK0) register provides a means to protect blocks from being modified.

Address: 0h base + 10h offset = 10h



C55FMC_LOCK0 field descriptions

Field	Description
0 TSLOCK	UTest NVM Lock. This bit is used to lock the UTest NVM block from programs (erase protection not needed since UTest NVM is OTP and not erasable). A value of 1 in the TSLOCK register signifies that the UTest NVM block is locked for program. A value of 0 in the TSLOCK register signifies that the UTest NVM block is available to receive program pulses. The TSLOCK register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation. Likewise, TSLOCK register is not writable if a high voltage operation is suspended.

Table continues on the next page...

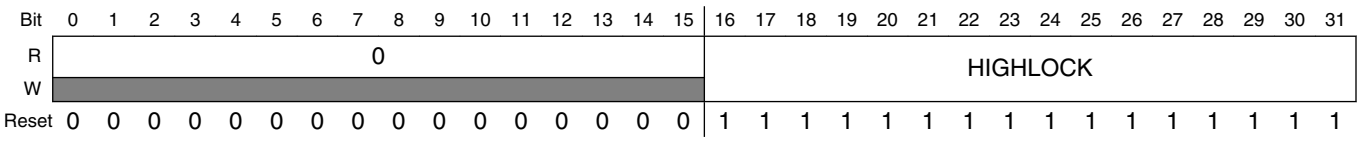
C55FMC_LOCK0 field descriptions (continued)

Field	Description
	0 UTest NVM block is available to be programmed. 1 UTest NVM block is locked and cannot be programmed.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–15 LOWLOCK	Low Block Lock A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase. A value of 0 in the lock register signifies that the corresponding block is available to receive program and erase pulses. The block numbering for the Low Blocks starts at LOWLOCK[0] with 16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted. Low Blocks exist in partitions 0 and 1. The lock register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation. Likewise, the lock register is not writable if a high voltage operation is suspended. The default value of the LOCK bits is locked. In the event that blocks are not present (due to configuration or total memory size), the LOCK bits default to be locked, and are not writable. The reset value is always 1, and register writes have no effect. 0 Block is available for program and erase operations. 1 Block is locked and unavailable for program and erase operations
16–31 MIDLOCK	Mid Block Lock A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase. A value of 0 in the lock register signifies that the corresponding block is available to receive program and erase pulses. The block numbering for the Mid Blocks starts at MIDLOCK[0] with 16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted. Mid Blocks exist in partitions 2 and 3. The lock register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation. Likewise, the lock register is not writable if a high-voltage operation is suspended. The default value of the LOCK bits is locked. In the event that blocks are not present (due to configuration or total memory size), the LOCK bits default to be locked, and are not writable. The reset value is always 1, and register writes have no effect. 0 Block is available for program and erase operations. 1 Block is locked and unavailable for program and erase operations

39.4.4 Lock 1 register (C55FMC_LOCK1)

The Lock 1 (LOCK1) register provides a means to protect blocks from being modified.

Address: 0h base + 14h offset = 14h



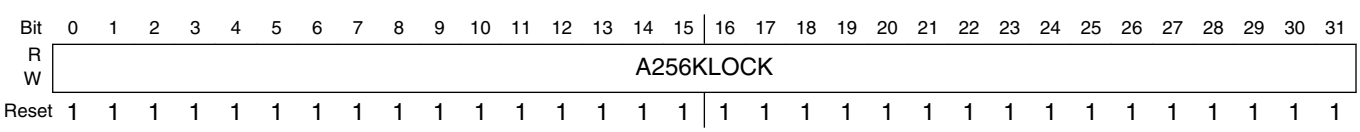
C55FMC_LOCK1 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 HIGHLOCK	High Block Lock A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase. A value of 0 in the lock register signifies that the corresponding block is available to receive program and erase pulses. The block numbering for the High Blocks starts at HIGHLOCK[0] with16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted. HIGH Blocks exist in partitions 4 and 5. The lock register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation. Likewise, the lock register is not writable if a high-voltage operation is suspended. The default value of the LOCK bits is locked. In the event that blocks are not present (due to configuration or total memory size), the LOCK bits default to be locked, and are not writable. The reset value is always 1, and register writes have no effect. 0 Block is available for program and erase operations. 1 Block is locked and unavailable for program and erase operations

39.4.5 Lock 2 register (C55FMC_LOCK2)

The Lock 2 (LOCK2) register provides a means to protect blocks from being modified.

Address: 0h base + 18h offset = 18h



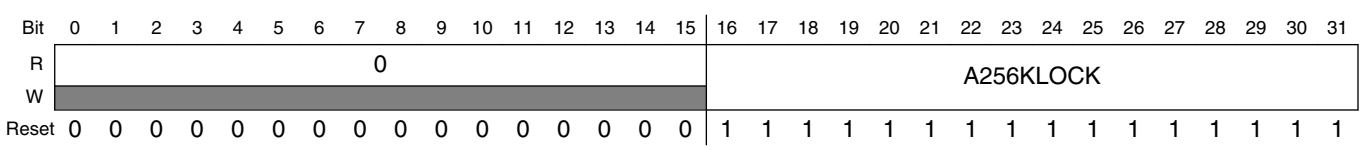
C55FMC_LOCK2 field descriptions

Field	Description
0–31 A256KLOCK	256 KB Block Lock 256KLOCK has the same characteristics as LOWLOCK. Please see that description for more information. The block numbering for the 256 KB blocks starts with 256KLOCK[0] and continues until all blocks are accounted. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase. A value of 0 in the lock register signifies that the corresponding block is available to receive program and erase pulses. The block numbering for the 256 KB blocks starts with 256KLOCK[0] and continues until all blocks are accounted. The lock register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation. Likewise, the lock register is not writable if a high-voltage operation is suspended. The default value of the LOCK bits is locked. In the event that blocks are not present (due to configuration or total memory size), the LOCK bits default to be locked, and are not writable. The reset value is always 1, and register writes have no effect. 0 Block is available for program and erase operations. 1 Block is locked and unavailable for program and erase operations

39.4.6 Lock 3 register (C55FMC_LOCK3)

The Lock 3 (LOCK3) register provides a means to protect blocks from being modified.

Address: 0h base + 1Ch offset = 1Ch



C55FMC_LOCK3 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 A256KLOCK	256 KB Block Lock 256KLOCK has the same characteristics as LOWLOCK. Please see that description for more information. The block numbering for the 256 KB blocks starts with 256KLOCK[0] and continues until all blocks are accounted. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase. A value of 0 in the lock register signifies that the corresponding block is available to receive program and erase pulses. The block numbering for the 256 KB blocks starts with 256KLOCK[0] and continues until all blocks are accounted.

Table continues on the next page...

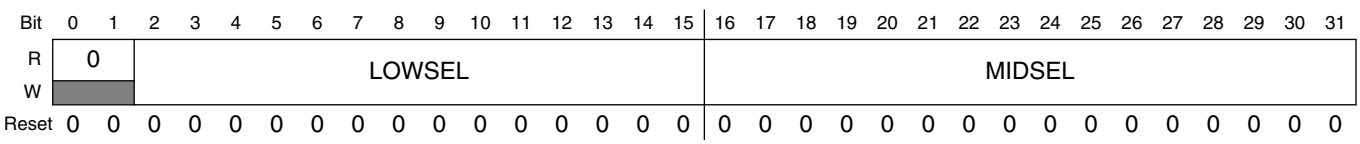
C55FMC_LOCK3 field descriptions (continued)

Field	Description
	The lock register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation. Likewise, the lock register is not writable if a high-voltage operation is suspended. The default value of the LOCK bits is locked. In the event that blocks are not present (due to configuration or total memory size), the LOCK bits default to be locked, and are not writable. The reset value is always 1, and register writes have no effect. 0 Block is available for program and erase operations. 1 Block is locked and unavailable for program and erase operations

39.4.7 Select 0 register (C55FMC_SEL0)

The Select 0 (SEL0) register provides a means to select blocks to be operated on during erase.

Address: 0h base + 38h offset = 38h



C55FMC_SEL0 field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–15 LOWSEL	LOW Block Select. A value of 1 in the select register signifies that the block is selected for erase. A value of 0 in the select register signifies that the block is not selected. The reset value for the select registers is 0, or unselected. The block numbering for the Low Blocks starts at LOWSEL[0] with16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted. Low Blocks exist in partitions 0 and 1. The blocks must be selected (or unselected) before doing an erase interlock write as part of the erase sequence. The select register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation, or if a high-voltage operation is suspended. LOWSEL is also not writeable during UTest operations, when AIE is high. In the event that blocks are not present (due to configuration or total memory size), the corresponding select bits default to unselected, and are not writable. The reset value is always 0, and register writes have no effect. 0 The block is not selected 1 The block is selected for erase

Table continues on the next page...

C55FMC_SEL0 field descriptions (continued)

Field	Description
16–31 MIDSEL	Mid Block Select. A value of 1 in the select register signifies that the block is selected for erase. A value of 0 in the select register signifies that the block is not selected. The reset value for the select registers is 0, or unselected. The block numbering for the Mid Blocks starts at MIDLSEL[0] with16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted. Mid Blocks exist in partitions 2 and 3. The blocks must be selected (or unselected) before doing an erase interlock write as part of the erase sequence. The select register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation, or if a high-voltage operation is suspended. MIDSEL is also not writeable during UTest operations, when AIE is high. In the event that blocks are not present (due to configuration or total memory size), the corresponding select bits default to unselected, and are not writable. The reset value is always 0, and register writes have no effect. 0 The block is not selected 1 The block is selected for erase

39.4.8 Select 1 register (C55FMC_SEL1)

The Select 1 (SEL1) register provides a means to select blocks to be operated on during erase.

Address: 0h base + 3Ch offset = 3Ch

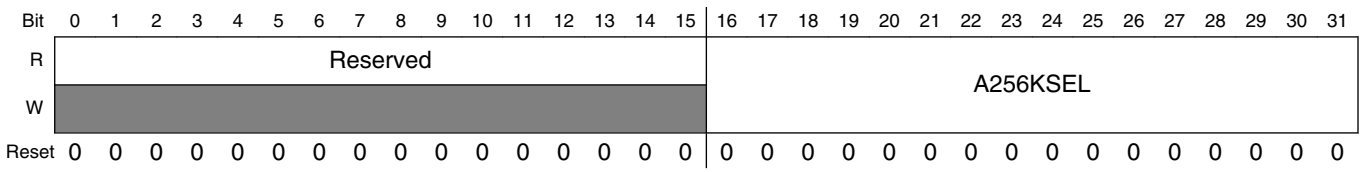
C55FMC_SEL2 field descriptions

Field	Description
0–31 A256KSEL	256 KB Block Select. A value of 1 in the select register signifies that the block is selected for erase. A value of 0 in the select register signifies that the block is not selected. The reset value for the select registers is 0, or unselected. The block numbering for the 256 KB blocks starts with 256KSEL[0] and continues until all blocks are accounted. The blocks must be selected (or unselected) before doing an erase interlock write as part of the erase sequence. The select register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation, or if a high-voltage operation is suspended. 256KSEL is also not writeable during UTest operations, when AIE is high. In the event that blocks are not present (due to configuration or total memory size), the corresponding select bits default to unselected, and are not writable. The reset value is always 0, and register writes have no effect. 0 The block is not selected 1 The block is selected for erase

39.4.10 Select 3 register (C55FMC_SEL3)

The Select 3 (SEL3) register provides a means to select blocks to be operated on during erase.

Address: 0h base + 44h offset = 44h



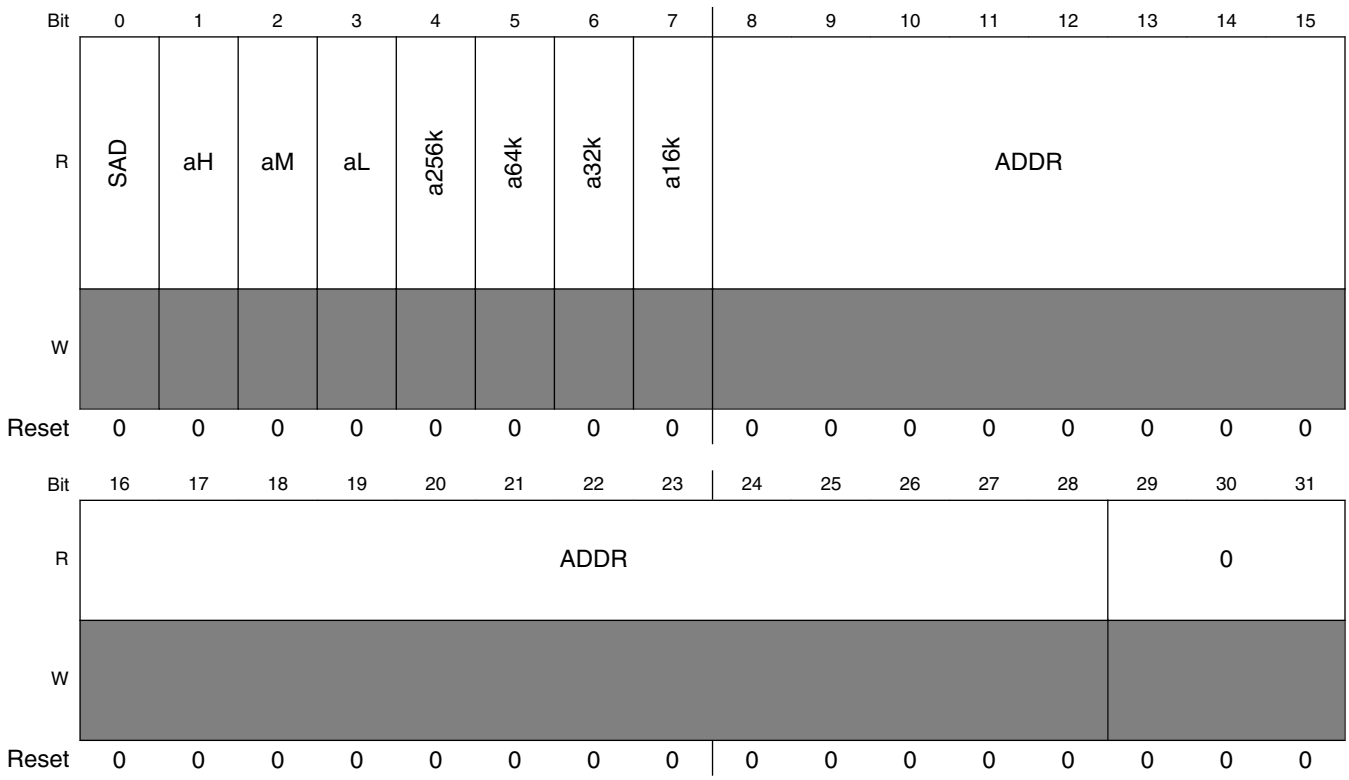
C55FMC_SEL3 field descriptions

Field	Description
0–15 Reserved	This field is reserved. Reserved, reset to 0.
16–31 A256KSEL	256 KB Block Select. A value of 1 in the select register signifies that the block is selected for erase. A value of 0 in the select register signifies that the block is not selected. The reset value for the select registers is 0, or unselected. The block numbering for the 256 KB blocks starts with 256KSEL[0] and continues until all blocks are accounted. The blocks must be selected (or unselected) before doing an erase interlock write as part of the erase sequence. The select register is not writable once an interlock write is completed until DONE is set at the completion of the requested operation, or if a high-voltage operation is suspended. 256KSEL is also not writeable during UTest operations, when AIE is high. In the event that blocks are not present (due to configuration or total memory size), the corresponding select bits default to unselected, and are not writable. The reset value is always 0, and register writes have no effect. 1 The block is selected for erase. 0 The block is not selected.

39.4.11 Address register (C55FMC_ADR)

The Address register (ADR) provides the first failing address in the event of a failure (ECC or PGM/Erase state machine), as well as single bit correction information.

Address: 0h base + 50h offset = 50h



C55FMC_ADR field descriptions

Field	Description
0 SAD	UTest NVM Address. The SAD bit qualifies the address captured during an ECC Event Error, Single Bit Correction, or State Machine operation. SAD has the same characteristics as ADDR related to capturing of addresses. The SAD field is not writable. 0 Address captured is from main array Space. 1 Address captured is from UTest NVM array space.
1 aH	Address High region. The aH bit qualifies the address field (ADDR) to the region of a16K, a32K and a64k. If aH is set, then the ADDR field maps to that region. See ADDR description for more information. 0 Address captured or to be accessed is not from high address region. 1 Address captured or to be accessed is from high address region.
2 aM	Address Mid region. The aM bit qualifies the address field (ADDR) to the region of a16K, a32K and a64k. If aM is set, then the ADDR field maps to that region. See ADDR description for more information.

Table continues on the next page...

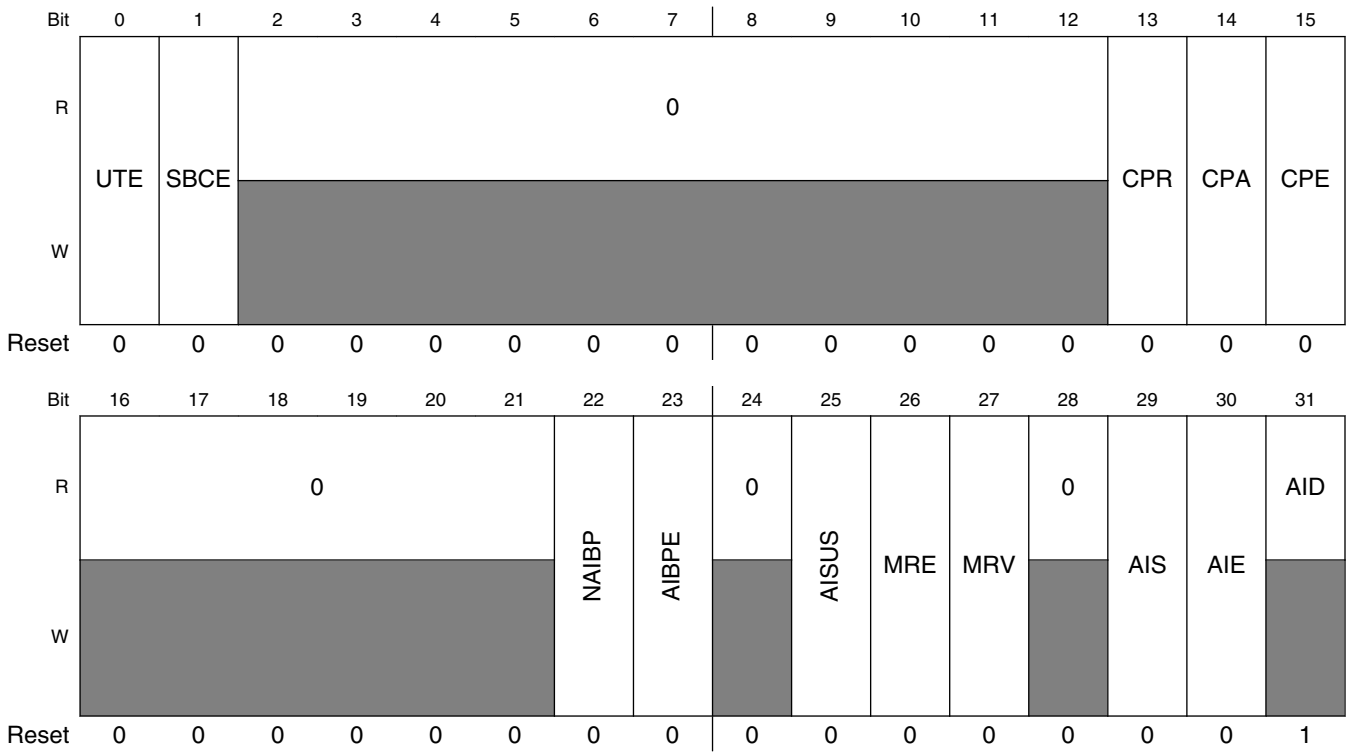
C55FMC_ADR field descriptions (continued)

Field	Description
	0 Address captured or to be accessed is not from mid address region. 1 Address captured or to be accessed is from mid address region.
3 aL	Address Low region. The aL bit qualifies the address field (ADDR) to the region of a16K, a32K and a64k. If aL is set, then the ADDR field maps to that region. See ADDR description for more information. 0 Address captured or to be accessed is not from low address region. 1 Address captured or to be accessed is from low address region.
4 a256k	Address 256 KB region. The a256k bit qualifies the address field (ADDR) to the region. If a256k is set, then the ADDR field maps to that region. See ADDR description for more information. The a256k register is writable. 0 Address captured or to be accessed is not from 256 KB region. 1 Address captured or to be accessed is from 256 KB region.
5 a64k	Address 64 KB region. The a64k bit qualifies the address field (ADDR) to the region. If a64k is set, then the ADDR field maps to that region. See ADDR description for more information. 0 Address captured or to be accessed is not from 64 KB region. 1 Address captured or to be accessed is from 64 KB region.
6 a32k	Address 32 KB region. The a32k bit qualifies the address field (ADDR) to the region. If a32k is set, then the ADDR field maps to that region. See ADDR description for more information. 0 Address captured or to be accessed is not from 32 KB region. 1 Address captured or to be accessed is from 32 KB region.
7 a16k	Address 16 KB region. The a16k bit qualifies the address field (ADDR) to the region. If a16k is set, then the ADDR field maps to that region. See ADDR description for more information. 0 Address captured or to be accessed is not from 16 KB region. 1 Address captured or to be accessed is from 16 KB region.
8–28 ADDR	Address. The ADR provides the first failing address in the event of ECC event error (EER set), Single Bit Correction (SBC set), as well as providing the address of a failure that may have occurred in a state machine operation (PEG cleared). ECC event errors take priority over Single Bit Corrections, which take priority over state machine errors. This is especially valuable in the event of an RWW operation, where the read senses an ECC error or Single Bit correction, and the state machine fails simultaneously. The failing address for ECC event error is held until EER is cleared. The failing address for Single Bit Correction is held until an ECC event error, or until SBC is cleared. State machine address is held until an ECC event error or Single Bit Correction event occurs, or until the next state machine event (PEG cleared) occurs. This address is always a doubleword address that selects 64 bits. ADDR[23:3] is an offset from a base address of 0x0 for each block size region. The aH, aM, aL, a16k, a32k, a64k, and a256k qualify the block size region the ADDR field.
29–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

39.4.12 UTest 0 register (C55FMC_UT0)

The User Test 0 (UT0) register provides a means to control UTest. UTest mode gives the ability to perform test features on the flash memory. This register is only writable when the flash memory is put into UTest mode by writing a passcode.

Address: 0h base + 54h offset = 54h



C55FMC_UT0 field descriptions

Field	Description
0 UTE	U-Test Enable. This status bit gives indication when U-Test is enabled. All bits in UT0, UM0, UM1, UM2, UM3, UM4, UM5, UM6, UM7, UM8 and UM9 are locked when this bit is 0. This bit is not writeable to a 1, but may be cleared. The reset value is 0. The method to set this bit is to provide a password, and if the password matches, the UTE bit is set to reflect the status of enabled, and is enabled until it is cleared by a register write. The UTE password will only be accepted if PGM = 0 and ERS = 0 (program and erase are not being requested). UTE can only be cleared if AID = 1, MRE and AIE = 0. While clearing UTE, writes to set AIE or MRE will be ignored. For UTE, the password 0xF9F9_9999 must be written to the UT0 register. 0 All bits in the UT0, UM0, UM1, UM2, UM3, UM4, UM5, UM6, UM7, UM8 and UM9 registers are locked 1 Bits in the UT0, UM0, UM1, UM2, UM3, UM4, UM5, UM6, UM7, UM8 and UM9 registers are unlocked
1 SBCE	Single Bit Correction Enable. SBCE enables Single Bit Correction results to be observed in SBC. ECC corrections that occur when SBCE is cleared will not be logged.

Table continues on the next page...

C55FMC_UT0 field descriptions (continued)

Field	Description
	0 Single Bit Corrections observation is disabled. 1 Single Bit Correction observation is enabled.
2–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 CPR	Customer Programmable Read Voltage and Reference Detection. This bit is used to control the error generation for the Customer Programmable Detection area in the UTest block. If this bit is set, and the Customer Programmable Detection location in UTest is read, a Read Voltage and Reference Error detection will be noted. This bit may not be set while CPE and CPA are set. If CPE or CPA are high, this bit will be locked. If attempts are made to write CPR, CPA or CPE simultaneously, none of them will be written. 0 Customer Programmable Read Voltage and Reference Detection Error is not enabled 1 Customer Programmable Read Voltage and Reference Detection Error is enabled
14 CPA	Customer Programmable Address Encode Detection. This bit is used to control the error generation for the Customer Programmable Detection area in the UTest block. If this bit is set, and the Customer Programmable Detection location in UTest is read, a Address Encode Error detection will be noted. This bit may not be set while CPE and CPR are set. If CPE or CPR are high, this bit will be locked. If attempts are made to write CPR, CPA or CPE simultaneously, none of them will be written. 0 Customer Programmable Address Encode Detection Error is not enabled 1 Customer Programmable Address Encode Detection Error is enabled
15 CPE	Customer Programmable EDC after ECC Detection. This bit is used to control the error generation for the Customer Programmable Detection area in the UTest block. If this bit is set, and the Customer Programmable Detection location in UTest is read, a EDC after ECC Error detection will be noted. This bit may not be set while CPR and CPA are set. If CPR or CPA are high, this bit will be locked. If attempts are made o write CPR, CPA or CPE simultaneously, none of them will be written. 0 Customer Programmable EDC after ECC Detection Error is not enabled 1 Customer Programmable EDC after ECC Detection Error is enabled
16–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 NAIBP	Next Array Integrity Break Point. If AIBPE is set, NAIBP will be set once a single bit correction (if enabled) or double bit detection is noted during the Array Integrity test. NAIBP is not writable to 1, but may be cleared to 0. Clearing NAIBP to 0, will enable the Array Integrity operation to be re-started after a breakpoint is encountered. If the Array Integrity operation completes without encountering another correction or detection, AID will be set with NAIBP remaining 0. 1 Array Integrity state machine is at a break point. 0 Array Integrity state machine is not currently at a break point.
23 AIBPE	Array Integrity Break Point Enable. If you want to enable breakpoints during an array integrity test, AIBPE may be set. See NAIBP description for more information about array integrity breakpoints. 1 Array Integrity breakpoints are enabled during Array Integrity Checks. 0 Array Integrity breakpoints are not enabled.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 AISUS	Array Integrity Suspend. AISUS enables a suspend of an Array Integrity Operation. Array Integrity may be suspend by Setting AISUS, and resumed by clearing AISUS. AISUS is writeable only when AID is low. AISUS is clearable only when AID is high. Attempting to write AISUS and AIE on the same clock cycle will result in only AIE getting written.

Table continues on the next page...

C55FMC_UT0 field descriptions (continued)

Field	Description
	1 Array integrity sequence is suspended. 0 Array integrity sequence not suspended.
26 MRE	Margin Read Enable. MRE combined with MRV enables user margin reads to be done. Normal user reads are not affected by MRE, although user reads while the margin read operation is ongoing are not supported. MRE is not writable if AID is low, or if AISUS is high, or if NAIBP is high. 1 Margin reads are enabled. 0 Margin reads are not enabled.
27 MRV	Margin Read Value. MRV selects the margin level that is being checked. Margin can be checked to an erased level (MRV=1) or to a programmed level (MRV=0). In order for this value to be valid, MRE must also be set. MRV is not writable if AID is low, or if AISUS is high, or if NAIBP is high. 1 One's margin reads are requested. 0 Zero's margin reads are requested.
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 AIS	Array Integrity Sequence. AIS determines the address sequence to be used during array integrity checks. The default sequence (AIS = 0) is meant to replicate sequences that normal user code follows, and thoroughly checks the read propagation paths. This sequence is proprietary. The alternative sequence (AIS = 1) is logically sequential. It should be noted that the time to run a sequential sequence is shorter than the time to run the proprietary sequence. AIS is not writeable if AIE is high. **NOTE:** Only sequential addressing is supported for margin read checks. 1 Array integrity sequence is sequential. 0 Array integrity sequence is proprietary sequence.
30 AIE	Array Integrity Enable. AIE set to one starts the array integrity check done on all selected blocks. The address sequence is determined by AIS, and the MISR (UM0 through UM9) can be checked after the operation is complete, to determine if a correct signature has been obtained. Once an array integrity operation is requested (AIE=1), it may be terminated by clearing AIE if the operation has finished (AID = 1) or aborted by clearing AIE if the operation is ongoing (AID = 0). AIE is not simultaneously writable to a 1 as UTE is being cleared to a 0. 0 Array integrity checks are not enabled. 1 Array integrity checks are enabled.
31 AID	Array Integrity Done. AID is cleared upon an array integrity check being enabled (to signify the operation is ongoing). Once completed, AID is set to indicate that the array integrity check is complete. At this time the MISR (UMR registers) can be checked. AID may also assert if breakpoints are enabled (AIBPE is set), an abort is requested or a suspend is requested. AID cannot be written, and is status only. 0 Array integrity check is ongoing. 1 Array integrity check is done.

39.4.13 UMISR register (C55FMC_UM*n*)

The Multiple Input Signature registers provide a means to evaluate array integrity.

Address: 0h base + 58h offset + (4d × i), where i=0d to 8d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	MISR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

C55FMC_UM*n* field descriptions

Field	Description
0–31 MISR	MISR[31:0]. The MISR registers accumulate a signature from an array integrity event. The MISR captures all data fields, as well as ECC fields, and the ECC error signal. Data (read and ECC) captured in the MISR is after the ECC logic, and represents corrected data (if required). The MISR can be seeded to any value by writing the MISR registers. **NOTE:** Writing the MISR register during an array integrity operation (including suspend or breakpoint) although possible, is not recommended. A write of the MISR registers at this point may alter the final signature in an unpredictable way. The MISR register provides a means to calculate a MISR during array integrity operations. The MISR can be represented by the following polynomial: $x^{289} + x^{7} + x^{6} + x^{5} + x^{4} + x^{2} + 1$ The MISR is calculated by taking the previous MISR value and then "exclusive ORing" the new data. In addition the most significant bit (in this case it is MISR[288]), is then "exclusive ORed" into input of MISR[7], MISR[6], MISR[5], MISR[4], MISR[2] and MISR[0]. The result of the "exclusive OR" is shifted left on each read. The MISR register is used in array integrity operations. If during address sequencing, reads extend into an invalid address location (in other words, greater than the maximum address for a given array size) then reads are still executed to the array, but the results from the array read are not deterministic. In this instance, the MISR registers is not recalculated, and the previous value is retained.

39.4.14 UMISR register (C55FMC_UM9)

The Multiple Input Signature registers provide a means to evaluate array integrity.

Address: 0h base + 7Ch offset = 7Ch

0–31 PWD	Password challenge

39.5 Functional Description

The embedded flash memory consists of address spaces in four groupings:

- Low address space
- Mid address space
- High address space
- 256 KB address space

The main address space is divided into partitions. Each address space mentioned above consists of a partition pair. Partitions are used to determine locations for valid read-while-write (RWW) operations. While the embedded flash memory is performing a write (program or erase) to a given partition, it can simultaneously perform a read from any other partition. For program operations, only the address specified by an interlock write determines the partition being written (block locking and block select registers do not determine the RWW partitions being written). For erase operations, only blocks that are selected and unlocked determine the RWW partitions being written.

The main address space is also divided into blocks to implement independent erase and program protection. The UTest NVM block also exists as a block, and has independent program protection. The UTest NVM block is included to support systems that require nonvolatile memory (NVM) for security or to store system initialization information.

A number of MCR bits are protected against write when another bit, or set of bits, is in a specific state. These write locks are covered on a bit-by-bit basis in Module Configuration Register (C55FMC_MCR). The write locks do not consider the effects of trying to write two or more bits simultaneously. The embedded flash memory does not allow bits to be written simultaneously which put the device into an illegal state. This is implemented through a priority mechanism among the bits. The bit changing priorities are detailed in the following table.

Table 39-2. MCR bit set/clear priority levels

Priority level	MCR Bit(s)
1	ERS
2	PGM
3	EHV
4	ESUS, PSUS

If two or more MCR bits are written simultaneously only the bit with the lowest priority number is accepted for modification. Setting two bits with the same priority number is prevented by existing write locks or do not put the flash memory in an illegal state.

For example, setting ERS and PGM simultaneously results in only ERS being set. Attempting to clear EHV while setting PSUS results in EHV being cleared, while PSUS is unaffected.

Each read of the embedded flash memory retrieves a page, or eight consecutive words (256 bits), of information. The address for each word retrieved within a page differs from the other addresses in the page only by address bits [4:2]. The flash memory page read architecture easily supports both cache and burst mode at the BIU level for high-speed read applications.

The embedded flash memory supports fault tolerance through error correction code (ECC) and error detection. ECC implemented within the embedded flash memory corrects single-bit failures and detects double-bit failures.

A software mechanism is provided to independently lock and unlock each block.

Program and erase of the embedded flash memory requires multiple system clock cycles to complete. The program and erase sequence may be suspended or aborted.

The embedded flash memory may reside in various modes. The modes that are available include:

- User mode
- UTest mode

Each of these modes is discussed in detail in the following sections.

39.5.1 User Mode

In user mode the embedded flash memory may be read and written (register writes and interlock writes), programmed or erased. The following sub-sections define all actions that may be performed in user mode.

39.5.1.1 Read and write

The default state of the embedded flash memory is read. The main and UTest NVM address space can be read only in the read state. The MCR is always available for read. The embedded flash memory enters the read state on reset. The embedded flash memory is in the read state under four sets of conditions:

- The read state is active when the embedded flash memory is enabled (User Mode Read).
- The read state is active when MCR[PGM] or MCR[ERS] are high and high-voltage operation is ongoing (read-while-write).

NOTE

Reads done to the partition(s) being operated on (either erased or programmed) result in an error and the MCR[RWE] bit is set.

- The read state is active when MCR[PGM] and MCR[PSUS] are high (program suspend).
- The read state is active when MCR[ERS] and MCR[ESUS] are high and MCR[PGM] is low (erase suspend).

In embedded flash memory, flash core reads return 256 bits (1 page). Register reads return 32 bits of data.

NOTE

Flash core reads are done through the BIU. In many cases the BIU does read page buffering to allow sequential reads to be done with higher performance. This could provide a data coherency issue that must be handled with software. Data coherency may be an issue after a program or erase operation, as well as UTest NVM block operations.

In user mode, registers may be written. Array may be written to do interlock writes.

Register reads to unmapped register address space return all zeroes.

Register writes to unmapped register address space have no effect.

Interlock writes that are attempted during a high-voltage operation (MCR[EHV] = 1 or MCR[DONE] =0) will result in the interlock write being ignored, and address and data will not be updated.

NOTE

Care must be taken when doing 32-bit interlock writes. Performing two 32-bit interlock writes to the same word location is not supported. In addition, mixing 32-bit interlock writes with 64-bit interlock writes to the same double-word location is not supported. If these combinations are done, and a program operation is executed, the result will be MCR[PEG] = 0. See the Module Configuration Register (MCR) section for more information.

39.5.1.2 Program

A flash memory program sequence operates on any page within the flash core. Within a page, up to eight words may be altered in a single program operation. Also, up to four pages can be altered in a single program operation. Whenever the array is programmed, the ECC bits also get programmed. ECC is handled on a 64-bit boundary. Thus, if only one word in any given 64-bit ECC segment is programmed, the adjoining word (in that segment) should not be programmed, since ECC calculation has already completed for that 64-bit segment. Attempts to program the adjoining word will probably result in an operation failure. It is recommended that all programming operations be from 64 bits to 1024 bits, and be 64-bit aligned. The programming operation should completely fill selected ECC segments within the page. Only one program is allowed per 64-bit ECC segment between erases.

Warning

In rare cases over-programming of a 64-bit ECC segment may be done (EEPROM emulation).

Programming changes the value stored in an array bit from logic 1 to logic 0 only. Programming cannot change a stored logic 0 to a logic 1.

NOTE

If a logic 0 is attempted to be over-programmed by a logic 1, the resulting operation will fail (MCR[PEG] = 0), and the 0's that are interlocked will be merged (ORed) with 0's that are already present in the 64-bit ECC segment, unless the block is designated as an Over-Program Protected block.

Addresses in locked/disabled blocks cannot be programmed. Values may be programmed in any or all of eight words, within a page, with a single program sequence. Page-bound words have addresses which differ only in address bits [4:2]. Up to four pages can be programmed at once on a quad-page boundary, which differ only in address bits [6:5]. The program operation consists of the following sequence of events:

1. Change the value in the MCR[PGM] bit from a 0 to a 1.

   NOTE

   Ensure the block that contains the address to be programmed is unlocked.

2. Write the first address to be programmed with the program data. The embedded flash memory latches address bits [22:7] and SoC-specific UTest NVM enable at this time. The embedded flash memory latches data written as well. This write is referred to as

a program data interlock write. An interlock write may be done as a 64-bit transaction or a 32-bit transaction. Refer to the Flash Memory Controller chapter for information on the size of writes that are allowed.

3. If more than one word or doubleword is to be programmed, write each additional address in the page with data to be programmed. This is referred to as a program data write. The embedded flash memory ignores address bits [22:7] and SoC-specific UTest NVM enable for program data writes. All unwritten data words default to 0xFFFF_FFFF.
4. Write a logic 1 to the MCR[EHV] bit to start the internal program sequence or skip to step 9 to terminate.
5. Wait until the MCR[DONE] bit goes high.

NOTE

Since MCR[DONE] clears with MCR[EHV] being set, it may not be possible for software to read MCR[DONE] as a 0 prior to this step, depending on the operation selected.

6. Confirm MCR[PEG] = 1.
7. Write a logic 0 to the MCR[EHV] bit.
8. If more addresses are to be programmed, return to step 2.
9. Write a logic 0 to the MCR[PGM] bit to terminate the program sequence.

The first write after a program is initiated determines the quad-page address to be programmed. Program may be initiated with the 0 to 1 transition of the MCR[PGM] bit or by clearing the MCR[EHV] bit at the end of a previous program. This first write is referred to as an interlock write. The interlock write determines if the UTest NVM or normal array space is to be programmed by sampling SoC-specific UTest NVM enable and causing MCR[PEAS] to be set/cleared.

In the case of an erase-suspended program, the values in MCR[PEAS] may be modified via the program interlock write, enabling erase-suspended programs to and from UTest NVM space.

An interlock write must be performed before setting MCR[EHV]. A program sequence may be terminated by clearing MCR[PGM] prior to setting MCR[EHV].

After the interlock write, additional writes affect the data to be programmed at the word location determined by address bits [4:2], as well as the page location within a 1024-bit segment (determined by address bits [6:5]). Unwritten locations default to a data value of 0xFFFF_FFFF. If multiple writes are done to the same location, the data for the last write is used in programming.

While DONE is low, EHV is high, and PSUS is low, then EHV may be cleared, resulting in a program abort. A program abort forces the embedded flash memory to step 8 of the program sequence. An aborted program results in PEG being set low, indicating a failed operation. The data space being operated on before the abort contains indeterminate data. A program sequence may not be aborted while in program suspend.

Warning

Aborting a program operation leaves the flash core addresses being programmed in an indeterminate data state. This may be recovered by executing an erase on the affected blocks.

39.5.1.2.1 Program software locking

A software mechanism is provided to independently lock/unlock blocks against program and erase.

Software locking is done through the LOCK0, LOCK1, LOCK2, and LOCK3 registers. These may be written through register writes, and may be read through register reads.

39.5.1.2.2 Program suspend/resume

The program sequence may be suspended to allow read access to the flash core. It is not possible to erase during a program suspend, or to program during a program suspend. These operations are prevented by register locking described in the Module Configuration Register (MCR) section. Read-while-write operation may also be used to read the array during a program sequence, providing the read is to a different partition.

A program suspend can be initiated by changing the value of the MCR[PSUS] bit from a 0 to a 1. MCR[PSUS] can be set high at any time when MCR[PGM] and MCR[EHV] are high. A 0 to 1 transition of MCR[PSUS] causes the embedded flash memory to start the sequence to enter program suspend, which is a read state. MCR[DONE] must become a logic level 1 before the embedded flash memory is suspended. At this time flash core reads may be attempted. Once suspended, the flash core may only be read. During suspend, all reads to flash core locations targeted for program, and blocks targeted for erase, return indeterminate data.

The program sequence is resumed by writing a logic 0 to MCR[PSUS]. MCR[EHV] must be set to a 1 before clearing MCR[PSUS] to resume operation. When the operation resumes, the embedded flash memory continues the program sequence from one of a set of predefined points. This may extend the time required for the program operation.

NOTE

Repeated suspends at a high frequency may result in the operation not completing normally. Although suspend

frequency is not limited, enabling at least 20 µs between suspend resume and future suspend requests improve the opportunity for the flash to complete the operation successfully.

39.5.1.2.3 Over-program protection enable

One-time programming can be enabled on a block basis. In an over-program protection enabled block, any doubleword which has already been programmed cannot be programmed again. The over-program protection enable does not affect erase operation. Attempts to over-program will result in MCR[PEG] being cleared. If any doubleword within the quad-page has an over-program protection violation, MCR[PEG] will be cleared, and no doublewords will be programmed.

One-time programming can be enabled for 16 KB, 32 KB, 64 KB, or 256 KB blocks.

Over-program protection is enabled by sideband signals, and if enabled, the program operation will be modified to check for programmed bits prior to doing a high-voltage program event.

39.5.1.2.4 Successful program address

To enable the SoC to create logic to authenticate operations with a program (such as in a diary operation), the flash module provides the last successful address programmed as a sideband signal. This value will be held until the next successful program. A successful program is defined as a program operation of data that is not all 1's to an unlocked block, and the operation results in MCR[PEG] returning a 1. If any doubleword within the pages being programmed is interlocked with all 1's, the sideband signal will not be updated. An address of all 1's, and each of the block size selects selected, is the default (and invalid) address after reset.

39.5.1.3 Erase

Erase changes the value stored in all bits of the selected block(s) to logic 1. An erase sequence operates on any combination of blocks in the main address space. The erase sequence is fully automated within the flash memory. Blocks to be erased must be selected prior to initiating the erase sequence. Locked/disabled blocks cannot be erased. If multiple blocks are selected for erase during an erase sequence, the blocks are erased sequentially starting with the lowest numbered block and terminating with the highest (low first, mid second, high last, 16 KB first, 32 KB second, 64 KB third, last blocks are 256 KB). The erase sequence consists of the following events:

1. Change the value in the MCR[ERS] bit from 0 to 1.

2. Select the block or blocks to be erased by writing ones to the appropriate registers in SEL0, SEL1, SEL2, or SEL3 registers.

NOTE

Lock and Select are independent. If a block is selected and locked, no erase occurs.

3. Write to any address in flash memory. This is referred to as an erase interlock write. An erase interlock write to UTest NVM space is not allowed if sealed (since erase is not allowed in the UTest NVM space when sealed).
4. Write a logic 1 to the MCR[EHV] bit to start an internal erase sequence or skip to step 9 to terminate.
5. Wait until the MCR[DONE] bit goes high.

NOTE

Since MCR[DONE] clears with MCR[EHV] being set, it may not be possible for software to read MCR[DONE] as a 0 prior to this step, depending on the operation selected.

6. Confirm MCR[PEG] = 1.
7. Write a logic 0 to the MCR[EHV] bit.
8. If more blocks are to be erased, return to step 2.
9. Write a logic 0 to the MCR[ERS] bit to terminate the erase.

After setting ERS, one write, referred to as an interlock write, must be performed before EHV can be set to a 1. Data words written during erase sequence interlock writes are ignored. The erase sequence may be terminated by clearing ERS before setting EHV.

An erase operation may be aborted by clearing EHV, assuming DONE is low, EHV is high, and ESUS is low. An erase abort forces the embedded flash memory to step eight of the erase sequence. An aborted erase results in PEG being set low, indicating a failed operation. The block(s) being operated on before the abort contain indeterminate data. An erase sequence may not be aborted while in erase suspend.

39.5.1.3.1 Erase software locking

Software Locking affect erase operation. For details on this see Program software locking.

39.5.1.3.2 Erase suspend/resume

The erase sequence may be suspended to allow read access to the flash core. The erase sequence may also be suspended to program (Erase-Suspended Program) the flash core. A program started during erase suspend can in turn be suspended. Only one erase

suspend and one program suspend are allowed at a time during an operation. It is not possible to erase during an erase suspend, or program during a program suspend. During suspend, all reads to flash core locations targeted for program and blocks targeted for erase return indeterminate data.

Read-while-write operation may also be used to read the array during an erase sequence, provided the read is to a partition not selected for erase.

An erase suspend can be initiated by changing the value of the MCR[ESUS] bit from a 0 to a 1. MCR[ESUS] can be set to a 1 at any time when MCR[ERS] and MCR[EHV] are high and MCR[PGM] is low. A 0 to 1 transition of MCR[ESUS] causes the embedded flash memory to start the sequence which places it in erase suspend. MCR[DONE] must become a logic level 1 before the embedded flash memory is suspended and further actions are attempted. Once suspended, the array may be read or a program sequence may be initiated (erase-suspended program). Before initiating a program sequence, MCR[EHV] must first be cleared. If a program sequence is initiated, the values of SoC-specific UTest NVM enable is recaptured. Once the erase-suspended program is completed, the value of PEAS is returned to its erase value. Flash core reads that occur while MCR[ESUS] = 1 from the block(s) being erased will return indeterminate data.

The erase sequence is resumed by writing a logic 0 to MCR[ESUS]. MCR[EHV] must be set to a 1 and MCR[PGM] must be cleared (in the event of an erase-suspended program) before MCR[ESUS] can be cleared to resume the operation. The embedded flash memory continues the erase sequence from one of a set of predefined points. This may extend the time required for the erase operation.

NOTE

1. In an erase-suspended program, programming flash core locations in blocks which were being operated on will respond by completing the operation with a fail code (MCR[PEG] = 0). Programming voltages will not be applied to the memory array in this case.
2. Repeated suspends at a high frequency may result in the operation not completing normally. Although suspend frequency is not limited, enabling at least 5ms between suspend resume and future suspend requests improve the opportunity for the flash to complete the operation successfully.

39.5.2 UTest mode

UTest mode is a mode into which customers can put the embedded flash memory so as to do specific tests that check the integrity of the embedded flash memory.

39.5.2.1 Array integrity self check

The Array Integrity (AI) operation is a flash-specific self-test feature in which a MISR signature value is generated from data read from selected flash blocks. After the operation is complete, customer code compares the resulting MISR signature to the expected value to determine if an incorrect read or ECC detection occurred.

Array integrity operations are fully contained within the flash module. Results of Array integrity operations are not reported beyond the boundary of the flash module.

During array integrity test, user mode array reads are ignored to ensure the array integrity operation is not corrupted. User mode array reads may be executed if suspended or at a breakpoint.

AI read operations are executed using a predefined address sequence selected via the UT0[AIS] register field value. The data to be read is customer-specific, e.g., user program code that has been programmed into the flash memory. Any random or nonrandom code is valid. The expected MISR signature is calculated based on the specific data to be read.

Note that array integrity MISR signature calculations are performed after ECC detection and correction so correctable ECC events do not cause the MISR signature to deviate from the expected value.

Array integrity processing requires the flash memory controller's PFLASH_PFCR1[RWSC] and PFLASH_PFCR1[APC] register fields to be set to values that are valid for the system frequency being used. Only the valid/recommended RWSC and APC values for a given frequency, as stated in the device data sheet, are supported.

The Array integrity check consists of the following sequence:

1. Enable UTest mode by setting the UT0[UTE] bit to 1.
2. Select one or more blocks for an array integrity check by writing 1's to the appropriate bits in the SEL0 – SEL3 registers. Blocks selected for AI test do not need to be unlocked.

Flash blocks that have not been selected are still read as part of the array integrity sequence to enable full transition coverage. Reads on unselected blocks are not captured in the MISR. Selecting fewer blocks may not result in a faster array integrity execution time, depending on the combinations of blocks selected and the sequence.

Blocks protected with the Test Mode Disable Seal are still read as part of the array integrity sequence. The resulting read on sealed blocks is not captured in the MISR, but the Single Bit Correction, Double Bit Detection and breakpoints are still honored.

NOTE

It is not possible to do array integrity operations on the UTest NVM block.

3. If desired, set the UT0[AIS] bit to 1 for sequential addressing only.

   For normal integrity checks of the flash memory, sequential addressing is recommended. If it is required to more fully check the read path (in a diagnostic mode), it is recommended that UT0[AIS] be left at 0, to use the address sequence that checks the read path more fully, and examine read transitions. This sequence takes more time.

4. Seed the MISR registers (UM0 — UM9) with desired values.
5. If breakpoints are desired, set UT0[AIBPE] to 1, and ensure that MCR[EER] and MCR[SBC] are cleared. If it is desired to break on single-bit correction, the UT0[SBCE] must be set.
6. Initiate AI by setting the UT0[AIE] bit to 1.

   The array integrity operation may be aborted prior to UT0[AID] going high. This may be done by clearing the UT0[AIE] bit and continuing to the next step. It should be noted that in the event of an aborted array integrity check the MISR registers contain a signature for the portion of the operation that was completed prior to the abort, and are not deterministic. Prior to doing another array integrity operation, the UM0 – UM9 registers may need to be initialized to the desired seed value by doing register writes.

   The array integrity operation may be suspended prior to UT0[AID] going high. UT0[AISUS] may be set to request an array integrity suspend. After the UT0[AISUS] bit is set, the user should wait for UT0[AID] bit to go high, which indicates the flash has entered the suspend state, and normal reads to the flash may be done. After the UT0[AID] bit goes high, the UT0[AISUS] bit may be cleared to resume the array integrity sequence.

7. Wait until the UT0[AID] bit goes high, indicating that array integrity test is complete.

8. If breakpoints are enabled, check the UT0[NAIBP] bit. If set to 1, the MCR[EER], MCR[SBC], and ADDR registers may be checked to determine the cause of the break and the address of the break. Prior to resuming the operation, clear the MCR[SBC] or MCR[EER] bits, then resume the operation by clearing the UT0[NAIBP] bit. Continue to wait until the UT0[AID] bit goes high. If breakpoints are not enabled, or if the UT0[NAIBP] bit is low when the UT0[AID] bit goes high, the operation is complete. Continue to the next step.
9. Read values in the MISR registers (UM0 — UM9) to ensure correct signature.

NOTE

Array integrity reads may be done to unselected (or non-present) locations. Reads done to these locations do not update the MISR, and do not update the MCR[EER] and MCR[SBC] error bits.

10. Write a logic 0 to the UT0[AIE] bit to complete array integrity test.

39.5.2.2 User margin read

User Margin Read is a flash-specific self-test feature that enables reads to be done at a Program margin or Erase margin level.

Margin reads are performed with an internal read reference voltage that has been adjusted, i.e., "margined" toward the threshold voltage being checked. The read reference voltage is either margined toward a 0 (programmed bit) or margined towards a 1 (erased bit), depending on the margin read operation selected.

User margin read is done using the array integrity interface, and has all the associated features of the array integrity interface (MISR and Breakpoints). User margin read is a self-timed event, and is independent of system clocks or wait states selected.

Margin read operations are fully contained within the flash module. Results of margin read operations are not reported beyond the boundary of the flash module.

During margin read operations, user mode array reads are ignored to ensure the operation is not corrupted. User mode array reads may be executed if suspended or at a breakpoint.

ECC corrections and detections are noted during the user margin read test. Note that margin read MISR signature calculations are performed *after* ECC detection and correction so correctable ECC events do not cause the MISR signature to deviate from the expected value.

The data to be read is customer-specific, e.g., user program code that has been programmed into the flash memory. Any random or non-random code is valid. The expected MISR signature is calculated based on the specific data to be read. After the operation is completed the margin read results can be checked by reading the MCR[EER] and MCR[SBC] bits to determine if zero, one, or two bits are being detected by the margin read, and comparing the generated MISR signature to the expected value.

The use model for margin read is in the event of a user-detected single bit correction (through user reads). A margin read may be done to check for a possible second bit falling within the selected margin levels.

The procedure for doing margin reads is:

1. Enable UTest mode by setting the UT0[UTE] bit to 1.
2. Select one or more blocks for margin read check by writing 1's to the appropriate bits in SEL0 – SEL3 registers. Blocks selected for margin read do not need to be unlocked.

   Flash blocks that have not been selected are still read as part of the margin read sequence to enable full transition coverage. Reads on unselected blocks are not captured in the MISR. Selecting fewer blocks does not result in a faster margin read execution time.

   Blocks protected with the Test Mode Disable Seal are still read as part of the margin read sequence. The resulting read on sealed blocks is not captured in the MISR, but the Single Bit Correction, Double Bit Detection and breakpoints are still honored.

   NOTE

   It is not possible to do margin read operations on the UTest NVM block.

3. Set the UT0[AIS] bit to 1 for sequential addressing only.

   NOTE

   Only sequential addressing is supported for margin read checks.

4. Seed the MISR registers (UM0 — UM9) with desired values.
5. If breakpoints are desired, set UT0[AIBPE] to 1, and ensure that MCR[EER] and MCR[SBC] are cleared. If it is desired to break on single-bit correction, the UT0[SBCE] bit must be set to 1.
6. Initiate margin read by setting the UT0[MRE] bit to 1.
7. Select either one's margin or zero's margin by setting the UT0[MRV] bit to the appropriate value.
8. Set the UT0[AIE] bit.

During margin read operations, with UT0[AID] low, it is not recommended to attempt write operations to the MCR[SBC] and MCR[EER] bits. It is recommended that these bits only be written during suspend, breakpoints, or at completion of the Margin Read operation.

9. Wait until the UT0[AID] bit goes high, indicating that margin read test is complete.

   If breakpoints were enabled or a suspend was requested during margin read, the operation may be at a breakpoint or a suspend state. See Step 8 in section Array integrity self check for more information.

10. Read values in the MISR registers (UM0 — UM9) to ensure correct signature.

NOTE

Margin reads may be done to unselected (or non-present) locations. Reads done to these locations do not update the MISR, and do not update the MCR[EER] and MCR[SBC] error bits.

11. Write a logic 0 to the UT0[AIE] bit.

39.6 Initialization information

A reset is the highest priority operation for the embedded flash memory and terminates all other operations.

The embedded flash memory uses reset to initialize register and status bits to their default reset values. If the embedded flash memory is executing a program or erase operation (PGM or ERS = 1) and a reset is issued, the operation is aborted and the embedded flash memory disables the high-voltage logic without damage to the high-voltage circuits. Reset aborts all operations and forces the embedded flash memory into user mode ready to receive accesses.

After reset is requested, MCR[DONE] goes low, and remains low during reset and reset recovery. At the end of reset recovery, MCR[DONE] transitions from a 0 to a 1.

After reset is completed, register reads may be done, although it should be noted that registers that require updating from UTest NVM information, or other inputs, may not read updated values until MCR[DONE] transitions high.

During reset recovery, register writes are not allowed until the MCR[DONE] bit transitions high to indicate reset recovery is completed.

Warning

Resetting during a program or erase operation leaves the flash core blocks being programmed or erased in an indeterminate data state. This may be recovered by executing an erase on the affected blocks.

Chapter 40
Cross-Triggering Unit (CTU)

40.1 Chip-specific CTU information

40.1.1 CTU Configuration

The device contains one instance of Cross Triggering Unit CTU_0.

40.1.2 Features

The ADC cross-triggering unit allows automatic generation of ADC conversion requests on user selected conditions without CPU load during the PWM period and with minimized CPU load for dynamic configuration.

It implements the following features:

- Cross triggering between ADC, FlexPWM, eTimer and external Pins
- Double buffered trigger generation unit with up to 8 independent triggers generated from external triggers
- Trigger generation unit configurable in sequential mode or in triggered mode
- Trigger delay unit to compensate the delay of external low pass filter
- Double buffered global trigger unit allowing eTimer synchronization and/or ADC command generation
- Double buffered ADC command list pointers to minimize ADC-trigger unit update
- Double buffered ADC conversion command list with up to 24 ADC commands
- Each trigger has the capability to generate consecutive commands
- ADC conversion command allows to control ADC channel from each ADC, single or synchronous sampling, independent result queue selection
- DMA support with safety features

NOTE

This device does not support eTimer1 pulse and eTimer4 pulse outputs of scheduler subunit.

40.1.3 CTU inter-module connections

The following table lists the inter-module connection of the CTU for the Motor Control related peripherals for the device.

Table 40-1. Motor Control peripheral interconnects

Input Module	Input Signal	Driving Module	Driver Signal
CTU_0	PWM_REL	FlexPWM_0	Master_Reload
CTU_0	PWM_ODD_0	FlexPWM_0	Out_Trigger0_0
CTU_0	PWM_ODD_1	FlexPWM_0	Out_Trigger0_1
CTU_0	PWM_ODD_2	FlexPWM_0	Out_Trigger0_2
CTU_0	PWM_ODD_3	FlexPWM_0	Out_Trigger0_3
CTU_0	PWM_EVEN_0	FlexPWM_0	Out_Trigger1_0
CTU_0	PWM_EVEN_1	FlexPWM_0	Out_Trigger1_1
CTU_0	PWM_EVEN_2	FlexPWM_0	Out_Trigger1_2
CTU_0	PWM_EVEN_3	FlexPWM_0	Out_Trigger1_3
CTU_0	RPWM_0	FlexPWM_0	PWMX_0
CTU_0	RPWM_1	FlexPWM_0	PWMX_1
CTU_0	RPWM_2	FlexPWM_0	PWMX_2
CTU_0	RPWM_3	FlexPWM_0	PWMX_3
CTU_0	NEXT_CMD_0	ADC_0	NEX_CMD
CTU_0	FIFO_0	ADC_0	OUT
CTU_0	NEXT_CMD_1	ADC_1	NEX_CMD
CTU_0	FIFO_1	ADC_1	OUT
CTU_0	ETMR0_IN	eTimer_2	T2
CTU_0	ETMR1_IN	eTimer_1	T2
ADC_0	TRIGGER	CTU_0	TRIGGER_0
ADC_0	CMD	CTU_0	CMD_0
ADC_1	TRIGGER	CTU_0	TRIGGER_1
ADC_1	CMD	CTU_0	CMD_1

40.1.4 TGSISR input assignments for CTU_0

The following table identifies the alignment among the following:

- The input number used in the InRE and InFE fields of the CTU's register TGSISR

- The generic name used in the CTU chapter for the CTU input with that input number
- For CTU_0, the specific source on this device for the CTU input with that input number

Table 40-2. TGSISR input assignments for CTU_0

TGISR I/P	CTU generic input name	Source	Signal
0	PWM_REL	FlexPWM_0	Master_Reload
1	PWM_ODD_0	FlexPWM_0	Out_Trigger0_0
2	PWM_ODD_1	FlexPWM_0	Out_Trigger0_1
3	PWM_ODD_2	FlexPWM_0	Out_Trigger0_2
4	PWM_ODD_3	FlexPWM_0	Out_Trigger0_3
5	PWM_EVEN_0	FlexPWM_0	Out_Trigger1_0
6	PWM_EVEN_1	FlexPWM_0	Out_Trigger1_1
7	PWM_EVEN_2	FlexPWM_0	Out_Trigger1_2
8	PWM_EVEN_3	FlexPWM_0	Out_Trigger1_3
9	RPWM_0	FlexPWM_0	PWMX_0
10	RPWM_1	FlexPWM_0	PWMX_1
11	RPWM_2	FlexPWM_0	PWMX_2
12	RPWM_3	FlexPWM_0	PWMX_3
13	ETMR0_IN	eTimer_2	T2
14	ETMR1_IN	eTimer_1	T2
15	EXT_IN	External Pin	External Pin

NOTE

In above table, ETMR0_IN and ETMR1_IN generic inputs corresponds to ETMR1_IN and ETMR2_IN inputs in Figure 40-1.

40.2 Introduction

In PWM driven systems it is important to schedule the acquisition of the state variables with respect to the PWM cycle. State variables are obtained through the following peripherals: ADC, position counter (for example, quadrature decoder, resolver, and sine-cos sensor), and PWM duty cycle decoder.

The Cross-Triggering Unit (CTU) is intended to completely avoid CPU involvement in the acquisition of state variables during a control cycle defined by the PWM cycle, the half PWM cycle, or a multiple number of PWM cycles. Several CTU registers are double-buffered, thus allowing coherent update during the transition from one control cycle to the next. Thus double-buffered registers updated at control cycle N will be updated during the transition from control cycle N to control cycle N+1.

The CTU provides four FIFO memory blocks to temporarily store ADC results for CPU access.

40.3 Block diagram

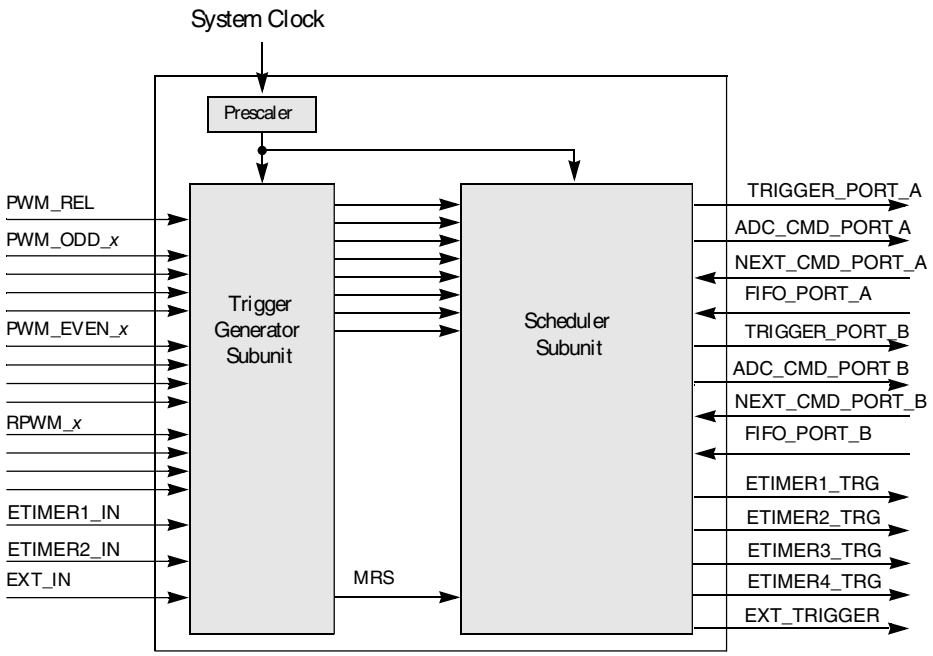

Figure 40-1. CTU block diagram

40.4 CTU overview

The CTU receives several signals from different sources such as PWM, timers, position decoder, and/or external pins. These signals are then processed to generate up to eight trigger events. An input event can be a rising edge, a falling edge, or both edges of the incoming signal. The output can be a pulse, an ADC command, or a stream of consecutive ADC commands for oversampling support. The outputs are targeted to one or more peripherals such as ADCs and timers.

The CTU implements the following features:

- Cross triggering between ADC, PWM timers, on-chip general purpose timers, and external pins
- Double-buffered trigger unit that generates up to 8 triggers
- Trigger generation unit configurable in sequential or triggered modes
- Trigger delay functionality to compensate for the delay of external low pass filters

- Double-buffered ADC command list pointers
- Double-buffered ADC conversion command list
- Each trigger has the capability to generate consecutive conversion commands
- ADC conversion commands allow two ADCs to be controlled synchronously with queue selection to store conversion results
- DMA support

In a typical application, the CTU interfaces with the following peripherals:

- PWM generators for motor control
- Timers
- External signals

The inputs are 16 digital signals. The CTU detects the rising and/or falling edges for each one of them.

Figure 40-1 shows a high level CTU block diagram. The CTU hardware architecture consists of two subunits:

- Trigger generator subunit
- Scheduler subunit

The Trigger generator subunit receives CTU input signals and selects the active edges in order to generate the Master Reload signal. The Master Reload is used to load several CTU double buffered registers. See sections TGS in triggered mode and TGS in sequential mode for more details about the Master Reload signal. The Trigger generator subunit also generates up to eight trigger event signals which are used by the Scheduler subunit.

The Scheduler subunit generates the trigger event output according to the trigger event signals from the Trigger generator subunit. The trigger event output starts an ADC conversion or generates output signals to trigger events for IPs in the SoC. See section Scheduler subunit (SU) for more detail about the Scheduler subunit.

40.4.1 Modes of operation

The CTU has two main modes of operation:

1. Triggered mode: the input event from the CTU interface is used to generate a sequence of up to 8 triggers to several outputs such as the ADCs, timers, and external triggers. Internal sequencer logic is used to schedule the triggers based upon the input event occurrence.

2. Sequential mode: each input event generates only one trigger for the selected output, such as ADCs, timers, and external triggers.

40.5 Signal description

The following table shows the chip-level signals for the CTU module.

Table 40-3. Signal properties

Name	Function
EXT_IN	Input pin for external triggers
EXT_TRG	Output pin for external triggers

40.6 Memory Map and Registers

CTU registers are implemented in two sizes:

- 32-bit registers: byte access for write operations and 32-bit access for read operation
- 16-bit registers: byte access for write operations and 32-bit access for read operations

If a 32-bit write operation is performed over a 16-bit register, the write operation is performed on the 4 aligned bytes. Read operation should be performed only at 32-bit boundary.

NOTE

Reserved bit registers, when available for write operations, should be written always with logic 0. Read access does not return meaningful data from reserved bit registers. This module does not issue transfer errors when trying to access its reserved locations.

NOTE

If the system attempts to access an invalid address within the CTU memory map, such as a non-existent register, it does not assert a slave bus error signal to the system. So the user should not rely on such an error when accessing the CTU.

The following tables describe the CTU memory mapped registers.

CTU memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Trigger Generator Subunit Input Selection Register (CTU_TGSISR)	32	R/W	0000_0000h	40.6.1/1461
4	Trigger Generator Subunit Control Register (CTU_TGSCR)	16	R/W	0000h	40.6.2/1465
6	Trigger Compare Register (CTU_T0CR)	16	R/W	0000h	40.6.3/1466
8	Trigger Compare Register (CTU_T1CR)	16	R/W	0000h	40.6.3/1466
A	Trigger Compare Register (CTU_T2CR)	16	R/W	0000h	40.6.3/1466
C	Trigger Compare Register (CTU_T3CR)	16	R/W	0000h	40.6.3/1466
E	Trigger Compare Register (CTU_T4CR)	16	R/W	0000h	40.6.3/1466
10	Trigger Compare Register (CTU_T5CR)	16	R/W	0000h	40.6.3/1466

40.6.1 Trigger Generator Subunit Input Selection Register (CTU_TGSISR)

The TGSISR register is double buffered. The load from the corresponding buffer to the register is controlled by the TGSISR_RE bit in the CTU_CR register. The TGSISR_RE bit is self negated. Once set, this bit remains set until the TGSISR register is updated from the corresponding buffer register. Reads to the TGSISR register actually return the content of the buffer and not the content of the register. Thus, a read will return the most recent data written to the register address even though the buffer data is not synchronized with the register data.

NOTE

For the particular input connection assigned to each field in this register, see the CTU's chip-specific configuration details.

Address: 0h base + 0h offset = 0h

CTU_T*n*CR field descriptions

Field	Description
0–15 TCRV	Trigger Compare Register Value.

40.6.4 TGS Counter Compare Register (CTU_TGSCCR)

Address: 0h base + 16h offset = 16h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	TGSCCV															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CTU_TGSCCR field descriptions

Field	Description
0–15 TGSCCV	TGS Counter Compare Value. The value in this register is compared against the TGS counter. When a match occurs, the TGS counter is stopped.

40.6.5 TGS Counter Reload Register (CTU_TGSCRR)

Address: 0h base + 18h offset = 18h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	TGSCRV															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CTU_TGSCRR field descriptions

Field	Description
0–15 TGSCRV	TGS Counter Reload Value. When an MRS occurs, the value in this register is used to reload the TGS counter.

40.6.6 Commands List Control Register 1 (CTU_CLCR1)

Address: 0h base + 1Ch offset = 1Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

CTU_CLCR2 field descriptions

Field	Description
0–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–7 T7_INDEX	Trigger 7 Commands List 1st command address. This is the address of the first command in the LIST associated with this trigger. Valid values range from 0 through 23.
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

CTU_CLCR2 field descriptions (continued)

Field	Description
11–15 T6_INDEX	Trigger 6 Commands List 1st command address. This is the address of the first command in the LIST associated with this trigger. Valid values range from 0 through 23.
16–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–23 T5_INDEX	Trigger 5 Commands List 1st command address. This is the address of the first command in the LIST associated with this trigger. Valid values range from 0 through 23.
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 T4_INDEX	Trigger 4 Commands List 1st command address. This is the address of the first command in the LIST associated with this trigger. Valid values range from 0 through 23.

40.6.8 Trigger Handler Control Register 1 (CTU_THCR1)

The THCR1 register is double buffered. The update from the corresponding buffer register is controlled by the MRS signal. The THCR1 and THCR2 registers are together organized into 8 groups of 7 enable bits. Each group is associated with one trigger from the Trigger subunit. Each group of enable bits has 7 enables corresponding to a master trigger enable, External Trigger output enable, 4 eTimer outputs, and the ADC command list enable, respectively. If the master trigger enable Tn_E is cleared, the trigger is disabled and the other trigger enable bits in the group have no effect.

40.6.9 Trigger Handler Control Register 2 (CTU_THCR2)

The THCR2 register is double buffered. The update from the corresponding buffer register is controlled by the MRS signal. The THCR1 and THCR2 registers are together organized into 8 groups of 7 enable bits. Each group is associated with one trigger from the Trigger subunit. Each group of enable bits has 7 enables corresponding to a master trigger enable, External Trigger output enable, 4 eTimer outputs, and the ADC command list enable, respectively. If the master trigger enable Tn_E is cleared, the trigger is disabled and the other trigger enable bits in the group have no effect.

40.6.10 Commands List Register A for ADC single-conversion mode commands (CTU_CLR_A_*n*)

The Command List Register (CLR_x_n), where n = 1,.....,24, has one of three formats (CLR_A_n, CLR_B_n, CLR_C_n) depending on the setting of its CMS and ST0 bits. If CMS=0 and ST0=0, the single conversion mode is selected and the CLR register assumes the CLR_A_n format described in the following figure.

Address: 0h base + 2Ch offset + (2d × i), where i=0d to 23d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	CIR	LC	CMS	FIFO			ST0	0			SU	0	CH			
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CTU_CLR_A_*n* field descriptions

Field	Description
0 CIR	Command execution Interrupt Request enable bit. 0 Disabled 1 Enabled
1 LC	Last Command bit. 0 Not last 1 Last
2 CMS	Conversion Mode Selection. Must be 0 in this register format. 0 Single conversion mode 1 Dual conversion mode
3–5 FIFO	FIFO used for ADC Port A / Port B. See CLR_A[SU] bit for Port A versus Port B selection. 000 FIFO_0 select ---- ---------- 111 FIFO_7 select

Table continues on the next page...

Field	Description
3–5 FIFO	FIFO used for ADC Port A / Port B. See CLR_A[SU] bit for Port A versus Port B selection. 000 FIFO_0 select --- ---------- 111 FIFO_7 select
6 ST0	Sel-Test mode control 0. Must be 0 in this register format.
7–10 CH_B	ADC Port B channel number.
11 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
12–15 CH_A	ADC Port A channel number.

40.6.12 Command List Register C for self-test commands (CTU_CLR_C_*n*)

The Command List Register (CLR_x_n), where n = 1,.....,24, has one of three formats (CLR_A_n, CLR_B_n, CLR_C_n) depending on the setting of its ST0 bit. You must first set ST0 to 1 to set the CLR register in the self-test mode register format. In this case, the CLR register assumes the CLR_C_n format described in the following figure.

Address: 0h base + 2Ch offset + (2d × i), where i=0d to 23d

Bit	0	1	2	3	4	5	6	7
Read Write	CIR	LC	ST1	ST_CMS	ST_SU	0	ST0	ALG
Reset	0	0	0	0	0	0	0	0

Read Write	ALG	BSIZE						
Reset	0	0	0	0	0	0	0	0

CTU_CLR_C_*n* field descriptions

Field	Description
0 CIR	Command Execution Interrupt Request enable bit (this bit has no influence in this mode). **NOTE:** CIR bit value has no influence in self-test mode. The interrupt request is disabled and cannot be enabled by using this bit in this mode.

Table continues on the next page...

CTU_CLR_C_*n* field descriptions (continued)

Field	Description
	0 Disabled 1 Enabled
1 LC	Last command bit. 0 Not last 1 Last
2 ST1	Self Test command control 1. ST1 must be 0 for a self test command.
3 ST_CMS	Conversion Mode Selection for Self Test command. 0 Single Conversion Mode 1 Dual Conversion Mode
4 ST_SU	Self Test Selection Unit bit. Usable only if ST_CMS is 0. 0 ADC Port A 1 ADC Port B
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 ST0	Self Test command control 0. ST0 must 1 in this register format.
7–8 ALG	Algorithm scheduled: 00 Algorithm S 01 Reserved 10 Algorithm C 11 Full algorithm (S + C)
9–15 BSIZE	Burst size of the algorithm iteration. 0000000 Single step execution ..... Two step execution through 511 step execution 1111111 512 step execution with one trigger

40.6.13 FIFO DMA Control Register (CTU_FDCR)

The FDCR register enables the DMA requests issued by the CTU FIFOs. The DMA request occurs when it is enabled and the corresponding FIFO had reached a threshold defined in register FTH.

NOTE

Interrupt and DMA are controlled independently, thus FIFO DMA operation and interrupts can be enabled at the same time.

Address: 0h base + 6Ch offset = 6Ch

Bit	0	1	2	3	4	5	6	7
Read	Reserved				Reserved	Reserved	Reserved	Reserved

	0 Disabled 1 Enabled
15 DE0	FIFO 0 DMA enable. 0 Disabled 1 Enabled

40.6.14 FIFO Control Register (CTU_FCR)

This register implements interrupt enable bits to signal FIFO behavior. FIFO overrun, overflow, empty, and full indication from one of the FIFOs are OR-ed together to indicate through one interrupt line that one or more flags are active. After receiving an interrupt the FST register should be checked to evaluate what caused that interrupt. There is one interrupt line per FIFO module.

Address: 0h base + 70h offset = 70h

31 FULL_EN0	FIFO 0 Full interrupt enable. 0 Disabled 1 Enabled

40.6.15 FIFO Threshold Register (CTU_FTH)

This register defines the threshold value for four FIFO modules. The threshold is used for comparison against the FIFO pointer and to evaluate if an overflow condition occurred for that FIFO. The overflow flag indicates that a certain amount of data, defined by the threshold value, is available in the FIFO for read. The overflow condition is set if the number of elements in the FIFO is greater than the threshold value. Thus, out of reset this register is set to detect one element in the respective FIFO since the initial value is zero.

NOTE

The threshold value should not exceed the FIFO size

Address: 0h base + 74h offset = 74h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Field	Description
0–7 TH3	FIFO 3 Threshold.
8–15 TH2	FIFO 2 Threshold.
16–23 TH1	FIFO 1 Threshold.
24–31 TH0	FIFO 0 Threshold.

40.6.16 FIFO Status Register (CTU_FST)

This register has the flags that indicate the status of the FIFO modules. Up to four FIFOs are supported. FIFO overrun, overflow, empty, and full flags are available. If enabled by the FCR register bits, these flags can generate an interrupt to the CPU. There is one interrupt signal per FIFO which combines overrun, overflow, empty, and full flags.

NOTE

The only actual error indication corresponds to the overrun flags which stay asserted once the overrun condition occurs. They are cleared by writing 1 to the respective flag. The overflow, empty, and full flags correspond to the current state of the FIFOs.

NOTE

Bits OR3, OR2, OR1, and OR0 can be read and cleared by software

Address: 0h base + 7Ch offset = 7Ch

17–28 LA_DATA	Data of stored channel.
29–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

40.6.19 Error Flag Register (CTU_EFR)

The EFR register bits are cleared if a 1 is written to the bit position. Otherwise, the bit retains the previous value.

NOTE

The ERRCMP field reads 0 at reset. When reset is released, this field remains cleared until the CTU timer clock is enabled. After the CTU timer clock is enabled, ERRCMP reads 1. This field must be cleared before enabling the interrupt requests.

Address: 0h base + C0h offset = C0h

Bit	0	1	2	3	4	5	6	7
Read	0		LIST_BE	CS	ET_OE	ERRCMP	T4_OE	T3_OE
Write			w1c	w1c	w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0

Read	T2_OE	T1_OE	ADC_OE	TGS_OSM	MRS_O	ICE	SM_TO	MRS_RE
Write	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0

CTU_EFR field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 LIST_BE	List Busy Error. Indicates that a list of commands is trying to send commands to a busy ADC or to the same ADC at the same time. It also indicates a conflict in the self-test algorithm execution by the ADCs, see Self-Test Execution Errors section. Cleared if 1 is written to this bit location. 0 No error 1 Error
3 CS	Self test Counter Status. This bit indicates if a self-test algorithm is in progress. If 1 is written to this bit, a reset to the self test counter will occur, thus terminating the self-test algorithm execution. As a status bit it indicates: 0 All the counters are at reset value, thus none of the self-test algorithm are executing 1 One of the counters used in self test mode is not in the reset state, thus self-test is in progress.
4 ET_OE	External Trigger generation Overrun Error. This bit is set when an external trigger occurs while a trigger input is being processed by the TGS. It is cleared if 1 is written to this bit location. 0 No error 1 Error
5 ERRCMP	Error Compare. When a match occurs, the TGS Counter has reached the TGSCCR value. Cleared if 1 is written to this bit location.

Table continues on the next page...

CTU_EFR field descriptions (continued)

Field	Description
	0 No match 1 Match
6 T4_OE	Timer 4 trigger generation Overrun Error. This bit is set when a timer trigger input occurs while a trigger input is being processed by the TGS. Cleared if 1 is written to this bit location. 0 No error 1 Error
7 T3_OE	Timer 3 trigger generation Overrun Error. This bit is set when a timer trigger input occurs while a trigger input is being processed by the TGS. Cleared if 1 is written to this bit location. 0 No error 1 Error
8 T2_OE	Timer 2 trigger generation Overrun Error. This bit is set when a timer trigger input occurs while a trigger input is being processed by the TGS. Cleared if 1 is written to this bit location. 0 No error 1 Error
9 T1_OE	Timer 1 trigger generation Overrun Error. This bit is set when a timer trigger input occurs while a trigger input is being processed by the TGS. Cleared if 1 is written to this bit location. 0 No error 1 Error
10 ADC_OE	ADC command generation Overrun Error. This bit is set if an ADC command is issued when there is a command already being processed. Cleared if 1 is written to this bit location. 0 No Error 1 Error
11 TGS_OSM	The TGS Overrun in Sequential Mode. This bit is set when a new event occurs before the trigger event selected by the previous event had occurred. The error is generated only if the trigger from the TGS is linked to a SU output. Cleared if 1 is written to this bit location. 0 No overrun 1 Overrun
12 MRS_O	Master Reload Signal Overrun. If the time window defined by two consecutive MRS is not enough for the number of programmed events in the THCR registers, an error occurs and MRS_O flag is set. Cleared if 1 is written to this bit location. 0 No overrun 1 Overrun
13 ICE	Invalid Command Error. An error that occurs when the shared channel is accessed by two ADCs at the same time, or when an ADC is already using the channel. This situation can occur with a dual conversion command or with two single conversions in parallel mode. 0 No error 1 Error
14 SM_TO	Trigger Overrun (more than 8 ES) in TGS Sequential Mode. If the number of positive edges of ES is higher than 8, an error occurs and SM_TO flag is set. Cleared if 1 is written to this bit location. 0 No overrun 1 Overrun

Table continues on the next page...

CTU_EFR field descriptions (continued)

Field	Description
15 MRS_RE	Master Reload Signal Reload Error. If an MRS occurs while the user is updating a double-buffered register, the MRS_RE is set indicating an error condition. Cleared if 1 is written to this bit location. 0 No error 1 Error

40.6.20 Interrupt Flag Register (CTU_IFR)

The IFR register bits are cleared if a 1 is written to the bit position. Otherwise, the bit retains the previous value.

NOTE

The Tn_I fields read 0 at reset. When reset is released, these fields remain cleared until the CTU timer clock is enabled. After the CTU timer clock is enabled, the Tn_I fields read 1. These flags must be cleared before enabling the interrupt requests.

Address: 0h base + C2h offset = C2h

Write	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c
Reset	1	1	1	1	1	1	1	0

CTU_IFR field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 SERR_B	If this bit is set, it means that the time between the start of a conversion and the end of that conversion is out of the expected range which is defined by the EXPBR and CNTRNGR registers. See Expected Value B (EXPBR) and Counter Range (CNTRNGR) registers. Cleared if 1 is written to this bit location.
5 SERR_A	If this bit is set, it means that the time between the start of a conversion and the end of that conversion is out of the expected range defined by the EXPAR and CNTRNGR registers. See the Expected value A (EXPAR) and Counter Range (CNTRNGR) registers. Cleared if 1 is written to this bit location.
6 ADC_I	ADC command interrupt flag is set when a new command is issued. The interrupt related to this flag is enabled by the CIR bit in the CLR_x_n registers. Cleared if 1 is written to this bit location.

Table continues on the next page...

CTU_IFR field descriptions (continued)

Field	Description
7 T7_I	Trigger 7 interrupt flag is set when the corresponding trigger is issued. Cleared if 1 is written to this bit location.
8 T6_I	Trigger 6 interrupt flag is set when the corresponding trigger is issued. Cleared if 1 is written to this bit location.
9 T5_I	Trigger 5 interrupt flag is set when the corresponding trigger is issued. Cleared if 1 is written to this bit location.
10 T4_I	Trigger 4 interrupt flag is set when the corresponding trigger is issued. Cleared if 1 is written to this bit location.
11 T3_I	Trigger 3 interrupt flag is set when the corresponding trigger is issued. Cleared if 1 is written to this bit location.
12 T2_I	Trigger 2 interrupt flag is set when the corresponding trigger is issued. Cleared if 1 is written to this bit location.
13 T1_I	Trigger 1 interrupt flag is set when the corresponding trigger is issued. Cleared if 1 is written to this bit location.
14 T0_I	Trigger 0 interrupt flag is set when the corresponding trigger is issued. Cleared if 1 is written to this bit location.
15 MRS_I	MRS Interrupt flag is set when the Master Reload Signal occurs. The interrupt associated with this flag is enabled by the MRS_IE bit in the IR register. Cleared if 1 is written to this bit location.

40.6.21 Interrupt/DMA Register (CTU_IR)

Address: 0h base + C4h offset = C4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

6 T1_IE	Trigger 1 Interrupt Enable. 0 Disabled 1 Enabled
7 T0_IE	Trigger 0 Interrupt Enable. 0 Disabled 1 Enabled
8–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 SAF_CNT_B_EN	Enable the ADC Port B counter to check the conversion time. 0 Disabled 1 Enabled
11 SAF_CNT_A_EN	Enable the ADC Port A counter to check the conversion time. 0 Disabled 1 Enabled
12 DMA_DE	If this bit is set, a dma done acts as a write '1' in the GRE bit.
13 MRS_DMAE	If GRE bit is set, DMA request is issued on MRS occurrence.
14 MRS_IE	MRS Interrupt Enable. 0 Disabled 1 Enabled
15 IEE	Interrupt Error Enable. 0 Disabled 1 Enabled

40.6.22 Control ON Time Register (CTU_COTR)

Address: 0h base + C6h offset = C6h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0								COTGT							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CTU_COTR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–15 COTGT	Control ON-Time and Guard Time for external trigger. See Scheduler subunit (SU) for a more detailed description.

40.6.23 Control Register (CTU_CR)

NOTE

The CTU_ADC_R bit resets all lists in execution. If CTU list execution is in parallel mode, this bit resets both lists even if they issued commands to different ADCs. Also, the self-test algorithm counters go to reset state.

NOTE

Bits Tn_SG, CTU_ADC_R, CGRE, and MRS_SG can be set by software. Bits CTU_ODIS, DFE, GRE, and TGSISR_RE can be read and set by software.

Address: 0h base + C8h offset = C8h

Bit	0	1	2	3	4	5	6	7
Read								
Write	T7_SG	T6_SG	T5_SG	T4_SG	T3_SG	T2_SG	T1_SG	T0_SG

Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CTU_DFR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–15 FILTER_N	Digital Filter value. The external signal (EXT_IN) is considered at 1 if it is latched FILTER_N times at 1 and is considered at 0 if it is latched FILTER_N times at 0. If FILTER_N = 0, the filter is in bypass. 00000000 Filter is in bypass 00000001 In all combinations of FILTERN_N greater than 0, the filter is not in bypass -------- ---------- 11111111 In all combinations of FILTERN_N greater than 0, the filter is not in bypass

40.6.25 Expected Value A Register (CTU_EXPAR)

The EXPAR register has the expected number of system clock cycles (the slave bus clock) for an AD conversion to be completed by the ADC connected to Port A. If SAF_CNT_A_EN is set in the IR register and a conversion takes a number of cycles out of the interval defined by EXPA and CNTRNG to complete, then the SERR_A error bit is set in the IFR register. Please see the CNTRNGR for more details.

Address: 0h base + CCh offset = CCh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	EXPA															
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

CTU_EXPAR field descriptions

Field	Description
0–15 EXPA	This value is the expected number of system clock cycles needed by ADC Port A to complete a conversion.

40.6.26 Expected Value B Register (CTU_EXPBR)

The EXPBR register has the expected number of system clock cycles (the slave bus clock) for an AD conversion to be completed by the ADC connected to Port B. If SAF_CNT_B_EN is set in the IR register and a conversion takes a number of cycles out of the interval defined by EXPB and CNTRNG to complete, then the SERR_B error bit is set in the IFR register. Please see the CNTRNGR for more details.

Address: 0h base + CEh offset = CEh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	EXPB															
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

CTU_EXPBR field descriptions

Field	Description
0–15 EXPB	This value is the expected number of system clock cycles needed by ADC Port B to complete a conversion.

40.6.27 Counter Range Register (CTU_CNTRNGR)

The CNTRNGR register provides a way to mask out the less significant bits in the EXP_A and EXP_B fields of EXPAR and EXPBR registers, respectively. If set, bits in CNTRNG mask out related bits in EXP_A and EXP_B fields, thus providing a range in which a conversion should occur. The expression used for the conversion range check is: set SERR_A bit if (conversion counter & ~CNTRNG > EXP_A & ~CNTRNG) or (conversion counter & ~CNTRNG < EXPP_A & ~CNTRNG), where the conversion counter increments at system clock rate (slave bus clock rate). This equation also applies to SERR_B and EXP_B.

NOTE

The 1s in the CNTRNG must be set from the right to the left (less significant bits) without gap with 0.

NOTE

The safety counter allowed range is obtained by taking the EXPA/B value and exchanging to "X" the corresponding positions where the CNTRNG bit is 1.

Address: 0h base + D0h offset = D0h

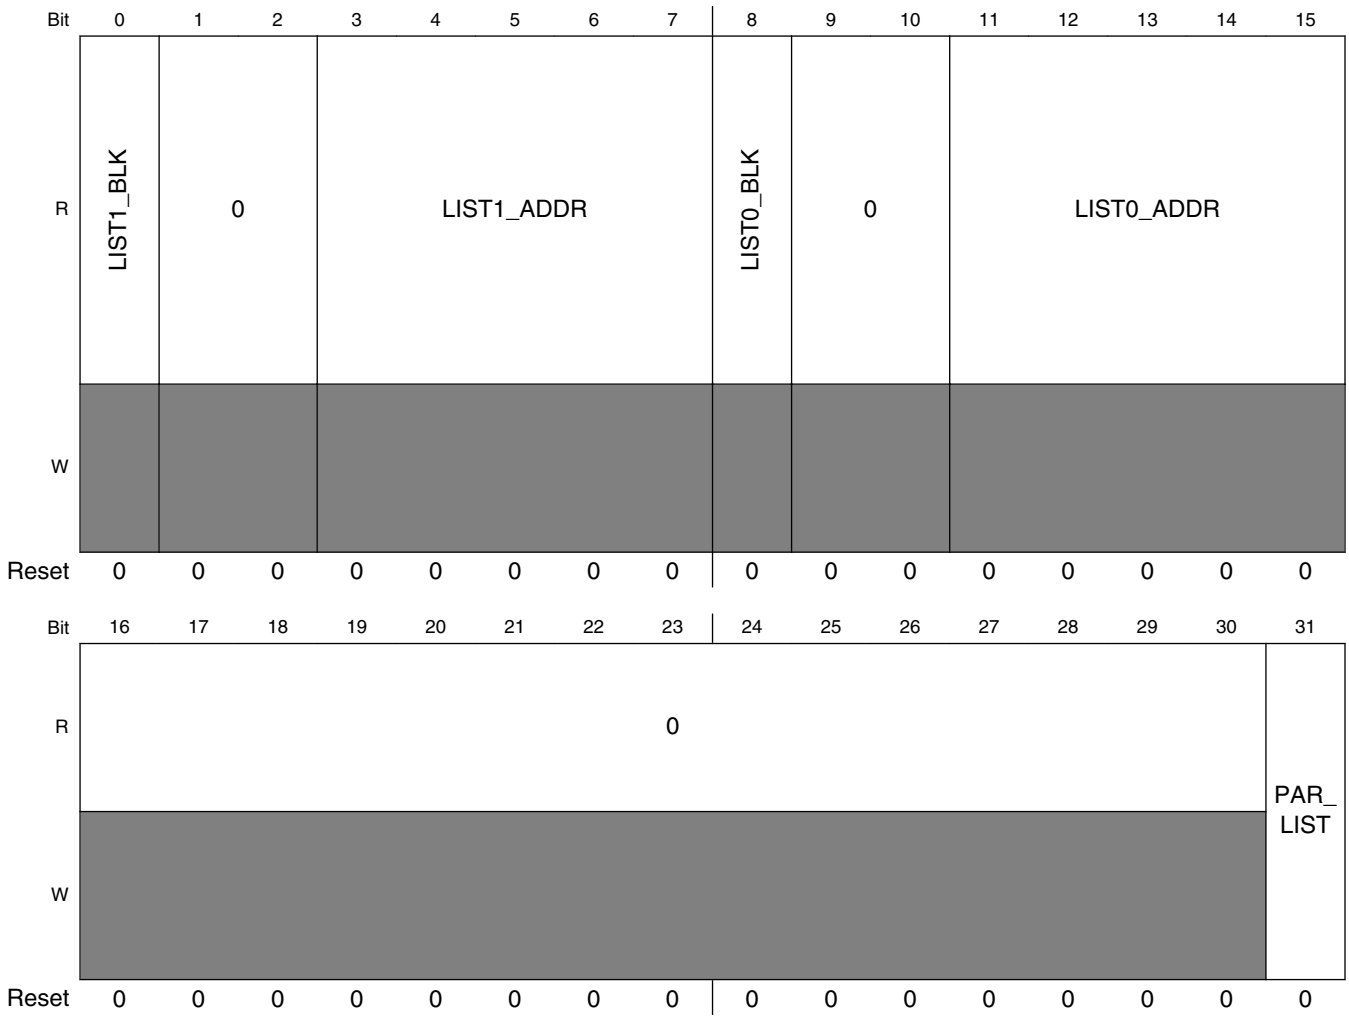
Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0								CNTRNG							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CTU_CNTRNGR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–15 CNTRNG	If set, the bits in this field mask out the equivalent bits of the expected values EXP_A and EXP_B. In this way, a range of system clock (slave bus clock) cycles is defined for a conversion to occur. This means the bit positions with 1s in the CNTRNG change the corresponding bits on EXPA/EXPB and safety counters A/B to "X". For example, with EXPA = 1b0010_1101 and CNTRNG = 0b0111, the safety counter can end with values of the format 0b0010_1XXX to avoid SERR_A error flag.

40.6.28 List Control/Status Register (CTU_LISTCSR)

Address: 0h base + D4h offset = D4h



CTU_LISTCSR field descriptions

Field	Description
0 LIST1_BLK	List 1 Blocked flag. When set, this bit indicates that the address indicated by LIST1_ADDR had failed when trying to issue a command to the corresponding ADC. This bit is only meaningful if LIST_BE flag in EFR register is set. This bit is cleared when LIST_BE flag is cleared.
1–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–7 LIST1_ADDR	List Address 1. This field shows the command address that was being executed when the LIST_BE flag in the EFR register was set.
8 LIST0_BLK	List 0 Blocked flag. This bit indicates that the address indicated by LIST0_ADDR had failed when trying to issue a command to the corresponding ADC. This bit is only meaningful if LIST_BE flag in EFR register is set. This bit is cleared when LIST_BE flag is cleared.

Table continues on the next page...

CTU_LISTCSR field descriptions (continued)

Field	Description
9–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–15 LIST0_ADDR	List Address 0. Indicates the command address being executed when LIST_BE flag in EFR register was set.
16–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 PAR_LIST	Parallel mode List. This bit selects the parallel mode for the list execution. 0 List is executed in streaming mode 1 List is executed in parallel mode

40.7 Functional description

The CTU is comprised by two subunits: the Trigger Generator subunit, or TGS, and the Scheduler subunit, or SU. The TGS is responsible for generating triggers based on the module input signals connected to timer modules. The trigger signal from TGS is then connected to the scheduler subunit, which is responsible for the generation of ADC commands or triggers to on-chip logic such as timers. The following sections describe the TGS and SU in more detail.

40.7.1 Trigger Generator subunit (TGS)

The Trigger Generator subunit, TGS, generates up to eight trigger events. The main sub-blocks in the TGS are:

- Counter: generates sequential trigger events
- Trigger List: with 8 x 16-bit double-buffered registers for timing comparison

The TGS has two modes of operation:

- **Triggered mode**: each event source generates up to eight trigger event outputs.
- **Sequential mode**: each event source generates only one trigger event output.

Note

An *event* means a pulse generated from the selected CTU trigger inputs. It is represented in Figure 40-4 by the ES signal (event signal).

External signals, represented by EXT_IN in Figure 40-4, may be asynchronous related to the CTU clock. For this reason the external trigger inputs are filtered by a CTU programmable digital filter. The external signal is considered at 1 if it is stable at 1 during FILTER_N CTU clock cycles and it is considered to be at 0 if it is stable at 0 during FILTER_N CTU clock cycles, where FILTER_N is defined in the digital filter register (DFR).

Trigger events can be initiated by hardware or by software. A software trigger is generated by writing to the CTU Control Register, CR. The CR register Tx_SG bits are automatically cleared by the CTU hardware when the respective trigger event is generated.

40.7.2 TGS in triggered mode

Figure 40-2 shows the TGS configuration in Triggered mode.

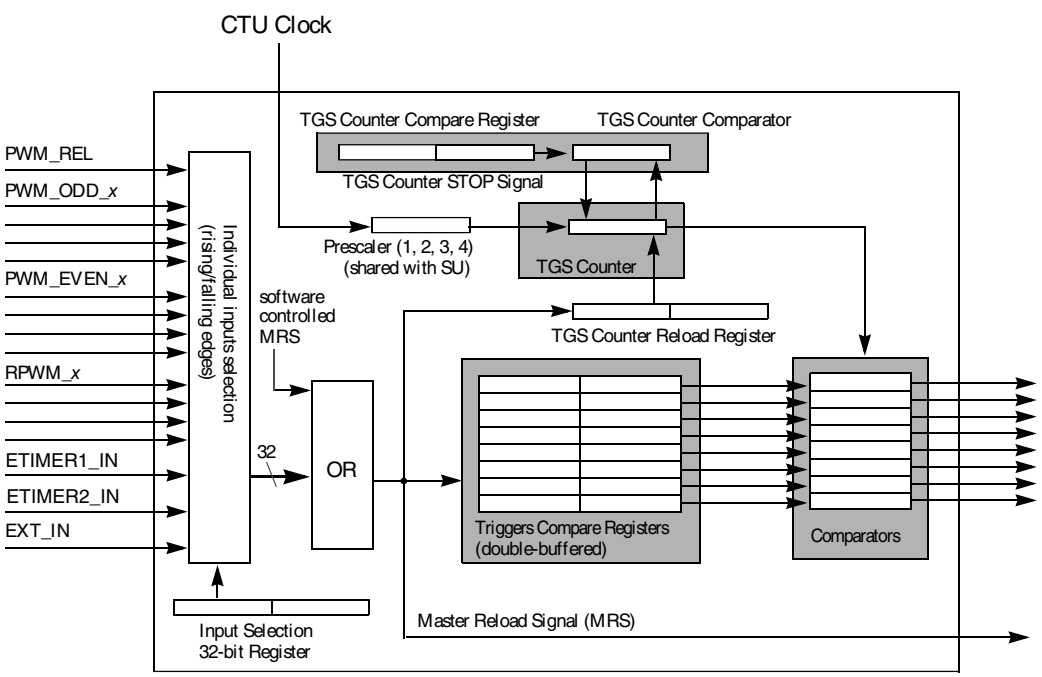


Figure 40-2. Trigger Generator subunit in triggered mode

Note

The CTU clock should be connected to the same clock source used by the CTU inputs clock. In Figure 40-2 these inputs are from the PWM generator, eTimers, and EXT_IN.

The TGS has 16 input signals selected from the input selection register (TGSISR). The available selections are:

- Inactive, no selection
- Rising edge
- Falling edge
- Both edges

Up to 32 input events corresponding to 16 input signals are selected through the TGSISR register and OR-ed in order to generate the Master Reload Signal (MRS), which defines a *control cycle*.

The MRS can also be generated by software. The software operation is done by writing to the MRS_SG bit in the CTU Control Register. The MRS_SG bit is self cleared; thus, it reads always as 0. The MRS is used to re-load the TGS Counter Register with the values from the double-buffered TGSCRR register. The MRS is also used to re-load all double-buffered registers, such as the trigger compare registers, TGSCR and TGSCRR, with the corresponding buffered values.

The triggers list registers consist of 8 compare registers (T0CR through T7CR). Each register is associated with a comparator, where a match generates an output trigger. On the occurrence of a re-load triggered by MRS, the comparison for trigger events generation starts from the first cycle of counting. However, the comparison with the TGS Counter Compare Register (TGSCCR) is always disabled during one TGS clock cycle and then re-enabled. A match between TGSCCR and the TGS counter stops the TGS counter. Therefore, this one cycle disable allows the user to configure the TGSCCR and TGSCRR with the same value.

The prescaler for TGS and SU is defined by the PRES bits in the TGS Control Register and divides the CTU clock. The available selections for the prescaler values are 1, 2, 3, and 4.

Figure 40-3 shows a timing diagram for the TGS operation in triggered mode. The MRS and the trigger event occurrences are indicated along with the delay relative to the MRS occurrence.

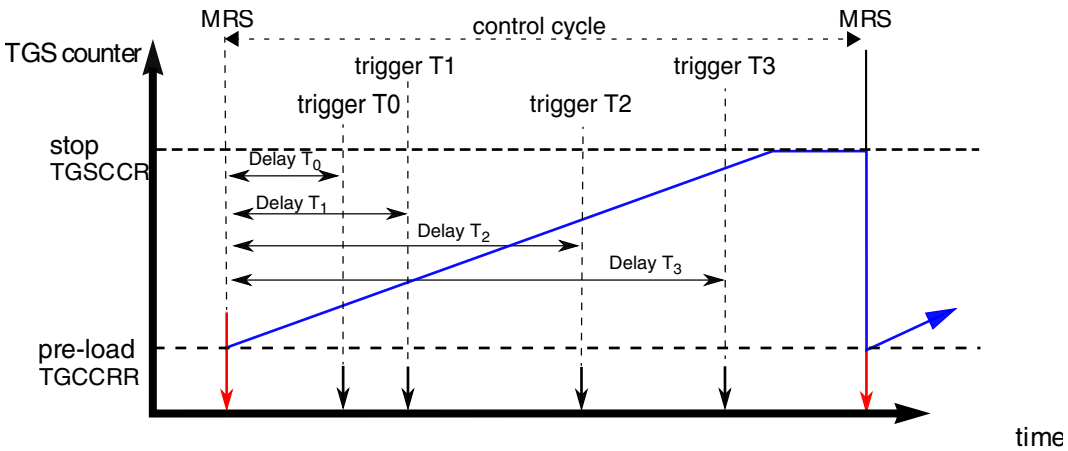

Figure 40-3. Example timing diagram for TGS in triggered mode

40.7.3 TGS in sequential mode

Figure 40-4 shows the blocks and signals related to the TGS in sequential mode.

In sequential mode only one of the 32 input signals is selected by the 5-bit MRS_SM (master reload selection). The selected signal re-loads the trigger list and resets the 3-bit ES counter which selects the trigger event. Sequences of up to eight trigger events are generated in one control cycle.

The 32 input events corresponding to 16 input signals with 2 edges detection per signal are individually enabled through the register TGSISR and OR-ed in order to generate the event signal ES. The ES signal is used to re-load the TGS counter register and to increment the 3-bit ES counter.

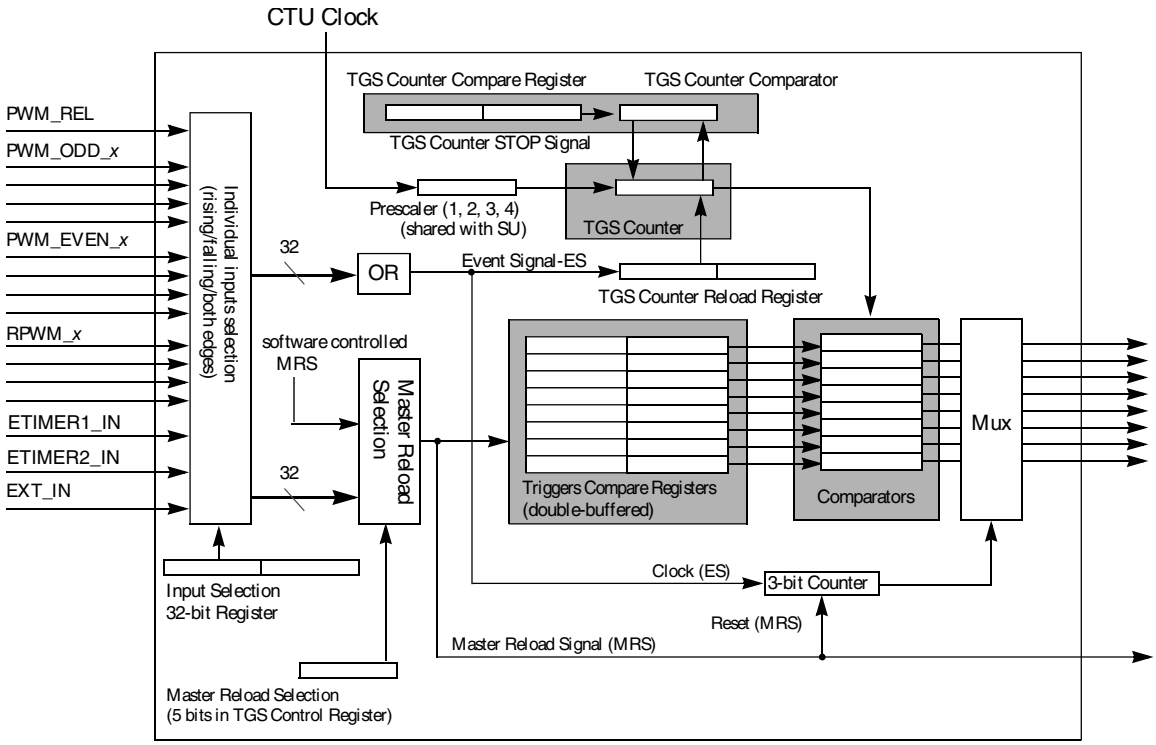

Figure 40-4. TGS in sequential mode

Figure 40-5 is a timing diagram for TGS in sequential mode showing the MRS and ES. The trigger events are indicated with the delay with respect to the ES. Note that initially ES and MRS are aligned. The TGS counter is re-loaded on each ES and starts counting up until the next ES or until it matches the value in TGSCCR register and stops.

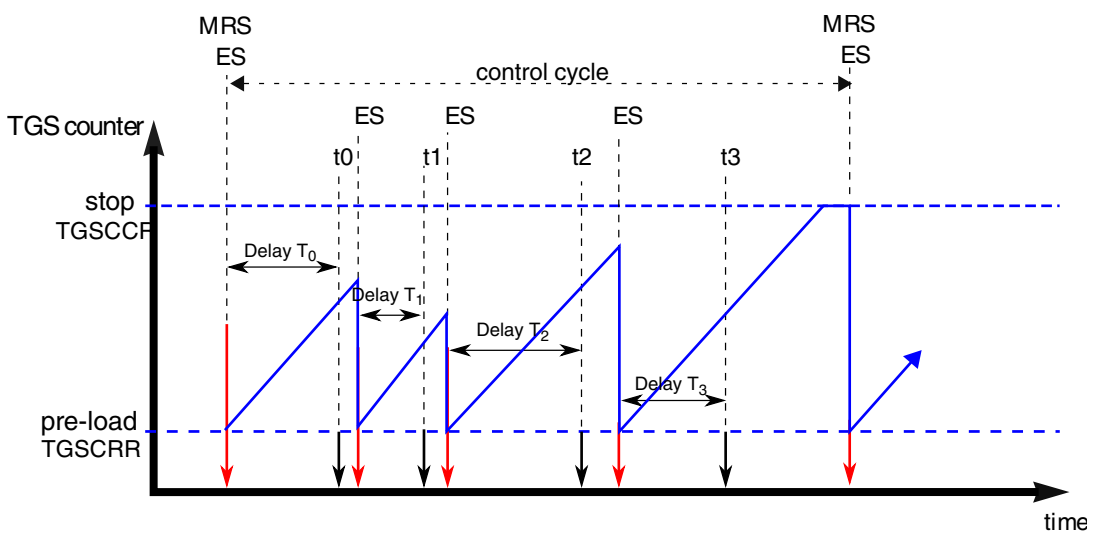

Figure 40-5. Example timing diagram for TGS in sequential mode

40.7.4 TGS counter

The TGS counter counts from negative to positive values as defined by the re-load and stop values defined in register TGSCRR and TGSCCR, respectively. The maximum counter value is 0x7FFF; after that, a counter wrap occurs and the counter value transitions from 0x7FFF to 0x8000. The following figure shows TGS counting examples.

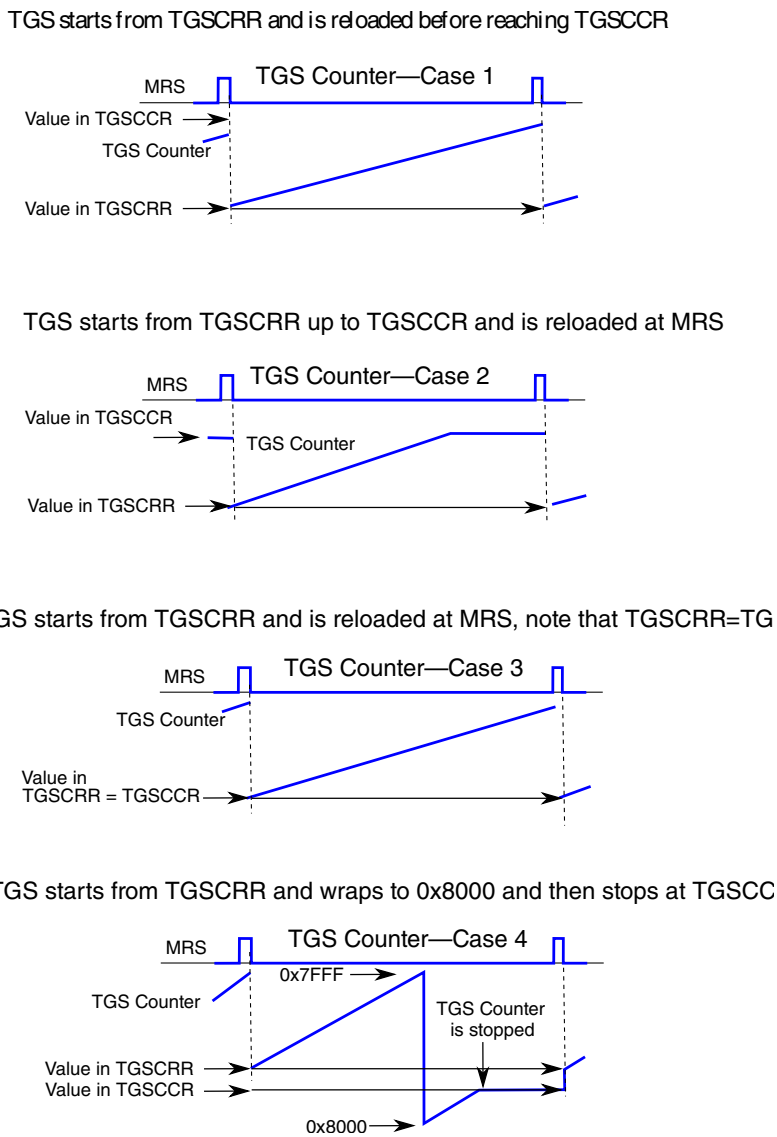

Figure 40-6. TGS counter behavior

Note

The TGS counter starts counting after an MRS and only stops if a counter wrap occurs and TGSCCR value is reached before the next MRS occurs.

40.7.5 Scheduler subunit (SU)

The following figure shows the block diagram of the Scheduler subunit. The SU trigger event outputs are:

1. ADC command or ADC stream of commands
2. eTimer1 pulse
3. eTimer2 pulse
4. eTimer3 pulse
5. eTimer4 pulse
6. External trigger pulse

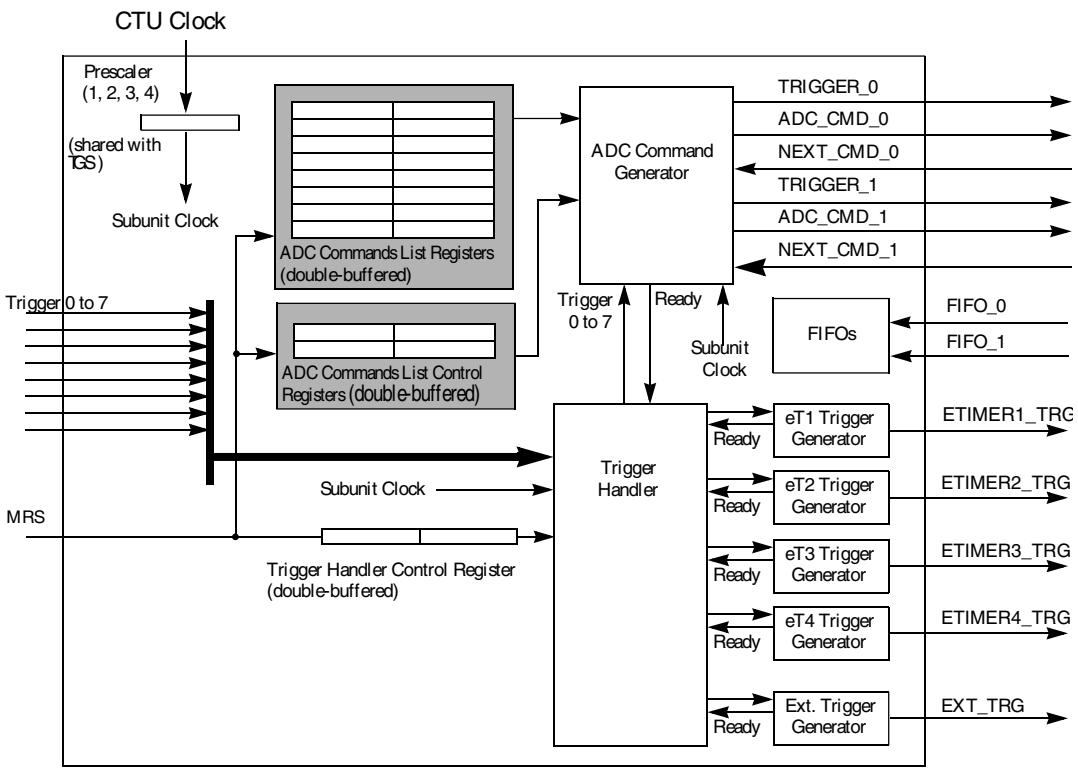

Figure 40-7. Scheduler subunit

The SU receives 8 trigger signals from the Trigger Generator subunit, TGS, and starts a command list to the selected ADC or generates the trigger event outputs. This module has the same functionality in both TGS modes: triggered and sequential. Each of the 4 SU outputs can be linked to any of the 8 trigger events from TGS. This is implemented by the Trigger Handler block. Each trigger event can be linked to one or more SU outputs.

If two events are linked at the same time to the same output (either ADC commands or output triggers) an error is generated and flagged in the EFR register's TnOE bits. In this case, only the trigger with the lowest index is used. For example, if trigger 0 and trigger 1 are linked to the same ADC output and they occur at the same time, an error is generated and the ADC command corresponding to trigger 0 is generated.

When a trigger is linked to an ADC, an associated ADC stream of commands is generated. The ADC Commands List Control Register CLCR1/2 defines the list entry point that is the first command to be executed. Subsequent list pointers are generated in an incremental way as the commands in the list are executed. When a trigger is linked to an eTimer or an EXT_TRG shown in the above figure, an event is generated on the corresponding output. The external trigger output has two modes of operation configured by TGSCR register bit ET_M:

- Pulse mode: a pulse with one system clock width is generated at the output pin
- Toggle mode: the output pin toggles its state as a result of each trigger event

An *ON-Time* and *Guard-Time* are defined for both Pulse and Toggle modes. The COTR register, Control *On-Time* Register, defines the (*ON-Time + Guard-Time)* duration. After a trigger has occurred a new trigger will be generated only after (*ON-time + Guard-Time)*. The COTR register only applies to external triggers; it does not affect ADC commands.

40.7.6 ADC commands list

The SU implements a command list that stores the ADC commands. The command list stores up to 24 x 16-bit commands (see ADC command list format) in a double-buffered implementation. The command list buffer registers may be updated at any time between two consecutive MRS, but the changes are transferred from the buffers to the actual registers only after an MRS occurs, so a correct reload procedure is performed (see Reload mechanism). The first command in a list is pointed by the 5-bit CLCRx register. Once a command list is triggered, it executes until the last command is found. The last command (n) is defined by the LC bit of the next command (n+1) in the list. Note that the command with LC=1 does not belong to the list and thus it is not executed. Note also that the LC bit is ignored in the first command of a list. See the command list registers, CLR_A_n, CLR_B_n, or CLR_C_n, where n = 1,….,24. The figure below describes the state diagram for the Commands List execution. A sequence of commands on the list is executed until the last command is found. See ADC command list format for more details.

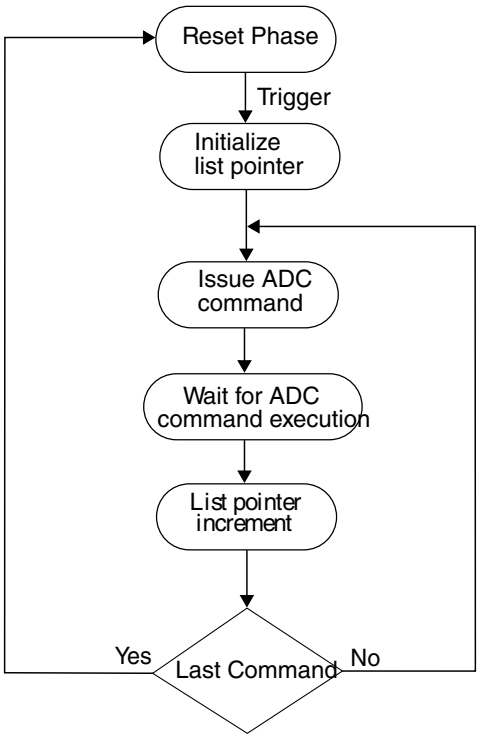

Figure 40-8. ADC command list scanning state diagram

Note

The CTU reads the next command line (the LC bit) to determine if the present command is the last one to be executed.

40.7.7 ADC command list format

The ADC command can be configured for single or dual conversion. In single conversion mode, the command targets one ADC only. In dual conversion mode, the conversion command is sent to both ADCs at the same time. Due to the clock domain crossing between CTU and ADCs, there could be a misalignment of up to one ADC clock cycle between the two commands.

The result of each conversion, in both modes, is stored in one of the four available FIFOs. In dual conversion mode, both ADCs store the result of their conversion in the same FIFO. If both ADCs access the FIFO in the same clock cycle, ADC unit A has higher priority, otherwise the first available conversion result is stored first.

The CTU supports up to 32 channels for both ADCs. The same physical channel cannot be assigned for both ADCs in a dual conversion mode. If there is an attempt to do so, an error is flagged in the EFR register's ICE bit, but the CTU sends the command to both ADCs.

In general, an ADC command is composed by the following fields depending upon the conversion format used (see Commands List Register A for ADC single-conversion mode commands (CTU_CLR_A_*n*)):

- Channel A: ADC A channel number (4 bits)
- Channel B: ADC B channel number (4 bits)
- Target ADC selection: ADC A or ADC B used in single conversion mode only (1 bit)
- FIFO selection bits for the selected ADC unit: up to four FIFOs (2 bits)
- Conversion mode selection: single or dual conversion mode (1 bit)
- Last command (LC): defines the last command in a list (1 bit)
- Interrupt request: enable interrupt request on command execution (1 bit)

The first command of a list is indicated by the CLCR1/2 registers' Tx_INDEX field. The last command is indicated by the LC (Last Command bit) of the following command in the command list. The first command is always executed. The execution of the following commands is controlled by the LC bit.

The figure below describes several scenarios for the command sequencing. If the first command indicated by the CLCR1/2 register is one of the lines identified as "Last command," then the list is a single command list. Note also that the list pointer wraps back to the first command in the list after command 24 is executed and if it is not the last command. If no command is defined as the last command, then the list will be executed continuously in a loop of 24 commands.

- Command List A: two command queues are available with elements 4 and 24 being last commands
- Command List B: sub-list 1 with one single command at address 1, and sub-list 2 with a queue of commands with last command at address 24
- Command List C: sub-list 2 with one single command at address 24, and sub-list 1 with a command queue with last command at address 23
- Command List D: two command queues with a wrap at address 24

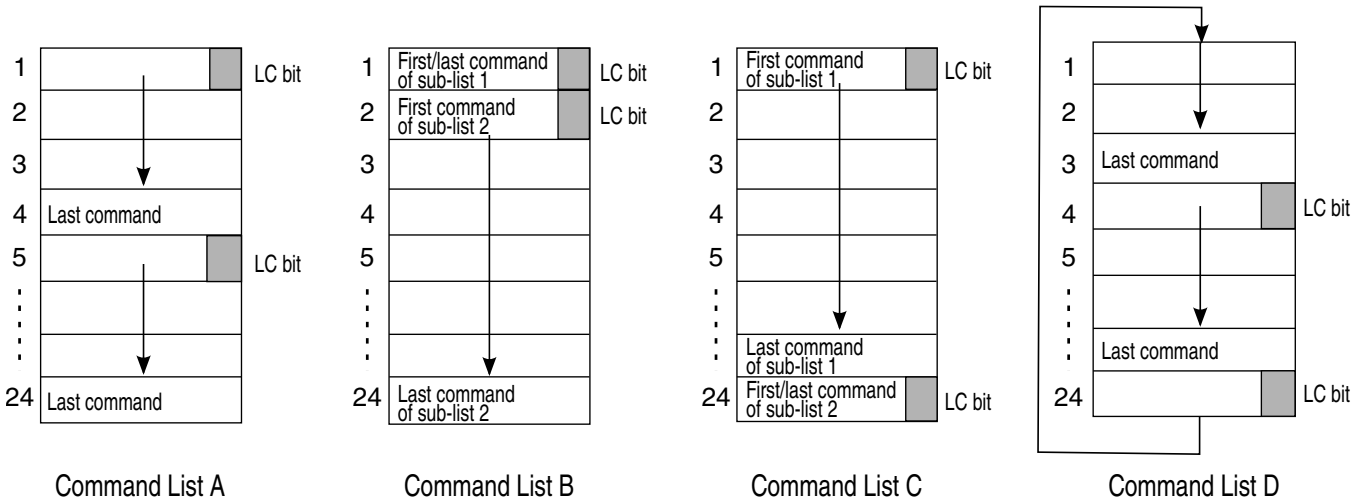

Figure 40-9. Command list sequencing

Note

The addresses shown in in the above figure do not represent addresses in the memory map. Please refer to the Memory Map section to check for the actual addresses.

40.7.8 ADC command list operation modes

There are two modes of operation regarding the ADC command list execution: ***streaming*** mode and ***parallel*** mode. In streaming mode, the command lists should behave as a stream of commands, meaning that two or more lists cannot be executed at the same time, but only in a sequence. Thus if list 1 is triggered, it should finish the execution of its last command before list 2 can be triggered. If there is an attempt to trigger more than one list at the same time, then an error occurs.

In parallel mode, up to two lists can be executed at the same time. In order to avoid errors during the execution of two parallel lists, they should not have commands for both ADCs. Therefore, if list 1 has commands for ADC A, then list 2 should only have commands for ADC B. Note also that if a shared analog input is used by one of the lists, it should not be used by the other list in order to avoid a contention and therefore an error. ADC dual conversion commands should also not be used in parallel mode.

Figure 40-10 shows the execution of two lists in streaming mode. While a list is being executed, any attempt to trigger the execution of another list while in this mode will cause an error. Note that both lists may have commands for ADC A or B with no restriction. Also, dual commands may be used.

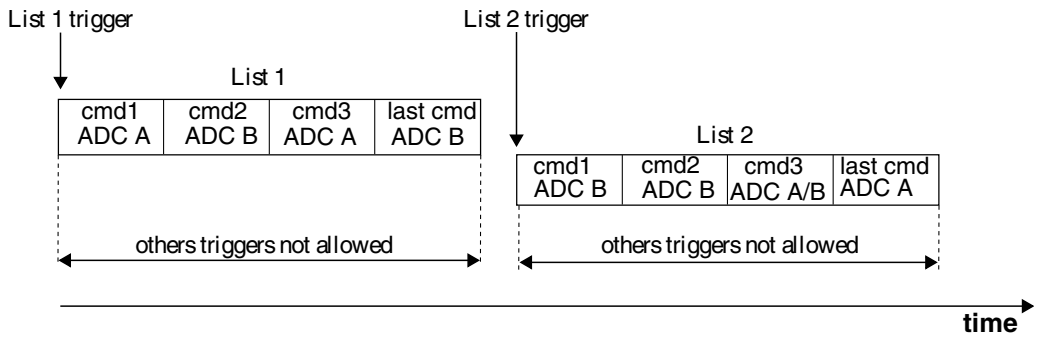

Figure 40-10. List execution in Streaming Mode

Figure 40-11 shows the execution of two lists in parallel mode. There are no restrictions for the triggers of both lists. After the two lists are triggered, no other triggers are allowed. If there is an attempt to trigger a third list while lists 1 and 2 are executing, then an error will be issued by setting ADC_OE bit in EFR register. Note that list 1 only has commands for ADC A and list 2 only has commands for ADC B. Having ADC A and ADC B commands in the same list may cause an error since two commands for the same ADC could be executed from different lists at the same time.

Note

The mixing of commands for both ADCs in the same list in parallel mode must not be used since the correct execution of commands in this case is not guaranteed by the CTU hardware.

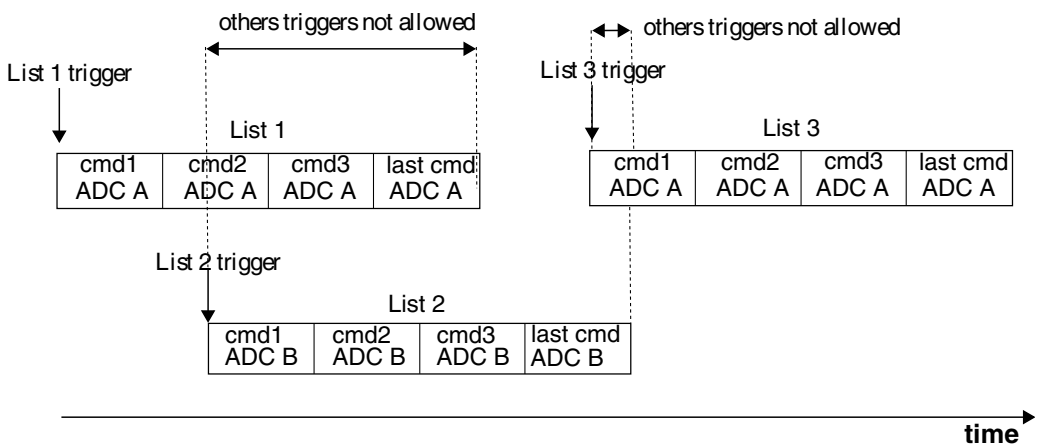

Figure 40-11. List execution in parallel mode

The list mode is controlled by the PAR_LIST bit in the LISTCSR register.

40.7.9 ADC results FIFOs

ADC results are stored in one of the four FIFOs. The FIFOs allow the storage of ADC results according to the type of data acquisition (phase currents, rotor position, ground-noise, and so on) so the software can distinguish data from several ADC channels. Each FIFO has its own interrupt line, DMA request signal, and a status register. The target FIFO for a conversion result is specified in the ADC command. Each FIFO element is 32 bits wide. The following figure shows the FIFO selection for ADC A and ADC B results.

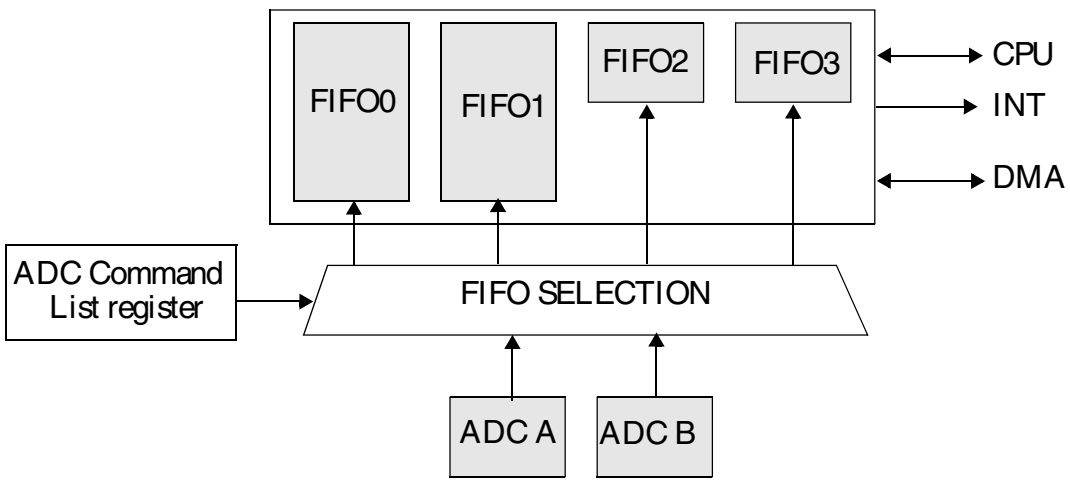

Figure 40-12. FIFO selection for ADC results storage

The CTU FIFOs are fixed depth. For example:

- FIFO0 and FIFO1: 16 entries each, dimensioned for full PWM period current acquisitions
- FIFO2 and FIFO3: 4 entries each, dimensioned for low rate acquisitions

FIFO access can be done by 16-bit or 32-bit read transaction. In 32-bit reads the conversion result, the target ADC, and the channel number are accessed. 8-bit access must not be used; otherwise, the FIFO pointer increments and the complete data is not retrieved. The FIFO result register can be read in a right- or left-aligned format using two different addresses:

- Unsigned right-justified, read from register FLx (for FIFO x)

  (Conversion result is unsigned right-justified data, i.e. bits [11:0] are used for 12-bit resolution and bits [15:12] always return zero)
- Signed left-justified, read from register FLx (for FIFO x)

(Conversion result is signed left-justified data, i.e. bit [15] is reserved for sign and is always read as zero, bits [14:3] are used for 12-bit resolution and bits [2:0] always return zero)

The FIFO access should be based on the status bits in the FCR register. Empty and full indication are provided. If data is read from an empty FIFO, then the read data should not be considered as valid data. Note that there is no indication of an underflow condition. If the FIFO is full and there is an attempt to write more data, then the new data is not written to the FIFO and an overrun flag is set.

40.7.10 Reload mechanism

In order to assure coherent programming, several CTU registers are double-buffered, thus allowing the programming of new data on the buffers while not affecting data being used. All registers are uploaded with buffer data at the same time. For the majority of the CTU registers the re-load is controlled by the Master Reload Signal, MRS.

Since the Master Reload Signal is generated by the hardware, it may occur while the software is still updating the buffer registers. In this case, noncoherent values are written to the registers because the CPU did not finish the programing of all registers. In order to avoid this situation, a General Reload Enable, GRE, control bit is provided. If GRE is cleared then no reload occurs. If this bit is set, then the reload is done when MRS occurs. The GRE bit is automatically cleared by MRS or is cleared by software using the CGRE bit in the same register. The CGRE bit is self-cleared and thus always read as zero.

The software should be able to program all registers buffers within a control cycle. In order to help the software to evaluate that a flawless register programing was executed, the MRS_RE flag is provided in the EFR register. If cleared, this flag indicates that all register buffers were programed before MRS occurred, as follows:

- If any of the double buffered registers is written, the FGRE flag is set indicating that a programing cycle has initiated.
- Set GRE to indicate that all updates to the buffer registers were performed.
- The reload of all registers is executed when the MRS occurs. Since GRE is set then MRS_RE will not be set.
- GRE and FGRE are cleared when MRS occurs.

See Figure 40-13 for more details.

An error is flagged by MRS_RE when MRS occurs, GRE is cleared, and FGRE is set. This scenario indicates that the software has initiated a register programming but has not finished it before the MRS, as follows:

- If any of the double buffered registers is written, the FGRE flag is set indicating that a programing cycle has initiated.
- MRS occurs and GRE is not set. In this case MRS_RE is set and, if enabled, an interrupt is generated.
- FGRE is not cleared when MRS occurs and no register is updated, since GRE is cleared.

Note that the software does not need to update all double-buffered registers during a *control cycle*. In order to avoid the error indication it is sufficient to set GRE before a MRS occurs.

A race condition occurs when GRE is being cleared by CGRE at the same time that an MRS occurs. In this case, GRE is considered to be cleared and no reload occurs. Another race condition may occur between CGRE and GRE being set. Since these two bits are in the same register they could eventually be set at the same time. In this case, CGRE has precedence; thus, GRE is cleared.

Note

MRS has priority over the TGSISR_RE bit in the CR register, which is the re-synchronization bit of the TGSISR.

The following figure describes two scenarios for the register re-load. Scenario (a) is a normal re-load where the buffers of the double-buffered registers are programmed and the GRE bit is set before the next MRS occurs. The scenario presented in (b) describes an error condition where the software did not signal the hardware that all registers are ready for re-load before the next MRS. This is indicated by GRE being at zero when MRS occurs. In this case, MRS_RE flag is set indicating the fault condition.

Figure 40-13. Reload scenarios

40.8 Interrupts and DMA Requests

40.8.1 DMA support

The DMA interface can be used to configure the CTU registers. A DMA request is issued if MRS occurs and the GRE bit is set. In this case, the previously transferred data is loaded from the buffers into the registers and a new transfer cycle is initiated with the DMA request. The DMA done signal from the DMA controller is used to set GRE bit which allows the reload to be performed. The following figure describes this operation.

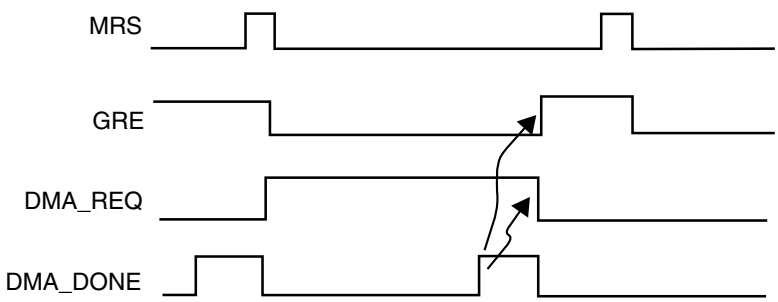

Figure 40-14. Register reload using DMA

DMA support can also be provided for reading FIFO stored data. Each FIFO can be configured to perform a DMA request when the number of stored words reaches a threshold value defined in the FTH register. See the FIFO Threshold, FTH, register for more information. After a DMA_DONE and the remaining data in the FIFO is below the watermark, then the DMA request is removed. Thus for an efficient operation, the DMA should be configured to execute a loop reading all data in the FIFO considering the amount of data the same as defined by the watermark.

40.8.2 CTU faults and errors

The CTU detects and signals the following error conditions:

- MRS reload error: MRS occurs while user is updating the double-buffered registers.
- Sequential mode trigger overrun SM_TO: more than 8 event signals occur before the next MRS in TGS sequential mode.

- Trigger event overrun indicated by 4 interrupt signals ADC_OE, T0_OE, T1_OE and ET_OE: a trigger event occurs during the time frame when the previous trigger was not completed.
- The CTU allows the user to pre-set a trigger to the eTimer1 in the middle of an ADC conversion. In parallel mode even two ADCs' commands can be issued at the same time. The error only occurs if the second trigger is targeting the same ADC.
- Invalid (unrecognized) ADC command occurs and the ICE bit is set.
- Master reload signal overrun MRS_O: MRS occurs before all triggers selected by (Tn_E and (TnETE or TnTmE or Tn_ADCE)) bits in THCR1/2 registers have occurred.
- TGS_OSM TGS overrun in sequential mode: a new event occurs before the trigger event selected by the previous event had occurred.

The faults/errors flags in the CTU error flag register and in the CTU interrupt flag register can be cleared by writing 1 to the respective bit. Writing 0 to these bits has no effect.

Note

The CTU does not support write-protection mechanism for any register, meaning that all registers are accessible at any time.

The CTU does not generate a transfer error when its reserved address space is accessed.

40.8.2.1 CTU parallel list errors

The command list operation in parallel mode may generate errors since two lists may be in execution at the same time. Below some error conditions are described.

Commands for the same ADC are issued at the same time by two lists. In this case:

- One of the commands is disregarded and an error is issued.
- The LIST_BE bit in the EFR register is set.
- The address of the list commands are shown in the LISTCSR register.
- The address of the command that was not executed is indicated in the LISTCSR register.

A third list is triggered when two lists are already being executed. In this case:

- The third list is not executed and an error is indicated by the ADC_OE bit in the EFR register.

One list is being executed and a second list is triggered; the first command of the second list is for the same ADC being used by the first list. In this case:

- The command of the second list is not executed.
- The address of the second list command is shown in the LISTCSR register.
- The LIST_BE bit in the EFR register is set.

40.8.3 CTU interrupt/DMA requests

The CTU generates the following interrupt/DMA requests which are controlled by the IR register:

- Error interrupt request, see CTU faults and errors (1 interrupt line)
- ADC command interrupt request (1 interrupt line).
- MRS interrupt request (1 interrupt line)
- Trigger event interrupt request (1 interrupt line for each trigger event)
- FIFOs interrupt and/or DMA transfer request (1 interrupt line for each FIFO). See FIFO control register, FCR.
- DMA transfer request on the MRS occurrence if GRE bit is set

40.9 Self test mode

The CTU is capable of issuing a self test command to the ADC.

The CLRx register is used to set up a self test command. Table 40-4 describes the ST0 and ST1 bits that control self-test functionality.

Table 40-4. Self-test command

ST_CMS bit	ST1 bit	ST0 bit	Command description
0	Not Used	0	no self test single conversion
1	Not Used	0	no self test dual conversion
Not Used	0	1	self test command

Table continues on the next page...

Table 40-4. Self-test command (continued)

ST_CMS bit	ST1 bit	ST0 bit	Command description
0	1	1	no self test command single conversion
1	1	1	no self test command dual conversion

Two algorithms are available in self test mode, see Table 40-5.

Table 40-5. Self-test algorithm selection

ALG[1]	Number of steps	Executed Algorithm
00	3	Algorithm S
01[2]	–	Reserved
10	12	Algorithm C
11	15	Algorithm FULL (S + C)

1. ALG refers to the CLRx register field.
2. The 01 selection causes a command execution error and the LIST_BE flag is set in the Error Flag Register (EFR).

The self-test S algorithm is executed in an atomic burst of conversions independent of the BSIZE value in the CLRx register. Below are described the steps for this algorithm execution.

- Step 0: VBGAP/VREF test
- Step 1: VDD/VREF test
- Step 2: VREF/VREF test

When the FULL algorithm is selected, the CTU executes the S algorithm followed by the C algorithm.

The self-test execution follows the trigger scheme selected for the CTU, either triggered mode or sequential mode can be selected.

In order to completely execute one of the algorithms described in Table 40-5 a certain number of steps need to be performed. Each step corresponds to the time for one ADC conversion to complete. These steps may be executed at once, by just one command, or they can be interleaved with other ADC commands. In order to executed self-test commands interleaved with other conversion commands it is sufficient to set the BSIZE field in the CLRx register for a value lower than the number of steps defined for the selected algorithm. The following figure shows the execution of the C algorithm interleaved with regular ADC commands.

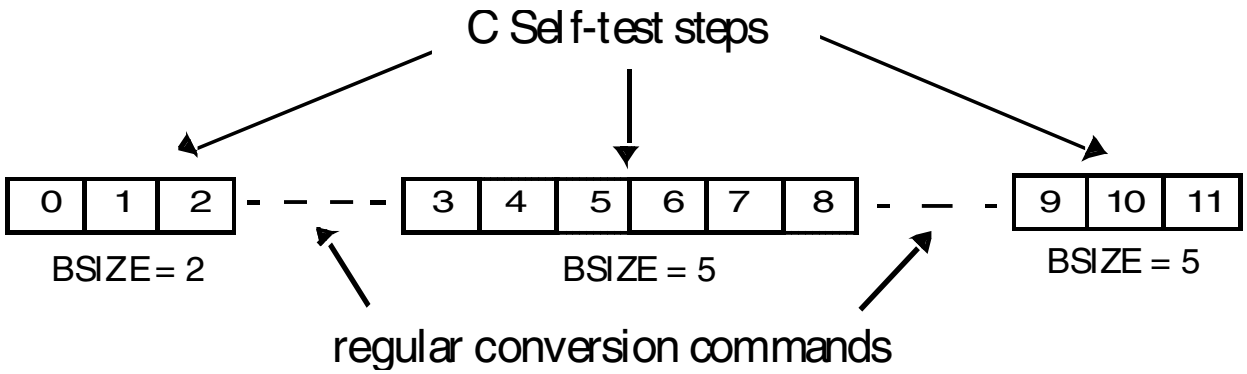

Figure 40-15. C Algorithm execution interleaved with others ADC commands

In the figure above, the last C self-test sequence intentionally shows BSIZE set to a larger value than the remaining steps needed to complete the C algorithm. In this case, the number of executed self-test steps does not follow BSIZE but instead it follows the number of remaining steps for the selected self-test algorithm, which in this case is 3 steps.

Note

The S algorithm steps do not interleave with other ADC commands even if BSIZE is smaller than 3. Independent of BSIZE value all the 3 steps of the S algorithm are executed in a contiguous sequence.

The number of steps needed to completely execute the selected self-test algorithm is as follows:

- S algorithm requires 3 steps
- C algorithm requires 12 steps
- FULL runs all algorithm and requires 15 steps

In the figure below, the FULL algorithm is executed interleaved with other ADC commands. The BSIZE = 3 in the first and second self-test commands produces different number of executed self-test steps.

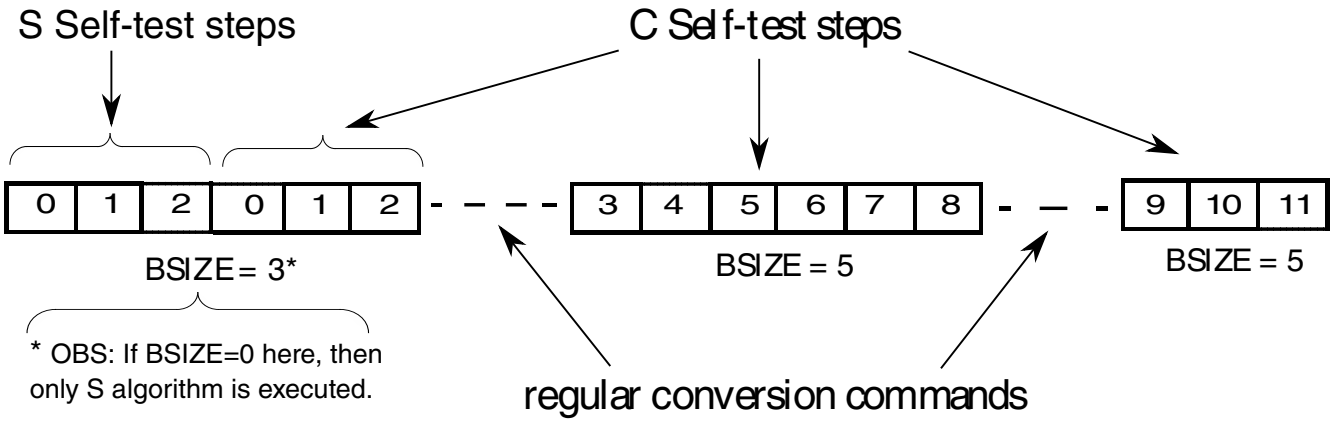

Figure 40-16. FULL algorithm execution interleaved with other ADC commands

40.9.1 Self-test execution errors

When a self-test algorithm is initiated for an ADC, it should complete before any other self-test algorithm is started in the same ADC. In other words, one self-test algorithm should not be interleaved with another self-test algorithm. Any attempt to do so will cause the ongoing list execution to be halted and cause the LIST_BE error flag (see LIST_BE) to be set. In order to evaluate if a self-test algorithm is running, the CS bit (see CS) can be checked. If set, this bit indicates a self-test has initiated in one of the ADCs. If a self-test algorithm conflict occurs, as described, the recovery procedure is to issue a software reset through the CTU_ADC_R bit in the CR register.

An error condition (see LIST_BE) is also caused when the reserved value 01 is selected for the self-test algorithm.

Chapter 41
Enhanced Motor Control Timer (eTimer)

41.1 Chip-specific eTimer information

41.1.1 Enhanced motor control timer (eTimer) configuration

This device contains two eTimer modules: eTIMER_1 and eTIMER_2.

The following table lists the eTimer primary timer/counter channel connections.

Table 41-1. eTimer primary timer/counter channel connections

Module	Channel	Source/Target
eTIMER_1	CH0-5 (Input)	From PAD (Refer to attached IO Signal Description and Input multiplexing tables spreadsheet)
eTIMER_1	CH6-7 (Input)	Reserved
eTIMER_2	CH0-5 (Input)	From PAD (Refer to attached IO Signal Description and Input multiplexing tables spreadsheet)
eTIMER_2	CH6-7 (Input)	Reserved
eTIMER_1	CH0-5 (Output)	To PAD (Refer to attached IO Signal Description and Input multiplexing tables spreadsheet)
eTIMER_1	CH6 (Output)	Reserved
eTIMER_1	CH7 (Output)	ENET - 1588 TIMER Channel0
eTIMER_2	CH0-5 (Output)	To PAD (Refer to attached IO Signal Description and Input multiplexing tables spreadsheet)
eTIMER_2	CH6-7 (Output)	Reserved

NOTE

Not all eTimer channels are available on the chip pads. Certain channels are connected internally with the ENET module.

NOTE

Interrupt for Channel7 of eTIMER_1 is disabled.

Table 41-2. eTimer module configurations

Module	Total number of channels	Auxiliary inputs	DMA channels	Channel used for injection conversion support
eTIMER_1	8	7	2	5
eTIMER_2	8	7	2	

The following table lists the eTIMER auxiliary connections.

Table 41-3. eTimer auxiliary connections

Input module	Input signal	Driving module	Driver signal
eTIMER_1	AUX_0	CTU_0	eTIMER1_TRG
eTIMER_1	AUX_1	eTIMER_2	T2
eTIMER_1	AUX_2	FlexRay	FR_CA_TX
eTIMER_1	AUX_3	SPI_1	SCK
eTIMER_1	AUX_4	CTE	AUX_0
eTIMER_1	AUX_5	MIPICSI2	SOP
eTIMER_1	AUX_6	ENET	TIMER_3
eTIMER_1	AUX_7	Reserved	-
eTIMER_2	AUX_0	Reserved	-
eTIMER_2	AUX_1	Reserved	-
eTIMER_2	AUX_2	CTU_0	eTIMER2_TRG
eTIMER_2	AUX_3	eTIMER_1	T4
eTIMER_2	AUX_4	MIPICSI2	EOP
eTIMER_2	AUX_5	CTE	AUX_1
eTIMER_2	AUX_6	ENET	TIMER_3
eTIMER_2	AUX_7	Reserved	-

NOTE

In above table, eTIMER1_TRG and eTIMER2_TRG triggers corresponds to ETIMER2_TRG and ETIMER3_TRG triggers in the Figure 40-1.

41.1.1.1 eTimer register accesses

NOTE

Address range from 10Ch to 116h will not give any transfer error for unimplemented registers in between in this range and writing on unimplemented spaces in between this range is not advised.

41.2 Introduction

This section briefly describes the eTimer, its features and customization, and contains block diagrams.

41.2.1 Overview

An eTimer module provides:

- Eight identical counter/timer channels

Each 16-bit counter/timer channel contains a prescaler, a counter, a load register, a hold register, two queued capture registers, two compare registers, two compare preload registers, and four control registers.

Note

This document uses the terms "Timer" and "Counter" interchangeably because the counter/timers may perform either or both tasks.

The Load register provides the initialization value to the counter when the counter's terminal value has been reached. For true modulo counting the counter can also be initialized by the CMPLD1 or CMPLD2 registers.

The Hold register captures the counter's value when other counters are being read. This feature supports the reading of cascaded counters coherently.

The Capture registers enable an external signal to take a "snap shot" of the counter's current value.

The COMP1 and COMP2 registers provide the values to which the counter is compared. If a match occurs, the OFLAG signal can be set, cleared, or toggled. At match time, an interrupt is generated if enabled, and the new compare value is loaded into the COMP1 or COMP2 registers from CMPLD1 and CMPLD2 if enabled.

The Prescaler provides different time bases useful for clocking the counter/timer.

The Counter provides the ability to count internal or external events.

Within the eTimer module, the input pins are shareable.

41.2.2 Features

The eTimer module design includes these distinctive features:

- 16-bit counters/timers: Eight.
- Count up/down.
- Counters are cascadable.
- Enhanced programmable up/down modulo counting.
- Max count rate equals peripheral clock/2 for external clocks.
- Max count rate equals peripheral clock for internal clocks.
- Count once or repeatedly.
- Counters are preloadable.
- Compare registers are preloadable.
- Counters can share available input pins.
- Separate prescaler for each counter.
- Each counter has capture and compare capability.
- Continuous and single shot capture for enhanced speed measurement.
- DMA support of capture registers and compare registers.
- OFLAG comparison for safety critical applications.
- Programmable operation during debug mode .
- Programmable input filter.
- Counting start can be synchronized across counters.

41.2.3 Module block diagram

The eTimer block diagram is shown in the following figure.

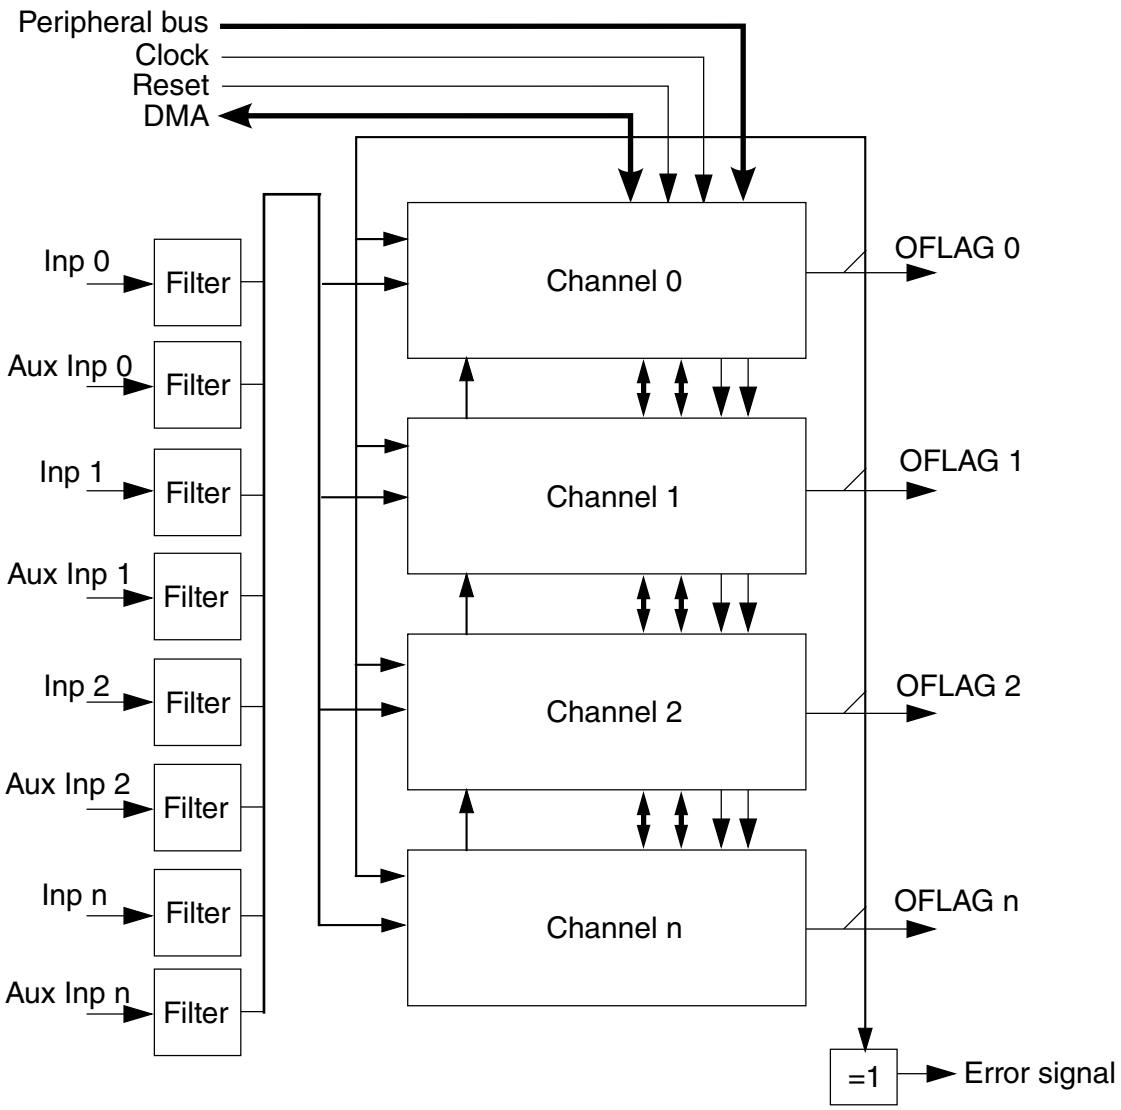

Figure 41-1. eTimer Block Diagram

41.2.4 Channel Block Diagram

Each of the timer/counter channels within the eTimer are shown in the following figure.

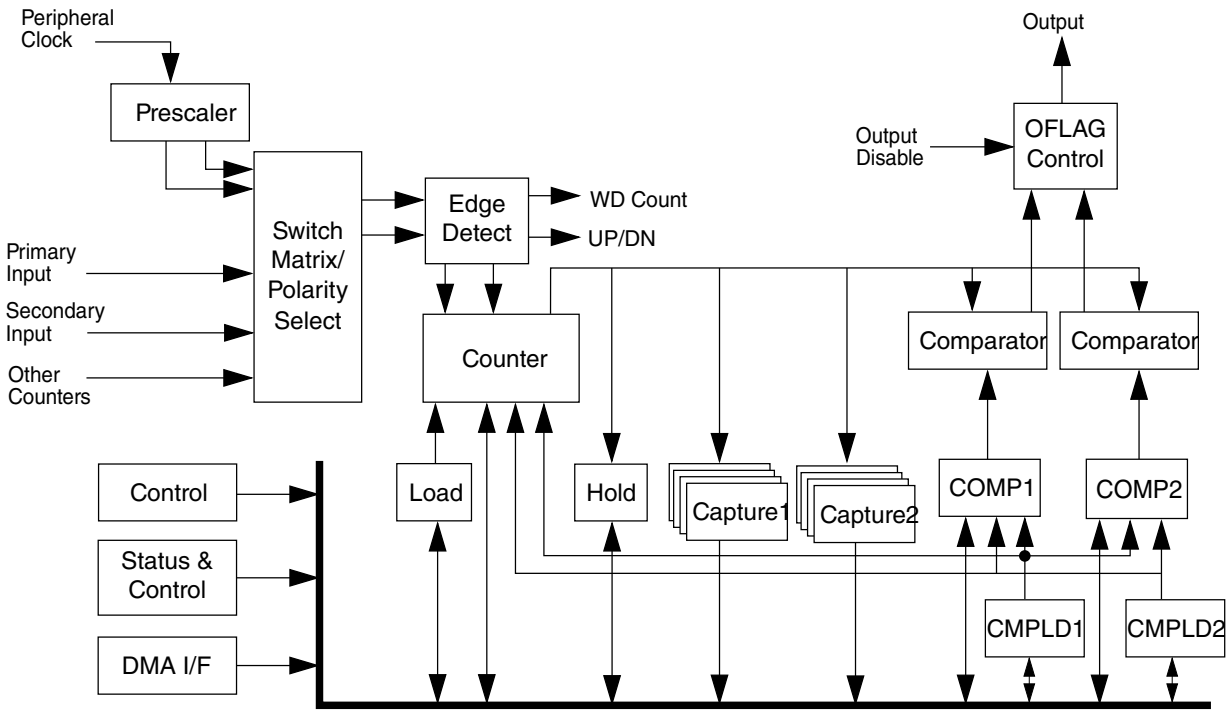

Figure 41-2. eTimer Channel Block Diagram

41.3 External Signal Descriptions

Each eTimer module has eight external signals that can be used as either inputs or outputs. The number of auxiliary inputs per module is device-dependent. See the configuration section for more information. The eTimer also interfaces to the Peripheral Bus.

41.3.1 TIO[n:0] - Timer Input/Outputs

These pins can be independently configured to be either timer input sources or output flags. In Figure 41-2, the TIO signals are shown as the Primary Inputs, and the Outputs from the OFLAG Control block.

41.3.2 TAI[n:0] - Timer Auxiliary Inputs

These pins act as alternate input choices for the timer channels. The TAI signals are shown as Aux Inp 1..n in Figure 41-1.

41.4 Memory map and register definition

The address of a register is the sum of a base address and an address offset. The base address is defined at the chip level and the address offset is defined at the module level.

There are a set of registers for each timer channel, and a set of configuration registers.

Certain registers are not byte-accessible. Registers which generate an error when a byte access occurs are noted as such in their register descriptions. Other registers which are not byte-accessible will not generate an error when a byte access occurs.

A write to a read-only register will produce an error.

ETIMER memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Channel n Compare Register 1 (ETIMER_CH0_COMP1)	16	R/W	0000h	41.4.1/1530

41.4.1 Channel n Compare Register 1 (ETIMER_CH*n*_COMP1)

This read/write register stores the value used for comparison with the counter value. This register is not byte accessible. More explanation on the use of COMP1 can be found in Usage of Compare Registers .

Address: 0h base + 0h offset + (32d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	COMP1															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ETIMER_CH*n*_COMP1 field descriptions

Field	Description
0–15 COMP1	Value used for comparison with the counter value

41.4.2 Channel n Compare Register 2 (ETIMER_CH*n*_COMP2)

This read/write register stores the value used for comparison with the counter value. This register is not byte accessible. More explanation on the use of COMP2 can be found in Usage of Compare Registers .

Address: 0h base + 2h offset + (32d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	COMP2															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ETIMER_CH*n*_COMP2 field descriptions

Field	Description
0–15 COMP2	Value used for comparison with the counter value

41.4.3 Channel n Capture Register 1 (ETIMER_CH*n*_CAPT1)

This read-only register stores the value captured from the counter. It is actually a 2-deep FIFO and not a single register. This register is not byte accessible. A byte access to this register will cause an error to be generated. CCCTRL[CPT1MODE] determines when a capture occurs.

Address: 0h base + 4h offset + (32d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	CAPT1															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ETIMER_CH*n*_CAPT1 field descriptions

Field	Description
0–15 CAPT1	Value captured from the counter

41.4.4 Channel n Capture Register 2 (ETIMER_CH*n*_CAPT2)

This read-only register stores the value captured from the counter. It is actually a 2-deep FIFO and not a single register. This register is not byte accessible. A byte access to this register will cause an error to be generated. CCCTRL[CPT2MODE] determines when a capture occurs.

Address: 0h base + 6h offset + (32d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	CAPT2															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ETIMER_CH*n*_CAPT2 field descriptions

Field	Description
0–15 CAPT2	Value captured from the counter

41.4.5 Channel n Load Register (ETIMER_CH*n*_LOAD)

This read/write register stores the value used to initialize the counter. This register is not byte accessible.

Address: 0h base + 8h offset + (32d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	LOAD															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ETIMER_CH*n*_LOAD field descriptions

Field	Description
0–15 LOAD	Value used to initialize the counter

41.4.6 Channel n Hold Register (ETIMER_CH*n*_HOLD)

This read-only register stores the counter's value whenever any of the counters within a module are read. This is used to support coherent reading of cascaded counters.

Address: 0h base + Ah offset + (32d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	HOLD															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ETIMER_CH*n*_HOLD field descriptions

Field	Description
0–15 HOLD	Stores the counter's value whenever any of the counters within a module are read.

41.4.7 Channel n Counter Register (ETIMER_CH*n*_CNTR)

This read/write register is the counter for this channel of the timer module. This register is not byte accessible.

Address: 0h base + Ch offset + (32d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	CNTR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ETIMER_CH*n*_CNTR field descriptions

Field	Description
0–15 CNTR	Counter for this channel of the timer module

41.4.8 Channel n Control Register 1 (ETIMER_CH*n*_CTRL1)

Address: 0h base + Eh offset + (32d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7
Read Write	CNTMODE			PRISRC				
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read Write	ONCE	LENGTH	DIR	SECSRC				
Reset	0	0	0	0	0	0	0	0

ETIMER_CH*n*_CTRL1 field descriptions

Field	Description
0–2 CNTMODE	Count mode These bits control the basic counting and behavior of the counter. 000 No Operation 001 Count rising edges of primary source (Rising edges counted only when PIPS = 0. Falling edges counted when PIPS = 1. If primary count source is IP bus clock, only rising edges are counted regardless of PIPS value.) 010 Count rising and falling edges of primary source (IP Bus clock divide by 1 can not be used as a primary count source in edge count mode.) 011 Count rising edges of primary source while secondary input high active 100 Quadrature count mode, uses primary and secondary sources 101 Count primary source rising edges, secondary source specifies direction (1 = minus) (Rising edges counted only when PIPS = 0. Falling edges counted when PIPS = 1.)

Table continues on the next page...

ETIMER_CH*n*_CTRL1 field descriptions (continued)

Field	Description
	110 Edge of secondary source triggers primary count till compare 111 Cascaded counter mode, up/down (Primary count source must be set to one of the counter outputs.)
3–7 PRISRC	Primary Count Source These bits select the primary count source. **NOTE:** A timer selecting its own output as its primary count source is not a legal choice. The result is no counting. — 00000 Counter #0 input pin 00001 Counter #1 input pin 00010 Counter #2 input pin 00011 Counter #3 input pin 00100 Counter #4 input pin 00101 Counter #5 input pin 00110 Counter #6 input pin 00111 Counter #7 input pin 01000 Auxiliary input #0 pin 01001 Auxiliary input #1 pin 01010 Auxiliary input #2 pin 01011 Auxiliary input #3 pin 01100 Auxiliary input #4 pin 01101 Auxiliary input #5 pin 01110 Auxiliary input #6 pin 01111 Auxiliary input #7 pin 10000 Counter #0 output 10001 Counter #1 output 10010 Counter #2 output 10011 Counter #3 output 10100 Counter #4 output 10101 Counter #5 output 10110 Counter #6 output pin 10111 Counter #7 output pin 11000 IP Bus clock divide by 1 prescaler 11001 IP Bus clock divide by 2 prescaler 11010 IP Bus clock divide by 4 prescaler 11011 IP Bus clock divide by 8 prescaler 11100 IP Bus clock divide by 16 prescaler 11101 IP Bus clock divide by 32 prescaler 11110 IP Bus clock divide by 64 prescaler 11111 IP Bus clock divide by 128 prescaler
8 ONCE	Count once This bit selects continuous or one shot counting mode.

Table continues on the next page...

ETIMER_CH*n*_CTRL1 field descriptions (continued)

Field	Description
	0 Count repeatedly. 1 Count until compare and then stop. When output mode 4h is used, the counter re-initializes after reaching the COMP1 value and continues to count to the COMP2 value then stops.
9 LENGTH	Count Length This bit determines whether the counter counts to the compare value and then re-initializes itself to the value specified in the LOAD, CMPLD1, or CMPLD2 registers, or the counter continues counting past the compare value, to the binary roll over. 0 Continue counting to roll over. 1 Count until compare, then reinitialize. The value that the counter is reinitialized with depends on the settings of CLC1 and CLC2. If neither of these indicates the counter is to be loaded from one of the CMPLD registers, then the LOAD register is used to reinitialize the counter upon matching either COMP register. If one of CLC1 or CLC2 indicates that the counter is to be loaded from one of the CMPLD registers, then the counter will reinitialize to the value in the appropriate CMPLD register upon a match with the appropriate COMP register. If both of the CLC1 and CLC2 fields indicate that the counter is to be loaded from the CMPLD registers, then CMPLD1 will have priority if both compares happen at the same value. When output mode 4h is used, alternating values of COMP1 and COMP2 are used to generate successful comparisons. For example, the counter counts until COMP1 value is reached, re-initializes, then counts until COMP2 value is reached, re-initializes, then counts until COMP1 value is reached, etc.
10 DIR	Count Direction This bit selects either the normal count direction up, or the reverse direction, down. 0 Count up 1 Count down
11–15 SECSRC	Secondary Count Source These bits identify the source to be used as a count command or timer command. The selected input can trigger the timer to capture the current value of the CNTR register. The selected input can also be used to specify the count direction. The polarity of the signal can be inverted by the SIPS bit of the CTRL2 register. 00000 Counter #0 input pin 00001 Counter #1 input pin 00010 Counter #2 input pin 00011 Counter #3 input pin 00100 Counter #4 input pin 00101 Counter #5 input pin 00110 Counter #6 input pin 00111 Counter #7 input pin 01000 Auxiliary input #0 pin 01001 Auxiliary input #1 pin 01010 Auxiliary input #2 pin 01011 Auxiliary input #3 pin 01100 Auxiliary input #4 pin 01101 Auxiliary input #5 pin 01110 Auxiliary input #6 pin 01111 Auxiliary input #7 pin 10000 Counter #0 output 10001 Counter #1 output

ETIMER_CH*n*_CTRL2 field descriptions

Field	Description
0 OEN	Output Enable This bit determines the direction of the external pin. 0 The external pin is configured as an input. 1 OFLAG output signal will be driven on the external pin. Other timer channels using this external pin as their input will see the driven value. The polarity of the signal will be determined by the OPS bit.
1 RDNT	Redundant Channel Enable This bit enables redundant channel checking between adjacent channels (0 and 1, 2 and 3, 4 and 5 , 6 and 7). When this bit is clear, the RCF bit in this channel cannot be set. When this bit is set, the RCF bit will be set by a miscompare between the OFLAG of this channel and the OFLAG of its redundant adjacent channel which will cause the output of this channel to go inactive (logic 0 prior to consideration of the OPS bit). 0 Disable redundant channel checking. 1 Enable redundant channel checking.
2 INPUT	External input signal This read only bit reflects the current state of the signal selected via SECSRC after application of the SIPS bit and filtering.

Table continues on the next page...

ETIMER_CH*n*_CTRL2 field descriptions (continued)

Field	Description
3 VAL	Forced OFLAG Value This bit determines the value of the OFLAG output signal when a software triggered FORCE command occurs.
4 FORCE	Force the OFLAG output This write only bit forces the current value of the VAL bit to be written to the OFLAG output. This bit always reads as a zero. The VAL and FORCE bits can be written simultaneously in a single write operation. Write to the FORCE bit only if OUTMODE is 0000 (software controlled). Setting this bit while the OUTMODE is a different value may yield unpredictable results.
5 COFRC	Co-channel OFLAG Force This bit enables the compare from another channel within the module to force the state of this counter's OFLAG output signal. 0 Other channels cannot force the OFLAG of this channel. 1 Other channels may force the OFLAG of this channel.
6–7 COINIT	Co-channel Initialization These bits enable another channel within the module to force the re-initialization of this channel when the other channel has an active compare event. 00 Other channels cannot force re-initialization of this channel. 01 Other channels may force a re-initialization of this channel's counter using the LOAD reg. 10 Other channels may force a re-initialization of this channel's counter with the CMPLD2 reg when this channel is counting down or the CMPLD1 reg when this channel is counting up. 11 Reserved
8 SIPS	Secondary Source Input Polarity Select This bit inverts the polarity of the signal selected by the SECSRC bits. 0 True polarity. 1 Inverted polarity.
9 PIPS	Primary Source Input Polarity Select This bit inverts the polarity of the signal selected by the PRISRC bits. This only applies if the signal selected by PRISRC is not the prescaled IP Bus clock. 0 True polarity. 1 Inverted polarity.
10 OPS	Output Polarity Select. This bit inverts the OFLAG output signal polarity. 0 True polarity. 1 Inverted polarity.
11 MSTR	Master Mode This bit enables the compare function's output to be broadcasted to the other channels in the module. The compare signal then can be used to reinitialize the other counters and/or force their OFLAG signal outputs.

Table continues on the next page...

ETIMER_CH*n*_CTRL2 field descriptions (continued)

Field	Description
	0 Disable broadcast of compare events from this channel. 1 Enable broadcast of compare events from this channel.
12–15 OUTMODE	Output Mode These bits determine the mode of operation for the OFLAG output signal. 0000 Software controlled 0001 Clear OFLAG output on successful compare (COMP1 or COMP2) 0010 Set OFLAG output on successful compare (COMP1 or COMP2) 0011 Toggle OFLAG output on successful compare (COMP1 or COMP2) 0100 Toggle OFLAG output using alternating compare registers 0101 Set on compare with COMP1, cleared on secondary source input edge 0110 Set on compare with COMP2, cleared on secondary source input edge 0111 Set on compare, cleared on counter roll-over 1000 Set on successful compare on COMP1, clear on successful compare on COMP2 1001 Asserted while counter is active, cleared when counter is stopped. 1010 Asserted when counting up, cleared when counting down. 1011 Reserved 1100 Reserved 1101 Reserved 1110 Reserved 1111 Enable gated clock output while counter is active

41.4.10 Channel n Control Register 3 (ETIMER_CH*n*_CTRL3)

Address: 0h base + 12h offset + (32d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7
Read Write	Reserved		ROC		Reserved			
Reset	0	0	0	0	1	1	1	1

ETIMER_CH*n*_CTRL3 field descriptions

Field	Description
0 Reserved	This field is reserved. Always write the reset value to this field.
1–2 ROC	Reload on Capture These bits enable the capture function to cause the counter to be reloaded from the LOAD register.

Table continues on the next page...

ETIMER_CH*n*_CTRL3 field descriptions (continued)

Field	Description
	00 Do not reload the counter on a capture event. 01 Reload the counter on a capture 1 event. 10 Reload the counter on a capture 2 event. 11 Reload the counter on both a capture 1 event and a capture 2 event.
3–7 Reserved	This field is reserved. Always write the reset value to this field.
8–10 C2FCNT	Capture 2 FIFO count This field reflects the number of words in the CAPT2 FIFO.
11–13 C1FCNT	Capture 1 FIFO count This field reflects the number of words in the CAPT1 FIFO.
14–15 DBGEN	Debug Actions Enable These bits allow the counter channel to perform certain actions in response to the chip entering debug mode. 00 Continue with normal operation during debug mode. (default) 01 Halt channel counter during debug mode. 10 Force OFLAG to logic 0 (prior to consideration of the OPS bit) during debug mode. 11 Both halt counter and force OFLAG to 0 during debug mode.

41.4.11 Channel n Status Register (ETIMER_CH*n*_STS)

Address: 0h base + 14h offset + (32d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0						0	RCF	ICF2	ICF1	IEHF	IELF	TOF	TCF2	TCF1	TCF
Write								w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ETIMER_CH*n*_STS field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 RCF	Redundant Channel Flag This field is set to 1 when there is a miscompare between this channel's OFLAG value and the OFLAG value of the corresponding redundant channel. Corresponding channels are grouped together in the following pairs: 0 and 1, 2 and 3, 4 and 5 , or 6 and 7 . This field can only be set to 1 if the RDNT bit is set. This field is cleared by writing a 1 to this field. **NOTE:** This field is functional only in the even channels, i.e., 0, 2, 4 , and 6. In the odd channels, this field cannot create an interrupt.

Table continues on the next page...

ETIMER_CH*n*_STS field descriptions (continued)

Field	Description
8 ICF2	Input Capture 2 Flag This bit is set when an input capture event (as defined by CPT2MODE) occurs while the word count of the CAPT2 FIFO meets or exceeds the value of the CFWM field. This bit is cleared by writing a one to this bit position if ICF2DE is clear (no DMA) or it is cleared automatically by the DMA access if ICF2DE is set (DMA).
9 ICF1	Input Capture 1 Flag This bit is set when an input capture event (as defined by CPT1MODE) occurs while the word count of the CAPT1 FIFO meets or exceeds the value of the CFWM field. This bit is cleared by writing a one to this bit position if ICF1DE is clear (no DMA) or it is cleared automatically by the DMA access if ICF1DE is set (DMA).
10 IEHF	Input Edge High Flag This bit is set when a positive input transition occurs (on an input selected by SECSRC) while the counter is enabled. This bit is cleared by writing a one to this bit position.
11 IELF	Input Edge Low Flag This bit is set when a negative input transition occurs (on an input selected by SECSRC) while the counter is enabled. This bit is cleared by writing a one to this bit position.
12 TOF	Timer Overflow Flag This bit is set when the counter rolls over its maximum value FFFFh or 0000h (depending on count direction). This bit is cleared by writing a one to this bit location.
13 TCF2	Timer Compare 2 Flag This bit is set when a successful compare occurs with COMP2. This bit is cleared by writing a one to this bit location.
14 TCF1	Timer Compare 1 Flag This bit is set when a successful compare occurs with COMP1. This bit is cleared by writing a one to this bit location.
15 TCF	This bit is set when a successful compare occurs. This bit is cleared by writing a one to this bit location.

41.4.12 Channel n Interrupt and DMA Enable Register (ETIMER_CH*n*_INTDMA)

Address: 0h base + 16h offset + (32d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7
Read Write	ICF2DE	ICF1DE	CMPLD2DE	CMPLD1DE	0		Reserved	RCFIE
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read Write	ICF2IE	ICF1IE	IEHFIE	IELFIE	TOFIE	TCF2IE	TCF1IE	TCFIE
Reset	0	0	0	0	0	0	0	0

ETIMER_CH*n*_INTDMA field descriptions

Field	Description
0 ICF2DE	Input Capture 2 Flag DMA Enable Setting this bit enables DMA read requests for CAPT2 when the ICF2 bit is set. Clearing this bit clears any pending DMA requests. Do not set both this bit and the ICF2IE bit.
1 ICF1DE	Input Capture 1 Flag DMA Enable Setting this bit enables DMA read requests for CAPT1 when the ICF1 bit is set. Clearing this bit clears any pending DMA requests. Do not set both this bit and the ICF1IE bit.
2 CMPLD2DE	Comparator Load Register 2 Flag DMA Enable Setting this bit enables DMA write requests to the CMPLD2 register whenever data is transferred out of the CMPLD2 reg into either the CNTR, COMP1, or COMP2 registers.
3 CMPLD1DE	Comparator Load Register 1 Flag DMA Enable Setting this bit enables DMA write requests to the CMPLD1 register whenever data is transferred out of the CMPLD1 reg into either the CNTR, COMP1, or COMP2 registers.
4–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 Reserved	This field is reserved. Always write the reset value to this field.
7 RCFIE	Redundant Channel Flag Interrupt Enable Setting this bit enables interrupts when the RCF bit is set. This bit is only in even channels (0, 2, 4 , and 6).
8 ICF2IE	Input Capture 2 Flag Interrupt Enable Setting this bit enables interrupts when the ICF2 bit is set. Do not set both this bit and the ICF2DE bit.
9 ICF1IE	Input Capture 1 Flag Interrupt Enable Setting this bit enables interrupts when the ICF1 bit is set. Do not set both this bit and the ICF1DE bit.
10 IEHFIE	Input Edge High Flag Interrupt Enable Setting this bit enables interrupts when the IEHF bit is set.
11 IELFIE	Input Edge Low Flag Interrupt Enable Setting this bit enables interrupts when the IELF bit is set.
12 TOFIE	Timer Overflow Flag Interrupt Enable Setting this bit enables interrupts when the TOF bit is set.
13 TCF2IE	Timer Compare 2 Flag Interrupt Enable Setting this bit enables interrupts when the TCF2 bit is set.
14 TCF1IE	Timer Compare 1 Flag Interrupt Enable Setting this bit enables interrupts when the TCF1 bit is set.
15 TCFIE	Timer Compare Flag Interrupt Enable Setting this bit enables interrupts when the TCF bit is set.

41.4.13 Channel n Comparator Load Register 1 (ETIMER_CH*n*_CMPLD1)

This read/write register is the preload value for the COMP1 register. This register can also be used to load into the CNTR register. This register is not byte accessible. More information on the use of this register can be found in Usage of Compare Load Registers .

Address: 0h base + 18h offset + (32d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read Write	CPT2MODE		CPT1MODE		CFWM		ONESHOT	ARM
Reset	0	0	0	0	0	0	0	0

ETIMER_CH*n*_CCCTRL field descriptions

Field	Description
0–2 CLC2	Compare Load Control 2 These bits control when COMP2 is preloaded. It also controls the loading of CNTR. 000 Never preload 001 Reserved 010 Load COMP2 with CMPLD1 upon successful compare with the value in COMP1. 011 Load COMP2 with CMPLD1 upon successful compare with the value in COMP2. 100 Load COMP2 with CMPLD2 upon successful compare with the value in COMP1. 101 Load COMP2 with CMPLD2 upon successful compare with the value in COMP2. 110 Load CNTR with CMPLD2 upon successful compare with the value in COMP1. 111 Load CNTR with CMPLD2 upon successful compare with the value in COMP2.
3–5 CLC1	Compare Load Control 1 These bits control when COMP1 is preloaded. It also controls the loading of CNTR. 000 Never preload 001 Reserved 010 Load COMP1 with CMPLD1 upon successful compare with the value in COMP1. 011 Load COMP1 with CMPLD1 upon successful compare with the value in COMP2. 100 Load COMP1 with CMPLD2 upon successful compare with the value in COMP1. 101 Load COMP1 with CMPLD2 upon successful compare with the value in COMP2. 110 Load CNTR with CMPLD1 upon successful compare with the value in COMP1. 111 Load CNTR with CMPLD1 upon successful compare with the value in COMP2.
6–7 CMPMODE	Compare Mode These bits control when the COMP1 and COMP2 registers are used in regards to the counting direction. 00 COMP1 register is used when the counter is counting up; COMP2 register is used when the counter is counting up. 01 COMP1 register is used when the counter is counting down; COMP2 register is used when the counter is counting up.

Table continues on the next page...

ETIMER_CH*n*_CCCTRL field descriptions (continued)

Field	Description
	10 COMP1 register is used when the counter is counting up. COMP2 register is used when the counter is counting down. 11 COMP1 register is used when the counter is counting down; COMP2 register is used when the counter is counting down.
8–9 CPT2MODE	Capture 2 Mode Control These bits control the operation of the CAPT2 register as well as the operation of the ICF2 flag by defining which input edges cause a capture event. The input source is the secondary count source. 00 Disabled 01 Capture falling edges 10 Capture rising edges. 11 Capture any edge.
10–11 CPT1MODE	Capture 1 Mode Control These bits control the operation of the CAPT1 register as well as the operation of the ICF1 flag by defining which input edges cause a capture event. The input source is the secondary count source. 00 Disabled 01 Capture falling edges 10 Capture rising edges. 11 Capture any edge.
12–13 CFWM	Capture FIFO Water Mark This field represents the water mark level for the CAPT1 and CAPT2 FIFOs. The capture flags, ICF1 and ICF2, won't be set until the word count of the corresponding FIFO is greater than this water mark level.
14 ONESHOT	One Shot Capture Mode This bit selects between free running and one shot mode for the input capture circuitry. 0 Free running mode is selected. If both capture circuits are enabled, then capture circuit 1 is armed first after the ARM bit is set. Once a capture occurs, capture circuit 1 is disarmed and capture circuit 2 is armed. After capture circuit 2 performs a capture, it is disarmed and capture circuit 1 is re-armed. The process continues indefinitely. If only one of the capture circuits is enabled, then captures continue indefinitely on the enabled capture circuit. 1 One shot mode is selected. If both capture circuits are enabled, then capture circuit 1 is armed first after the ARM bit is set. Once a capture occurs, capture circuit 1 is disarmed and capture circuit 2 is armed. After capture circuit 2 performs a capture, it is disarmed and the ARM bit is cleared. No further captures will be performed until the ARM bit is set again. If only one of the capture circuits is enabled, then a single capture will occur on the enabled capture circuit and the ARM bit is then cleared.
15 ARM	Arm Capture Setting this bit high starts the input capture process. This bit can be cleared at any time to disable input capture operation. This bit is self cleared when in one shot mode and the enabled capture circuit(s) has had a capture event(s). 0 Input capture operation is disabled. 1 Input capture operation as specified by the CPT1MODE and CPT2MODE bits is enabled.

41.4.16 Channel n Input Filter Register (ETIMER_CH*n*_FILT)

The FILT register programs the values for the filtering of the corresponding input without regard for the fact that any eTimer channel can use the input as a count source. The FILT register is also used to control the filtering of the corresponding auxiliary input if one exists.

The FILT_PER value should be set such that the sampling period is larger the period of the expected noise. This way a noise spike will only corrupt one sample. The FILT_CNT value should be chosen to reduce the probability of noisy samples causing an incorrect transition to be recognized. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the FILT_CNT + 3 power.

The values of FILT_PER and FILT_CNT must also be traded off against the desire for minimal latency in recognizing input transitions. Turning on the input filter (setting FILT_PER to a non-zero value) introduces a latency of: (((FILT_CNT + 3) x FILT_PER) + 2) peripheral clock periods.

Address: 0h base + 1Eh offset + (32d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0					FILT_CNT			FILT_PER							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ETIMER_CH*n*_FILT field descriptions

Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–7 FILT_CNT	Input Filter Sample Count These bits represent the number of consecutive samples that must agree prior to the input filter accepting an input transition. A value of 0 represents 3 samples. A value of 7 represents 10 samples. The value of FILT_CNT affects the input latency as described in this section.
8–15 FILT_PER	Input Filter Sample Period These bits represent the sampling period (in peripheral clock cycles) of the eTimer input signal. Each input is sampled multiple times at the rate specified by FILT_PER. If FILT_PER is $00 (default), then the input filter is bypassed. The value of FILT_PER affects the input latency as described in this section.

41.4.17 Channel Enable Register (ETIMER_ENBL)

Address: 0h base + 10Ch offset = 10Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0								ENBL							
Write																
Reset	0	0	0	0	0	0	0	0	1*	1*	1*	1*	1*	1*	1*	1*

* Notes:
- ENBL field: Reset value depends on field width. Unimplemented bits (channels) will reset to 0. See the chip-specific information for the eTimer module.

ETIMER_ENBL field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–15 ENBL	Timer Channel Enable These bits enable the prescaler (if it is being used) and counter in each channel. Multiple ENBL bits can be set at the same time to synchronize the start of separate channels. If an ENBL bit is set, then the corresponding channel will start counting as soon as the CNTMODE field has a value other than 000. When an ENBL bit is clear, the corresponding channel maintains its current value. **NOTE:** The width of this field is equal to the number of channels a particular eTimer instance supports. If the chip has more than one eTimer instance, refer to the chip-specific information for the eTimer module for the configuration of each eTimer instance. 0 Timer channel is disabled 1 Timer channel is enabled. This is the reset value.

41.4.18 DMA Request 0 Select Register (ETIMER_DREQ0)

Address: 0h base + 110h offset = 110h

	11111: Channel 7 CMPLD2 DMA write request

41.5 Functional Description

This section provides a functional description of eTimer.

41.5.1 General

Each channel has two basic modes of operation: it can count internal or external events, or it can count an internal clock source while an external input signal is asserted, thus timing the width of the external input signal.

- The counter can count the rising, falling, or both edges of the selected input pin.
- The counter can decode and count quadrature encoded input signals.
- The counter can count up and down using dual inputs in a "count with direction" format.
- The counter's terminal count value (modulo) is programmable.
    - The value that is loaded into the counter after reaching its terminal count is programmable.
- The counter can count repeatedly, or it can stop after completing one count cycle.
- The counter can be programmed to count to a programmed value and then immediately reinitialize, or it can count through the compare value until the count "rolls over" to zero.

The external inputs to each counter/timer are shareable among each of the channels within the module. The external inputs can be used as:

- Count commands
- Timer commands
- They can trigger the current counter value to be "captured"
- They can be used to generate interrupt requests

The polarity of the external inputs is selectable.

The primary output of each channel is the output signal OFLAG. The OFLAG output signal can be:

- Set, cleared, or toggled when the counter reaches the programmed value.
- The OFLAG output signal may be output to an external pin instead of having that pin serve as a timer input.
- The OFLAG output signal enables each counter to generate square waves, PWM, or pulse stream outputs.
- The polarity of the OFLAG output signal is programmable.

Any channel can be assigned as a "Master". A master's compare signal can be broadcasted to the other channels within the module. The other channels can be configured to reinitialize their counters and/or force their OFLAG output signals to predetermined values when a Master channel's compare event occurs.

41.5.2 Counting Modes

The selected external signals are sampled at the eTimer's base clock rate and then run through a transition detector. The maximum count rate is one-half of the eTimer's base clock rate when using an external signal. Internal clock sources can be used to clock the counters at the eTimer's base clock rate.

If a counter is programmed to count to a specific value and then stop, the CNTMODE field in the CTRL1 register is cleared when the count terminates.

41.5.2.1 STOP Mode

If the CNTMODE field is set to '000', the counter is inert. No counting will occur. Stop mode will also disable the interrupts caused by input transitions on a selected input pin.

41.5.2.2 COUNT Mode

If the CNTMODE field is set to '001', the counter will count the rising edges of the selected clock source. This mode is useful for generating periodic interrupts for timing purposes, or counting external events such as "widgets" on a conveyor belt passing a sensor. If the selected input is inverted by setting the PIPS bit, then the negative edge of the selected external input signal is counted.

See CASCADE-COUNT Mode through VARIABLE-FREQUENCY PWM Mode for additional capabilities of this operating mode.

41.5.2.3 EDGE-COUNT Mode

If the CNTMODE field is set to '010', the counter will count both edges of the selected external clock source. This mode is useful for counting the changes in the external environment such as a simple encoder wheel.

41.5.2.4 GATED-COUNT Mode

If the CNTMODE field is set to '011', the counter will count while the selected secondary input signal is high. This mode is used to time the duration of external events. If the selected input is inverted by setting the SIPS bit, then the counter will count while the selected secondary input is low.

41.5.2.5 QUADRATURE-COUNT Mode

If the CNTMODE field is set to 100, the counter will decode the primary and secondary external inputs as quadrature encoded signals. Quadrature signals are usually generated by rotary or linear sensors used to monitor movement of motor shafts or mechanical equipment. The quadrature signals are square waves that are 90 degrees out of phase. The decoding of quadrature signals provides both count and direction information.

The following figure shows a timing diagram illustrating the basic operation of a quadrature incremental position encoder.

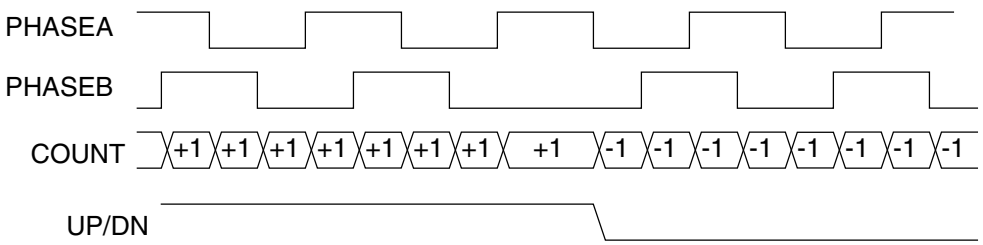

Figure 41-3. Quadrature Incremental Position Encoder

41.5.2.6 SIGNED-COUNT Mode

If the CNTMODE field is set to '101', the counter counts the primary clock source while the selected secondary source provides the selected count direction (up/down).

41.5.2.7 TRIGGERED-COUNT Mode

If the CNTMODE field is set to '110', the counter will begin counting the primary clock source after a positive transition (negative if SIPS = 1) of the secondary input occurs. The counting will continue until a compare event occurs or another positive input transition is detected. Subsequent secondary positive input transitions will continue to restart and stop the counting until a compare event occurs.

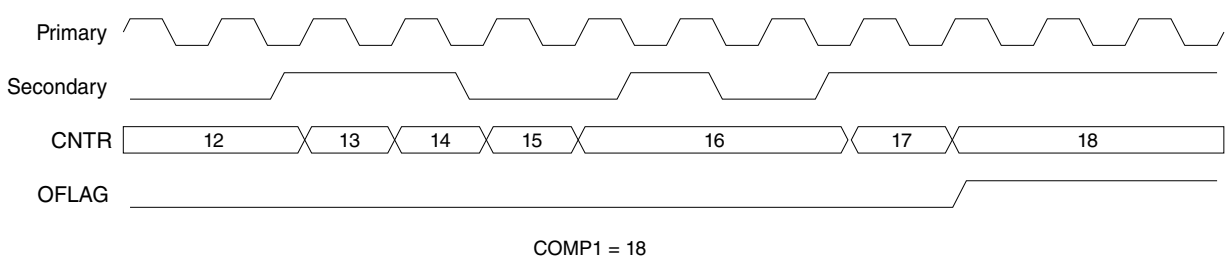

Figure 41-4. Triggered Count Mode (Length=1)

41.5.2.8 ONE-SHOT Mode

If the CNTMODE field is set to '110', and the counter is set to reinitialize at a compare event (LENGTH =1), and the OFLAG OUTMODE is set to '0101' (cleared on init, set on compare), the counter works in a "One-Shot Mode". An external events causes the counter to count, when terminal count is reached, the output is asserted. This "delayed" output can be used to provide timing delays.

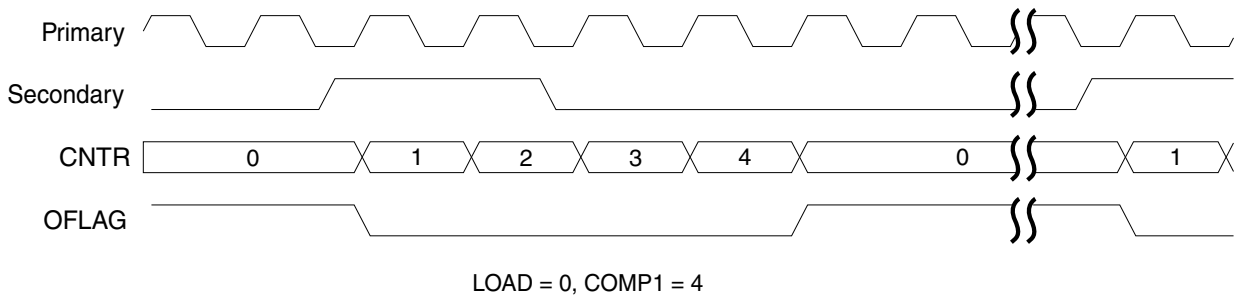

Figure 41-5. One-Shot Mode (Length=1)

41.5.2.9 CASCADE-COUNT Mode

If the CNTMODE field is set to '111', the counter's input is connected to the output of another selected counter. The counter will count up and down as compare events occur in the selected source counter. This "Cascade" or "Daisy-Chained" mode enables multiple counters to be cascaded to yield longer counter lengths. When operating in cascade mode, a special high speed signal path is used between modules rather than the OFLAG output signal. If the selected source counter is counting up and it experiences a compare event, the counter will be incremented. If the selected source counter is counting down and it experiences a compare event, the counter will be decremented.

Up to two counters may be cascaded to create a 32 bit wide synchronous counter.

Whenever any counter is read within a counter module, all of the counters' values within the module are captured in their respective HOLD registers. This action supports the reading of a cascaded counter chain. First read any counter of a cascaded counter chain, then read the HOLD registers of the other counters in the chain. The cascaded counter mode is synchronous.

Note

It is possible to connect counters together by using the other (non-cascade) counter modes and selecting the outputs of other counters as a clock source. In this case, the counters are operating in a "ripple" mode, where higher order counters will transition a clock later than a purely synchronous design.

Note

A channel can be cascaded with any other channel, but you can't cascade more than 2 channels together. You can create separate cascades of pairs of channels. For example, you can cascade channels 0 and 1 and separately cascade channels 6 and 5. You can't cascade channels 0, 1, and 5.

41.5.2.10 PULSE-OUTPUT Mode

If the counter is setup for CNTMODE = 001, and the OFLAG OUTMODE is set to '1111' (gated clock output), and the ONCE bit is set, then the counter will output a pulse stream of pulses that has the same frequency of the selected clock source, and the number of output pulses is equal to the compare value minus the init value. This mode is useful for driving step motor systems.

Note

This does not work if the PRISRC is set to 11000 (IP_bus/1).

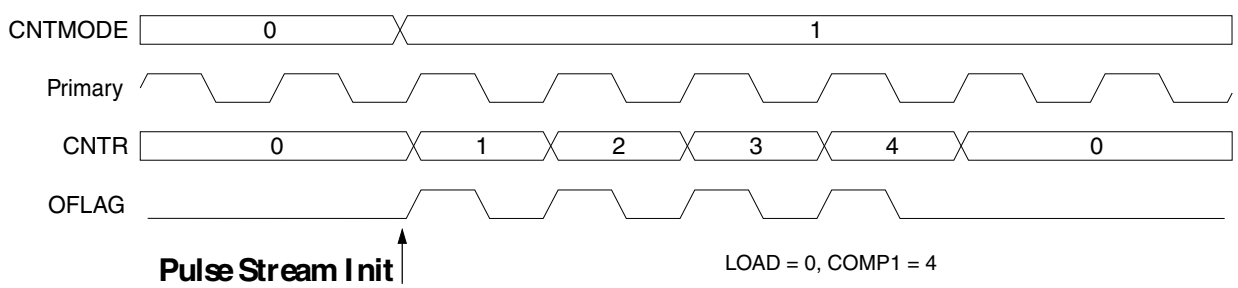

Figure 41-6. Pulse Output Mode

41.5.2.11 FIXED-FREQUENCY PWM Mode

If the counter is setup for CNTMODE = 001, count through roll-over (LENGTH = 0), continuous count (ONCE = 0) and the OFLAG OUTMODE is '0111' (set on compare, cleared on counter roll-over) then the counter output yields a Pulse Width Modulated

(PWM) signal with a frequency equal to the count clock frequency divided by 65,536 and a pulse width duty cycle equal to the compare value divided by 65,536. This mode of operation is often used to drive PWM amplifiers used to power motors and inverters.

41.5.2.12 VARIABLE-FREQUENCY PWM Mode

If the counter is setup for CNTMODE = 001, count till compare (LENGTH = 1), continuous count (ONCE = 0) and the OFLAG OUTMMODE is '0100' (toggle OFLAG and alternate compare registers) then the counter output yields a Pulse Width Modulated (PWM) signal whose frequency and pulse width is determined by the values programmed into the COMP1 and COMP2 registers, and the input clock frequency. This method of PWM generation has the advantage of allowing almost any desired PWM frequency and/or constant on or off periods. This mode of operation is often used to drive PWM amplifiers used to power motors and inverters. The CMPLD1 and CMPLD2 registers are especially useful for this mode, as they allow the programmer time to calculate values for the next PWM cycle while the PWM current cycle is underway.

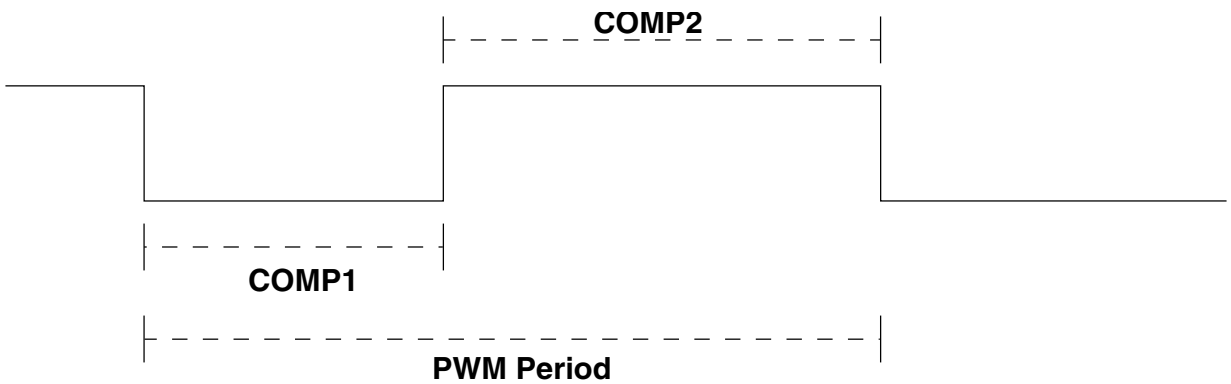

Figure 41-7. Variable PWM Waveform

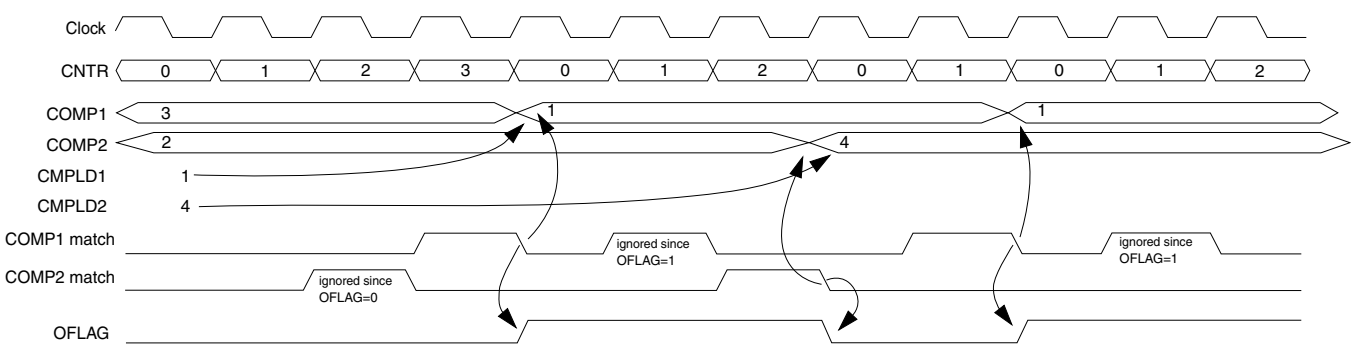

CLC1=010, load COMP1 when CNTR=COMP1
CLC2=101, load COMP2 when CNTR=COMP2

Figure 41-8. Variable Frequency PWM Mode Timing

41.5.2.13 Usage of Compare Registers

The dual compare registers (COMP1 and COMP2) provide a bidirectional modulo count capability.

The COMP1 register should be set to the desired maximum count value or FFFFh to indicate the maximum unsigned value prior to roll-over, and the COMP2 register should be set to the minimum count value or 0000h to indicate the minimum unsigned value prior to roll-under.

If the output mode is set to 0100, the OFLAG will toggle while using alternating compare registers. In this variable frequency PWM mode, the COMP2 value defines the desired pulse width of the on time, and the COMP1 register defines the off time. COMP1 is used when OFLAG=0 and COMP2 is used when OFLAG=1. OFLAG can be forced to a value using CTRL2[FORCE] and CTRL2[VAL].

Use caution when changing COMP1 and COMP2 while the counter is active. If the counter has already passed the new value, it will count to FFFFh or 0000h, roll over, then begin counting toward the new value. The check is: CNTR = COMPx, *not* CNTR > COMP1 or CNTR < COMP2.

The use of the CMPLD1 and CMPLD2 registers to preload compare values will help to minimize this problem.

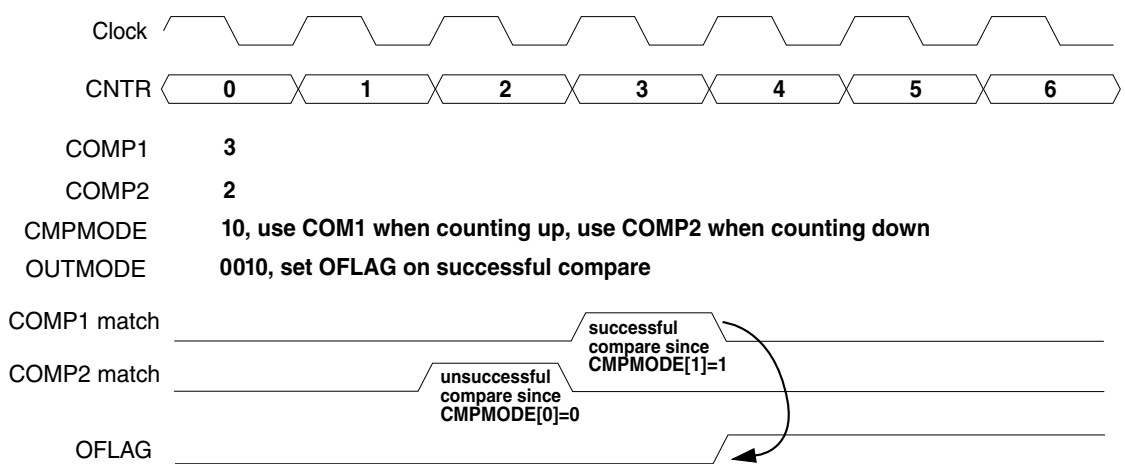

Figure 41-9. Compare Register and OFLAG Timing

41.5.2.14 Usage of Compare Load Registers

The CMPLD1, CMPLD2 and CCCTRL registers offer a high degree of flexibility for loading compare registers with user-defined values on different compare events. To ensure correct functionality while using these registers we strongly suggest using the following method described in this section.

The purpose of the compare load feature is to allow quicker updating of the compare registers. A compare register can be updated using interrupts. However, because of the latency between an interrupt event occurring and the service of that interrupt, there is the possibility that the counter may have already counted past the new compare value by the time the compare register is updated by the interrupt service routine. The counter would then continue counting until it rolled over and reached the new compare value.

To address this, the compare registers are updated in hardware in the same way the counter register is re-initialized to the value stored in the LOAD register. The compare load feature allows the user to calculate new compare values and store them in to the comparator load registers. When a compare event occurs, the new compare values in the comparator load registers are written to the compare registers eliminating the use of software to do this.

The compare load feature is intended to be used in variable frequency PWM mode. The COMP1 register determines the pulse width for the logic low part of OFLAG and COMP2 determines the pulse width for the logic high part of OFLAG. The period of the waveform is determined by the COMP1 and COMP2 values and the frequency of the primary clock source. See Figure 41-8.

41.5.2.15 MODULO COUNTING Mode

To create a modulo counter using COMP1 and COMP2 as the counter boundaries (instead of $0000 and $FFFF), set the registers in the following manner. Set CNTMODE to either 100 (quadrature count mode) or 101 (count with direction mode). Use count through roll-over (LENGTH = 0) and continuous count (ONCE = 0). Set COMP1 and CMPLD1 to the upper boundary value. Set COMP2 and CMPLD2 to the lower boundary value. Set CMPMODE = 10 (COMP1 is used when counting up and COMP2 is used when counting down). Set CLC2 = 110 (load CNTR with value of CMPLD2 on COMP1 compare) and CLC1 = 111 (load CNTR with value of CMPLD1 on COMP2 compare).

41.5.2.16 Compare Register and OFLAG Operation

The compare flags and output flag are registered signals and can only change state after the counter reached the compare value. This means that, if the counter is continuously counting, then the compare flag is set on the count after the counter reaches the compare value. When counting is not continuous (such as when using a prescaler or when counting edges on the primary input), the compare flag or OFLAG are not updated until the counter is about to transition to the next count. This means that if the compare value is 4, then the flags will be changed on the same clock edge that transitions the counter from 4 to its next value.

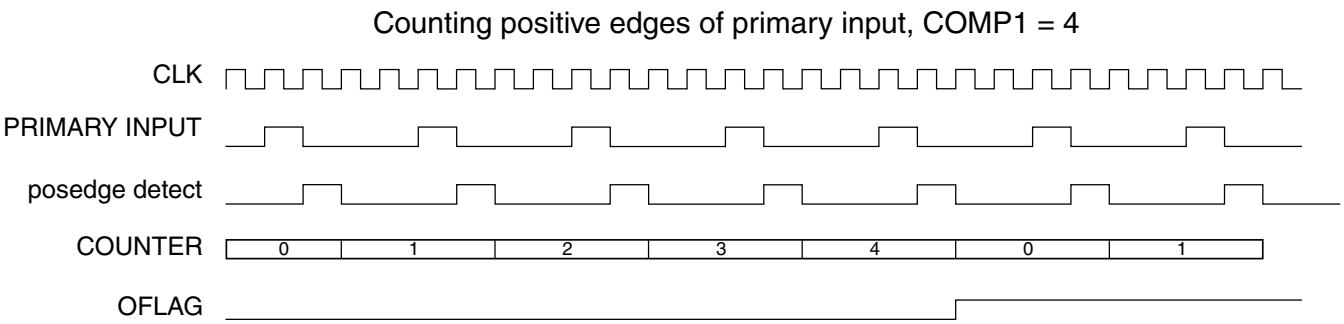

Figure 41-10. OFLAG timing during non-continuous counting

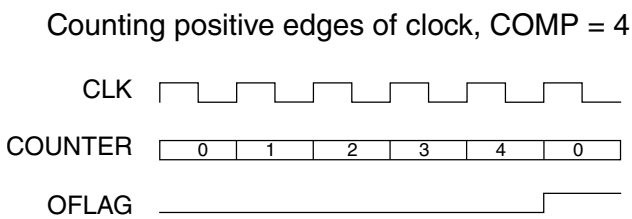

Figure 41-11. OFLAG timing during continuous counting

41.5.3 Other Features

This section describes other features of eTimer.

41.5.3.1 Redundant OFLAG Checking

This mode allows the user to bundle two timer functions generating any pattern to compare their resulting OFLAG behaviors (output signal).

The redundant mode is used to support online checks for reliability and functional safety reasons. Whenever a mismatch between the two adjacent channels occurs, it is reported via an interrupt to the core and the two outputs are put into their inactive states. An error is flagged via the RCF flag.

This feature can be tested by forcing a transition on one of the OFLAGs using the VAL and FORCE bits of the channel.

41.5.3.2 Loopback Checking

This mode is always available in that one channel can generate an OFLAG while another channel uses the first channels OFLAG as its input to be measured and verified to be as expected.

41.5.3.3 Input Capture Mode

Input capture is used to measure pulse width (by capturing the counter value on two successive input edges) or waveform period (by capturing the counter value on two consecutive rising edges or two consecutive falling edges). The Capture Registers store a copy of the counter's value when an input edge (positive, negative, or both) is detected. The type of edge to be captured by each circuit is determined by the CPT1MODE and CPT2MODE bits whose functionality is listed in CPT1MODE. Also, controlling the operation of the capture circuits is the arming logic which allows captures to be performed in a free running (continuous) or one shot fashion. In free running mode, the capture sequences will be performed indefinitely. If both capture circuits are enabled, they will work together in a ping-pong style where a capture event from one circuit leads to the arming of the other and vice versa. In one shot mode, only one capture sequence will be performed. If both capture circuits are enabled, capture circuit 0 is first armed and when a capture event occurs, capture circuit 1 is armed. Once the second capture occurs, further captures are disabled until another capture sequence is initiated. Both capture circuits are also capable of generating an interrupt to the CPU.

41.5.3.4 Master/Slave Mode

Any timer channel can be assigned as a Master (MSTR = 1). A Master's compare signal can be broadcasted to the other channels within the module. The other counters can be configured to reinitialize their counters (COINIT = 1) and/or force their OFLAG output signals (COFRC = 1) to predetermined values when a Master counter compare event occurs.

41.6 Resets

The eTimer module can only be reset by a full system reset. This forces all registers to their reset state and clears the OFLAG signals if they are asserted. The counters will be turned off until the settings in the CTRL registers are changed.

41.7 Clocks

Each timer channel receives its own copy of the peripheral bus clock. This allows for better power management by turning off the clock to unused channels. Each bit of the ENBL register uses the clock for that corresponding channel. The DREQn registers use the clock for channel, 0 but this clock can be turned off after these registers have been programmed.

41.8 Interrupts

The following can generate interrupts within the eTimer.

- Each channel can generate an interrupt from several sources

The interrupt service routine (ISR) must check the related interrupt enables and interrupt flags to determine the actual cause of the interrupt.

Table 41-4. Interrupt summary

Core interrupt	Interrupt flag	Interrupt enable	Name	Description
Channels 0-n	TCF	TCFIE	Compare interrupt	Compare of counter and related compare register
	TCF1	TCF1IE	Compare 1 interrupt	Compare of the counter and COMP1 register
	TCF2	TCF2IE	Compare 2 interrupt	Compare of the counter and COMP2 register
	TOF	TOFIE	Overflow interrupt	Generated on counter roll-over or roll-under
	IELF	IELFIE	Input Low Edge interrupt	Falling edge of the secondary input signal
	IEHF	IEHFIE	Input High Edge interrupt	Rising edge of the secondary input signal
	ICF1	ICF1IE	Input Capture 1 interrupt	Input capture event for CAPT1
	ICF2	ICF2IE	Input Capture 2 interrupt	Input capture event for CAPT2
Redundant Channel Checking	RCF	RCFIE	Redundant Channel Fault interrupt	Miscompare with redundant channel

41.9 DMA

Each channel can request a DMA read access for each of the capture registers and a DMA write request for each of the compare preload registers. The DREQ registers select amongst these 32 DMA request sources to generate the 4 top level DMA request outputs.

Table 41-5. DMA Summary

DMA Request	DMA Enable	Name	Description
Channels 0-n	ICF1DE	CAPT1 read request	CAPT1 contains a value
	ICF2DE	CAPT2 read request	CAPT2 contains a value
	CMPLD1DE	CMPLD1 write request	CMPLD1 needs an update
	CMPLD2DE	CMPLD2 write request	CMPLD2 needs an update

Motor Control Pulse Width Modulator (FlexPWM)

42.1 Chip-specific FlexPWM information

The following table show the inter-module connection of the FlexPWM for the Motor Control related peripherals for the device.

Table 42-1. Motor Control peripheral interconnects

Input Module	Input Signal	Driving Module	Driver Signal
FLEXPWM	EXT_FORCE	eTIMER_2	T1
FLEXPWM	CLOCK	eTIMER_1	T1
FLEXPWM	EXTA	-	-
FLEXPWM	EXTB	-	-
FLEXPWM	EXT_SWITCH	-	-

42.1.1 FlexPWM chip-specific register reset values

FlexPWM_FSTS reset values for this chip is 0x0F0F when SIUL2_MSCR and SIUL2_IMCR registers are not programmed.

42.2 Introduction

This section contains features, modes of operation, and block diagrams of the FlexPWM.

42.2.1 Overview

The pulse width modulator module (FlexPWM) contains one or more PWM submodules, each capable of controlling a single half-bridge power stage. One or more fault channels may also be included.

This PWM is capable of controlling most motor types: AC induction motors (ACIM), Permanent Magnet AC motors (PMAC), both brushless (BLDC) and brush DC motors (BDC), switched (SRM) and variable reluctance motors (VRM), and stepper motors.

42.2.2 Features

The FlexPWM module provides the following features:

- 16 bits of resolution for center, edge aligned, and asymmetrical PWMs
- PWM outputs capable of operating as complementary pairs or independent channels
- Can accept signed numbers for PWM generation
- Independent control of both edges of each PWM output
- Synchronization to external hardware or other PWM supported
- Double buffered PWM registers
  - Integral reload rates from 1 to 16
  - Half cycle reload capability
- Multiple output trigger events can be generated per PWM cycle via hardware
- Support for double switching PWM outputs
- Fault inputs can be assigned to control multiple PWM outputs
- Programmable filters for fault inputs
- Independently programmable PWM output polarity
- Independent top and bottom deadtime insertion
- Each complementary pair can operate with its own PWM frequency and deadtime values
- Individual software control for each PWM output
- All outputs can be programmed to change simultaneously via a "Force Out" event
- PWMX pin can optionally output a third PWM signal from each submodule
- PWMX channels not used for PWM generation can be used for buffered output compare functions
- Channels not used for PWM generation can be used for input capture functions

- Capture is supported only for X channels not A and B channels
- Dual edge capture functionality
- Option to supply the source for each complementary PWM signal pair from SOC external or internal signals

42.2.3 Modes of operation

Care must be exercised when using this module in certain chip operating modes. Some motors (such 3-phase AC motors) require regular software updates for proper operation. Failure to do so could result in destroying the motor or inverter. Because of this, PWM outputs are placed in their inactive states in STOP mode, and optionally under debug mode. PWM outputs are reactivated (assuming they were active to begin with) when these modes are exited.

Table 42-2. Modes when PWM operation is restricted

Mode	Description
STOP	Peripheral and CPU clocks are stopped. PWM outputs are driven inactive.
DEBUG	CPU and peripheral clocks continue to run, but CPU maybe stalled for periods of time. PWM outputs are driven inactive as a function of the DBGEN bit.

42.2.4 Block Diagrams

This section contains block diagrams of the FlexPWM.

42.2.4.1 Module level

Note that not all signals are shown in this diagram.

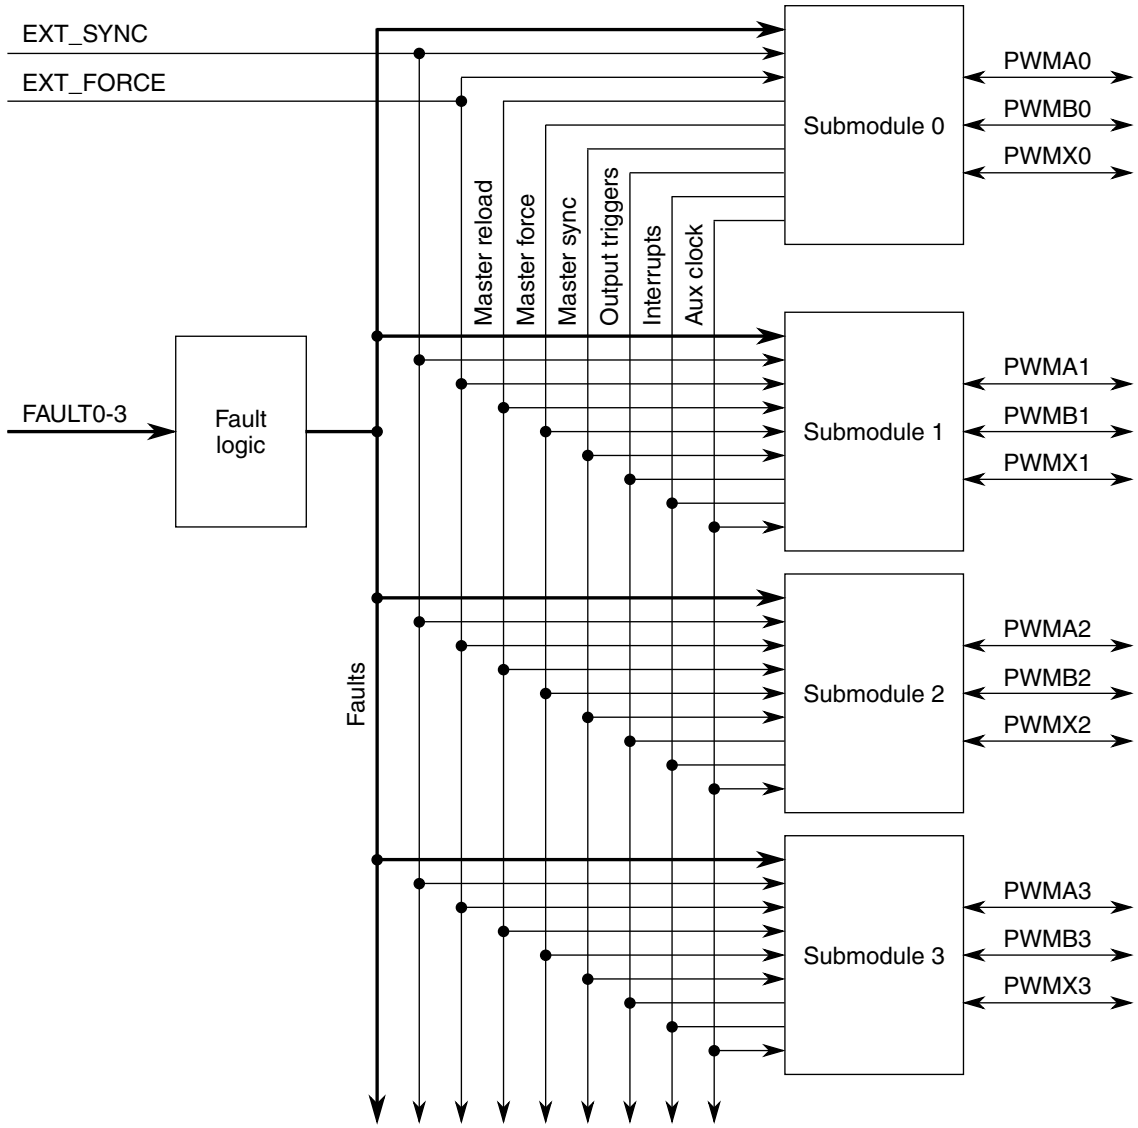

Figure 42-1. PWM block diagram

42.2.4.2 PWM submodule

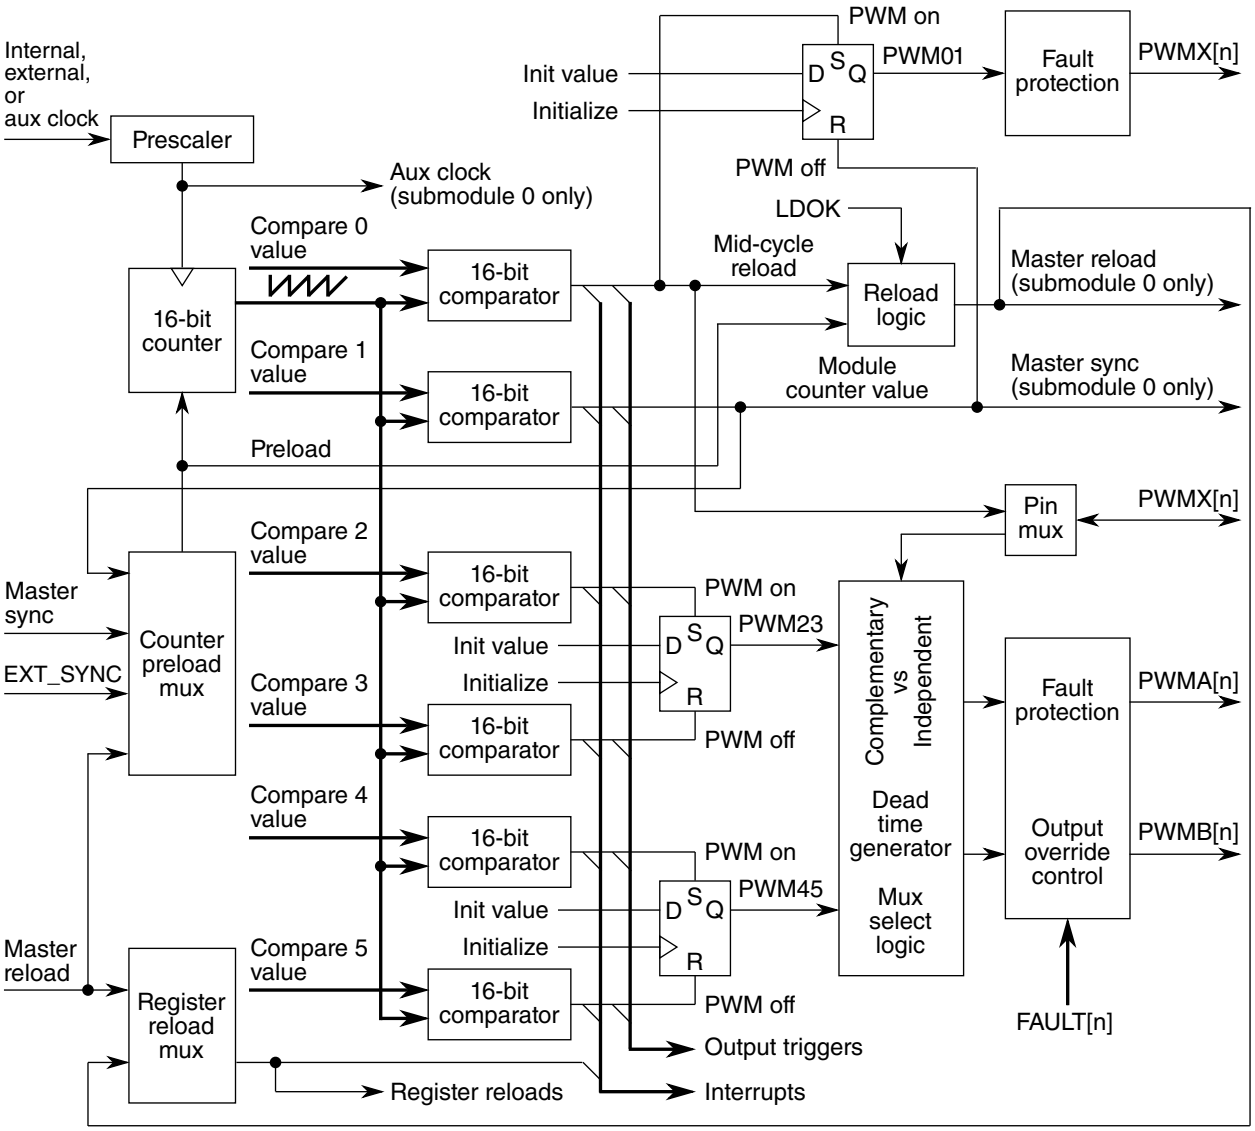

Figure 42-2. PWM submodule block diagram

42.3 External Signal Descriptions

The PWM module has external pins named PWMA[n], PWMB[n], PWMX[n], FAULT[n], EXT_SYNC, EXT_FORCE, EXTA[n], and EXTB[n]. The PWM module also has an external clock input called EXT_CLK and an output triggers bus.

42.3.1 PWMA[n] and PWMB[n] - External PWM Pair

These pins are the output pins of the PWM submodules. They can be independent PWM signals or a complementary pair.

42.3.2 PWMX[n] - Auxiliary PWM signal

These pins are the auxiliary output pins of the PWM submodules. They can be independent PWM signals. When not needed as an output, they can be used as inputs to the input capture circuitry or they can be used to generate the IPOL bit during deadtime correction.

42.3.3 FAULT[n] - Fault inputs

These are input pins for disabling selected PWM outputs.

42.3.4 EXT_SYNC - External Synchronization Signal

This input signal allows a source external to the PWM to initialize the PWM counter. In this manner the PWM can be synchronized to external circuitry.

42.3.5 EXT_FORCE - External Output Force Signal

This input signal allows a source external to the PWM to force an update of the PWM outputs. In this manner the PWM can be synchronized to external circuitry. An example would be to simultaneously switch all of the PWM outputs on a commutation boundary for trapezoidal control of a BLDC motor. The boundary can be established via external logic or an on-chip timer.

42.3.6 EXTA[n] and EXTB[n] - Alternate PWM Control Signals

These pins allow an alternate source to control the PWMA and PWMB outputs although typically, the EXTA input will be used for the generation of a complementary pair. Typical connections include ADC results registers, TMR outputs, GPIO inputs, and comparator outputs.

42.3.7 OUT_TRIG_EVEN[n] and OUT_TRIG_ODD[n] - Output Triggers

These outputs allow the PWM submodules to control timing of the ADC conversions. See Submodule n Output Trigger Control Register (FlexPWM_SUB*n*_TCTRL) for a description of how to enable these outputs and how the compare registers match up to the output triggers.

42.3.8 EXT_CLK - External Clock Enable

This on-chip input signal allows an on-chip source external to the PWM (typically a Timer) to control the PWM clocking. In this manner the PWM can be synchronized to the Timer. This signal must be generated synchronously to the PWM's clock since it is not resynchronized in the PWM.

42.3.9 EXT_SWITCH - External Switch Signal

This input signal allows a source external to the PWM to control the PWM generation source within submodule1. This signal only functions on submodule1 and selects the source of the generated PWM signal to be either submodule1 or submodule0.

42.4 Memory Map and Registers

The address of a register is the sum of a base address and an address offset. The base address is defined at the core level and the address offset is defined at the module level. There are a set of registers for each PWM submodule, for the configuration logic, and for each Fault channel.

Registers are only accessible using 16- or 32-bit accesses. Byte accesses are not allowed.

Submodule registers are repeated for each PWM submodule. The base address of submodule 0 is the same as the base address for the PWM module as a whole. The base address of submodule 1 is 50h. This is the base address of the PWM module plus an offset based on the number of registers in a submodule. The base address of submodule 2 is equal to the base address of submodule 1 plus this same offset.

The base address of the configuration registers is equal to the base address of the FlexPWM plus as offset of 140h.

The base address of the fault logic is equal to the base address of the FlexPWM plus an offset of 14Ch.

NOTE

A write access to the read-only Capture Value and Capture Value Cycle registers will result in a bus error.

NOTE

The space at offset 14Ah is reserved. Accessing this location does not result in a transfer error. Read accesses return 0h, and write accesses have no effect.

42.4.1 Submodule n Counter Register (FlexPWM_SUB*n*_CNT)

This read-only register displays the state of the signed 16-bit submodule counter. This register is not byte accessible.

Access:

- Supervisor read-only
- User read-only

Address: 0h base + 0h offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	CNT															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FlexPWM_SUB*n*_CNT field descriptions

Field	Description
0–15 CNT	Count State of the signed 16-bit submodule counter

42.4.2 Submodule n Initial Count Register (FlexPWM_SUB*n*_INIT)

The 16-bit signed value in this buffered, read/write register defines the initial count value for the PWM in clock periods. This is the value loaded into the submodule counter when local sync, master sync, or master reload is asserted (based on the value of INIT_SEL) or when FORCE is asserted and force init is enabled. For PWM operation, the buffered contents of this register are loaded into the counter at the start of every PWM cycle. This register is not byte accessible.

NOTE

The INIT register is buffered. The value written does not take effect until the LDOK bit is set and the next PWM load cycle begins or LDMOD is set. This register cannot be written when LDOK is set. Reading INIT reads the value in a buffer and not necessarily the value the PWM generator is currently using.

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 2h offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	INIT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FlexPWM_SUB*n*_INIT field descriptions

Field	Description
0–15 INIT	Initial count Initial count value for the PWM in clock periods

42.4.3 Submodule n Control 2 Register (FlexPWM_SUB*n*_CTRL2)

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 4h offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7
Read / Write	DBGEN	Reserved	INDEP	PWM23_INIT	PWM45_INIT	PWMX_INIT	INIT_SEL	
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read	FRCEN	0	FORCE_SEL			RELOAD_SEL	CLK_SEL	
Write		FORCE						
Reset	0	0	0	0	0	0	0	0

FlexPWM_SUB*n*_CTRL2 field descriptions

Field	Description
0 DBGEN	Debug Enable When set to one, the PWM will continue to run while the chip is in debug mode. If the device enters debug mode and this bit is zero, then the PWM outputs will be disabled until debug mode is exited. At that point the PWM pins will resume operation as programmed in the PWM registers. For certain types of motors (such as 3-phase AC), it is imperative that this bit be left in its default state (in which the PWM is disabled in debug mode). Failure to do so could result in damage to the motor or inverter. For other types of motors (example: DC motors), this bit might safely be set to one, enabling the PWM in debug mode. The key point is PWM parameter updates will not occur in debug mode. Any motors requiring such updates should be disabled during debug mode. If in doubt, leave this bit set to zero.
1 Reserved	This field is reserved. Always write the reset value to this field.
2 INDEP	Independent or Complementary Pair Operation This bit determines if the PWMA and PWMB channels will be independent PWMs or a complementary PWM pair. 0 PWMA and PWMB form a complementary PWM pair. 1 PWMA and PWMB outputs are independent PWMs.
3 PWM23_INIT	PWM23 Initial Value This read/write bit determines the initial value for PWM23 and the value to which it is forced when FORCE_INIT, (see PWM Generation), is asserted.
4 PWM45_INIT	PWM45 Initial Value This read/write bit determines the initial value for PWM45 and the value to which it is forced when FORCE_INIT, (see PWM Generation), is asserted.
5 PWMX_INIT	PWMX Initial Value This read/write bit determines the initial value for PWMX and the value to which it is forced when FORCE_INIT, (see PWM Generation), is asserted.
6–7 INIT_SEL	Initialization Control Select These read/write bits control the source of the INIT signal which goes to the counter. 00 Local sync (PWMX) causes initialization. 01 Master reload from submodule 0 causes initialization. This setting should not be used in submodule 0 as it will force the INIT signal to logic 0.

Table continues on the next page...

FlexPWM_SUB*n*_CTRL2 field descriptions (continued)

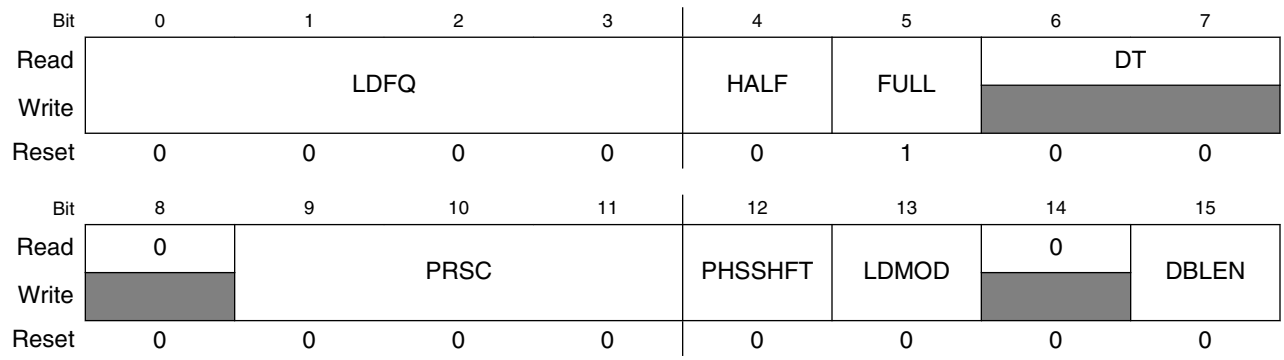
Field	Description
	10 Master sync from submodule 0 causes initialization. This setting should not be used in submodule 0 as it will force the INIT signal to logic 0. 11 EXT_SYNC causes initialization.
8 FRCEN	Force Initialization Enable This bit allows the FORCE_OUT signal to initialize the counter without regard to the signal selected by INIT_SEL. This is a software controlled initialization. 0 Initialization from a Force Out event is disabled. 1 Initialization from a Force Out event is enabled.
9 FORCE	Force Initialization If the FORCE_SEL bits are set to 000, writing a 1 to this bit results in a Force Out event. This causes the following actions to be taken: • The PWMA and PWMB output pins will assume values based on the SEL23 and SEL45 bits. • If the FRCEN bit is set, the counter value will be initialized with the INIT register value.
10–12 FORCE_SEL	Force Source Select This read/write bit determines the source of the FORCE OUTPUT signal for this submodule. 000 The local force signal, FORCE, from this submodule is used to force updates. 001 The master force signal from submodule 0 is used to force updates. This setting should not be used in submodule 0 as it will hold the FORCE OUTPUT signal to logic 0. 010 The local reload signal from this submodule is used to force updates without regard to the state of LDOK. 011 The master reload signal from submodule0 is used to force updates if LDOK is set. This setting should not be used in submodule0 as it will hold the FORCE OUTPUT signal to logic 0. 100 The local sync signal from this submodule is used to force updates. 101 The master sync signal from submodule0 is used to force updates. This setting should not be used in submodule0 as it will hold the FORCE OUTPUT signal to logic 0. 110 The external force signal, EXT_FORCE, from outside the PWM module causes updates. 111 reserved
13 RELOAD_SEL	Reload Source Select This read/write bit determines the source of the RELOAD signal for this submodule. When this bit is set, the LDOK bit in submodule 0 should be used since the local LDOK bit will be ignored. 0 The local RELOAD signal is used to reload registers. 1 The master RELOAD signal (from submodule 0) is used to reload registers. This setting should not be used in submodule 0 as it will force the RELOAD signal to logic 0.
14–15 CLK_SEL	Clock Source Select These read/write bits determine the source of the clock signal for this submodule. 00 The peripheral clock is used as the clock for the local prescaler and counter. 01 EXT_CLK is used as the clock for the local prescaler and counter. 10 Submodule 0's clock (AUX_CLK) is used as the source clock for the local prescaler and counter. This setting should not be used in submodule 0 as it will force the clock to logic 0. 11 reserved

42.4.4 Submodule n Control 1 Register (FlexPWM_SUB*n*_CTRL1)

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 6h offset + (80d × i), where i=0d to 3d



FlexPWM_SUB*n*_CTRL1 field descriptions

Field	Description
0–3 LDFQ	Load Frequency These buffered read/write bits select the PWM load frequency. The PWM reload frequency is at every LDFQ+1 PWM opportunities. Reset clears the LDFQ bits, selecting loading every PWM opportunity. A PWM opportunity is determined by the HALF and FULL bits. **NOTE:** The LDFQx bits take effect when the current load cycle is complete regardless of the state of the LDOK bit. Reading the LDFQx bits reads the buffered values and not necessarily the values currently in effect.
4 HALF	Half Cycle Reload This read/write bit enables half-cycle reloads. A half cycle is defined by when the submodule counter matches the SUB*n*_VAL0 register and does not have to be half way through the PWM cycle. 0 Half-cycle reloads disabled. 1 Half-cycle reloads enabled.
5 FULL	Full Cycle Reload This read/write bit enables full-cycle reloads. A full cycle is defined by when the submodule counter matches the SUB*n*_VAL1 register. Either the HALF or FULL bit must be set in order to move the buffered data into the registers used by the PWM generators. If both the HALF and FULL bits are set, then reloads can occur twice per cycle. 0 Full-cycle reloads disabled. 1 Full-cycle reloads enabled.
6–7 DT	Deadtime These read only bits reflect the sampled values of the PWMX input at the end of each deadtime. Sampling occurs at the end of deadtime 0 for DT[0] and the end of deadtime 1 for DT[1]. Reset clears these bits.

Table continues on the next page...

FlexPWM_SUB*n*_CTRL1 field descriptions (continued)

Field	Description
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–11 PRSC	Prescaler These buffered read/write bits select the divide ratio of the PWM clock frequency selected by CLK_SEL. **NOTE:** Reading the PRSCx bits reads the buffered values and not necessarily the values currently in effect. The PRSCx bits take effect at the beginning of the next PWM cycle and only when the load okay bit, LDOK, is set or LDMOD is set. This field cannot be written when LDOK is set. 000 PWM clock frequency = f_{CLK} 001 PWM clock frequency = f_{CLK} / 2 010 PWM clock frequency = f_{CLK} / 4 011 PWM clock frequency = f_{CLK} / 8 100 PWM clock frequency = f_{CLK} / 16 101 PWM clock frequency = f_{CLK} / 32 110 PWM clock frequency = f_{CLK} / 64 111 PWM clock frequency = f_{CLK} / 128
12 PHSSHFT	Phase Shift Mode Enable This read/write bit is only functional in submodule 0. It is used to enable the EXT_SWITCH input to select the source of the generated PWM23/PWM45 signals within submodule 0. If this enable is clear or the EXT_SWITCH signal is 0, then the PWM23/PWM45 signals generated within submodule 0 are used by the force out logic in submodule 0. If this enable is set and the EXT_SWITCH signal is also set, then the PWM23/PWM45 signals from submodule 1 are used by the force out logic in submodule 0. 0 Phase shifted mode is disabled. The EXT_SWITCH input is ignored. Normal operation. 1 Phase shifted mode is enabled. The EXT_SWITCH input is used to select generated PWM source for force out logic in submodule 0.
13 LDMOD	Load Mode Select This read/write bit selects the timing of loading the buffered registers for this submodule. 0 Buffered registers of this submodule are loaded and take effect at the next PWM reload if LDOK is set. 1 Buffered registers of this submodule are loaded and take effect immediately upon LDOK being set.
14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 DBLEN	Double Switching Enable This read/write bit enables the double switching PWM behavior. 0 Double switching disabled. 1 Double switching enabled.

42.4.5 Submodule n Value Register 0 (FlexPWM_SUB*n*_VAL0)

The 16-bit signed value in this buffered, read/write register defines the mid-cycle reload point for the PWM in clock periods. This value also defines when the PWMX signal is set and the local sync signal is reset. This register is not byte accessible.

NOTE

The SUB*n*_VAL0 register is buffered. The value written does not take effect until the LDOK bit is set and the next PWM load cycle begins or LDMOD is set. VAL0 cannot be written when LDOK is set. Reading VAL0 reads the value in a buffer. It is not necessarily the value the PWM generator is currently using.

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 8h offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	VAL0															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FlexPWM_SUB*n*_VAL0 field descriptions

Field	Description
0–15 VAL0	Value 0 Mid-cycle reload point for the PWM in clock periods

42.4.6 Submodule n Value Register 1 (FlexPWM_SUB*n*_VAL1)

The 16-bit signed value written to this buffered, read/write register defines the modulo count value (maximum count) for the submodule counter. Upon reaching this count value, the counter will reload itself with the contents of the INIT register and assert the local sync signal while resetting PWMX. This register is not byte accessible.

NOTE

The SUB*n*_VAL1 register is buffered. The value written does not take effect until the LDOK bit is set and the next PWM load cycle begins or LDMOD is set. VAL1 cannot be written when LDOK is set. Reading VAL1 reads the value in a buffer and not necessarily the value the PWM generator is currently using.

NOTE

If SUB*n*_VAL1 register defines the timer period (Local Sync is selected as the counter initialization signal), a 100% duty cycle cannot be achieved on the PWMX output. The PWMX output will be low for a minimum of one count every cycle after the count reaches VAL1. When the Master Sync signal (only

originated by the Local Sync from sub-module 0) is used to control the timer period, the SUB*n*_VAL1 register can be free for other functions such as PWM generation without duty cycle limitation.

Access:

- Supervisor read/write
- User read/write

Address: 0h base + Ah offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	VAL1															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FlexPWM_SUB*n*_VAL1 field descriptions

Field	Description
0–15 VAL1	Value 1 Modulo count value (maximum count) for the submodule counter

42.4.7 Submodule n Value Register 2 (FlexPWM_SUB*n*_VAL2)

The 16-bit signed value in this buffered, read/write register defines the count value to set PWM23 high (PWM submodule). This register is not byte accessible.

NOTE

The SUB*n*_VAL2 register is buffered. The value written does not take effect until the LDOK bit is set and the next PWM load cycle begins or LDMOD is set. VAL2 cannot be written when LDOK is set. Reading VAL2 reads the value in a buffer and not necessarily the value the PWM generator is currently using.

Access:

- Supervisor read/write
- User read/write

Address: 0h base + Ch offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	VAL2															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FlexPWM_SUB*n*_VAL2 field descriptions

Field	Description
0–15 VAL2	Value 2 Count value to set PWM23 high

42.4.8 Submodule n Value Register 3 (FlexPWM_SUB*n*_VAL3)

The 16-bit signed value in this buffered, read/write register defines the count value to set PWM23 low (PWM submodule). This register is not byte accessible.

NOTE

The SUB*n*_VAL3 register is buffered. The value written does not take effect until the LDOK bit is set and the next PWM load cycle begins or LDMOD is set. VAL3 cannot be written when LDOK is set. Reading VAL3 reads the value in a buffer and not necessarily the value the PWM generator is currently using.

Access:

- Supervisor read/write
- User read/write

Address: 0h base + Eh offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

0–15 VAL3	Value 3 Count value to set PWM23 low

42.4.9 Submodule n Value Register 4 (FlexPWM_SUB*n*_VAL4)

The 16-bit signed value in this buffered, read/write register defines the count value to set PWM45 high (PWM submodule). This register is not byte accessible.

NOTE

The SUB*n*_VAL4 register is buffered. The value written does not take effect until the LDOK bit is set and the next PWM load cycle begins or LDMOD is set. VAL4 cannot be written when

LDOK is set. Reading VAL4 reads the value in a buffer and not necessarily the value the PWM generator is currently using.

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 10h offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	VAL4															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FlexPWM_SUB*n*_VAL4 field descriptions

Field	Description
0–15 VAL4	Count value to set PWM45 high

42.4.10 Submodule n Value Register 5 (FlexPWM_SUB*n*_VAL5)

The 16-bit signed value in this buffered, read/write register defines the count value to set PWM45 low (PWM submodule). This register is not byte accessible.

NOTE

The SUB*n*_VAL5 register is buffered. The value written does not take effect until the LDOK bit is set and the next PWM load cycle begins or LDMOD is set. VAL5 cannot be written when LDOK is set. Reading VAL5 reads the value in a buffer and not necessarily the value the PWM generator is currently using.

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 12h offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	VAL5															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FlexPWM_SUB*n*_VAL5 field descriptions

Field	Description
0–15 VAL5	Count value to set PWM45 low

42.4.11 Submodule n Output Control Register (FlexPWM_SUB*n*_OCTRL)

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 18h offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7
Read	0	0	PWMX_IN	0		POLA	POLB	POLX
Write								
Reset	0	0	*	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read	0		PWMAFS		PWMBFS		PWMXFS	
Write								
Reset	0	0	0	0	0	0	0	0

* Notes:
- PWMX_IN field: Undefined

FlexPWM_SUB*n*_OCTRL field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 PWMX_IN	PWMX Input This read only bit shows the logic value currently being driven into the PWMX input.
3–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 POLA	PWMA Output Polarity This bit inverts the PWMA output polarity. 0 PWMA output not inverted. A high level on the PWMA pin represents the "on" or "active" state. 1 PWMA output inverted. A low level on the PWMA pin represents the "on" or "active" state.
6 POLB	PWMB Output Polarity This bit inverts the PWMB output polarity. 0 PWMB output not inverted. A high level on the PWMB pin represents the "on" or "active" state. 1 PWMB output inverted. A low level on the PWMB pin represents the "on" or "active" state.
7 POLX	PWMX Output Polarity This bit inverts the PWMX output polarity.

Table continues on the next page...

FlexPWM_SUB*n*_OCTRL field descriptions (continued)

Field	Description
	0 PWMX output not inverted. A high level on the PWMX pin represents the "on" or "active" state. 1 PWMX output inverted. A low level on the PWMX pin represents the "on" or "active" state.
8–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–11 PWMAFS	PWMA Fault State These bits determine the fault state for the PWMA output during fault conditions and STOP mode . It may also define the output state during DEBUG modes depending on the settings of DBGEN. 00 Output is forced to logic 0 state prior to consideration of output polarity control. 01 Output is forced to logic 1 state prior to consideration of output polarity control. 10 Output is tristated. 11 Output is tristated.
12–13 PWMBFS	PWMB Fault State These bits determine the fault state for the PWMB output during fault conditions and STOP mode . It may also define the output state during DEBUG modes depending on the settings of DBGEN. 00 Output is forced to logic 0 state prior to consideration of output polarity control. 01 Output is forced to logic 1 state prior to consideration of output polarity control. 10 Output is tristated. 11 Output is tristated.
14–15 PWMXFS	PWMX Fault State These bits determine the fault state for the PWMX output during fault conditions and STOP mode . It may also define the output state during DEBUG modes depending on the settings of DBGEN. 00 Output is forced to logic 0 state prior to consideration of output polarity control. 01 Output is forced to logic 1 state prior to consideration of output polarity control. 10 Output is tristated. 11 Output is tristated.

42.4.12 Submodule n Status Register (FlexPWM_SUB*n*_STS)

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 1Ah offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0	RUF	REF	RF	0				CFX1	CFX0	CMPF					
Write			w1c	w1c					w1c	w1c	w1c					
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FlexPWM_SUB*n*_STS field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 RUF	Registers Updated Flag This read-only flag is set when SUB*n*_INIT, SUB*n*_VAL*x*, or SUB*n*_CTRL1[PRSC] has been written resulting in non-coherent data in the set of double-buffered registers. Clear RUF by a proper reload sequence consisting of a reload signal while LDOK = 1. Reset clears RUF. 0 No register update has occurred since last reload. 1 At least one of the double buffered registers has been updated since the last reload.
2 REF	Reload Error Flag This read/write flag is set when a reload cycle occurs while LDOK is 0 and the double buffered registers are in a non-coherent state (RUF = 1). Clear REF by writing a logic one to the REF bit. Reset clears REF. 0 No reload error occurred. 1 Reload signal occurred with non-coherent data and LDOK = 0.
3 RF	Reload Flag This read/write flag is set at the beginning of every reload cycle regardless of the state of the LDOK bit. Clear RF by writing a logic one to the RF bit when VALDE is clear (non-DMA mode). RF can also be cleared by the DMA done signal when VALDE is set (DMA mode). Reset clears RF. 0 No new reload cycle since last RF clearing 1 New reload cycle since last RF clearing
4–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 CFX1	Capture Flag X1 This bit is set when the word count of the Capture X1 FIFO (CX1CNT) exceeds the value of the CFXWM field. This bit is cleared by writing a one to this bit position if CX1DE is clear (non-DMA mode) or by the DMA done signal if CX1DE is set (DMA mode). Reset clears this bit.
9 CFX0	Capture Flag X0 This bit is set when the word count of the Capture X0 FIFO (CX0CNT) exceeds the value of the CFXWM field. This bit is cleared by writing a one to this bit position if CX0DE is clear (non-DMA mode) or by the DMA done signal if CX0DE is set (DMA mode). Reset clears this bit.
10–15 CMPF	Compare Flags These bits are set when the submodule counter value matches the value of one of the SUB*n*_VAL*x* registers. Clear these bits by writing a 1 to a bit position.

CMPF bit	Value register
0	SUB*n*_VAL0
1	SUB*n*_VAL1
2	SUB*n*_VAL2
3	SUB*n*_VAL3
4	SUB*n*_VAL4
5	SUB*n*_VAL5

Table continues on the next page...

FlexPWM_SUB*n*_STS field descriptions (continued)

Field	Description
	0 No compare event has occurred for a particular VAL*x* value. 1 A compare event has occurred for a particular VAL*x* value.

42.4.13 Submodule n Interrupt Enable Register (FlexPWM_SUB*n*_INTEN)

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 1Ch offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7
Read	0		REIE	RIE	Reserved			
Write								
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read Write	CX1IE	CX0IE	CMPIE					
Reset	0	0	0	0	0	0	0	0

FlexPWM_SUB*n*_INTEN field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 REIE	Reload Error Interrupt Enable This read/write bit enables the reload error flag (REF) to generate CPU interrupt requests. Reset clears RIE. 0 REF CPU interrupt requests disabled 1 REF CPU interrupt requests enabled
3 RIE	Reload Interrupt Enable This read/write bit enables the reload flag (RF) to generate CPU interrupt requests. Reset clears RIE. 0 RF CPU interrupt requests disabled 1 RF CPU interrupt requests enabled
4–7 Reserved	This field is reserved. Always write the reset value to this field.
8 CX1IE	Capture X 1 Interrupt Enable This bit allows the CFX1 flag to create an interrupt request to the CPU. Do not set both this bit and the CX1DE bit. 0 Interrupt request disabled for CFX1. 1 Interrupt request enabled for CFX1.

Table continues on the next page...

FlexPWM_SUB*n*_INTEN field descriptions (continued)

Field	Description
9 CX0IE	Capture X 0 Interrupt Enable This bit allows the CFX0 flag to create an interrupt request to the CPU. Do not set both this bit and the CX0DE bit. 0 Interrupt request disabled for CFX0. 1 Interrupt request enabled for CFX0.
10–15 CMPIE	Compare Interrupt Enables These bits enable the CMPF flags to cause a compare interrupt request to the CPU. **CMPIE bit** / **Value register** 0 / SUB*n*_VAL0 1 / SUB*n*_VAL1 2 / SUB*n*_VAL2 3 / SUB*n*_VAL3 4 / SUB*n*_VAL4 5 / VAL5 0 The corresponding CMPF bit will not cause an interrupt request. 1 The corresponding CMPF bit will cause an interrupt request.

42.4.14 Submodule n DMA Enable Register (FlexPWM_SUB*n*_DMAEN)

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 1Eh offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7
Read	0						VALDE	FAND
Write								
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read	CAPTDE		Reserved				CX1DE	CX0DE
Write								
Reset	0	0	0	0	0	0	0	0

FlexPWM_SUB*n*_DMAEN field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 VALDE	Value Registers DMA Enable This read/write bit enables DMA write requests for the SUB*n*_VAL*x* registers when RF is set. Reset clears VALDE. Clearing this field clears any pending DMA requests. 0 DMA write requests disabled 1 DMA write requests for the SUB*n*_VAL*x* registers enabled
7 FAND	FIFO Watermark AND Control This read/write bit works in conjunction with the CAPTDE field when it is set to watermark mode (CAPTDE = 01). While the CAxDE, CBxDE, and CXxDE bits determine which FIFO watermarks the DMA read request is sensitive to, this bit determines if the selected watermarks are AND'ed together or OR'ed together in order to create the request. 0 Selected FIFO watermarks are OR'ed together. 1 Selected FIFO watermarks are AND'ed together.
8–9 CAPTDE	Capture DMA Enable Source Select These read/write bits select the source of enabling the DMA read requests for the capture FIFOs. Reset clears these bits. 00 Read DMA requests disabled. 01 Exceeding a FIFO watermark sets the DMA read request. This requires at least 1 of the CA1DE, CA0DE, CB1DE, CB0DE, CX1DE, or CX0DE bits to also be set in order to determine which watermark(s) the DMA request is sensitive to. 10 A local sync (VAL1 matches counter) sets the read DMA request. 11 A local reload (RF being set) sets the read DMA request.
10–13 Reserved	This field is reserved. Always write the reset value to this field.
14 CX1DE	Capture X1 FIFO DMA Enable This read/write bit enables DMA read requests for the Capture X1 FIFO data when CFX1 is set. Reset clears CX1DE. Clearing this field clears any pending DMA requests. Do not set both this bit and the CX1IE bit.
15 CX0DE	Capture X0 FIFO DMA Enable This read/write bit enables DMA read requests for the Capture X0 FIFO data when CFX0 is set. Reset clears CX0DE. Clearing this field clears any pending DMA requests. Do not set both this bit and the CX0IE bit.

42.4.15 Submodule n Output Trigger Control Register (FlexPWM_SUB*n*_TCTRL)

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 20h offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0										OUT_TRIG_EN					
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FlexPWM_SUB*n*_TCTRL field descriptions

Field	Description
0–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–15 OUT_TRIG_EN	Output Trigger Enables These bits enable the generation of OUT_TRIG_EVEN and OUT_TRIG_ODD outputs based on the counter value matching the value in one or more of the SUB*n*_VAL*x* registers. VAL0, VAL2, and VAL4 are used to generate OUT_TRIG_EVEN and VAL1, VAL3, and VAL5 are used to generate OUT_TRIG_ODD. The OUT_TRIGx signals are only asserted as long as the counter value matches the VAL*x* value, therefore up to six triggers can be generated (three each on OUT_TRIG_EVEN and OUT_TRIG_ODD) per PWM cycle per submodule.

OUT_TRIG_EN bit	Value register
0	SUB*n*_VAL0
1	SUB*n*_VAL1
2	SUB*n*_VAL2
3	SUB*n*_VAL3
4	SUB*n*_VAL4
5	SUB*n*_VAL5

0 OUT_TRIGx will not set when the counter value matches the VAL*x* value.
1 OUT_TRIGx will set when the counter value matches the VAL*x* value.

42.4.16 Submodule n Fault Disable Mapping Register (FlexPWM_SUB*n*_DISMAP)

This register determines which PWM pins are disabled by the fault protection inputs, illustrated in the table in Fault Protection. Reset sets all of the bits in the fault disable mapping register.

NOTE

The FAULT pin still detects a signal even if the associated pin is not configured for the FlexPWM FAULT function. Read the FAULT pin value at FSTS[FFPIN].

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 22h offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	1				DISX				DISB				DISA			
Write																
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

FlexPWM_SUB*n*_DISMAP field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
4–7 DISX	PWMX Fault Disable Mask Each of the four bit of this read/write field is one-to-one associated with the four FAULT*x* inputs. The PWMX output will be turned off if there is a logic 1 on a FAULT*x* input and a 1 in the corresponding bit of the DISX field. A reset sets all DISX bits.
8–11 DISB	PWMB Fault Disable Mask Each of the four bit of this read/write field is one-to-one associated with the four FAULT*x* inputs. The PWMB output will be turned off if there is a logic 1 on a FAULT*x* input and a 1 in the corresponding bit of the DISB field. A reset sets all DISB bits.
12–15 DISA	PWMA Fault Disable Mask Each of the four bit of this read/write field is one-to-one associated with the four FAULT*x* inputs. The PWMA output will be turned off if there is a logic 1 on a FAULT*x* input and a 1 in the corresponding bit of the DISA field. A reset sets all DISA bits.

DISX bit	Fault input
0	0
1	1
2	2
3	3

DISB bit	Fault input
0	0
1	1
2	2
3	3

DISA bit	Fault input
0	0
1	1
2	2
3	3

42.4.17 Submodule n Deadtime Count Register 0 (FlexPWM_SUB*n*_DTCNT0)

Deadtime operation is only applicable to complementary channel operation. The 11-bit value written to this register is in terms of peripheral clock cycles regardless of the setting of PRSC and/or CLK_SEL. Reset sets the deadtime count register to a default value of 0x07FF, selecting a deadtime of 2047 clock cycles. This register is not byte accessible.

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 24h offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0					DTCNT0										
Write																
Reset	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1

FlexPWM_SUB*n*_DTCNT0 field descriptions

Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–15 DTCNT0	Controls the deadtime during 0 to 1 transitions of the PWMA output (assuming normal polarity) in terms of clock cycles regardless of the setting of PRSC and/or CLK_SEL

42.4.18 Submodule n Deadtime Count Register 1 (FlexPWM_SUB*n*_DTCNT1)

Deadtime operation is only applicable to complementary channel operation. The 11-bit value written to this register is in terms of peripheral clock cycles regardless of the setting of PRSC and/or CLK_SEL. Reset sets the deadtime count register to a default value of 0x07FF, selecting a deadtime of 2047 clock cycles. This register is not byte accessible.

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 26h offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0					DTCNT1										
Write																
Reset	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1

FlexPWM_SUB*n*_DTCNT1 field descriptions

Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–15 DTCNT1	Controls the deadtime during 0 to 1 transitions of the complementary PWMB output, in terms of clock cycles regardless of the setting of PRSC and/or CLK_SEL

42.4.19 Submodule n Capture Control X Register (FlexPWM_SUB*n*_CAPTCTRLX)

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 30h offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7
Read	CX1CNT				CX0CNT		CFXWM	
Write								
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read	EDGCNTX_EN	INPSELX	EDGX1		EDGX0		ONESHOTX	ARMX
Write								
Reset	0	0	0	0	0	0	0	0

FlexPWM_SUB*n*_CAPTCTRLX field descriptions

Field	Description
0–2 CX1CNT	Capture X1 FIFO Word Count This field reflects the number of words in the Capture X1 FIFO.
3–5 CX0CNT	Capture X0 FIFO Word Count This field reflects the number of words in the Capture X0 FIFO.
6–7 CFXWM	Capture X FIFOs Watermark This field represents the watermark level for capture X FIFOs. The capture flags, CFX1 and CFX0, won't be set until the word count of the corresponding FIFO is greater than this watermark level.
8 EDGCNTX_EN	Edge Counter X Enable This bit enables the edge counter which counts rising and falling edges on the PWMX input signal. 0 Edge counter disabled and held in reset. 1 Edge counter enabled.
9 INPSELX	Input Select X

Table continues on the next page...

FlexPWM_SUB*n*_CAPTCTRLX field descriptions (continued)

Field	Description
	This bit selects between the raw PWMX input signal and the output of the edge counter/compare circuitry as the source for the input capture circuit. **NOTE:** When INPSELX = 1, the internal edge counter is enabled and the rising and/or falling edges specified by the EDGX0 and EDGX1 fields are ignored. The software must still place a value other than 00 in either or both of the EDGX0 and/or EDGX1 fields in order to enable one or both of the capture registers. 0 Raw PWMX input signal selected as source. 1 Output of edge counter/compare selected as source.
10–11 EDGX1	Edge X 1 These bits control the input capture 1 circuitry by determining which input edges cause a capture event. 00 Disabled. 01 Capture falling edges. 10 Capture rising edges. 11 Capture any edge.
12–13 EDGX0	Edge X 0 These bits control the input capture 0 circuitry by determining which input edges cause a capture event. 00 Disabled. 01 Capture falling edges. 10 Capture rising edges. 11 Capture any edge.
14 ONESHOTX	One Shot Mode Aux This bit selects between free running and one shot mode for the input capture circuitry. 0 Free running mode is selected If both capture circuits are enabled, then capture circuit 0 is armed first after the ARMX bit is set. Once a capture occurs, capture circuit 0 is disarmed and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed and capture circuit 0 is re-armed. The process continues indefinitely. If only one of the capture circuits is enabled, then captures continue indefinitely on the enabled capture circuit. 1 One shot mode is selected. If both capture circuits are enabled, then capture circuit 0 is armed first after the ARMX bit is set. Once a capture occurs, capture circuit 0 is disarmed and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed and the ARMX bit is cleared. No further captures will be performed until the ARMX bit is set again. If only one of the capture circuits is enabled, then a single capture will occur on the enabled capture circuit and the ARMX bit is then cleared.
15 ARMX	Arm X Setting this bit high starts the input capture process. This bit can be cleared at any time to disable input capture operation. This bit is self cleared when in one shot mode and the enabled capture circuit(s) has had a capture event(s). 0 Input capture operation is disabled. 1 Input capture operation as specified by the EDGX bits is enabled.

42.4.20 Submodule n Capture Compare X Register (FlexPWM_SUB*n*_CAPTCMPX)

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 32h offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	EDGCNTX								EDGCMPX							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FlexPWM_SUB*n*_CAPTCMPX field descriptions

Field	Description
0–7 EDGCNTX	Edge Counter X This read only field contains the edge counter value for the PWMX input capture circuitry.
8–15 EDGCMPX	Edge Compare X This read/write field is the compare value associated with the edge counter for the PWMX input capture circuitry.

42.4.21 Submodule n Capture Value 0 Register (FlexPWM_SUB*n*_CVAL0)

This read only register stores the value captured from the submodule counter. Exactly when this capture occurs is defined by the EDGX0 bits. This is actually a 4-deep FIFO and not a single register. This register is not byte accessible.

Access:

- Supervisor read-only
- User read-only

Address: 0h base + 34h offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	CAPTVAL0															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FlexPWM_SUB*n*_CVAL0 field descriptions

Field	Description
0–15 CAPTVAL0	Value captured from the submodule counter

42.4.22 Submodule n Capture Value 0 Cycle Register (FlexPWM_SUB*n*_CVAL0CYC)

This read only register stores the cycle number corresponding to the value captured in CVAL0. The PWM cycle is reset to 0 and is incremented each time the counter is loaded with the INIT value. This is actually a 4 deep FIFO and not a single register.

Access:

- Supervisor read-only
- User read-only

Address: 0h base + 36h offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0													CVAL0CYC		
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FlexPWM_SUB*n*_CVAL0CYC field descriptions

Field	Description
0–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–15 CVAL0CYC	CVAL0 Cycle Cycle number corresponding to the value captured in CVAL0

42.4.23 Submodule n Capture Value 1 Register (FlexPWM_SUB*n*_CVAL1)

This read only register stores the value captured from the submodule counter. Exactly when this capture occurs is defined by the EDGX1 bits. This is actually a 4 deep FIFO and not a single register. This register is not byte accessible.

Access:

- Supervisor read-only
- User read-only

Address: 0h base + 38h offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	CAPTVAL1															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FlexPWM_SUB*n*_CVAL1 field descriptions

Field	Description
0–15 CAPTVAL1	Value captured from the submodule counter

42.4.24 Submodule n Capture Value 1 Cycle Register (FlexPWM_SUB*n*_CVAL1CYC)

This read only register stores the cycle number corresponding to the value captured in CVAL1. The PWM cycle is reset to 0 and is incremented each time the counter is loaded with the INIT value. This is actually a 4 deep FIFO and not a single register.

Access:

- Supervisor read-only
- User read-only

Address: 0h base + 3Ah offset + (80d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0													CVAL1CYC		
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FlexPWM_SUB*n*_CVAL1CYC field descriptions

Field	Description
0–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–15 CVAL1CYC	CVAL1 Cycle Cycle number corresponding to the value captured in CVAL1

42.4.25 Output Enable Register (FlexPWM_OUTEN)

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 140h offset = 140h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0				PWMA_EN				PWMB_EN				PWMX_EN			
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FlexPWM_OUTEN field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–7 PWMA_EN	PWMA Output Enables These bits enable the PWMA outputs of each submodule. **PWMA_EN bit** / **PWM submodule** 0 / 0 1 / 1 2 / 2 3 / 3 0 PWMA output disabled. 1 PWMA output enabled.
8–11 PWMB_EN	PWMB Output Enables These bits enable the PWMB outputs of each submodule. **PWMB_EN bit** / **PWM submodule** 0 / 0 1 / 1 2 / 2 3 / 3 0 PWMB output disabled. 1 PWMB output enabled.
12–15 PWMX_EN	PWMX Output Enables These bits enable the PWMX outputs of each submodule. These bits should be set to 0 (output disabled) when a PWMX pin is being used for input capture or deadtime correction. **PWMX_EN bit** / **PWM submodule** 0 / 0 1 / 1 2 / 2 3 / 3

Table continues on the next page...

FlexPWM_OUTEN field descriptions (continued)

Field	Description
	0 PWMX output disabled. 1 PWMX output enabled.

42.4.26 Mask Register (FlexPWM_MASK)

NOTE

The MASKx bits are double buffered and do not take effect until a FORCE_OUT event occurs within the appropriate submodule. Refer to the figure in Force Out Logic to see how FORCE_OUT is generated. Reading the MASK bits reads the buffered value and not necessarily the value currently in effect. This double buffering can be overridden by setting the UPDATE_MASK bits.

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 142h offset = 142h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0				MASKA				MASKB				MASKX			
Write	UPDATE_MASK															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FlexPWM_MASK field descriptions

Field	Description
0–3 UPDATE_MASK	Update Mask These self-clearing bits force the MASK* bits to be immediately updated within each of the submodules without waiting for a FORCE_OUT event. Software may write to any or all of these bits and may set these bits in the same write operation that updates the MASKA, MASKB, and MASKX fields of this register. 0 Normal operation. MASK* bits within the submodules aren't updated until a FORCE_OUT event occurs within the submodule. 1 Immediate operation. MASK* bits within the corresponding submodules are updated on the following clock edge after setting this bit.
4–7 MASKA	PWMA Masks These bits mask the PWMA outputs of each submodule forcing the output to logic 0 prior to consideration of the output polarity.

Table continues on the next page...

42.4.29 Master Control Register (FlexPWM_MCTRL)

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 148h offset = 148h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	IPOL				RUN				0				LDOK			
Write									CLDOK							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FlexPWM_MCTRL field descriptions

Field	Description
0–3 IPOL	Current Polarity This buffered read/write bit is used to select between PWM23 and PWM45 as the source for the generation of the complementary PWM pair output in each submodule. IPOL is ignored in independent mode.

Table continues on the next page...

FlexPWM_MCTRL field descriptions (continued)

Field	Description
	IPOL bit / **PWM submodule** 0 / 0 1 / 1 2 / 2 3 / 3 **NOTE:** The IPOL bit does not take effect until a FORCE_OUT event takes place in the appropriate submodule. Reading the IPOL bit reads the buffered value and not necessarily the value currently in effect. 0 PWM23 (PWM submodule) is used to generate complementary PWM pair. 1 PWM45 (PWM submodule) is used to generate complementary PWM pair.
4–7 RUN	Run This read/write bit enables the clocks to the PWM generator in each submodule. When RUN equals zero, the submodule counter is reset. A reset clears RUN. **RUN bit** / **PWM submodule** 0 / 0 1 / 1 2 / 2 3 / 3 **NOTE:** For proper initialization of the LDOK and RUN bits, see Initialization . 0 PWM generator disabled 1 PWM generator enabled
8–11 CLDOK	Clear Load Okay This write only bit is used to clear the LDOK bit. Write a 1 to this location to clear the corresponding LDOK. If a reload occurs with LDOK set at the same time that CLDOK is written, then the reload will not be performed and LDOK will be cleared. This bit is self clearing and always reads as a 0. **CLDOK bit** / **PWM submodule** 0 / 0 1 / 1 2 / 2 3 / 3
12–15 LDOK	Load Okay This field loads the PRSC bits of SUB*n*_CTRL1, SUB*n*_INIT, and SUB*n*_VAL*x* registers into a set of buffers in each submodule. The buffered prescaler divisor, submodule counter modulus value, and PWM pulse width take effect at the next PWM reload if LDMOD is clear or immediately if LDMOD is set. Set LDOK by reading it when it is logic zero and then writing a logic one to it. SUB*n*_VAL*x*, SUB*n*_INIT, and

Table continues on the next page...

FlexPWM_MCTRL field descriptions (continued)

Field	Description
	SUB*n*_CTRL*x*[PRSC] cannot be written while LDOK is set. LDOK is automatically cleared after the new values are loaded, or can be manually cleared before a reload by writing a logic 1 to CLDOK. This bit cannot be written with a zero. LDOK can be set in DMA mode when the DMA indicates that it has completed the update of all SUB*n*_INIT, SUB*n*_VAL*x*, or SUB*n*_CTRL*x*[PRSC]> registers. Reset clears LDOK. **LDOK bit** / **PWM submodule** 0 / 0 1 / 1 2 / 2 3 / 3 **NOTE:** For proper initialization of the LDOK and RUN bits, see Initialization . 0 Do not load new values. 1 Load prescaler, modulus, and PWM values.

42.4.30 Fault Control Register (FlexPWM_FCTRL)

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 14Ch offset = 14Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	FLVL				FAUTO				FSAFE				FIE			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FlexPWM_FCTRL field descriptions

Field	Description
0–3 FLVL	Fault Level These read/write bits select the active logic level of the individual fault inputs. A reset clears FLVL. **FLVL bit** / **Fault input** 0 / 0 1 / 1 2 / 2 3 / 3

Table continues on the next page...

FlexPWM_FCTRL field descriptions (continued)

<table>
<tr><th>Field</th><th>Description</th></tr>
<tr><td></td><td>0 A logic 0 on the fault input indicates a fault condition.
1 A logic 1 on the fault input indicates a fault condition.</td></tr>
<tr><td>4–7
FAUTO</td><td>Automatic Fault Clearing
These read/write bits select automatic or manual clearing of faults. A reset clears FAUTO.
<table><tr><th>FAUTO bit</th><th>Fault input</th></tr><tr><td>0</td><td>0</td></tr><tr><td>1</td><td>1</td></tr><tr><td>2</td><td>2</td></tr><tr><td>3</td><td>3</td></tr></table>
0 Manual fault clearing. PWM outputs disabled by this fault are not enabled until the FFLAGx bit is clear at the start of a half cycle or full cycle depending the state of the FFULL bits. This is further controlled by the FSAFE bits.
1 Automatic fault clearing. PWM outputs disabled by this fault are enabled when the FFPINx bit is clear at the start of a half cycle or full cycle depending on the state of the FFULL bits without regard to the state of FFLAGx bit.</td></tr>
<tr><td>8–11
FSAFE</td><td>Fail Safe Mode
These read/write bits select the safety mode during manual fault clearing. A reset clears FSAFE.
<table><tr><th>FSAFE bit</th><th>Fault input</th></tr><tr><td>0</td><td>0</td></tr><tr><td>1</td><td>1</td></tr><tr><td>2</td><td>2</td></tr><tr><td>3</td><td>3</td></tr></table>
NOTE: The FFPINx bit may indicate a fault condition still exists even though the actual fault signal at the FAULTx pin is clear due to the fault filter latency.
0 Normal mode. PWM outputs disabled by this fault are not enabled until the FFLAGx bit is clear at the start of a half cycle or full cycle depending on the state of the FFULL bits without regard to the state of the FFPINx bit. The PWM outputs disabled by this fault input will not be re-enabled until the actual FAULTx input signal de-asserts. This is because the fault inputs have a direct combinational link to disable the PWM outputs (as programmed in DISMAP).
1 Safe mode. PWM outputs disabled by this fault are not enabled until the FFLAGx bit is clear and the FFPINx bit is clear at the start of a half cycle or full cycle depending on the state of the FFULL bits.</td></tr>
<tr><td>12–15
FIE</td><td>Fault Interrupt Enables
This read/write bit enables CPU interrupt requests generated by the FAULTx pins. A reset clears FIE.
<table><tr><th>FIE bit</th><th>Fault input</th></tr><tr><td>0</td><td>0</td></tr><tr><td>1</td><td>1</td></tr><tr><td>2</td><td>2</td></tr></table></td></tr>

</table>

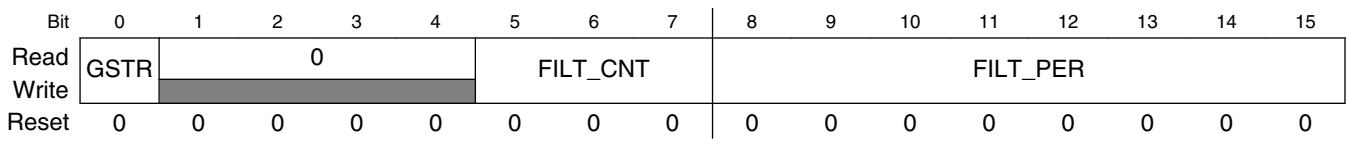
42.4.32 Fault Filter Register (FlexPWM_FFILT)

The settings in this register are shared among each of the fault input filters.

Access:

- Supervisor read/write
- User read/write

Address: 0h base + 150h offset = 150h

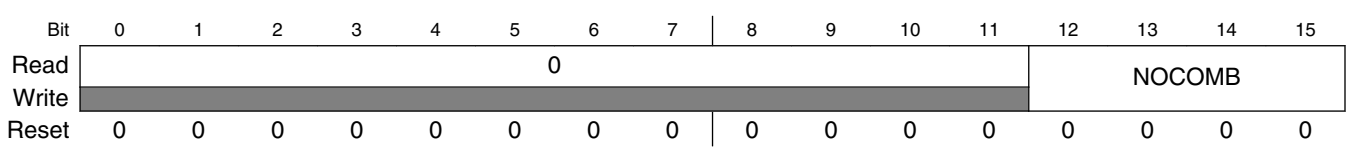


FlexPWM_FFILT field descriptions

Field	Description
0 GSTR	Fault Glitch Stretch Enable This bit is used to enable the fault glitch stretching logic. This logic ensures that narrow fault glitches are stretched to be at least 2 peripheral clock cycles wide. In some cases a narrow fault input can cause problems due to the short PWM output shutdown/re-activation time. The stretching logic ensures that a glitch on the fault input, when the fault filter is disabled, will be registered in the fault flags. 0 Fault input glitch stretching is disabled. 1 Input fault signals will be stretched to at least 2 peripheral clock cycles.
1–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–7 FILT_CNT	Fault Filter Count These bits represent the number of consecutive samples that must agree prior to the input filter accepting an input transition. A value of 0 represents 3 samples. A value of 7 represents 10 samples. The value of FILT_CNT affects the input latency as described in Input Filter Considerations .
8–15 FILT_PER	Fault Filter Period These bits represent the sampling period (in peripheral clock cycles) of the fault pin input filter. Each input is sampled multiple times at the rate specified by FILT_PER. If FILT_PER is 0x00 (default), then the input filter is bypassed. The value of FILT_PER affects the input latency as described in Input Filter Considerations .

42.4.33 Fault Control 2 Register (FlexPWM_FCTRL2)

Address: 0h base + 152h offset = 152h



FlexPWM_FCTRL2 field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 NOCOMB	No combinational path from fault inputs to PWM outputs This read/write field is used to control the combinational path from the fault inputs to the PWM outputs. When these bits are low (default), the corresponding fault inputs have a combinational path to the PWM outputs that are sensitive to these fault inputs (as defined by DISMAP). This combinational path is a safety feature that ensures the output is disabled even if the SOC has a failure of its clocking system. The combinational path also means that a pulse on the fault input can cause a brief disable of the PWM output even if the fault pulse is not wide enough to get through the input filter and be latched in the fault logic. Setting these bits removes the combinational path and uses the filtered and latched fault signals as the fault source to disable the PWM outputs. This eliminates fault glitches from creating PWM output glitches but also increases the latency to respond to a real fault. 0 There is a combinational link from the fault inputs to the PWM outputs. The fault inputs are combined with the filtered and latched fault signals to disable the PWM outputs. 1 The direct combinational path from the fault inputs to the PWM outputs is disabled and the filtered and latched fault signals are used to disable the PWM outputs.

42.4.34 Input Filter Considerations

The FILT_PER value should be set such that the sampling period is larger than the period of the expected noise. This way a noise spike will only corrupt one sample. The FILT_CNT value should be chosen to reduce the probability of noisy samples causing an incorrect transition to be recognized. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the FILT_CNT+3 power.

The values of FILT_PER and FILT_CNT must also be traded off against the desire for minimal latency in recognizing input transitions. Turning on the input filter (setting FILT_PER to a non-zero value) introduces a latency of ((FILT_CNT+4) x FILT_PER x peripheral clock period). Note that even when the filter is enabled, there is a combinational path to disable the PWM outputs. This is to ensure rapid response to fault conditions and also to ensure fault response if the PWM module loses its clock. The latency induced by the filter will be seen in the time to set the FFLAG and FFPIN bits of the FSTS register.

42.5 Functional Description

This section describes the functionality of the FlexPWM.

42.5.1 PWM Capabilities

This section describes some capabilities of the PWM module.

42.5.1.1 Center Aligned PWMs

Each submodule has its own timer that is capable of generating PWM signals on two output pins. The edges of each of these signals are controlled independently as shown in following figure.

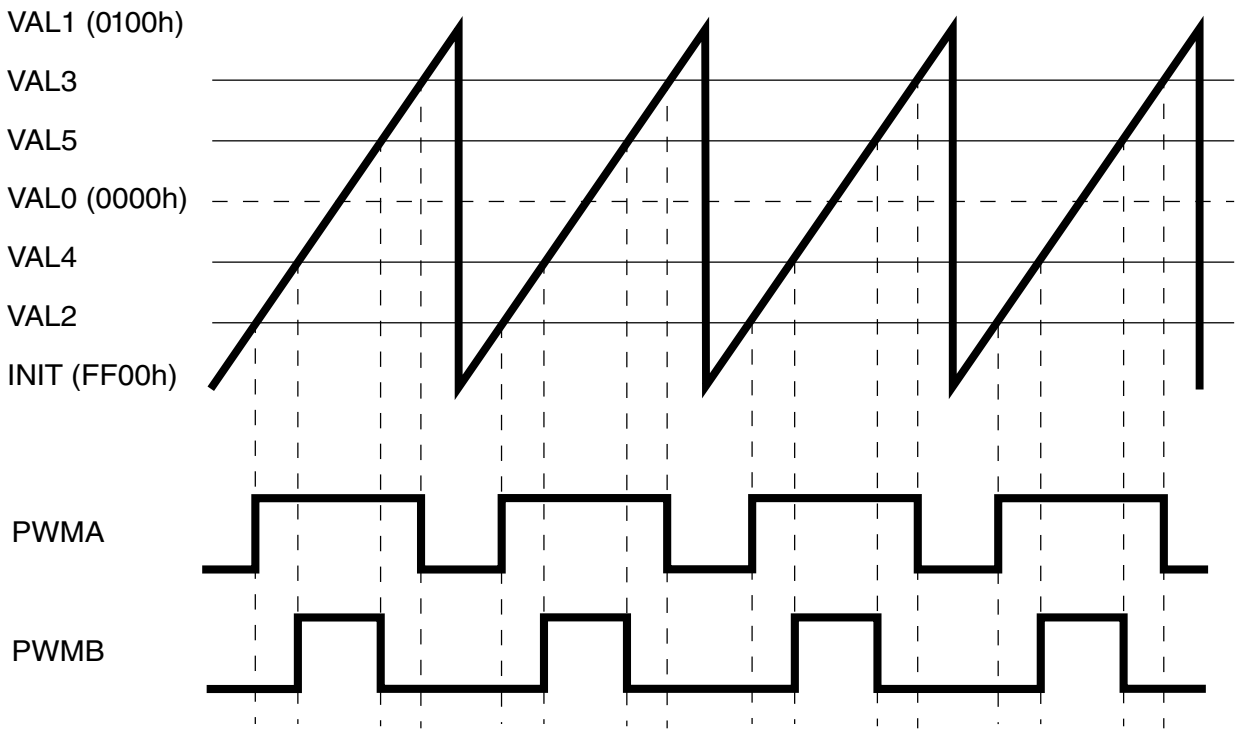


Figure 42-3. Center Aligned Example

The submodule timers only count in the up direction and then reset to the INIT value. Instead of having a single value that determines pulse width, there are two values that must be specified: the turn on edge and the turn off edge. This double action edge generation not only gives the user control over the pulse width, but over the relative alignment of the signal as well. As a result, there is no need to support separate PWM alignment modes since the PWM alignment mode is inherently a function of the turn on and turn off edge values.

The figure above also illustrates an additional enhancement to the PWM generation process. When the counter resets, it is reloaded with a user specified value, which may or may not be zero. If the value chosen happens to be the 2's complement of the modulus value, then the PWM generator operates in "signed" mode. This means that if each PWM's turn on and turn off edge values are also the same number but only different in

their sign, the "on" portion of the output signal will be centered around a count value of zero. Therefore, only one PWM value needs to be calculated in software and then this value and its negative are provided to the submodule as the turn off and turn on edges respectively. This technique will result in a pulse width that always consists of an odd number of timer counts. If all PWM signal edge calculations follow this same convention, then the signals will be center aligned with respect to each other, which is the goal. Of course, center alignment between the signals is not restricted to symmetry around the zero count value, as any other number would also work. However, centering on zero provides the greatest range in signed mode and also simplifies the calculations.

42.5.1.2 Edge Aligned PWMs

When the turn on edge for each pulse is specified to be the INIT value, then edge aligned operation results, as illustrated in the following figure. Therefore, only the turn off edge value needs to be periodically updated to change the pulse width.

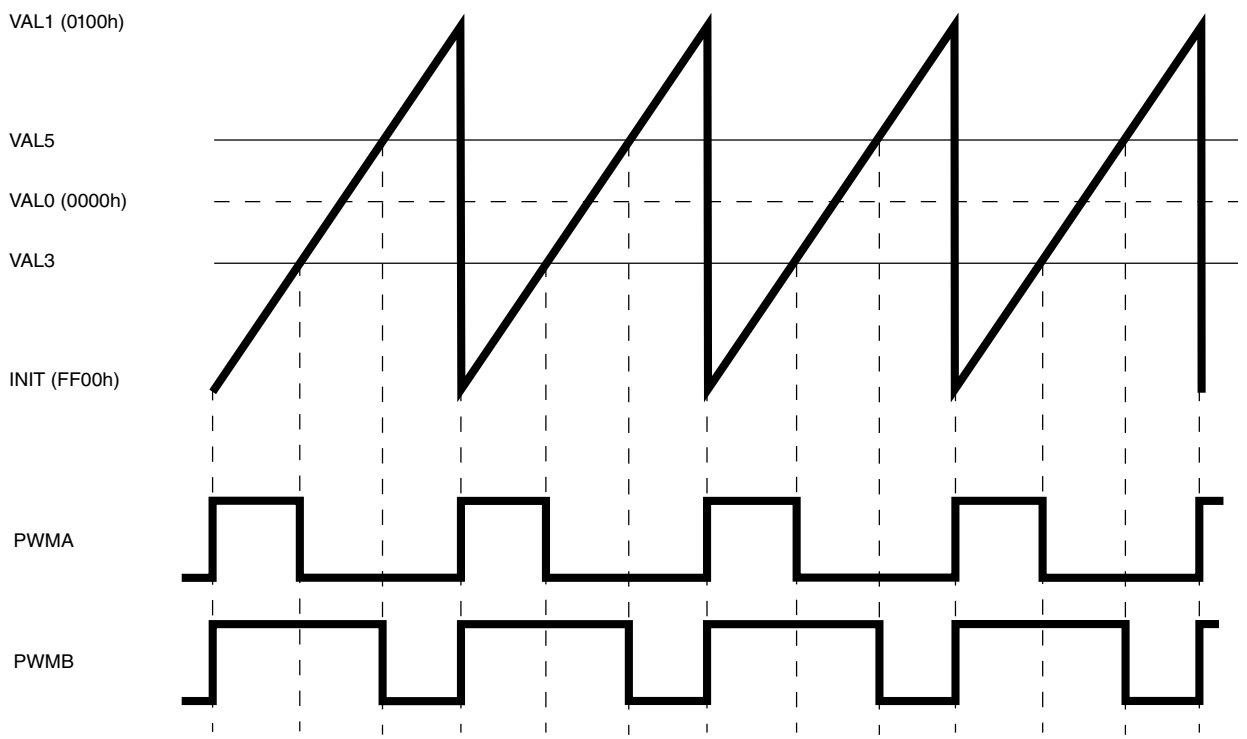

Figure 42-4. Edge Aligned Example (INIT=VAL2=VAL4)

With edge aligned PWMs, another example of the benefits of signed mode can be seen. A common way to drive an H-bridge is to use a technique called "bipolar" PWMs where a 50% duty cycle results in zero volts on the load. Duty cycles less than 50% result in negative load voltages and duty cycles greater than 50% generate positive load voltages. If the module is set to signed mode operation (the INIT and VAL1 values are the same number with opposite signs), then there is a direct proportionality between the PWM turn

off edge value and the motor voltage, INCLUDING the sign. So once again, signed mode of operation simplifies the software interface to the PWM module since no offset calculations are required to translate the output variable control algorithm to the voltage on an H-Bridge load.

42.5.1.3 Phase Shifted PWMs

In the previous sections, the benefits of signed mode of operation were discussed in the context of simplifying the required software calculations by eliminating the requirement to bias up signed variables before applying them to the module. However, if numerical biases ARE applied to the turn on and turn off edges of different PWM signal, the signals will be phase shifted with respect to each other, as illustrated in the following figure. This results in certain advantages when applied to a power stage. For example, when operating a multi-phase inverter at a low modulation index, all of the PWM switching edges from the different phases occur at nearly the same time. This can be troublesome from a noise standpoint, especially if ADC readings of the inverter must be scheduled near those times. Phase shifting the PWM signals can open up timing windows between the switching edges to allow a signal to be sampled by the ADC. However, phase shifting does NOT affect the duty cycle so average load voltage is not affected.

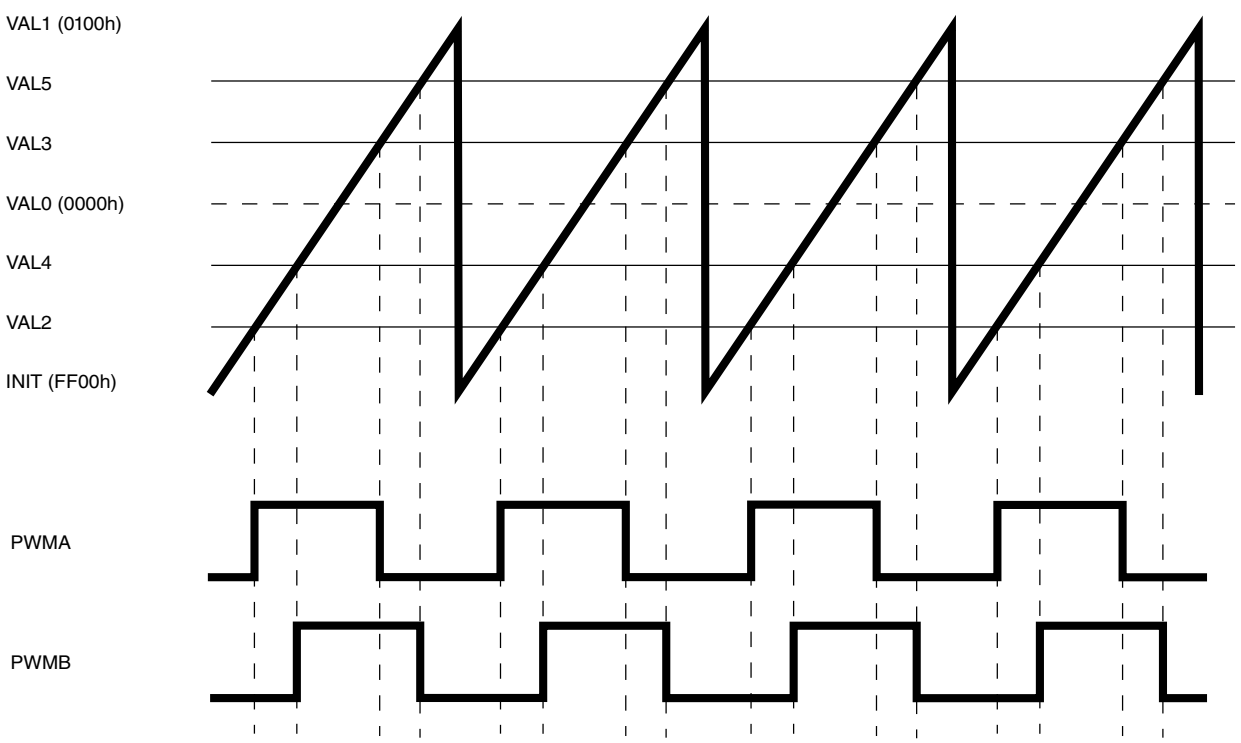

Figure 42-5. Phase Shifted Outputs Example

An additional benefit of phase shifted PWMs can be seen in the following figure. In this case, an H-Bridge circuit is driven by 4 PWM signals to control the voltage waveform on the primary of a transformer. Both left and right side PWMs are configured to always generate a square wave with 50% duty cycle. This works out nicely for the H-Bridge since no narrow pulse widths are generated reducing the high frequency switching requirements of the transistors. Notice that the square wave on the right side of the H-Bridge is phase shifted compared to the left side of the H-Bridge. As a result, the transformer primary sees the bottom waveform across its terminals. The RMS value of this waveform is directly controlled by the amount of phase shift of the square waves. Regardless of the phase shift, no DC component appears in the load voltage as long as the duty cycle of each square wave remains at 50% making this technique ideally suited for transformer loads. As a result, this topology is frequently used in industrial welders to adjust the amount of energy delivered to the weld arc.

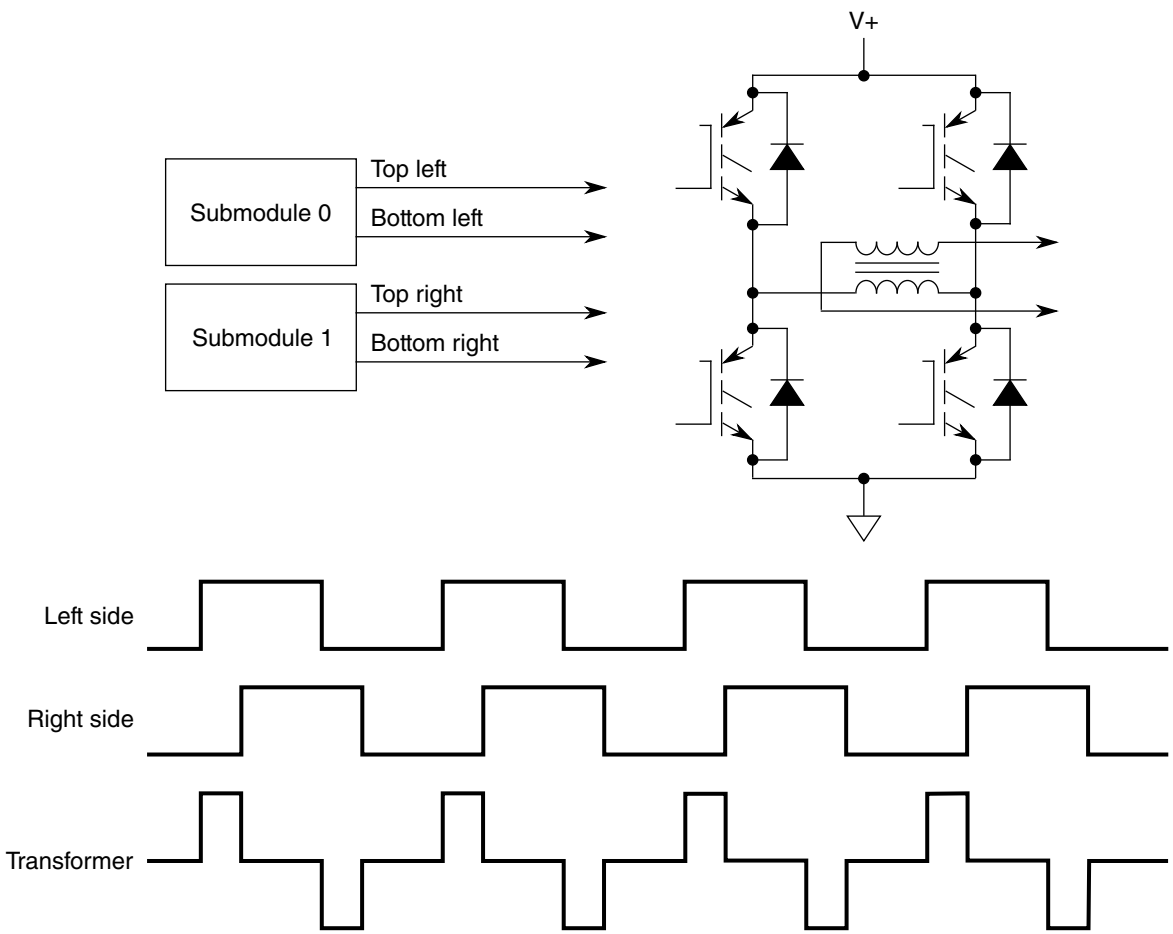

Figure 42-6. Phase Shifted PWMs Applied to a Transformer Primary

42.5.1.4 Double Switching PWMs

Double switching PWM output is supported to aid in single shunt current measurement and three phase reconstruction. This method support two independent rising edges and two independent falling edges per PWM cycle. The VAL2 and VAL3 registers are used to generate the even channel (labelled as PWMA in the figure) while VAL4 and VAL5 are used to generate the odd channel. The two channels are combined using XOR logic (see Figure 42-17) as shown in the following figure. The DBLPWM signal can be run through the deadtime insertion logic.

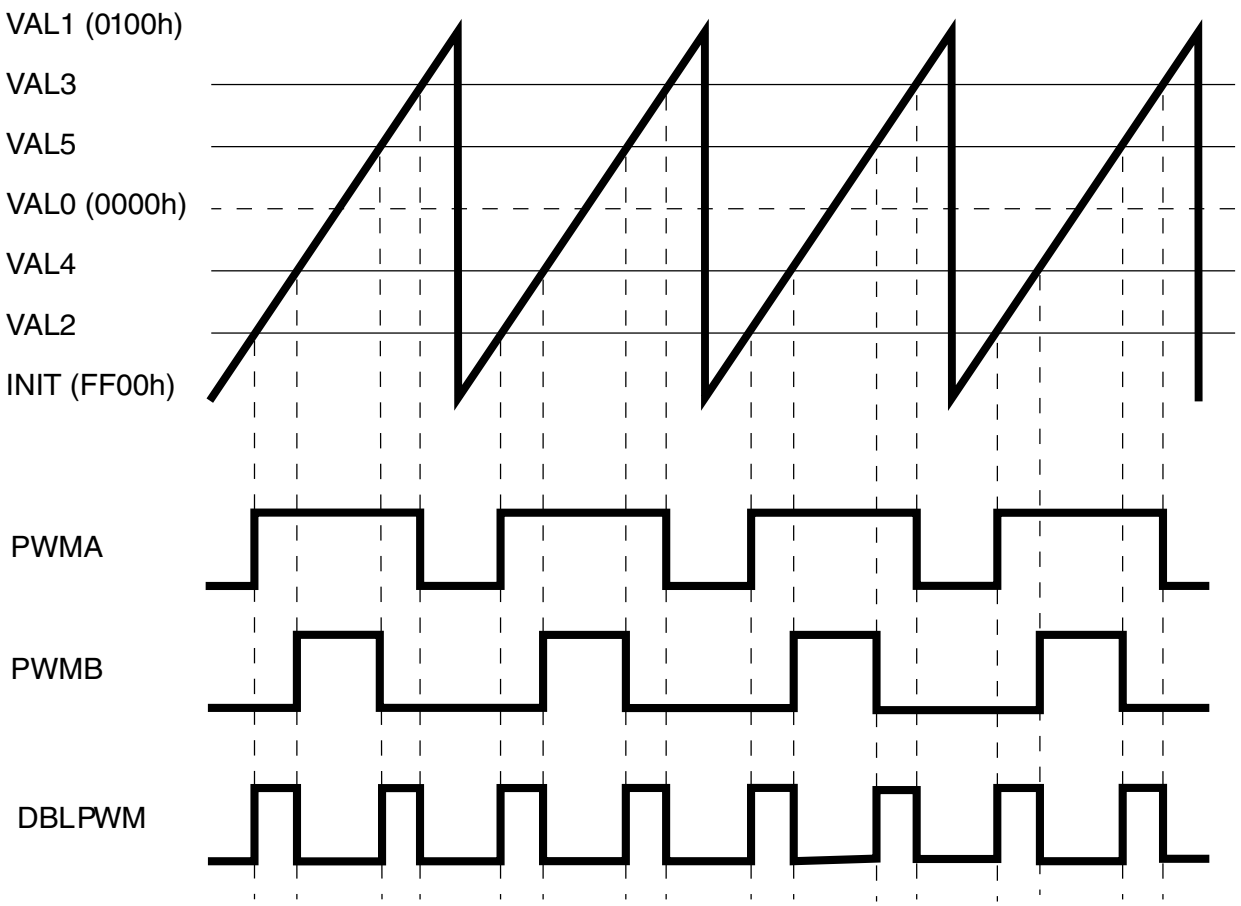

Figure 42-7. Double Switching Output Example

42.5.1.5 ADC Triggering

In cases where the timing of the ADC triggering is critical, it must be scheduled as a hardware event instead of software activated. With this PWM module, multiple ADC triggers can be generated in hardware per PWM cycle without the requirement of another timer module. the following figure shows how this is accomplished. When specifying complimentary mode of operation, only two edge comparators are required to generate the output PWM signals for a given submodule. This means that the other comparators

are free to perform other functions. In this example, the software doesn't have to quickly respond after the first conversion to set up other conversions that must occur in the same PWM cycle.

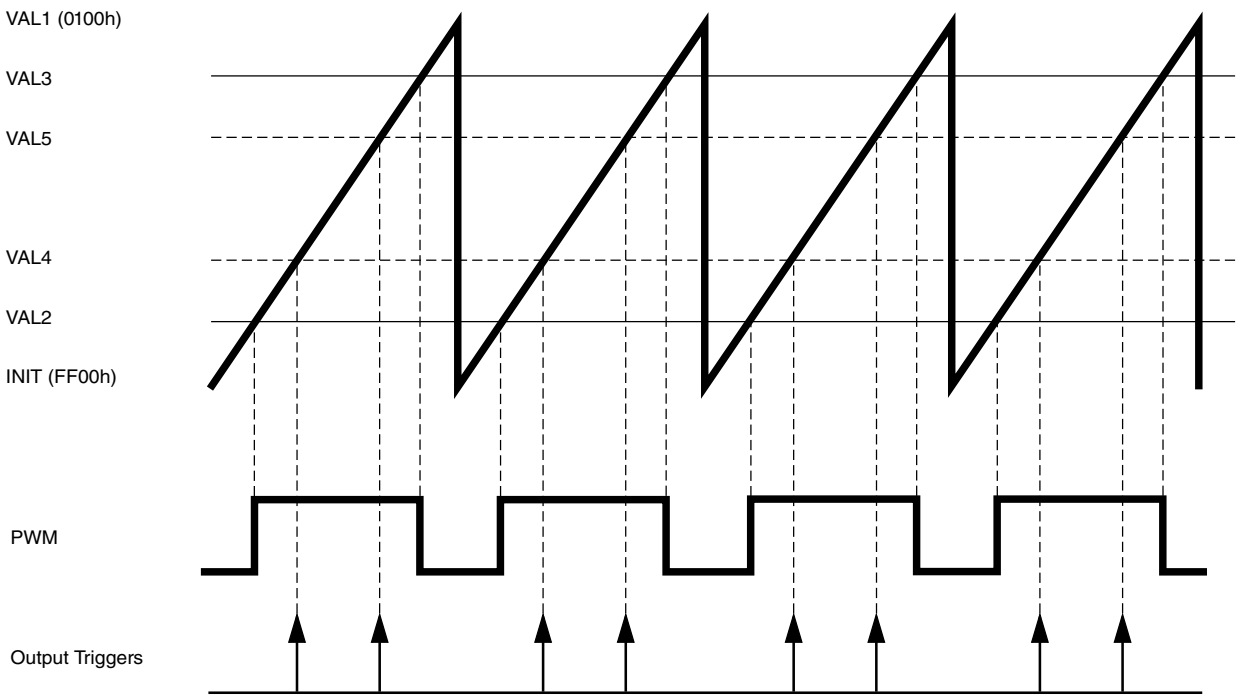

Figure 42-8. Multiple Output Trigger Generation in Hardware

Since each submodule has its own timer, it is possible for each submodule to run at a different frequency. One of the options possible with this PWM module is to have one or more submodules running at a lower frequency, but still synchronized to the timer in submodule0. The following figure shows how this feature can be used to schedule ADC triggers over multiple PWM cycles. A suggested use for this configuration would be to use the lower frequency submodule to control the sampling frequency of the software control algorithm where multiple ADC triggers can now be scheduled over the entire sampling period. In this figure, ALL submodule comparators are shown being used for ADC trigger generation.

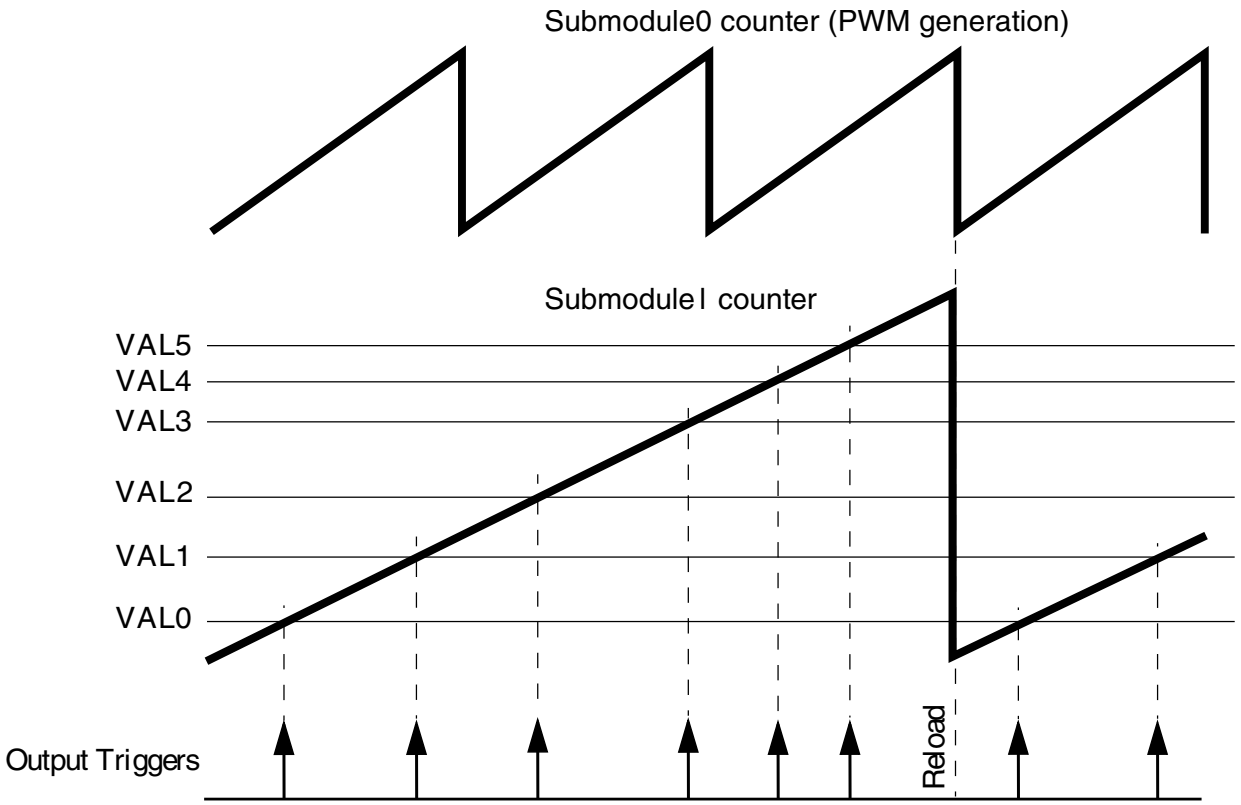

Figure 42-9. Multiple Output Triggers Over Several PWM Cycles

42.5.1.6 Enhanced Capture Capabilities (E-Capture)

When a PWMX pin is not being used for PWM generation, it can be used to perform input captures. Recall that for PWM generation BOTH edges of the PWM signal are specified via separate compare register values. When programmed for input capture, both of these registers work on the same pin to capture multiple edges, toggling from one to the other in either a free running or one-shot fashion. By simply programming the desired edge of each capture circuit, period and pulse width of an input signal can easily be measured without the requirement to re-arm the circuit. In addition, each edge of the input signal can clock an 8 bit counter where the counter output is compared to a user specified value (EDGCMP). When the counter output equals EDGCMP, the value of the submodule timer is captured and the counter is automatically reset. This feature allows the module to count a specified number of edge events and then perform a capture and interrupt. The following figure illustrates some of the functionality of the E-Capture circuit.

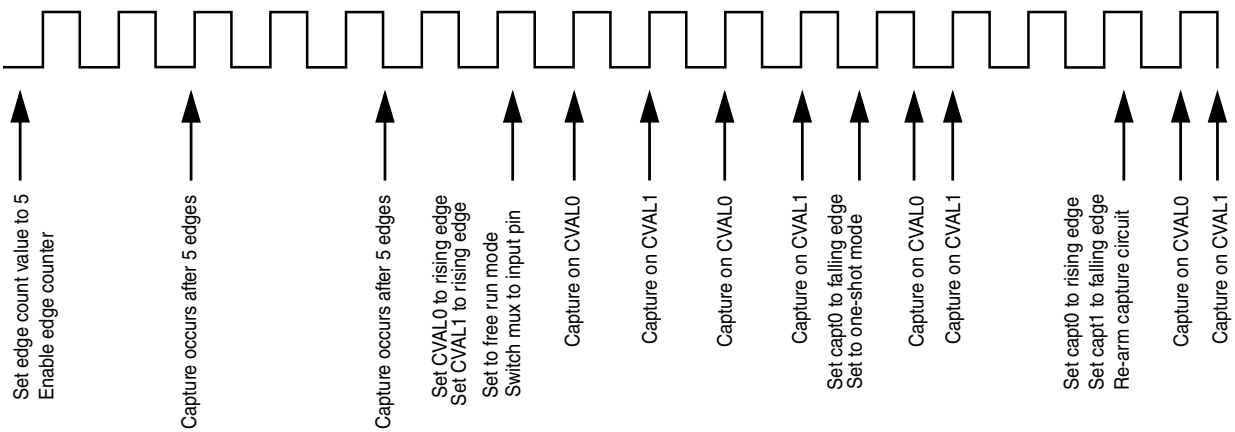

Figure 42-10. Capture Capabilities of the E-Capture Circuit

When a submodule is being used for PWM generation, its timer counts up to the modulus value used to specify the PWM frequency and then is re-initialized. Therefore, using this timer for input captures on one of the other pins (e.g, PWMX) has limited utility since it does not count through all of the numbers and the timer reset represents a discontinuity in the 16 bit number range. However, when measuring a signal that is synchronous to the PWM frequency, the timer modulus range is perfectly suited for the application. As an example, consider the following figure. In this application the output of a PWM power stage is connected to the PWMX pin that is configured for free running input captures. Specifically, the CVAL0 capture circuitry is programmed for rising edges and the CVAL1 capture circuitry is set for falling edges. This will result in new load pulse width data being acquired every PWM cycle. To calculate the pulse width, simply subtract the CVAL0 register value from the CVAL1 register value. This measurement is extremely beneficial when performing dead-time distortion correction on a half bridge circuit driving an inductive load. Also, these values can be directly compared to the VALx registers responsible for generating the PWM outputs to obtain a measurement of system propagation delays.

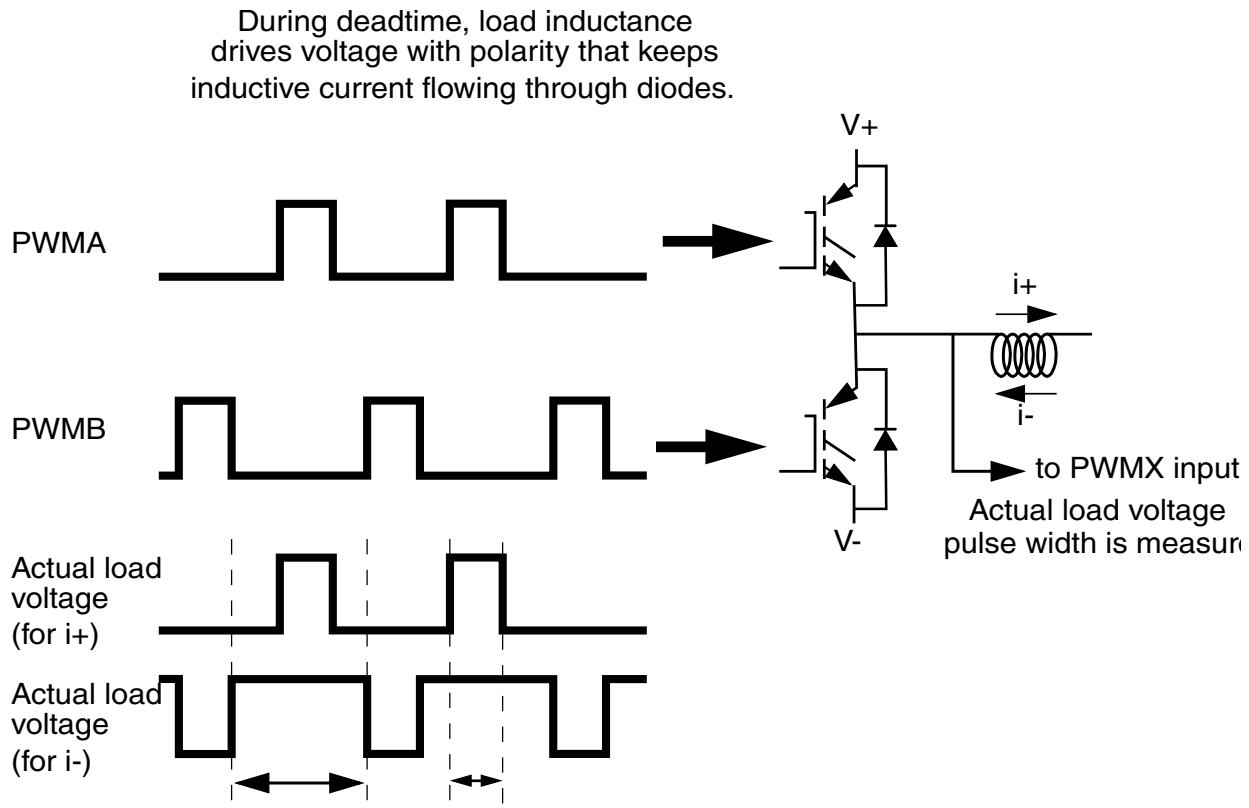

Figure 42-11. Output Pulse Width Measurement Possible with the E-Capture Circuit

42.5.1.7 Synchronous Switching of Multiple Outputs

Before the PWM signals are routed to the output pins, they are processed by a hardware block that permits all submodule outputs to be switched synchronously. This feature can be extremely useful in commutated motor applications where the next commutation state can be laid in ahead of time and then immediately switched to the outputs when the appropriate condition or time is reached. Not only do all the changes occur synchronously on all submodule outputs, but they occur IMMEDIATELY after the trigger event occurs eliminating any interrupt latency.

The synchronous output switching is accomplished via a signal called FORCE_OUT. This signal originates from the local FORCE bit within the submodule, from submodule0, or from external to the PWM module and, in most cases, is supplied from an external timer channel configured for output compare. In a typical application, software sets up the desired states of the output pins in preparation for the next FORCE_OUT event using the SWCOUT and DTSRCSEL registers. This selection lays dormant until the FORCE_OUT signal transitions and then all outputs are switched simultaneously. The signal switching is performed upstream from the deadtime generator so that any abrupt changes that might occur do not violate deadtime on the power stage when in complementary mode.

The following figure shows a popular application that can benefit from this feature. On a brushless DC motor it is desirable on many cases to spin the motor without need of hall-effect sensor feedback. Instead, the back EMF of the motor phases is monitored and this information is used to schedule the next commutation event. The top waveforms of the following figure are a simplistic representation of these back EMF signals. Timer compare events (represented by the long vertical lines in the diagram) are scheduled based on the zero crossings of the back-EMF waveforms. The PWM module is configured via software ahead of time with the next state of the PWM pins in anticipation of the compare event. When it happens, the output compare of the timer drives the FORCE_OUT signal which immediately changes the state of the PWM pins to the next commutation state with no software latency.

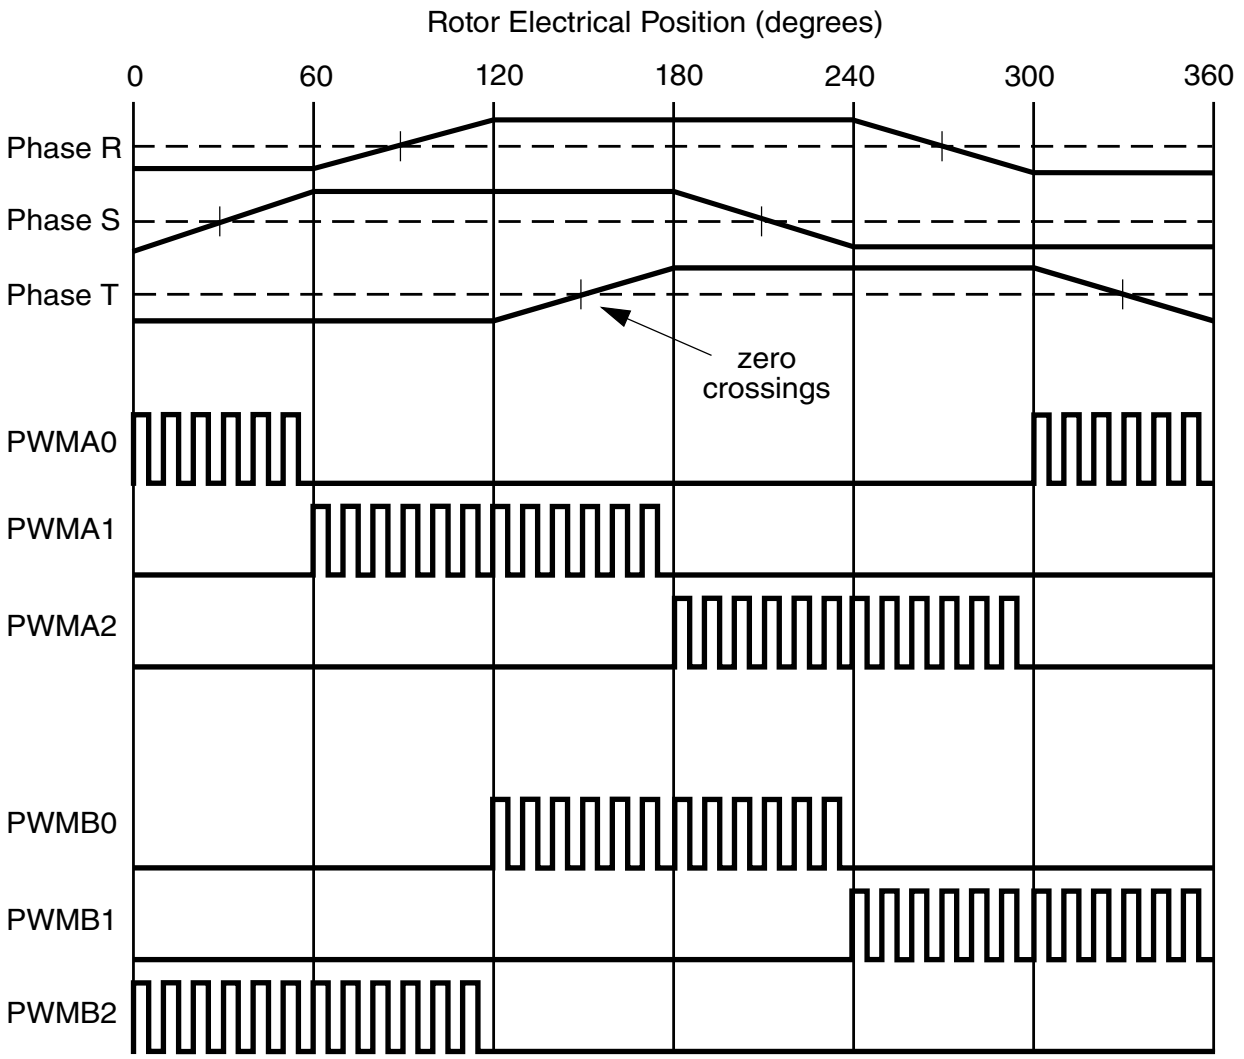

Figure 42-12. Sensorless BLDC Commutation Using the Force Out Function

42.5.1.8 Phase shifted full bridge for DC/DC converters

Use CTRL1[PHSSHFT] to allow the EXT_SWITCH input to control the output of PWMA0/PWMB0. The EXT_SWITCH input switches the source of the submodule0 output from the SUB0_VAL*x* registers to the SUB1_VAL*x* registers. This muxing can be seen in Figure 42-16.

42.5.2 Functional Details

This section describes the implementation of various features of the PWM in greater detail.

42.5.2.1 PWM Clocking

The following figure shows the logic used to generate the main counter clock. Each submodule can select between three clock signals: the peripheral clock, EXT_CLK, and AUX_CLK. The EXT_CLK is generated by an on-chip resource such as a Timer module and goes to all of the submodules. The AUX_CLK signal is broadcast from submodule0 and can be selected as the clock source by other submodules so that the 8 bit prescaler from submodule0 can control all of the submodules.

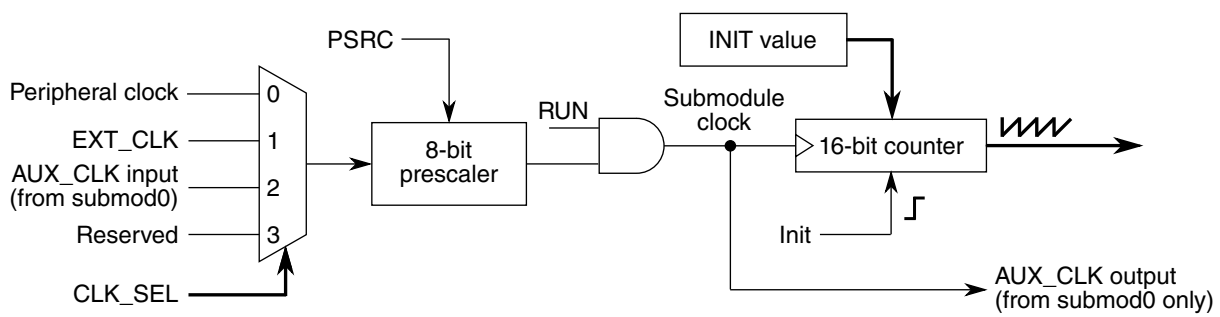

Figure 42-13. Clocking Block Diagram for Each PWM Submodule

To permit lower PWM frequencies, the prescaler produces the PWM clock frequency by dividing the peripheral clock frequency by 1-128. The prescaler bits, PRSC, in the control register (CTRL1), select the prescaler divisor. This prescaler is buffered and will not be used by the PWM generator until the LDOK bit is set and a new PWM reload cycle begins or LDMOD is set.

42.5.2.2 Register Reload Logic

The register reload logic is used to determine when the outer set of registers for all double buffered register pairs will be transferred to the inner set of registers. The register reload event can be scheduled to occur every "n" PWM cycles using the LDFQ bits and the FULL bit. A half cycle reload option is also supported (HALF) where the reload can take place in the middle of a PWM cycle. The half cycle point is defined by the SUB*n*VAL0 register and does not have to be exactly in the middle of the PWM cycle.

As illustrated in the following figure, the reload signal from submodule0 can be broadcast as the Master Reload signal allowing the reload logic from submodule0 to control the reload of registers in other submodules.

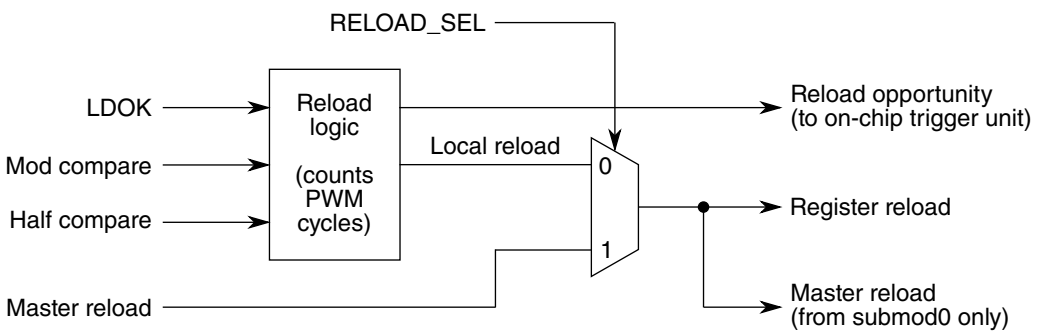

Figure 42-14. Register Reload Logic

42.5.2.3 Counter Synchronization

Referring to the following figure, the 16 bit counter will count up until its output equals VAL1 which is used to specify the counter modulus value. The resulting compare causes a rising edge to occur on the Local Sync signal which is one of four possible sources used to cause the 16 bit counter to be initialized with INIT. If Local Sync is selected as the counter initialization signal, then VAL1 within the submodule effectively controls the timer period (and thus the PWM frequency generated by that submodule) and everything works on a local level.

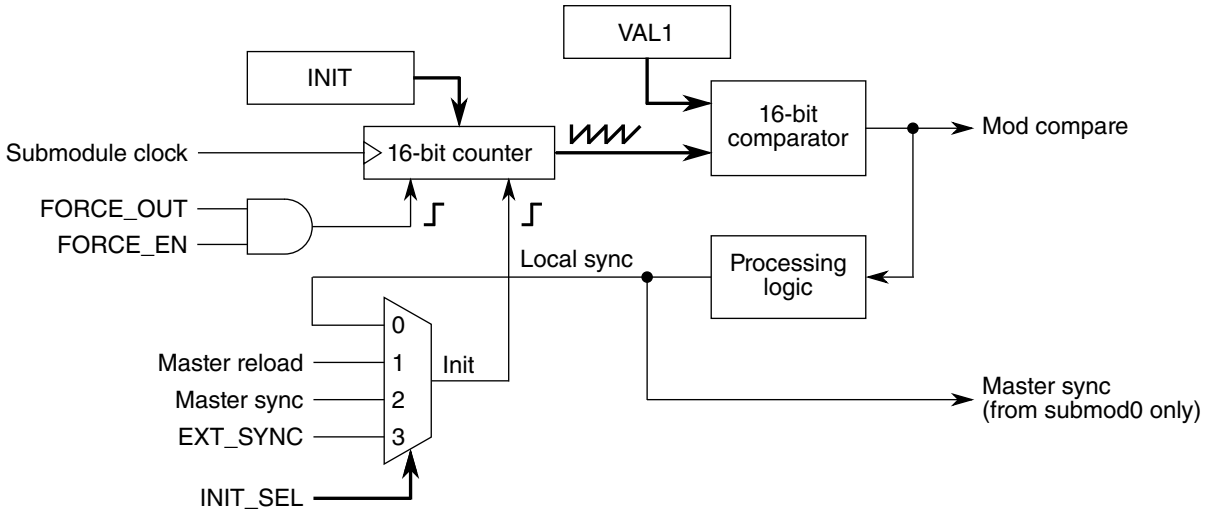

Figure 42-15. Submodule Timer Synchronization

The Master Sync signal originates as the Local Sync from submodule0. If configured to do so, the timer period of any submodule can be locked to the period of the timer in submodule0. The SUB*n*_VAL1 register and associated comparator of the other submodules can then be freed up for other functions such as PWM generation, input captures, output compares, or output triggers.

The EXT_SYNC signal originates on chip or off chip depending on the system architecture. This signal may be selected as the source for counter initialization so that an external source can control the period of all submodules.

If the Master Reload signal is selected as the source for counter initialization, then the period of the counter will be locked to the register reload frequency of submodule0. Since the reload frequency is usually commensurate to the sampling frequency of the software control algorithm, the submodule counter period will therefore equal the sampling period. As a result, this timer can be used to generate output compares or output triggers over the entire sampling period which may consist of several PWM cycles. The Master Reload signal can only originate from submodule0.

The counter can optionally initialize upon the assertion of the FORCE_OUT signal assuming that the FORCE_EN bit is set. As indicated by the figure above, this constitutes a second init input into the counter which will cause the counter to initialize regardless of which signal is selected as the counter init signal. The FORCE_OUT signal is provided mainly for commutated applications. When PWM signals are commutated on an inverter controlling a brushless DC motor, it is necessary to restart the PWM cycle at the beginning of the commutation interval. This action effectively resynchronizes the PWM waveform to the commutation timing. Otherwise, the average voltage applied to a motor winding integrated over the entire commutation interval will be a function of the timing between the asynchronous commutation event with respect to the PWM cycle. The effect is more critical at higher motor speeds where each commutation interval may consist of

only a few PWM cycles. If the counter is not initialized at the start of each commutation interval, the result will be an oscillation caused by the beating between the PWM frequency and the commutation frequency.

42.5.2.4 PWM Generation

The following figure illustrates how PWM generation is accomplished in each submodule. In each case, two comparators and associated SUB*n*_VAL*x* registers are utilized for each PWM output signal. One comparator and VALx register is used to control the turn on edge while a second comparator and SUB*n*_VAL*x* register control the turn off edge.

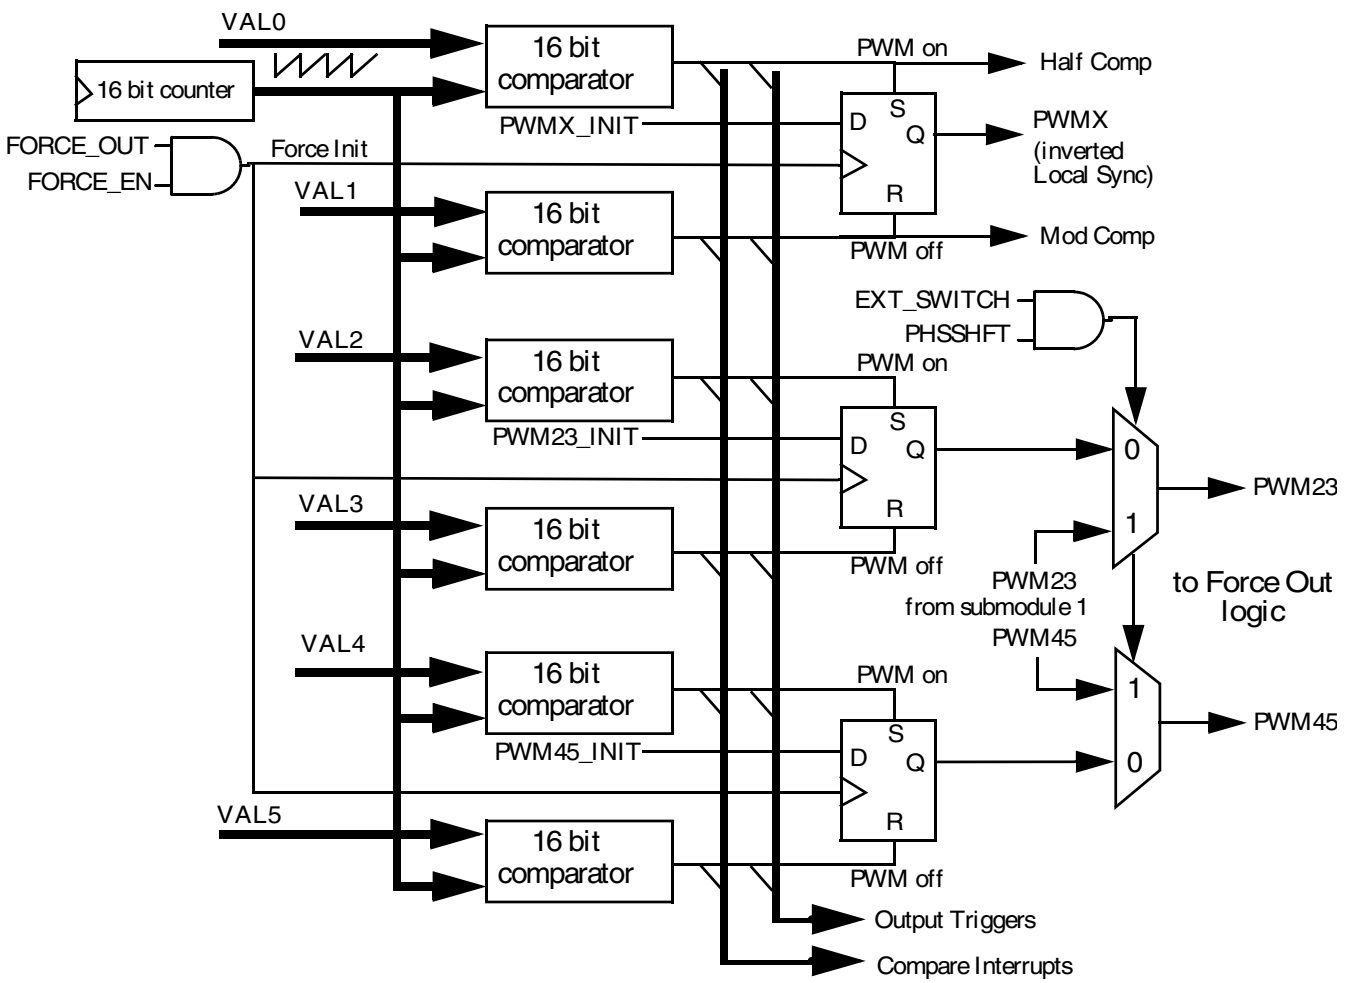

Figure 42-16. PWM Generation Hardware

The generation of the Local Sync signal is performed exactly the same way as the other PWM signals in the submodule. While comparator 0 causes a rising edge of the Local Sync signal, comparator 1 generates a falling edge. Comparator 1 is also hardwired to the reload logic to generate the half cycle reload indicator.

If VAL1 is controlling the modulus of the counter and VAL0 is half of the SUB*n*_VAL1 register minus the INIT value, then the half cycle reload pulse will occur exactly half way through the timer count period and the Local Sync will have a 50% duty cycle. On the other hand, if the SUB*n*_VAL1 and SUB*n*_VAL0 registers are not required for register reloading or counter initialization, they can be used to modulate the duty cycle of the Local Sync signal effectively turning it into an auxiliary PWM signal (PWMX) assuming that the PWMX pin is not being used for another function such as input capture or deadtime distortion correction. Including the Local Sync signal, each submodule is capable of generating 3 PWM signals where software has complete control over each edge of each of the signals.

If the comparators and edge value registers are not required for PWM generation, they can also be used for other functions such as output compares, generating output triggers, or generating interrupts at timed intervals.

The muxes for PWM23 and PWM45, shown in the figure above, are only in submodule0.

If the comparators assert both the set and reset of the flip-flop at the same time, then the flop output goes to 0.

42.5.2.5 Output Compare Capabilities

By using the SUB*n*_VAL*x* registers in conjunction with the submodule timer and 16 bit comparators, buffered output compare functionality can be achieved with no additional hardware required. Specifically, the following output compare functions are possible:

- An output compare sets the output high
- An output compare sets the output low
- An output compare generates an interrupt
- An output compare generates an output trigger

Referring again to Figure 42-16, an output compare is initiated by programming a SUB*n*_VAL*x* register for a timer compare which in turn causes the output of the D flip-flop to either set or reset. For example, if an output compare is desired on the PWMA signal that sets it high, VAL2 would be programmed with the counter value where the output compare should take place. However, to prevent the D flip-flop from being reset again after the compare has occurred, the SUB*n*_VAL3 register must be programmed to a value outside of the modulus range of the counter. Therefore, a compare that would result in resetting the D flip-flop output would never occur. Conversely, if an output compare is desired on the PWMA signal that sets it low, the SUB*n*_VAL3 register is programmed with the appropriate count value and the SUB*n*_VAL2 register is programmed with a

value outside the counter modulus range. Regardless of whether a high compare or low compare is programmed, an interrupt or output trigger can be generated when the compare event occurs.

42.5.2.6 Force Out Logic

For each submodule software can select between seven signal sources for the FORCE_OUT signal: the local FORCE bit, the Master Force signal from submodule0, the local Reload signal, the Master Reload signal from submodule0, the Local Sync signal, the Master Sync signal from submodule0, or the EXT_FORCE signal from on or off chip depending on the chip architecture. The local signals are used when the user simply wants to change the signals on the output pins of the submodule without regard for synchronization with other submodules. However, if it is required that all signals on all submodule outputs change at the same time, the Master signals or EXT_FORCE signal should be selected.

The following figure illustrates the Force logic. The SEL23 and SEL45 fields each choose from one of four signals that can be supplied to the submodule outputs: the PWM signal, the inverted PWM signal, a binary level specified by software via the OUT23 and OUT45 bits, or the EXTA or EXTB alternate external control signals. The selection can be determined ahead of time and, when a FORCE_OUT event occurs, these values are presented to the signal selection mux which immediately switches the requested signal to the output of the mux for further processing downstream.

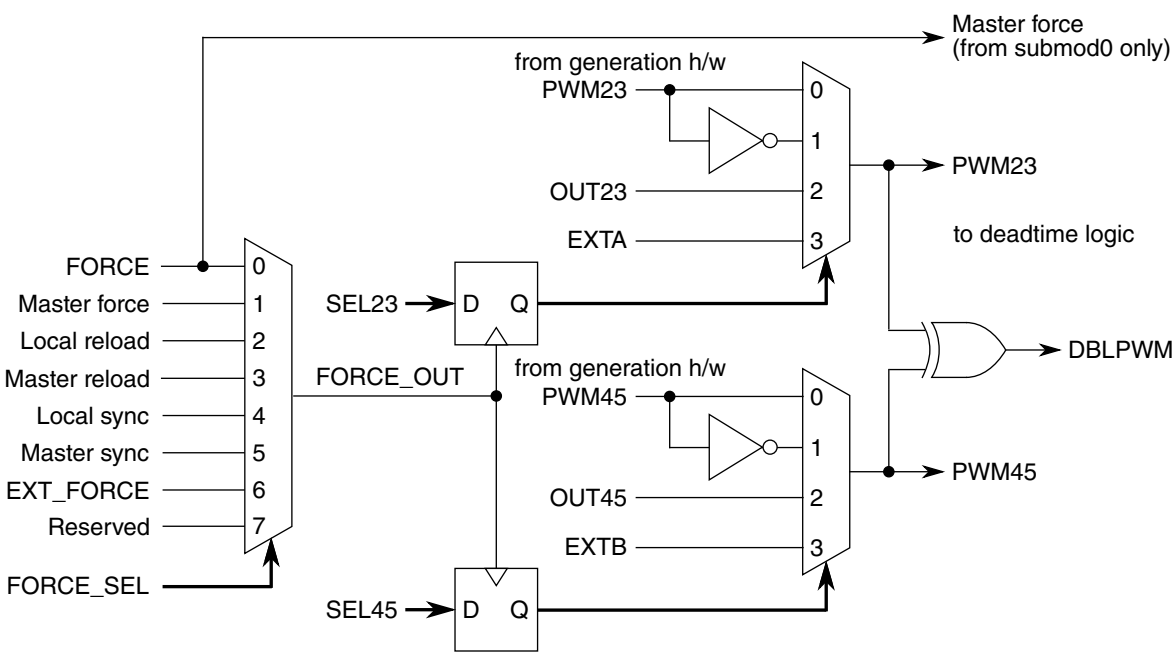

Figure 42-17. Force Out Logic

The local FORCE signal of submodule0 can be broadcast as the Master Force signal to other submodules. This feature allows the local FORCE bit of submodule0 to synchronously update all of the submodule outputs at the same time. The EXT_FORCE signal originates from outside the PWM module from a source such as a timer or digital comparators in the Analog-to-Digital Converter.

42.5.2.7 Independent or Complementary Channel Operation

Writing a logic one to the INDEP bit of the CTRL2 register configures the pair of PWM outputs as two independent PWM channels. Each PWM output is controlled by its own VALx pair operating independently of the other output.

Writing a logic zero to the INDEP bit configures the PWM output as a pair of complementary channels. The PWM pins are paired as shown in the following figure in complementary channel operation. Which signal is connected to the output pin (PWM23 or PWM45) is determined by the IPOL bit.

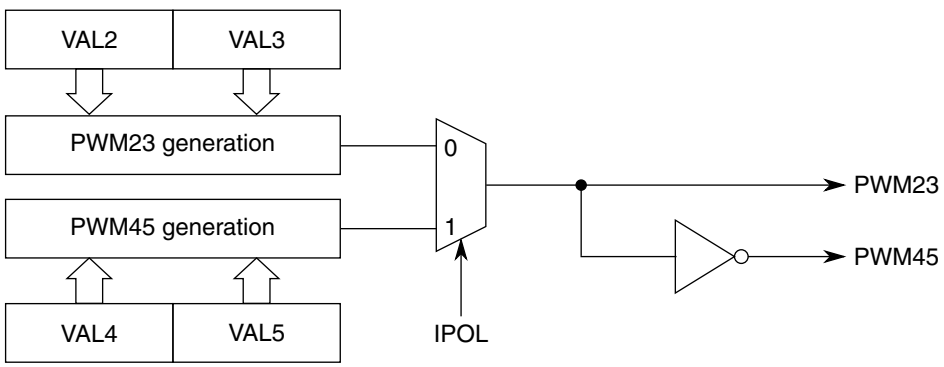

Figure 42-18. Complementary Channel Pair

The complementary channel operation is for driving top and bottom transistors in a motor drive circuit, such as the one in the following figure.

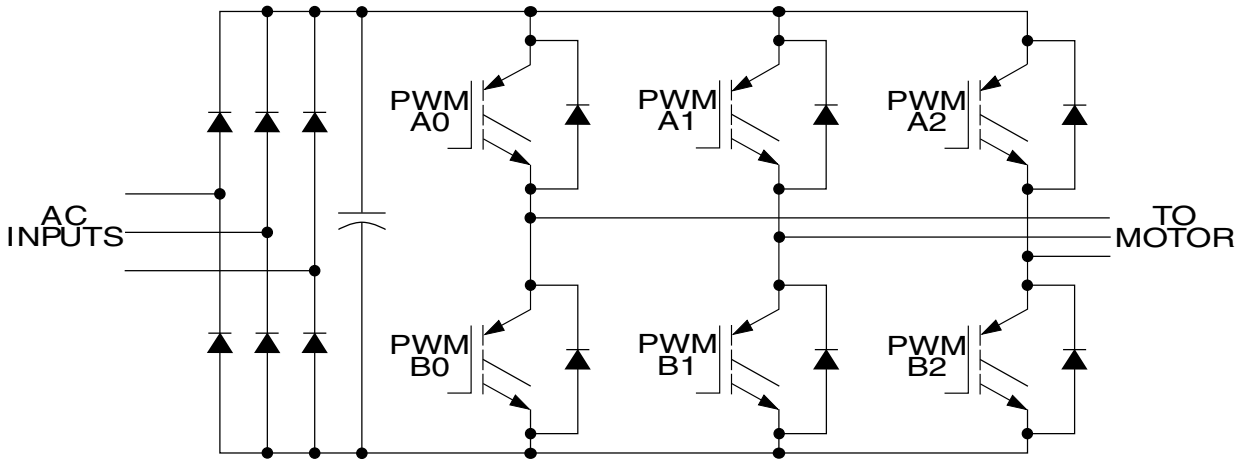

Figure 42-19. Typical 3 Phase AC Motor Drive

Complementary operation allows the use of the deadtime insertion feature.

42.5.2.8 Deadtime Insertion Logic

The following figure shows the deadtime insertion logic of each submodule which is used to create non-overlapping complementary signals when not in independent mode.

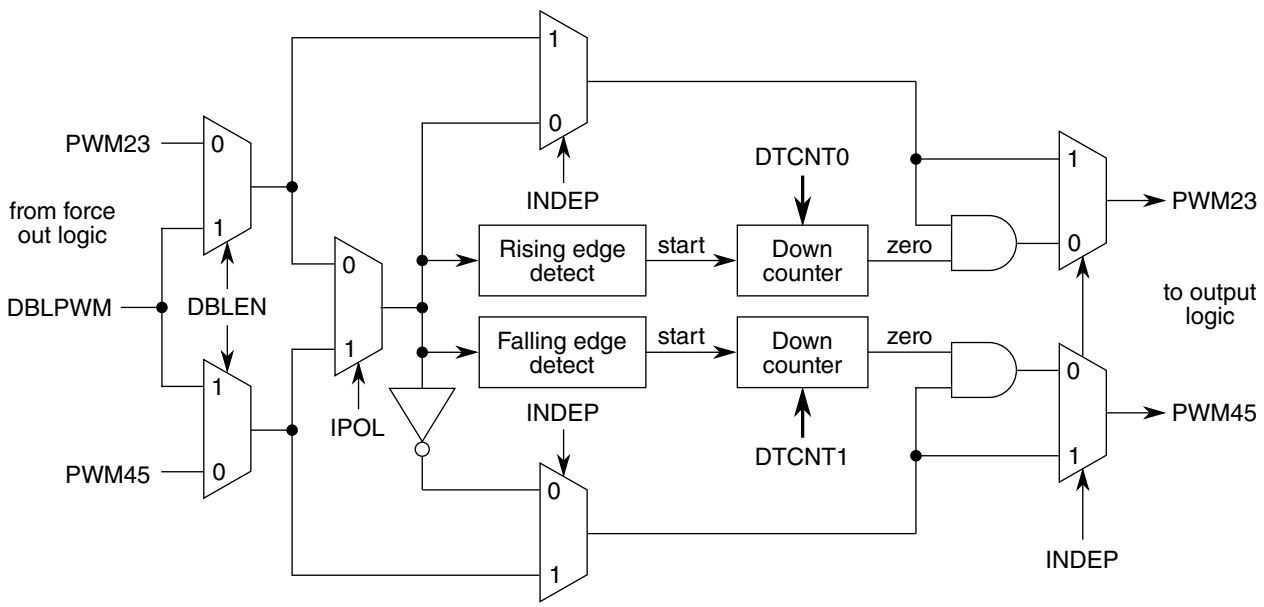

Figure 42-20. Deadtime Insertion and Fine Control Logic

While in the complementary mode, a PWM pair can be used to drive top/bottom transistors, as shown in the figure above. When the top PWM channel is active, the bottom PWM channel is inactive, and vice versa.

Note

To avoid short circuiting the DC bus and endangering the transistor, there must be no overlap of conducting intervals between top and bottom transistor. However, the transistor's characteristics may cause its switching-off time to be longer than its switching-on time. To avoid the conducting overlap of top and bottom transistors, deadtime needs to be inserted in the switching period, as illustrated in the following figure.

The deadtime generators automatically insert software-selectable activation delays into the pair of PWM outputs. The deadtime registers (DTCNT0 and DTCNT1) specify the number of peripheral clock cycles to use for deadtime delay. Every time the deadtime generator inputs change state, deadtime is inserted. Deadtime forces both PWM outputs in the pair to the inactive state.

When deadtime is inserted in complementary PWM signals connected to an inverter driving an inductive load, the PWM waveform on the inverter output will have a different duty cycle than what appears on the output pins of the PWM module. This results in a distortion in the voltage applied to the load. A method of correcting this, adding to or subtracting from the PWM value used, is discussed next.

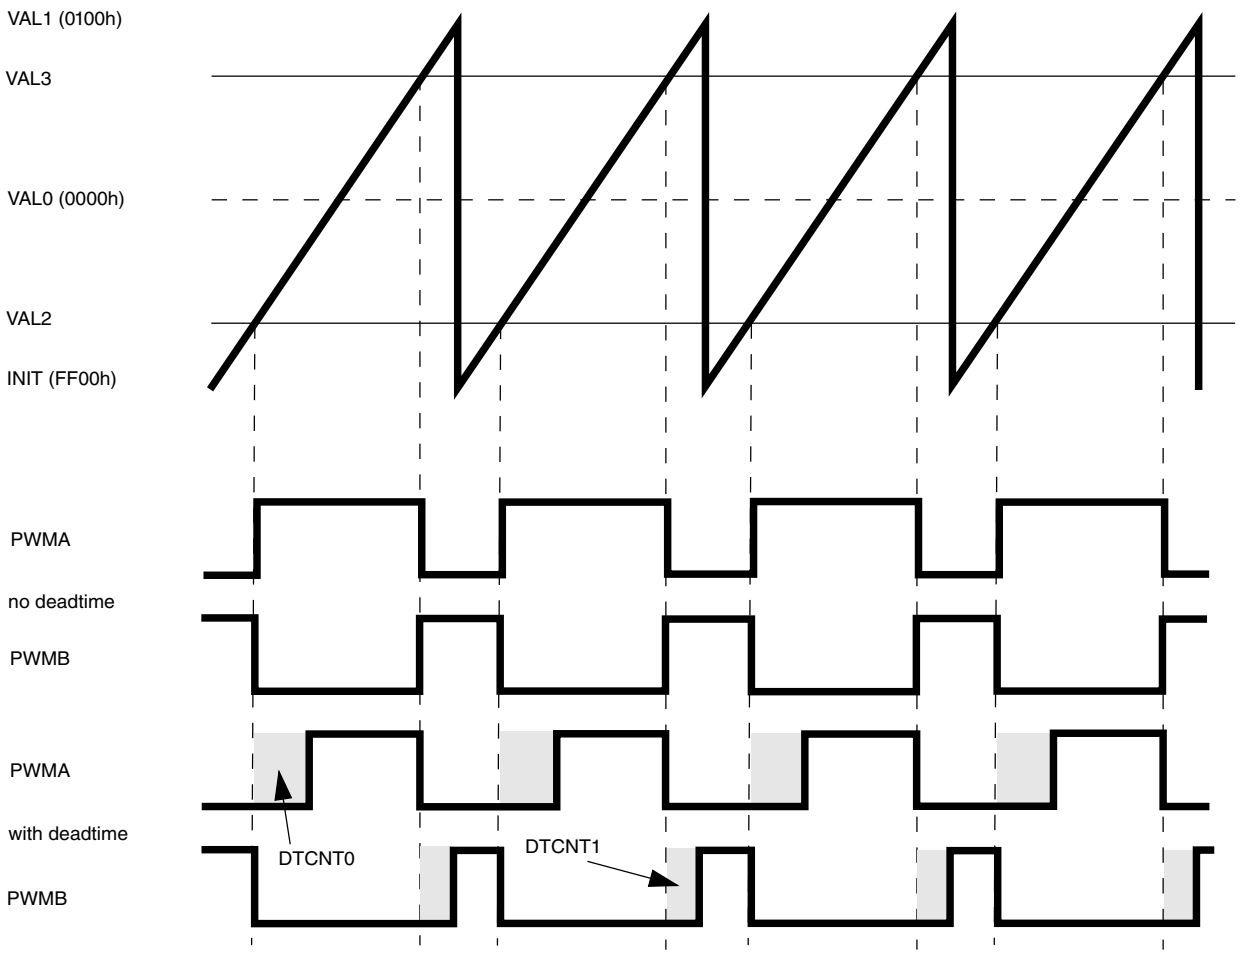

Figure 42-21. Deadtime Insertion

42.5.2.8.1 Top/Bottom Correction

In complementary mode, either the top or the bottom transistor controls the output voltage. However, deadtime has to be inserted to avoid overlap of conducting interval between the top and bottom transistor. Both transistors in complementary mode are off during deadtime, allowing the output voltage to be determined by the current status of load and introduce distortion in the output voltage. See the following figure. On AC induction motors running open-loop, the distortion typically manifests itself as poor low-speed performance, such as torque ripple and rough operation.

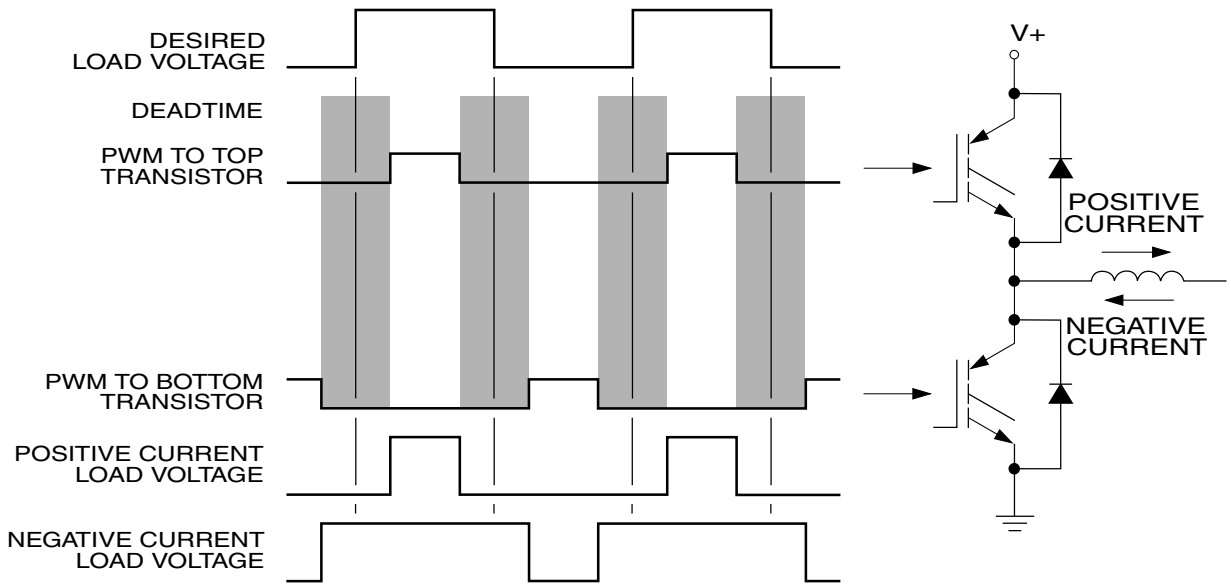

Figure 42-22. Deadtime Distortion

During deadtime, load inductance distorts output voltage by keeping current flowing through the diodes. This deadtime current flow creates a load voltage that varies with current direction. With a positive current flow, the load voltage during deadtime is equal to the bottom supply, putting the top transistor in control. With a negative current flow, the load voltage during deadtime is equal to the top supply putting the bottom transistor in control.

Remembering that the original PWM pulse widths where shortened by deadtime insertion, the averaged sinusoidal output will be less than the desired value. However, when deadtime is inserted, it creates a distortion in the motor current waveform. This distortion is aggravated by dissimilar turn-on and turn-off delays of each of the transistors. By giving the PWM module information on which transistor is controlling at a given time this distortion can be corrected.

For a typical circuit in complementary channel operation, only one of the transistors will be effective in controlling the output voltage at any given time. This depends on the direction of the motor current for that pair. See the figure above. To correct distortion one of two different factors must be added to the desired PWM value, depending on whether the top or bottom transistor is controlling the output voltage. Therefore, the software is responsible for calculating both compensated PWM values prior to placing them in the SUB*n*_VAL*x* registers. Either the SUB*n*_VAL2/SUB*n*_VAL3 or the SUB*n*_VAL4/SUB*n*_VAL5 register pair controls the pulse width at any given time. For a given PWM pair, whether the SUB*n*_VAL2/SUB*n*_VAL3 or SUB*n*_VAL4/SUB*n*_VAL5 pair is active depends on either:

- The state of the current status pin, PWMx, for that driver
- The state of the odd/even correction bit, IPOL, for that driver

To correct deadtime distortion, software can decrease or increase the value in the appropriate SUB*n*_VAL*x* register.

- In edge-aligned operation, decreasing or increasing the PWM value by a correction value equal to the deadtime typically compensates for deadtime distortion.
- In center-aligned operation, decreasing or increasing the PWM value by a correction value equal to one-half the deadtime typically compensates for deadtime distortion.

42.5.2.8.2 Manual Correction

To detect the current status, the voltage on each PWMx pin is sampled twice in a PWM period, at the end of each deadtime. The value is stored in the DTx bits in the CTRL1 register. The DTx bits are a timing marker especially indicating when to toggle between PWM value registers. Software can then set the IPOL bit to switch between SUB*n*_VAL2/SUB*n*_VAL3 and SUB*n*_VAL4/SUB*n*_VAL5 register pairs according to DTx values.

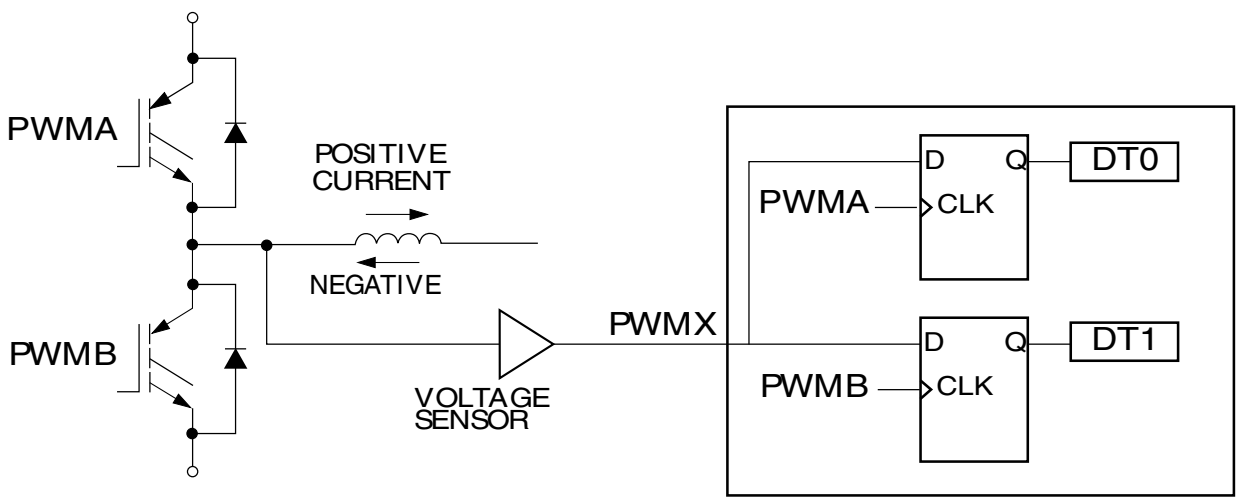

Figure 42-23. Current-status Sense Scheme for Deadtime Correction

Both D flip-flops latch low, DT0 = 0, DT1 = 0, during deadtime periods if current is large and flowing out of the complementary circuit. See the figure above. Both D flip-flops latch the high, DT0 = 1, DT1 = 1, during deadtime periods if current is also large and flowing into the complementary circuit.

However, under low-current, the output voltage of the complementary circuit during deadtime is somewhere between the high and low levels. The current cannot free-wheel through the opposition anti-body diode, regardless of polarity, giving additional distortion when the current crosses zero. Sampled results will be DT0 = 0 and DT1 = 1. Thus, the best time to change one PWM value register to another is just before the current zero crossing.

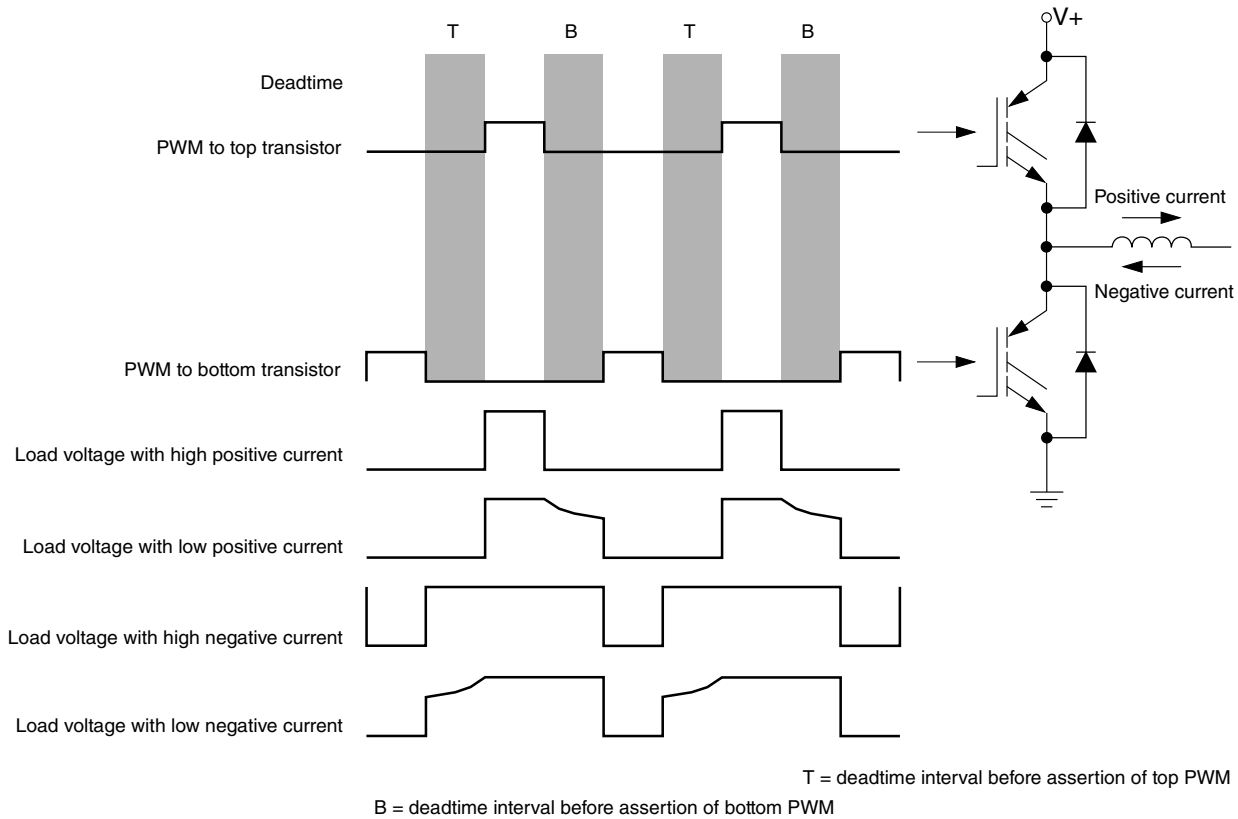

Figure 42-24. Output Voltage Waveforms

42.5.2.9 Output Logic

The following figure shows the output logic of each submodule including how each PWM output has individual fault disabling, polarity control, and output enable. This allows for maximum flexibility when interfacing to the external circuitry.

The PWM23 and PWM45 signals which are output from the deadtime logic in the figure are positive true signals. In other words, a high level on these signals should result in the corresponding transistor in the PWM inverter being turned ON. The voltage level required at the PWM output pin to turn the transistor ON or OFF is a function of the logic between the pin and the transistor. Therefore, it is imperative that the user program the

POLA and POLB bits before enabling the output pins. A fault condition can result in the PWM output being tristated, forced to a logic 1, or forced to a logic 0 depending on the values programmed into the PWMxFS fields.

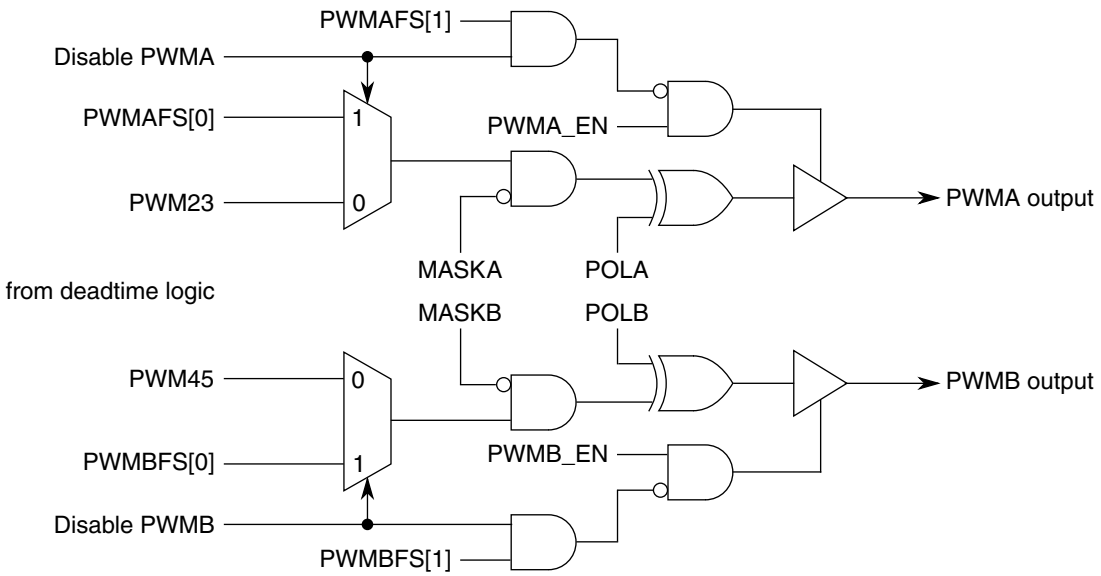

Figure 42-25. Output Logic Section

42.5.2.10 E-Capture

Commensurate with the idea of controlling both edges of an output signal, the Enhanced Capture (E-Capture) logic is designed to measure both edges of an input signal. As a result, when a submodule pin is configured for input capture, the CVALx registers associated with that pin are used to record the edge values.

The following figure illustrates the block diagram of the E-Capture circuit. Upon entering the pin input, the signal is split into two paths. One goes straight to a mux input where software can select to pass the signal directly to the capture logic for processing. The other path connects the signal to an 8-bit counter which counts both the rising and falling edges of the signal. The output of this counter is compared to an 8-bit value that is specified by the user (EDGCMPx) and when the two values are equal, the comparator generates a pulse that resets the counter. This pulse is also supplied to the mux input where software can select it to be processed by the capture logic. This feature permits the E-Capture circuit to count up to 256 edge events before initiating a capture event. this feature is useful for dividing down high frequency signals for capture processing so that capture interrupts don't overwhelm the CPU. Also, this feature can be used to simply generate an interrupt after "n" events have been counted.

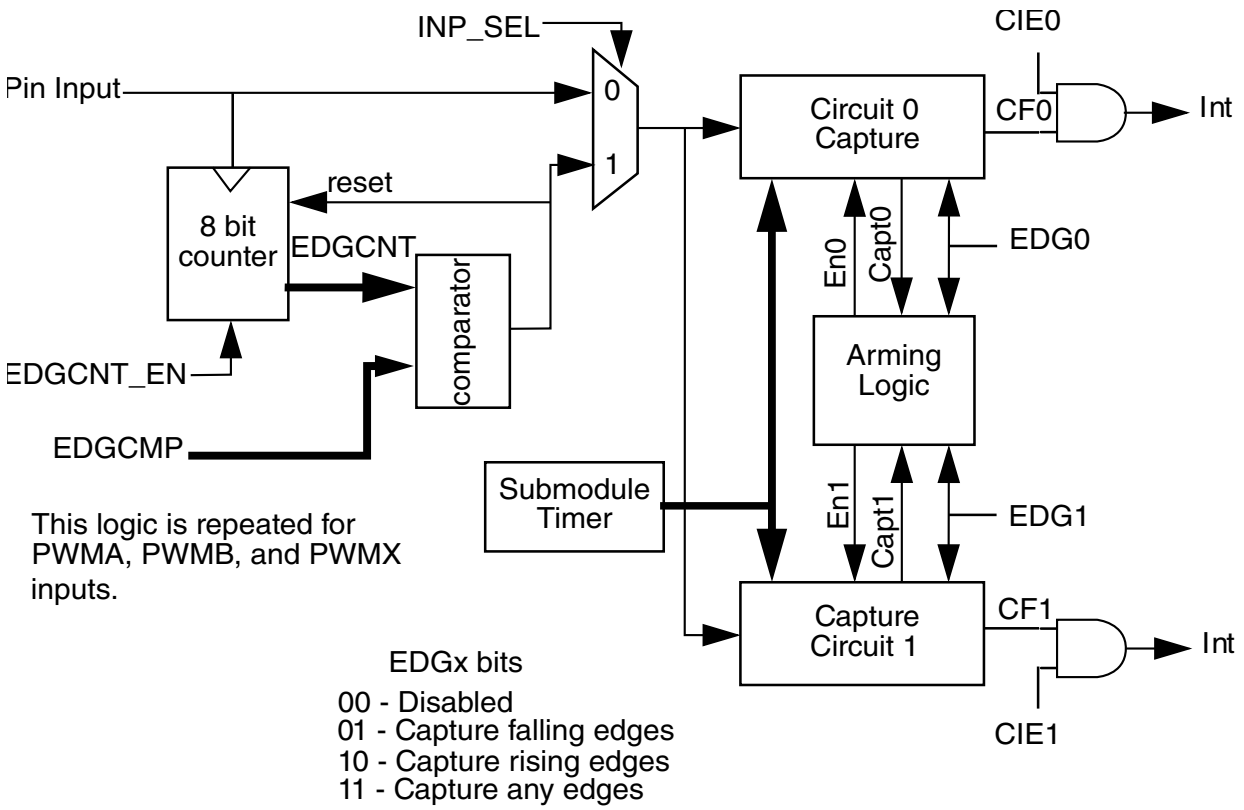

Figure 42-26. Enhanced Capture (E-Capture) Logic

Based on the mode selection, the mux selects either the pin input or the compare output from the count/compare circuit to be processed by the capture logic. The selected signal is routed to two separate capture circuits which work in tandem to capture sequential edges of the signal. The type of edge to be captured by each circuit is determined by the EDGx1 and EDGx0 bits whose functionality is listed in the figure above. Also, controlling the operation of the capture circuits is the arming logic which allows captures to be performed in a free running (continuous) or one shot fashion. In free running mode, the capture sequences will be performed indefinitely. If both capture circuits are enabled, they will work together in a ping-pong style where a capture event from one circuit leads to the arming of the other and vice versa. In one shot mode, only one capture sequence will be performed. If both capture circuits are enabled, capture circuit 0 is first armed and when a capture event occurs, capture circuit 1 is armed. Once the second capture occurs, further captures are disabled until another capture sequence is initiated. Both capture circuits are also capable of generating an interrupt to the CPU.

42.5.2.11 Fault Protection

Fault protection can control any combination of PWM output pins. Faults are generated by a logic one on any of the FAULTx pins. This polarity can be changed via the FLVL bits. Each FAULTx pin can be mapped arbitrarily to any of the PWM outputs. When

fault protection hardware disables PWM outputs, the PWM generator continues to run, only the output pins are forced to logic 0, logic 1, or tristated depending the values of the PWMxFS bits.

The fault decoder disables PWM pins selected by the fault logic and the disable mapping register (DISMAP). See the following figure for an example of the fault disable logic. Each bank of bits in DISMAP control the mapping for a single PWM pin. Refer to following table.

The fault protection is enabled even when the PWM module is not enabled; therefore, a fault will be latched in and must be cleared in order to prevent an interrupt when the PWM is enabled.

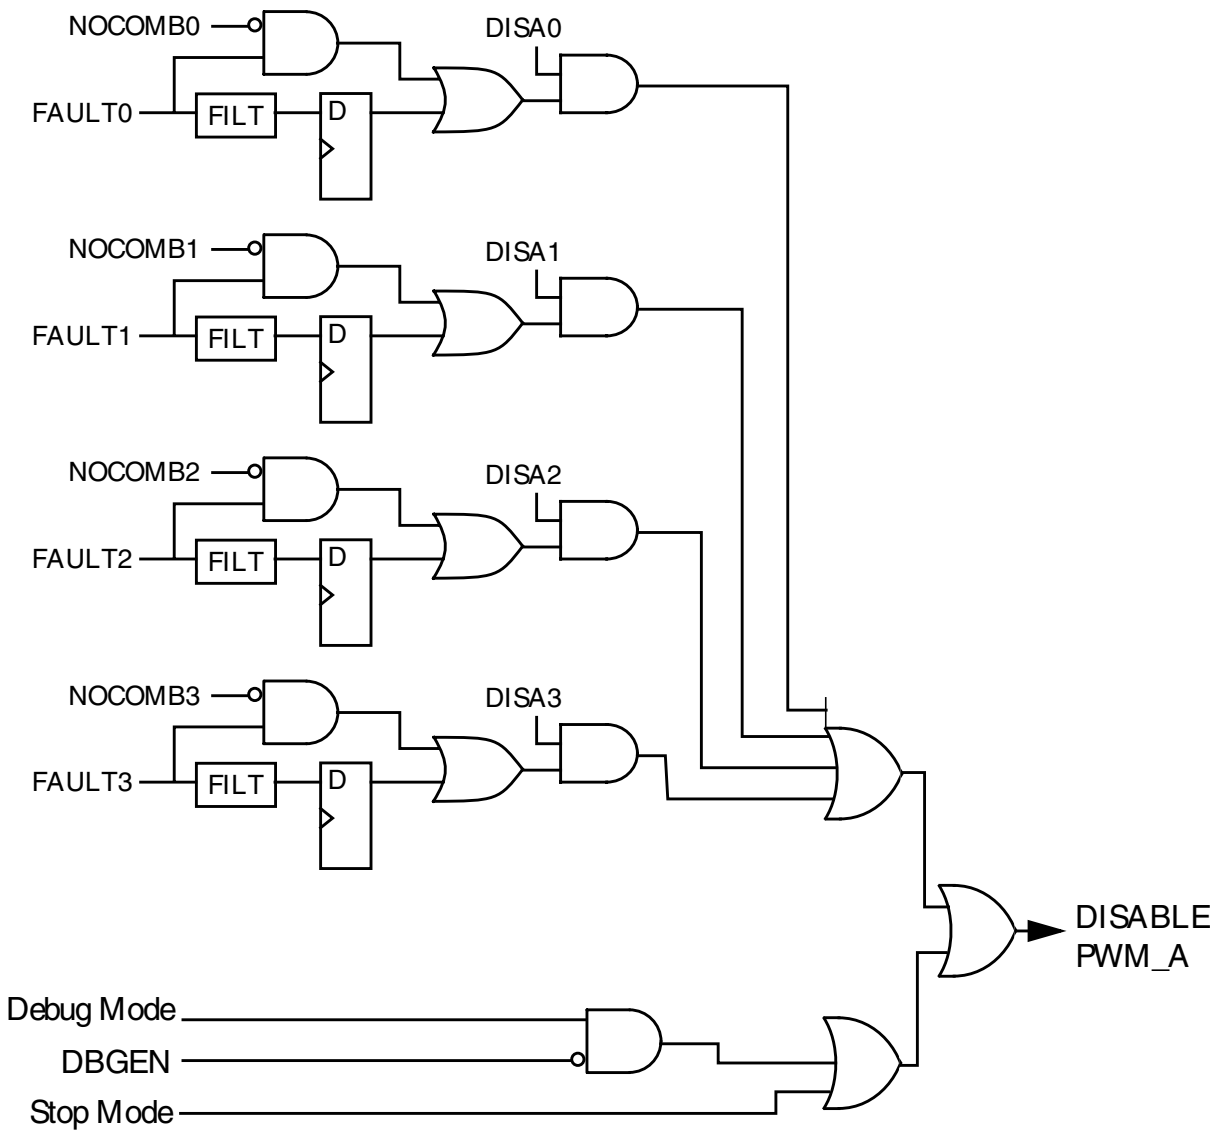

Figure 42-27. Fault decoder for PWMA

Table 42-3. Fault Mapping

PWM Pin	Controlling Register Bits
PWMA	DISA[3:0]
PWMB	DISB[3:0]
PWMX	DISX[3:0]

42.5.2.11.1 Fault Pin Filter

Each fault pin has a programmable filter that can be bypassed. The sampling period of the filter can be adjusted with the FILT_PER field of the FFILTx register. The number of consecutive samples that must agree before an input transition is recognized can be adjusted using the FILT_CNT field of the same register. Setting FILT_PER to all 0 disables the input filter for a given FAULTx pin.

Upon detecting a logic 0 on the filtered FAULTx pin (or a logic 1 if FLVLx is set), the corresponding FFPINx and fault flag, FFLAGx, bits are set. The FFPINx bit remains set as long as the filtered FAULTx pin is zero. Clear FFLAGx by writing a logic 1 to FFLAGx.

If the FIEx, FAULTx pin interrupt enable bit is set, the FFLAGx flag generates a CPU interrupt request. The interrupt request latch remains set until:

- Software clears the FFLAGx flag by writing a logic one to the bit
- Software clears the FIEx bit by writing a logic zero to it
- A reset occurs

Even with the filter enabled, there is a combinational path from the FAULTx inputs to the PWM pins. This logic is also capable of holding a fault condition in the event of loss of clock to the PWM module.

42.5.2.11.2 Automatic Fault Clearing

Setting an automatic clearing mode bit, FAUTOx, configures faults from the FAULTx pin for automatic clearing.

When FAUTOx is set, disabled PWM pins are enabled when the FAULTx pin returns to logic one and a new PWM full or half cycle begins. See the following figure. If FFULLx is set, then the disabled PWM pins are enabled only at the start of a full cycle and not at the half cycle. Clearing the FFLAGx flag does not affect disabled PWM pins when FAUTOx is set.

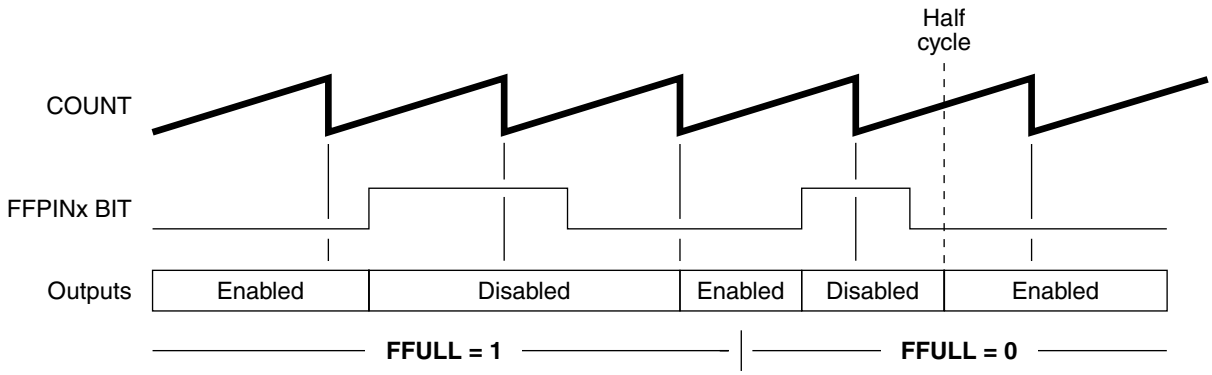

Figure 42-28. Automatic Fault Clearing

42.5.2.11.3 Manual Fault Clearing

Clearing the automatic clearing mode bit, FAUTOx, configures faults from the FAULTx pin for manual clearing:

- If the fail safe mode bits, FSAFEx, are clear, then PWM pins disabled by the FAULTx pins are enabled when:
  - Software clears the corresponding FFLAGx flag
  - The pins are enabled when the next PWM full or half cycle begins regardless of the logic level detected by the filter at the FAULTx pin. See the following figure. If FFULLx is set, then the disabled PWM pins are enabled only at the start of a full cycle and not at the half cycle.
- If the fail safe mode bits, FSAFEx, are set, then PWM pins disabled by the FAULTx pins are enabled when:
  - Software clears the corresponding FFLAGx flag
  - The filter detects a logic one on the FAULTx pin at the start of the next PWM full or half cycle boundary. See Figure 42-30. If FFULLx is set, then the disabled PWM pins are enabled only at the start of a full cycle and not at the half cycle.

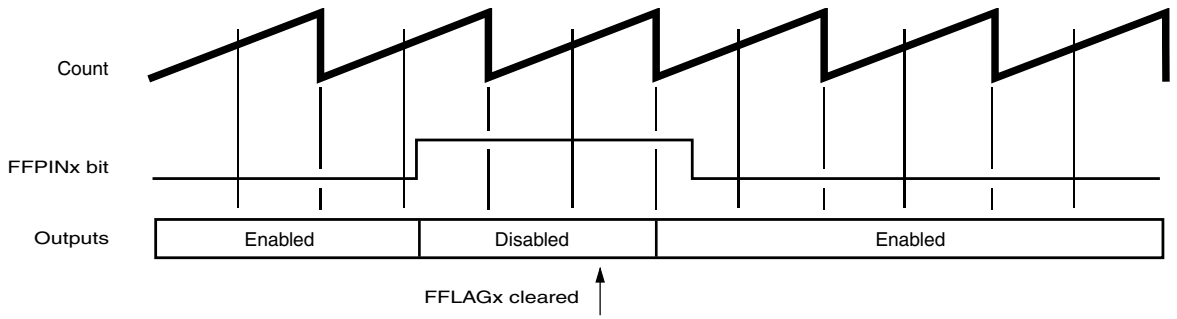

Figure 42-29. Manual Fault Clearing (FSAFE=0)

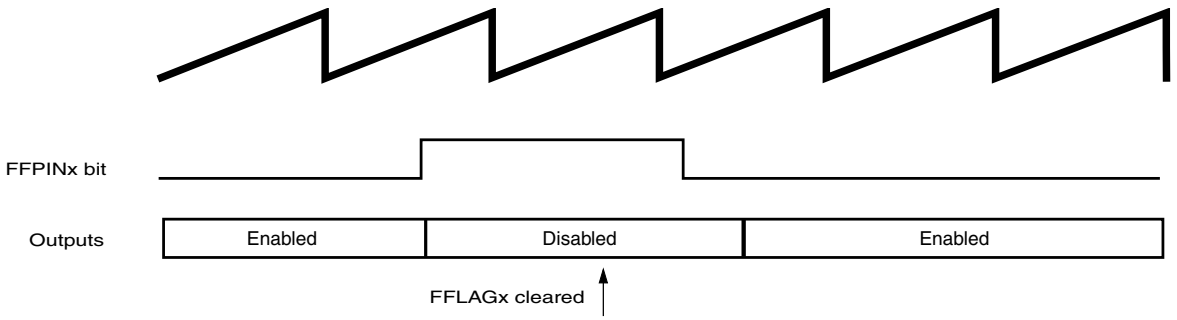

Figure 42-30. Manual Fault Clearing (FSAFE=1)

Note

Fault protection also applies during software output control when the SEL23 and SEL45 fields are set to select OUT23 and OUT45 bits or EXTA and EXTB. Fault clearing still occurs at half PWM cycle boundaries while the PWM generator is engaged, RUN equals one. But the OUTx bits can control the PWM pins while the PWM generator is off, RUN equals zero. Thus, fault clearing occurs at peripheral cycles while the PWM generator is off and at the start of PWM cycles when the generator is engaged.

42.5.2.11.4 Fault Testing

The FTEST bit is used to simulate a fault condition on each of the fault inputs.

42.5.3 PWM Generator Loading

This section describes load enabling, load frequency, the reload flag, reload errors, and initialization of the PWM generator.

42.5.3.1 Load Enable

The LDOK bit enables loading of the following PWM generator parameters:

- The prescaler divisor—from SUB*n*_CTRL1[PRSC]
- The PWM period and pulse width—from the SUB*n*_INIT and SUB*n*_VAL*x* registers

LDOK allows software to finish calculating all of these PWM parameters so they can be synchronously updated. SUB*n*_CTRL1[PRSC], SUB*n*_INIT and SUB*n*_VAL*x* are loaded by software into a set of outer buffers. When LDOK is set, these values are transferred to an inner set of registers at the beginning of the next PWM reload cycle to be used by the PWM generator. These values can be transferred to the inner set of registers immediately upon setting LDOK if LDMOD is set. Set LDOK by reading it when it is a logic zero and then writing a logic one to it. After loading, LDOK is automatically cleared.

42.5.3.2 Load Frequency

The LDFQ bits in the CTRL1 register select an integral loading frequency of one to 16 PWM reload opportunities. The LDFQ bits take effect at every PWM reload opportunity, regardless the state of the LDOK bit. The HALF and FULL bits in the CTRL1 register control reload timing. If FULL is set, a reload opportunity occurs at the end of every PWM cycle when the count equals VAL1. If HALF is set, a reload opportunity occurs at the half cycle when the count equals VAL0. If both HALF and FULL are set, a reload opportunity occurs twice per PWM cycle when the count equals VAL1 and when it equals VAL0.

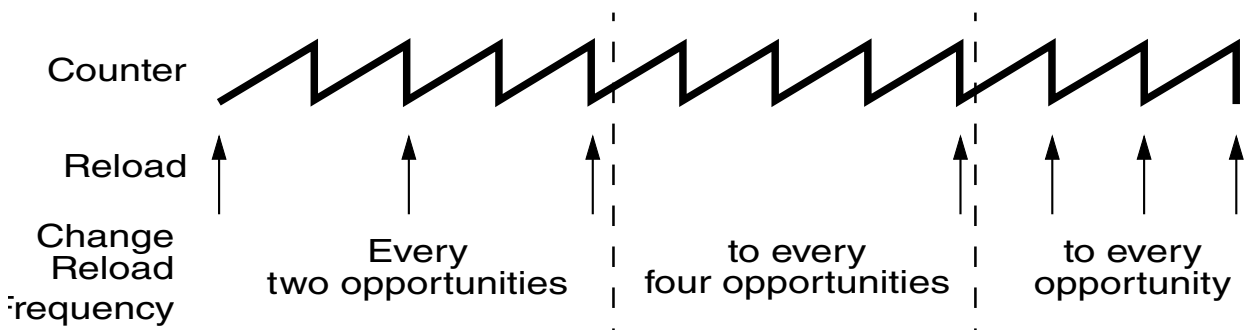

Figure 42-31. Full Cycle Reload Frequency Change

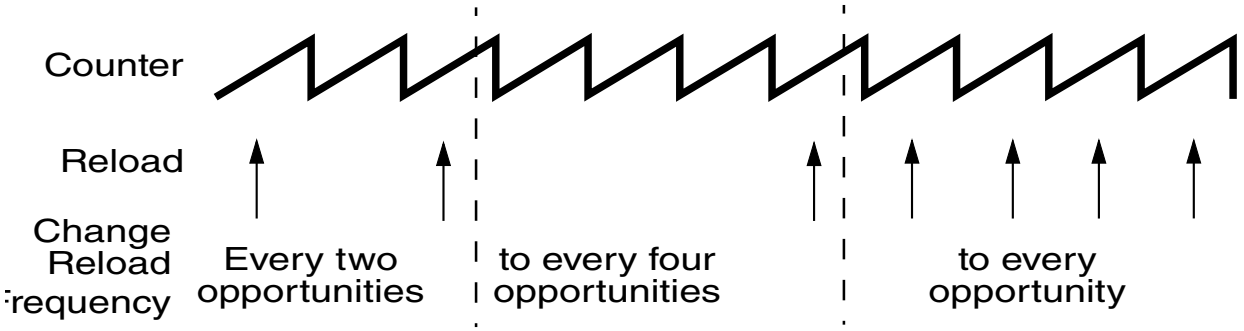

Figure 42-32. Half Cycle Reload Frequency Change

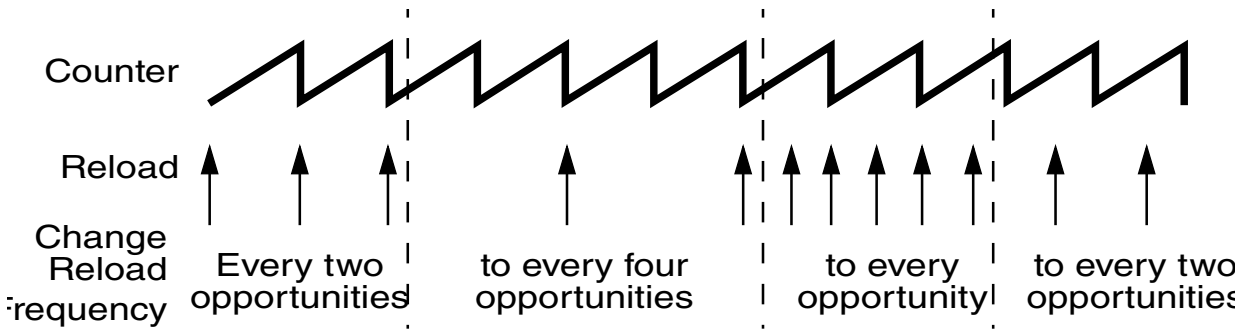

Figure 42-33. Full and Half Cycle Reload Frequency Change

42.5.3.3 Reload Flag

At every reload opportunity the PWM Reload Flag (RF) in the FlexPWM_SUBn_STS register is set. Setting RF happens even if an actual reload is prevented by the LDOK bit. If the PWM reload interrupt enable bit, RIE is set, the RF flag generates CPU interrupt requests allowing software to calculate new PWM parameters in real time. When RIE is not set, reloads still occur at the selected reload rate without generating CPU interrupt requests.

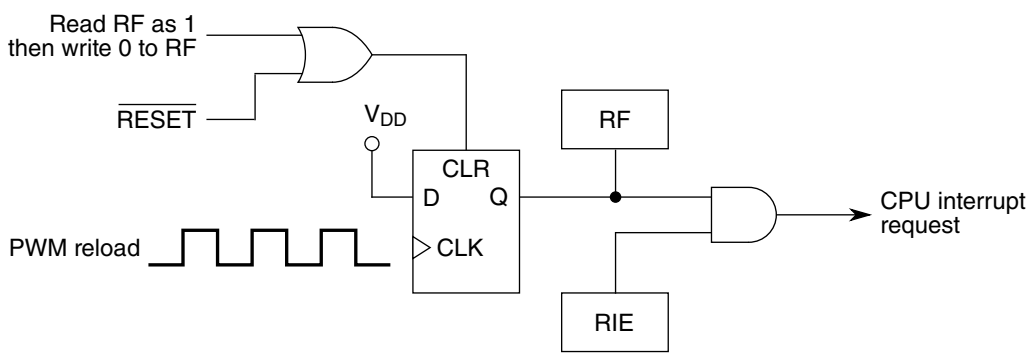

Figure 42-34. PWMF Reload Interrupt Request

42.5.3.4 Reload Errors

Whenever either SUB*n*_VAL*x* or SUB*n*_CTRL1[PSRC] is updated, the RUF flag is set to indicate that the data is not coherent. RUF will be cleared by a successful reload which consists of the reload signal while LDOK is set. If RUF is set and LDOK is clear when the reload signal occurs, a reload error has taken place and the REF bit is set. If RUF is clear when a reload signal asserts, then the data is coherent and no error will be flagged.

42.5.3.5 Initialization

Initialize all registers and set the LDOK bit before setting the RUN bit.

Note

Even if LDOK is not set, setting RUN also sets the RF flag. To prevent a CPU interrupt request, clear the RIE bit before setting RUN.

The PWM generator uses the last values loaded if RUN is cleared and then set while LDOK equals zero.

When the RUN bit is cleared:

- The RF flag and pending CPU interrupt requests are not cleared
- All fault circuitry remains active
- Software/external output control remains active
- Deadtime insertion continues during software/external output control

NOTE

For any FAULT inputs not being used by the FlexPWM, the corresponding SUB*n*_DISMAP bits should be cleared.

42.6 Resets

A reset will force all registers to their reset states and tri-state the PWM outputs.

42.7 Interrupts

Each of the submodules within the FlexPWM can generate an interrupt from several sources. The fault logic can also generate interrupts. The interrupt service routine (ISR) must check the related interrupt enables and interrupt flags to determine the actual cause of the interrupt.

Table 42-4. Interrupt Summary

Core Interrupt	Interrupt Flag	Interrupt Enable	Name	Description
ipi_int_comp0	CMPF_0	CMPIE_0	Submodule 0 compare interrupt	Compare event has occurred
ipi_int_capt0	CFX1_0, CFX0_0	CFX1IE_0, CFX0IE_0	Submodule 0 input capture interrupt	Input capture event has occurred
ipi_int_reload0	RF_0	RIE_0	Submodule 0 reload interrupt	Reload event has occurred
ipi_int_comp1	CMPF_1	CMPIE_1	Submodule 1 compare interrupt	Compare event has occurred
ipi_int_capt1	CFX1_1, CFX0_1	CFX1IE_1, CFX0IE_1	Submodule 1 input capture interrupt	Input capture event has occurred
ipi_int_reload1	RF_1	RIE_1	Submodule 1 reload interrupt	Reload event has occurred
ipi_int_comp2	CMPF_2	CMPIE_2	Submodule 2 compare interrupt	Compare event has occurred
ipi_int_capt2	CFX1_2, CFX0_2	CFX1IE_2, CFX0IE_2	Submodule 2 input capture interrupt	Input capture event has occurred
ipi_int_reload2	RF_2	RIE_2	Submodule 2 reload interrupt	Reload event has occurred
ipi_int_comp3	CMPF_3	CMPIE_3	Submodule 3 compare interrupt	Compare event has occurred
ipi_int_capt3	CFX1_3, CFX0_3	CFX1IE_3, CFX0IE_3	Submodule 3 input capture interrupt	Input capture event has occurred
ipi_int_reload3	RF_3	RIE_3	Submodule 3 reload interrupt	Reload event has occurred
ipi_int_rerr	REF_0	REIE_0	Submodule 0 reload error interrupt	Reload error has occurred
	REF_1	REIE_1	Submodule 1 reload error interrupt	
	REF_2	REIE_2	Submodule 2 reload error interrupt	
	REF_3	REIE_3	Submodule 3 reload error interrupt	
ipi_int_fault	FFLAG	FIE	Fault input interrupt	Fault condition has been detected

42.8 DMA

Each submodule can request a DMA read access for its capture FIFOs and a DMA write request for its double buffered SUB*n*_VAL*x* registers.

Table 42-5. DMA Summary

DMA Request	DMA Enable	Name	Description
Submodule 0 read request	CX0DE_0	Capture FIFO X0 read request	CVAL0 contains a value to be read

Table continues on the next page...

Table 42-5. DMA Summary (continued)

DMA Request	DMA Enable	Name	Description
	CX1DE_0	Capture FIFO X1 read request	CVAL1 contains a value to be read
	CAPTDE_0	Capture FIFO read request source select	Selects source of read DMA request
Submodule 0 write request	VALDE_0	SUB*n*_VAL*x* write request	SUB*n*_VAL*x* registers need to be updated
Submodule 1 read request	CX0DE_1	Capture FIFO X0 read request	CVAL0 contains a value to be read
	CX1DE_1	Capture FIFO X1 read request	CVAL1 contains a value to be read
	CAPTDE_1	Capture FIFO read request source select	Selects source of read DMA request
Submodule 1 write request	VALDE_1	SUB*n*_VAL*x* write request	SUB*n*_VAL*x* registers need to be updated
Submodule 2 read request	CX0DE_2	Capture FIFO X0 read request	CVAL0 contains a value to be read
	CX1DE_2	Capture FIFO X1 read request	CVAL1 contains a value to be read
	CAPTDE_2	Capture FIFO read request source select	Selects source of read DMA request
Submodule 2 write request	VALDE_2	SUB*n*_VAL*x* write request	SUB*n*_VAL*x* registers need to be updated
Submodule 3 read request	CX0DE_3	Capture FIFO X0 read request	CVAL0 contains a value to be read
	CX1DE_3	Capture FIFO X1 read request	CVAL1 contains a value to be read
	CAPTDE_3	Capture FIFO read request source select	Selects source of read DMA request
Submodule 3 write request	VALDE_3	SUB*n*_VAL*x* write request	SUB*n*_VAL*x* registers need to be updated

Chapter 43
Analog-to-Digital Converter (ADC)

43.1 Chip-specific SAR-ADC information

43.1.1 SAR-ADC Overview

There are two 12-bit Successive Approximation Analog to Digital Converter (ADC) modules located on this chip. Both ADC_0 and ADC_1 support 16 analog watchdogs. The critical and non critical faults of ADC_0 and ADC_1 are mapped to FCCU. Refer Fault inputs for details.

43.1.2 eTimer interface

Table 43-1. Interconnection between ETIMER and ADC

Input Module	Input Signal	Driving Module	Driver Signal
ADC_0	INJECT	eTimer_1	T5
ADC_1	INJECT	eTimer_1	T5

43.1.3 ADC pin muxing

The following table provides ADC pin multiplexing details.

Channel Number	ADC_0	ADC_1	Channel Type
Channel 0	PB[7] (GPIO_23)	PB[13] (GPIO_29)	External
Channel 1	PB[8] (GPIO_24)	PB[14] (GPIO_30)	External
Channel 2	PC[1] (GPIO_33)	PB[15] (GPIO_31)	External
Channel 3	PC[2] (GPIO_34)	PC[0] (GPIO_32)	External
Channel 4	PE[6] (GPIO_70)		External

Table continues on the next page...

Channel 5	PE[2] (GPIO_66)		External
Channel 6	PE[7] (GPIO_71)		External
Channel 7	PE[4] (GPIO_68)		External
Channel 8	PE[5] (GPIO_69)		External
Channel 9			Internal
Channel 10	Bandgap Reference PMC [1]	Bandgap Reference PMC [1]	Internal
Channel 11	PB[9] (GPIO_25)	PB[9] (GPIO_25)	External
Channel 12	PB[10] GPIO_26)	PB[10] (GPIO_26)	External
Channel 13	PB[11] (GPIO_27)	PB[11] (GPIO_27)	External
Channel 14	PB[12] (GPIO_28)	PB[12] (GPIO_28)	External
Channel 15	TSENS0 [2]	TSENS1 [2]	Internal

1. For sampling bandgap reference PMC, set the CTR0[INSAMP] = 0x50 minimum given an ADC clock of 80 MHz. This gives a minimum sample time of 1 microsecond.
2. For sampling TSENSn, set the CTR1[INSAMP] = 0xFF minimum given an ADC clock of 80 MHz.

NOTE

Any reserved channel if tried to be converted would give garbage value.

43.1.4 ADC channel conversion

For ADC channel conversion:

- Both Vref VDD_HV_ADCREF1 and VDD_HV_ADCREF2 must be powered up.
- Both must be at the same level.

43.1.5 ADC_0 valid control registers and bits

1. This register affects only ADC_1 Ch. 15 (TSENS1)
2. CALBISTREG retains value after all Long Functional Resets except the one caused by External reset event. It also retains value after Short Functional Resets.
3. OFSGNUSR retains value after all Long Functional Resets except the one caused by External reset event. It also retains value after Short Functional Resets.

43.2 Introduction

The analog-to-digital converter (ADC) uses Successive Approximation Register (SAR) architecture and provides accurate and fast conversions for a wide range of applications.

43.3 Overview

43.3.1 Parts of the ADC

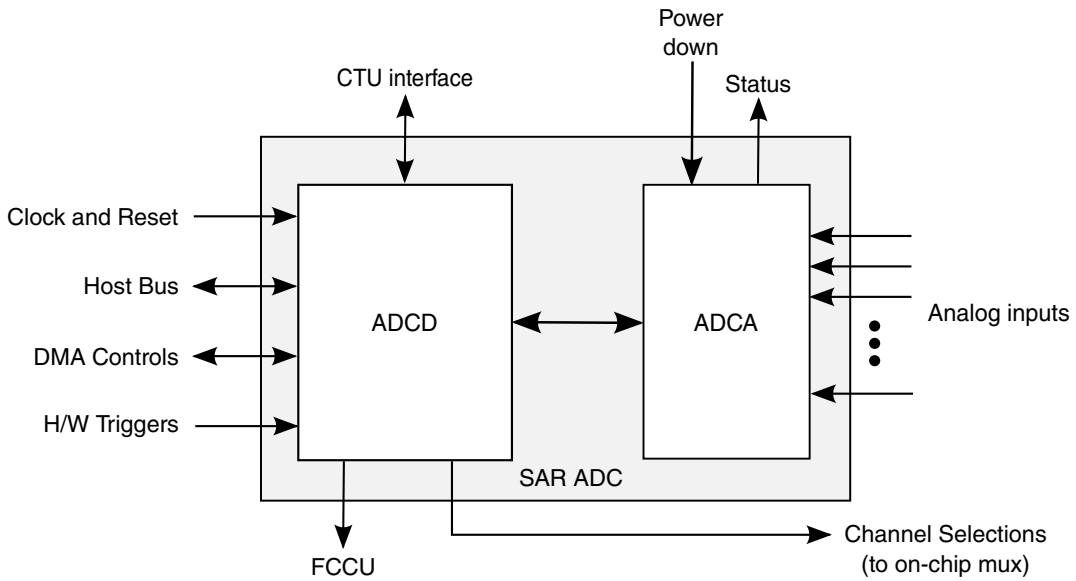

Figure 43-1. ADC high-level block diagram

The ADC is comprised of:

- An ADC digital interface (ADCD). The ADCD holds the configuration, control, and status registers accessible to software via the host bus. The converted value is stored in a register and then transferred through the DMA or host access.
- An ADC analog hard macrocell (ADCA). The analog channel inputs are fed to the inputs of the ADCA. Each channel is sampled for a specific duration and compared with an analog voltage generated with digital code via a digital-to-analog converter (DAC) in the ADCA. The comparison result is given to the ADCD to generate the converted digital value.

43.3.2 ADC clock signals

The ADC uses the following clock signals:

- Bus clock—bus clock at ADCD. Used to access the registers and the operating clock of inter-module interfaces.
- AD_clk—derived from *bus clock*, this signal serves as the operating clock for the ADCA and the SAR controller inside the ADCD.

The relation between the two clocks is determined by the setting of the ADC_MCR[ADCLKSEL] field.

- If ADC_MCR[ADCLKSEL] is 1, the clock signals are the same
- If ADC_MCR[ADCLKSEL] is 0, AD_clk is half of the bus clock.

NOTE

1. Regardless of the setting of the ADC_MCR[ADCLKSEL] field, the maximum clock speed for the ADC clock (AD_clk) is 80 MHz.
2. Depending on your chip's configuration and timing needs, MCR[ADCLKSEL] may always need to be 1.

If the bus clock for the microcontroller is 80 MHz and ADC_MCR[ADCLKSEL] is 1, the ADC clock (AD_clk) is 80 MHz.

If the bus clock for the microcontroller is 80 MHz and ADC_MCR[ADCLKSEL] is 0, the ADC clock (AD_clk) is 40 MHz.

See ADCLKSEL for details on the ADC_MCR register fields.

43.3.3 About ADC channels

43.3.3.1 Channel configuration

ADC channels can be configured in the following ways:

- The sampling duration is controlled independently, through programming the Conversion Timing Register (CTR).
- Separate mask registers can be programmed to configure the channels to be converted (each bit in these registers represents one channel).
- Temperature Sensor (TSENS) and other special channels (band gap, supply etc.) are available on specific channels. (See the chip-specific configuration for availability.)
- Analog watchdogs allow continuous hardware monitoring of the converted value from input channels. (See the chip-specific configuration for availability.)
- Capacitive self test
- Presampling

43.3.3.2 Initiating conversions

Conversions can be initiated by either software or hardware.

The ADCD has an on-chip Cross-Triggering Unit (CTU) interface that can also initiate conversions. The CTU interface supports CTU Control mode.

An example of an application for which CTU triggering is suitable is a current control loop for lamps or LEDs. Using an on-chip timer module as trigger source, a CTU can initiate periodic conversions.

43.3.3.3 Interrupt/DMA support

The ADCD provides interrupt/DMA support for each type of channel for various end-of-channel conversion conditions. Data can be transferred via DMA.

43.3.3.4 Self-test

The ADCD can be configured to periodically check the health of the ADCA through various self-tests and communicate any critical/non-critical faults to an on-chip Fault Collection and Control Unit (FCCU) if available (See the chip-specific section for availability). The severity (critical/noncritical) of the different tests is programmable.

43.4 Features

The following general features are implemented in the ADC. (See the chip-specific section for availability of features, as each instance of an ADC within a chip may support different features.)

- Resolution: 12-bit
- Maximum speed: 1 Mega samples/second at 80 MHz
- 16 channels
- Sampling time register
  - *precision* channels:
    - 0 - 15 (ADC0)
    - 0 - 15 (ADC1)

NOTE

The Temperature Sensor uses the value in the CTR1 register

- Modes of operation:
  - Normal

    - Injected
    - CTU
- Normal mode supports One-Shot/Scan (continuous)
- Injected mode supports One-Shot
- Presampling
- Power-Down mode
- Two abort features that allow you to abort either a single channel in a chain or the full chain in normal and injected mode
- Each channel has a dedicated register for conversion results and mode of operation (normal, injected, or CTU)
- Analog watchdog support:
    - Up to 16 analog watchdogs
    - Configurable for different channels
- Auto clock-off feature
- Programmable clock prescaler (bus clock divided by 2)
- CTU Control mode
- DMA support for each channel
- Interrupts for the following conditions:
    - End of conversion for a single channel for both normal and injected conversions
    - End of conversion for a chain for both normal and injected conversions
    - End of CTU conversion
    - Watchdog thresholds crossover
- Software-initiated calibration
- Self-testing feature

43.5 Memory Map/Register Definition

The following tables describe the registers and bit meanings for this module.

NOTE

There will be an Access Error for Reserved and out-of-range addresses. Special exceptions are the Reserved spaces at 039Ch and 03A4h: Do not write or change any value in these locations, or the ADC might malfunction.

NOTE

See the chip-specific configuration information because not all registers are available in all ADC instances.

Control logic registers:

- Main Configuration Register (ADC_MCR)
- Main Status register (ADC_MSR)
- Interrupt Status Register (ADC_ISR)
- Channel Pending register 0 (ADC_CEOCFR0)
- Interrupt Mask Register (ADC_IMR)
- Channel Interrupt Mask Register 0 (ADC_CIMR0)
- Watchdog Threshold Interrupt Status Register (ADC_WTISR)
- Watchdog Threshold Interrupt Mask Register (ADC_WTIMR)
- Analog Watchdog Out of Range Register 0 (ADC_AWORR0)

DMA registers:
- DMA Enable register (ADC_DMAE)
- DMA Channel Select Register 0 (ADC_DMAR0)

Threshold registers:

These registers are used to store the user programmable lower and upper thresholds 12-bit values. These registers include:
- Threshold Register (ADC_THRHLR*n*)

Presampling registers:
- Presampling Control Register (ADC_PSCR)
- Presampling register 0 (ADC_PSR0)

Conversion timing registers:

- Conversion Timing Register 0 (ADC_CTR0)
- Conversion Timing Register 1 (ADC_CTR1)

Mask register: These registers are used to program which input channels must be converted during Normal and Injected conversion. These registers include:
- Normal Conversion Mask Register 0 (ADC_NCMR0)
- Injected Conversion Mask Register 0 (ADC_JCMR0)

Delay registers:
- Power Down Exit Delay Register (ADC_PDEDR)

Data registers:

The conversion results for the internal channels are loaded into data registers. Each data register also gives information regarding the corresponding result. These registers start with CDR0:
- Channel Data Register *n* (Precision Channels) (ADC_CDR*n*)

Self test registers:
- Self Test Configuration Register 1 (ADC_STCR1)

- Self Test Configuration Register 2 (ADC_STCR2)
- Self Test Configuration Register 3 (ADC_STCR3)
- Self Test Status Register 1 (ADC_STSR1)
- Self Test Status Register 2 (ADC_STSR2)
- Self Test Status Register 3 (ADC_STSR3)
- Self Test Status Register 4 (ADC_STSR4)
- Self Test Baud Rate Register (ADC_STBRR)
- Self Test Analog Watchdog Register 0 (ADC_STAW0R)
- Self Test Analog Watchdog Register 4 (ADC_STAW4R)
- Self Test Analog Watchdog Register 1A (ADC_STAW1AR)
- Self Test Analog Watchdog Register 1B (ADC_STAW1BR)
- Self Test Analog Watchdog Register 2 (ADC_STAW2R)
- Self Test Analog Watchdog Register 5 (ADC_STAW5R)
- Self Test Data Register 1 (ADC_STDR1)
- Self Test Data Register 2 (ADC_STDR2)

Other registers include:

- Calibration, BIST Control and status Register (ADC_CALBISTREG)
- Offset and Gain User Register (ADC_OFSGNUSR)

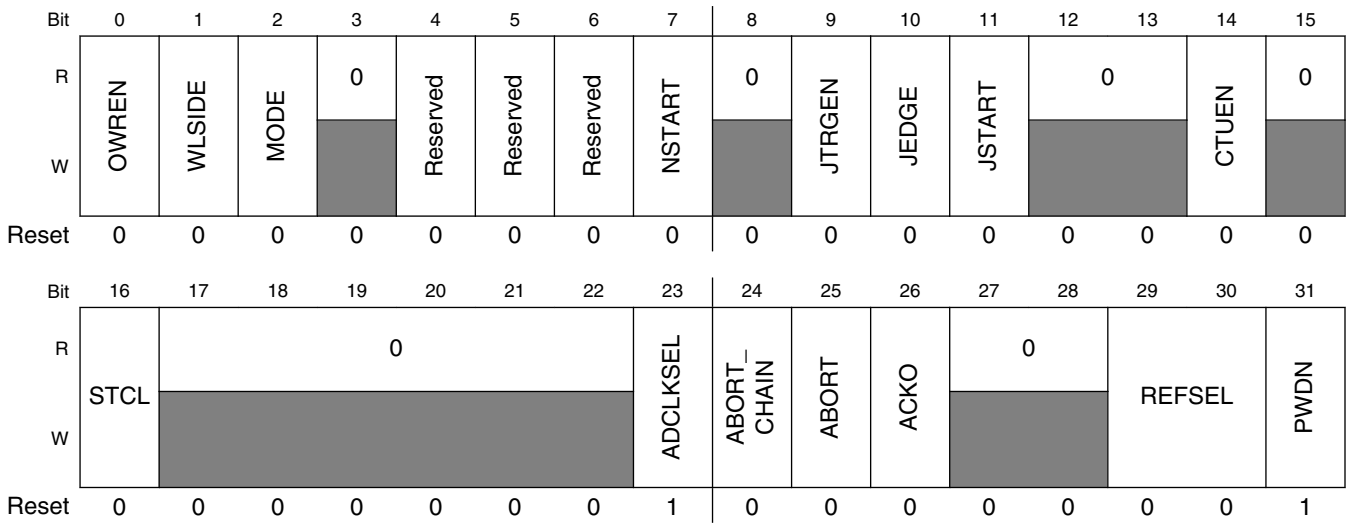
43.5.1 Main Configuration Register (ADC_MCR)

Address: 0h base + 0h offset = 0h



ADC_MCR field descriptions

Field	Description
0 OWREN	Overwrite enable. 0 Older valid conversion data is not overwritten by newer conversion data. 1 Newer conversion result is always overwritten, irrespective of the validity of older conversion data.
1 WLSIDE	Write Left/Right aligned. 0 The conversion data is written right aligned from (32-resolution) to 31). 1 Data is left aligned (from 16 to (16 + resolution - 1).
2 MODE	One_Shot/Scan. 0 One_Shot Mode: configure the Normal conversion of one chain. 1 Scan Mode: configure continuous chain conversion mode; when the programmed chain conversion is finished it restarts immediately.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 Reserved	This field is reserved. Writing a value to this field has no effect.
5 Reserved	This field is reserved. Writing a value to this field has no effect.
6 Reserved	This field is reserved. **NOTE:** User must not overwrite default value of this field.
7 NSTART	Start of Normal conversion. Setting this field starts a normal conversion. In One shot mode: This field is cleared as soon as conversion is started. Setting this field during any ongoing conversion keeps this bit high until the requested conversion is started.

Table continues on the next page...

ADC_MCR field descriptions (continued)

Field	Description
	NOTE: This bit cannot be set (1) when PWDN = 1. This bit is always cleared when PWDN = 1.
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 JTRGEN	Injection external trigger enable. When set, enables the external trigger to start a injected conversion; if the external trigger feature is needed for injected conversion then this field must be set.
10 JEDGE	Injection trigger edge selection. Edge selection for external trigger; if JTRGEN is one this bit selects the falling (JEDGE = zero) or rising (JEDGE = one) edge for the external trigger.
11 JSTART	Injection start. Setting this field will start the configured injected conversion chain. Resetting this field has no effect, as the injected chain conversion cannot be interrupted. Setting this field during ongoing Injected conversion keeps this field high value until the requested conversion is started.
12–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 CTUEN	Crosstrigger Unit Enable. Enables the crosstriggering unit (CTU). 0 The crosstriggering unit is disabled and the CTU-triggered injected conversion cannot take place. 1 The crosstriggering unit is enabled and the CTUtriggered injected conversion can take place.
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 STCL	Self Testing Configuration Lock. 0 No lock 1 The self-testing configuration is locked i.e. STCR1, STCR2, STCR3, STBRR, STAW0R, STAW1AR, STAW1BR, STAW2R, STAW4R, STAW5R are write-protected. It can be used only in CPU and SCAN mode. The lock bit is cleared only by a peripheral reset.
17–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 ADCLKSEL	Analog Clock frequency Selector. This field can be written in Power Down mode only. Please check device specific additional restriction on programming of this field. 0 ADC clock frequency is half of bus clock 1 ADC clock frequency is equal to bus clock
24 ABORT_CHAIN	Abort Chain. If this bit is set the ongoing Chain Conversion is aborted. This bit gets reset by hardware as soon as a new conversion is requested. **NOTE:** Setting this bit in idle state (no normal/injected conversion is ongoing) has no effect. In this case it is reset immediately. During ongoing CTU conversion this bit also cannot be programmed.
25 ABORT	Abort Conversion.

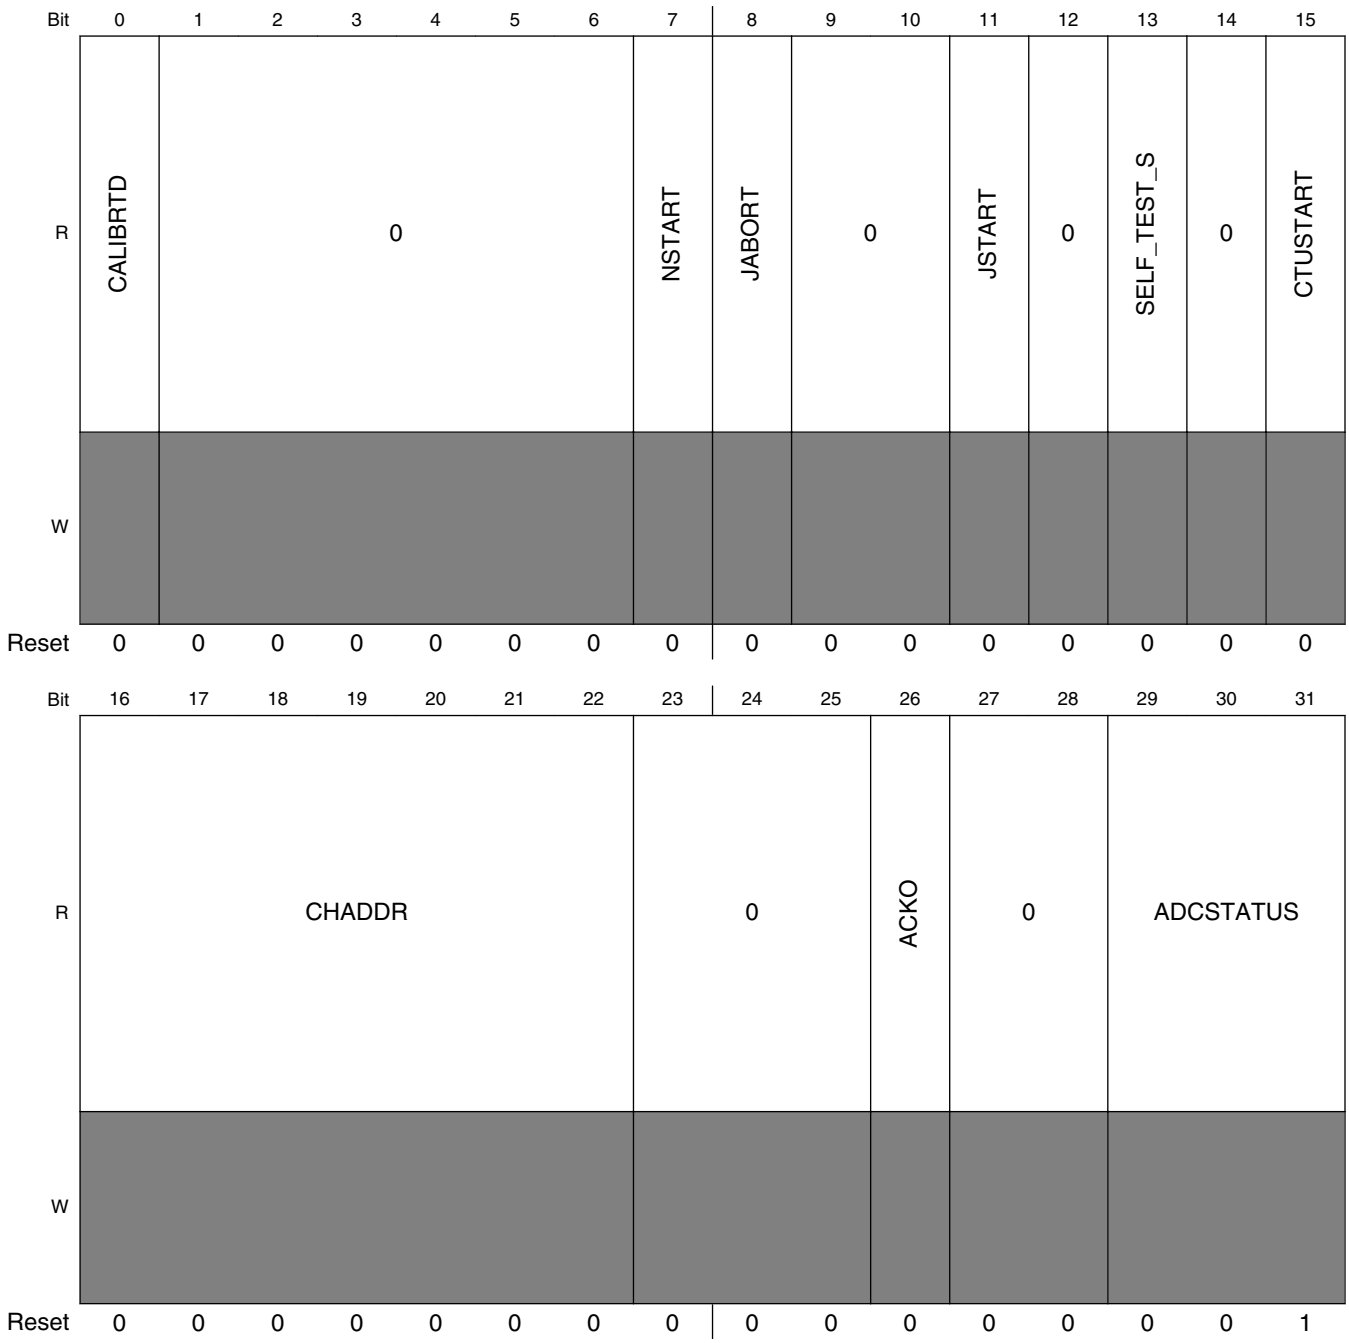
Table continues on the next page...

ADC_MCR field descriptions (continued)

Field	Description
	If this bit is set, the ongoing channel conversion is aborted and the next channel conversion is invoked. This bit gets reset by hardware as soon as the new conversion is invoked. This bit cannot be written while self test conversion is ongoing. **NOTE:** Setting this bit in idle state (No Normal/injected conversion is ongoing) has no effect. In this case it is reset immediately. During ongoing CTU conversion this bit cannot be programmed
26 ACKO	Auto clock off enable. If set, enables the Auto clock off feature.
27–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–30 REFSEL	Reference voltage selection for ADC analog part. 00 Select VREFH as reference voltage 01 Reserved 10 Reserved 11 Reserved
31 PWDN	Power-down enable. When this bit is set, the analog module is requested to enter Power-Down mode. When the ADC's status is PWDN, resetting this bit will start the ADC's transition to IDLE mode. In CTU control mode MCR[CTUEN] must be reset before entering into power-down mode.

43.5.2 Main Status register (ADC_MSR)

Address: 0h base + 4h offset = 4h



ADC_MSR field descriptions

Field	Description
0 CALIBRTD	This bit indicates the ADC calibration status. This bit gets updated after running the High Accuracy Calibration mode.

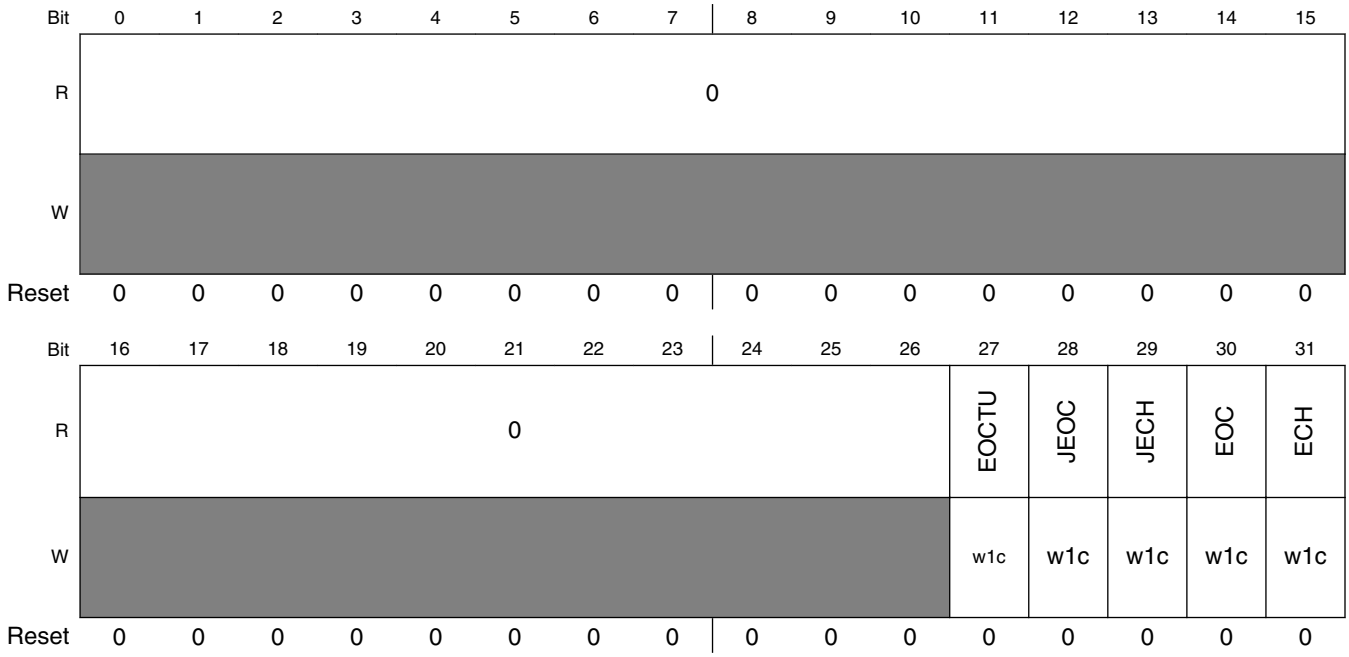
Table continues on the next page...

ADC_MSR field descriptions (continued)

Field	Description
	0 Uncalibrated or calibration unsuccessful 1 Calibration was run and it was successful
1–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 NSTART	This status bit is used to signal that a Normal conversion is ongoing.
8 JABORT	This status bit is used to signal that an Injected conversion has been aborted by CTU. That bit is reset when a new injected conversion starts.
9–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 JSTART	This status bit is used to signal that an Injected conversion is ongoing.
12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 SELF_TEST_S	This status bit signals that self test conversion is ongoing.
14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 CTUSTART	This status bit is used to signal that a CTU conversion is ongoing. This bit is set when a CTU trigger pulse is received and the CTU conversion starts.When Control Mode is enabled this bit is reset when the CTU is disabled (CTUEN set to 0).
16–22 CHADDR	Channel under measure address. Status bits are used to signal which channel is under measure. MSR[CHADDR] is only valid when the SARADC is in the sample phase of the conversion (MSR[ADCSTATUS] = 100b).
23–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 ACKO	Auto clock off enable. This status bit is used to signal if the Auto clock off feature is on.
27–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 ADCSTATUS	Status of the ADC. 000 Idle 001 Power Down 100 Sample 110 Conversion 010 Wait state (waiting to start conversion [external trigger]) 011 Busy in Calibration

43.5.3 Interrupt Status Register (ADC_ISR)

Address: 0h base + 10h offset = 10h



ADC_ISR field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 EOCTU	End of CTU conversion. This bit is set for a digital end of conversion on a the CTU Channel; active when set.
28 JEOC	End of injected channel conversion. This bit is set for a digital end of conversion on an injected channel; active when set.
29 JECH	End of injected chain conversion. This bit is set for a digital end of chain conversion on an injected channel; active when set. **NOTE:** If there is no channel selected in the ADC_JCMR*n* register(s) and there is a start of conversion trigger, then ADC_ISR[JECH] is set and a JECH interrupt is immediately issued (if enabled). Similarly, if no channel is selected in the ADC_NCMR*n* register and a normal conversion is triggered, ADC_ISR[ECH] is set and an ECH interrupt is immediately issued, if enabled.
30 EOC	End of channel conversion. This bit is set for a digital end of conversion on a Normal Channel; active when set.
31 ECH	End of chain conversion. This bit is set for a digital end of chain conversion on a Normal Channel; active when set. **NOTE:** If there is no channel selected in the ADC_NCMR*n* register(s) and there is a start of conversion trigger, then ADC_ISR[ECH] is set and an ECH interrupt is immediately issued (if enabled).

Table continues on the next page...

ADC_ISR field descriptions (continued)

Field	Description
	Similarly, if no channel is selected in the ADC_JCMR*n* register and an injected conversion is triggered, ADC_ISR[JECH] is set and a JECH interrupt is immediately issued, if enabled.

43.5.4 Channel Pending register 0 (ADC_CEOCFR0)

NOTE

This register may contain fields for channels that have not been implemented. See the chip-specific information to find which channels are applicable.

Address: 0h base + 14h offset = 14h

ADC_CEOCFR0 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 EOCCH15	EOC Channel 15. When set, the measure of channel 15 is completed.

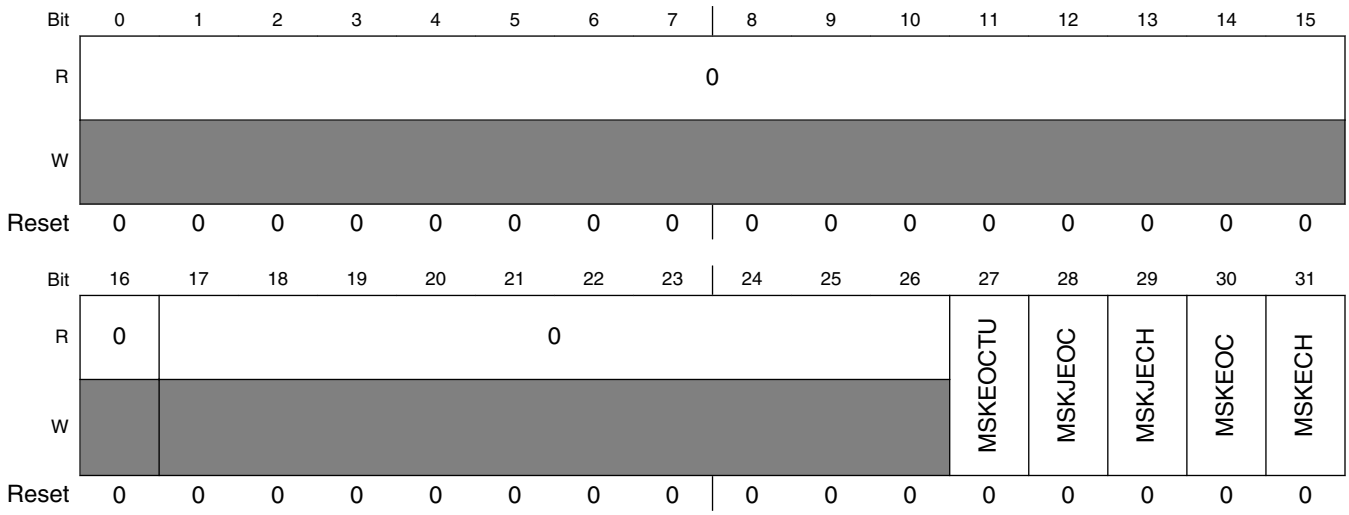
Table continues on the next page...

ADC_CEOCFR0 field descriptions (continued)

Field	Description
17 EOCCH14	EOC Channel 14. When set, the measure of channel 14 is completed.
18 EOCCH13	EOC Channel 13. When set, the measure of channel 13 is completed.
19 EOCCH12	EOC Channel 12. When set, the measure of channel 12 is completed.
20 EOCCH11	EOC Channel 11. When set, the measure of channel 11 is completed.
21 EOCCH10	EOC Channel 10. When set, the measure of channel 10 is completed.
22 EOCCH9	EOC Channel 9. When set, the measure of channel 9 is completed.
23 EOCCH8	EOC Channel 8. When set, the measure of channel 8 is completed.
24 EOCCH7	EOC Channel 7. When set, the measure of channel 7 is completed.
25 EOCCH6	EOC Channel 6. When set, the measure of channel 6 is completed.
26 EOCCH5	EOC Channel 5. When set, the measure of channel 5 is completed.
27 EOCCH4	EOC Channel 4. When set, the measure of channel 4 is completed.
28 EOCCH3	EOC Channel 3. When set, the measure of channel 3 is completed.
29 EOCCH2	EOC Channel 2. When set, the measure of channel 2 is completed.
30 EOCCH1	EOC Channel 1. When set, the measure of channel 1 is completed.
31 EOCCH0	EOC Channel 0. When set, the measure of channel 0 is completed.

43.5.5 Interrupt Mask Register (ADC_IMR)

Address: 0h base + 20h offset = 20h



ADC_IMR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 MSKEOCTU	Mask bit for EOCTU. When set, the interrupt is enabled.
28 MSKJEOC	Mask bit for JEOC. When set, the interrupt is enabled.
29 MSKJECH	Mask bit for JECH. When set, the interrupt is enabled.
30 MSKEOC	Mask bit for EOC. When set, the interrupt is enabled.
31 MSKECH	Mask bit for ECH. When set, the interrupt is enabled.

43.5.6 Channel Interrupt Mask Register 0 (ADC_CIMR0)

The fields in this register globally enable or disable end of conversion interrupts by channels within the range of Channel 0 through 31.

NOTE

This register may contain fields for channels that have not been implemented. See the chip-specific details to find which channels are applicable.

Address: 0h base + 24h offset = 24h

ADC_CIMR0 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 CIM15	Channel 15 interrupt enable. When this field is set, the interrupt for channel 15 is enabled.
17 CIM14	Channel 14 interrupt enable. When this field is set, the interrupt for channel 14 is enabled.
18 CIM13	Channel 13 interrupt enable. When this field is set, the interrupt for channel 13 is enabled.
19 CIM12	Channel 12 interrupt enable. When this field is set, the interrupt for channel 12 is enabled.
20 CIM11	Channel 11 interrupt enable. When this field is set, the interrupt for channel 11 is enabled.
21 CIM10	Channel 10 interrupt enable. When this field is set, the interrupt for channel 10 is enabled.
22 CIM9	Channel 9 interrupt enable. When this field is set, the interrupt for channel 9 is enabled.
23 CIM8	Channel 8 interrupt enable. When this field is set, the interrupt for channel 8 is enabled.
24 CIM7	Channel 7 interrupt enable. When this field is set, the interrupt for channel 7 is enabled.

Table continues on the next page...

ADC_CIMR0 field descriptions (continued)

Field	Description
25 CIM6	Channel 6 interrupt enable. When this field is set, the interrupt for channel 6 is enabled.
26 CIM5	Channel 5 interrupt enable. When this field is set, the interrupt for channel 5 is enabled.
27 CIM4	Channel 4 interrupt enable. When this field is set, the interrupt for channel 4 is enabled.
28 CIM3	Channel 3 interrupt enable. When this field is set, the interrupt for channel 3 is enabled.
29 CIM2	Channel 2 interrupt enable. When this field is set, the interrupt for channel 2 is enabled.
30 CIM1	Channel 1 interrupt enable. When this field is set, the interrupt for channel 1 is enabled.
31 CIM0	Channel 0 interrupt enable. When this field is set, the interrupt for channel 0 is enabled.

43.5.7 Watchdog Threshold Interrupt Status Register (ADC_WTISR)

The fields in this register, when set, indicate either the upper or lower threshold value has been crossed for a specific watchdog.

Address: 0h base + 30h offset = 30h

ADC_WTISR field descriptions

Field	Description
0 WDG15H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 15 (WD15). **NOTE:** Write a '1' to this field to clear it.
1 WDG15L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 15 (WD15). **NOTE:** Write a '1' to this field to clear it.
2 WDG14H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 14 (WD14). **NOTE:** Write a '1' to this field to clear it.
3 WDG14L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 14 (WD14). **NOTE:** Write a '1' to this field to clear it.

ADC_WTISR field descriptions (continued)

Field	Description
4 WDG13H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 13 (WD13). **NOTE:** Write a '1' to this field to clear it.
5 WDG13L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 13 (WD13). **NOTE:** Write a '1' to this field to clear it.
6 WDG12H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 12 (WD12). **NOTE:** Write a '1' to this field to clear it.
7 WDG12L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 12 (WD12). **NOTE:** Write a '1' to this field to clear it.
8 WDG11H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 11 (WD11). **NOTE:** Write a '1' to this field to clear it.
9 WDG11L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 11 (WD11). **NOTE:** Write a '1' to this field to clear it.
10 WDG10H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 10 (WD10). **NOTE:** Write a '1' to this field to clear it.
11 WDG10L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 10 (WD10). **NOTE:** Write a '1' to this field to clear it.
12 WDG9H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 9 (WD9). **NOTE:** Write a '1' to this field to clear it.
13 WDG9L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 9 (WD9). **NOTE:** Write a '1' to this field to clear it.
14 WDG8H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 8 (WD8). **NOTE:** Write a '1' to this field to clear it.
15 WDG8L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 8 (WD8). **NOTE:** Write a '1' to this field to clear it.
16 WDG7H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 7 (WD7). **NOTE:** Write a '1' to this field to clear it.

Table continues on the next page...

ADC_WTISR field descriptions (continued)

Field	Description
17 WDG7L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 7 (WD7). **NOTE:** Write a '1' to this field to clear it.
18 WDG6H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 6 (WD6). **NOTE:** Write a '1' to this field to clear it.
19 WDG6L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 6 (WD6). **NOTE:** Write a '1' to this field to clear it.
20 WDG5H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 5 (WD5). **NOTE:** Write a '1' to this field to clear it.
21 WDG5L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 5 (WD5). **NOTE:** Write a '1' to this field to clear it.
22 WDG4H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 4 (WD4). **NOTE:** Write a '1' to this field to clear it.
23 WDG4L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 4 (WD4). **NOTE:** Write a '1' to this field to clear it.
24 WDG3H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 3 (WD3). **NOTE:** Write a '1' to this field to clear it.
25 WDG3L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 3 (WD3). **NOTE:** Write a '1' to this field to clear it.
26 WDG2H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 2 (WD2). **NOTE:** Write a '1' to this field to clear it.
27 WDG2L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 2 (WD2). **NOTE:** Write a '1' to this field to clear it.
28 WDG1H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 1 (WD1). **NOTE:** Write a '1' to this field to clear it.
29 WDG1L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 1 (WD1). **NOTE:** Write a '1' to this field to clear it.

Table continues on the next page...

ADC_WTISR field descriptions (continued)

Field	Description
30 WDG0H	This bit corresponds to the interrupt generated on the converted value being higher than the programmed higher threshold for a channel monitored by Watchdog 0 (WD0). **NOTE:** Write a '1' to this field to clear it.
31 WDG0L	This bit corresponds to the interrupt generated on the converted value being lower than the programmed lower threshold for a channel monitored by Watchdog 0 (WD0). **NOTE:** Write a '1' to this field to clear it.

43.5.8 Watchdog Threshold Interrupt Mask Register (ADC_WTIMR)

ADC_WTIMR field descriptions (continued)

Field	Description
5 MSKWDG13L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 13 (WD13) being lower than the programmed lower threshold. When set, the interrupt is enabled.
6 MSKWDG12H	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 12 (WD12) being higher than the programmed higher threshold. When set, the interrupt is enabled.
7 MSKWDG12L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 12 (WD12) being lower than the programmed lower threshold. When set, the interrupt is enabled.
8 MSKWDG11H	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 11 (WD11) being higher than the programmed higher threshold. When set, the interrupt is enabled.
9 MSKWDG11L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 11 (WD11) being lower than the programmed lower threshold. When set, the interrupt is enabled.
10 MSKWDG10H	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 10 (WD10) being higher than the programmed higher threshold. When set, the interrupt is enabled.
11 MSKWDG10L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 10 (WD10) being lower than the programmed lower threshold. When set, the interrupt is enabled.
12 MSKWDG9H	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 9 (WD9) being higher than the programmed higher threshold. When set, the interrupt is enabled.
13 MSKWDG9L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 9 (WD9) being lower than the programmed lower threshold. When set, the interrupt is enabled.
14 MSKWDG8H	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 8 (WD8) being higher than the programmed higher threshold. When set, the interrupt is enabled.
15 MSKWDG8L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 8 (WD8) being lower than the programmed lower threshold. When set, the interrupt is enabled.
16 MSKWDG7H	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 7 (WD7) being higher than the programmed higher threshold. When set, the interrupt is enabled.
17 MSKWDG7L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 7 (WD7) being lower than the programmed lower threshold. When set, the interrupt is enabled.
18 MSKWDG6H	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 6 (WD6) being higher than the programmed higher threshold. When set, the interrupt is enabled.
19 MSKWDG6L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 6 (WD6) being lower than the programmed lower threshold. When set, the interrupt is enabled.
20 MSKWDG5H	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 5 (WD5) being higher than the programmed higher threshold. When set, the interrupt is enabled.

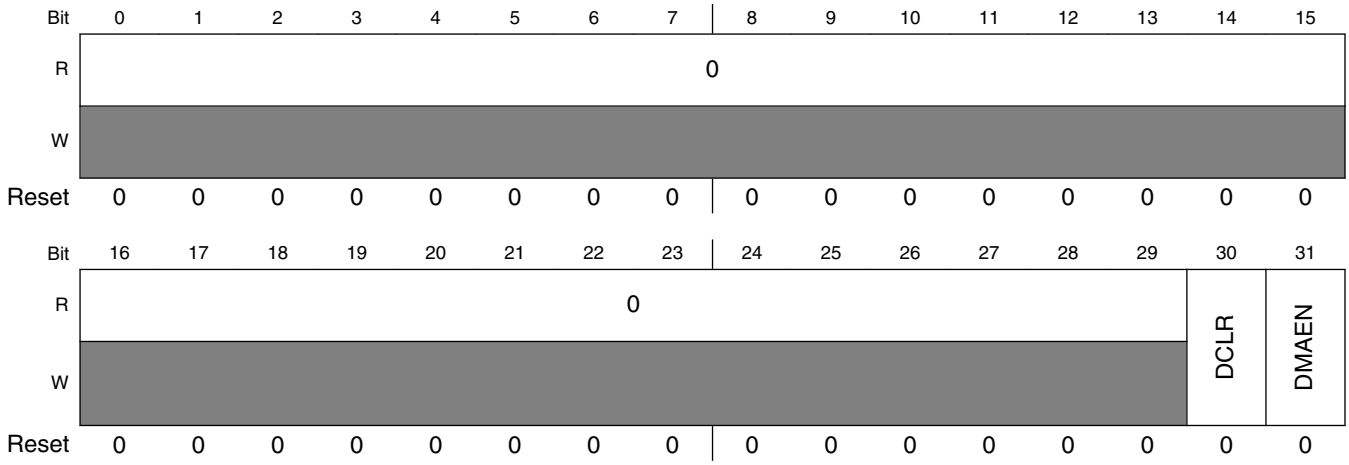
Table continues on the next page...

ADC_WTIMR field descriptions (continued)

Field	Description
21 MSKWDG5L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 5 (WD5) being lower than the programmed lower threshold. When set, the interrupt is enabled.
22 MSKWDG4H	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 4 (WD4) being higher than the programmed higher threshold. When set, the interrupt is enabled.
23 MSKWDG4L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 4 (WD4) being lower than the programmed lower threshold. When set, the interrupt is enabled.
24 MSKWDG3H	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 3 (WD3) being higher than the programmed higher threshold. When set, the interrupt is enabled.
25 MSKWDG3L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 3 (WD3) being lower than the programmed lower threshold. When set, the interrupt is enabled.
26 MSKWDG2H	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 2 (WD2) being higher than the programmed higher threshold. When set, the interrupt is enabled.
27 MSKWDG2L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 2 (WD2) being lower than the programmed lower threshold. When set, the interrupt is enabled.
28 MSKWDG1H	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 1 (WD1) being higher than the programmed higher threshold. When set, the interrupt is enabled.
29 MSKWDG1L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 1 (WD1) being lower than the programmed lower threshold. When set, the interrupt is enabled.
30 MSKWDG0H	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 0 (WD0) being higher than the programmed higher threshold. When set, the interrupt is enabled.
31 MSKWDG0L	This bit enables/disables the interrupt generated by the converted value sampled from a channel monitored by Watchdog 0 (WD0) being lower than the programmed lower threshold. When set, the interrupt is enabled.

43.5.9 DMA Enable register (ADC_DMAE)

Address: 0h base + 40h offset = 40h



ADC_DMAE field descriptions

Field	Description
0–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 DCLR	DMA Clear sequence enable. 0 DMA request cleared by Acknowledge from DMA controller 1 DMA request cleared on read of data registers
31 DMAEN	DMA global enable. When this bit is set, the DMA feature is enabled.

43.5.10 DMA Channel Select Register 0 (ADC_DMAR0)

NOTE

This register may contain fields for channels that have not been implemented. See the chip-specific information to find which channels are applicable.

Address: 0h base + 44h offset = 44h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ADC_DMAR0 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 DMA15	DMA enable for channel 15. When set, transferring data in DMA mode is enabled for channel 15.
17 DMA14	DMA enable for channel 14. When set, transferring data in DMA mode is enabled for channel 14.
18 DMA13	DMA enable for channel 13. When set, transferring data in DMA mode is enabled for channel 13.
19 DMA12	DMA enable for channel 12. When set, transferring data in DMA mode is enabled for channel 12.
20 DMA11	DMA enable for channel 11. When set, transferring data in DMA mode is enabled for channel 11.
21 DMA10	DMA enable for channel 10. When set, transferring data in DMA mode is enabled for channel 10.
22 DMA9	DMA enable for channel 9.

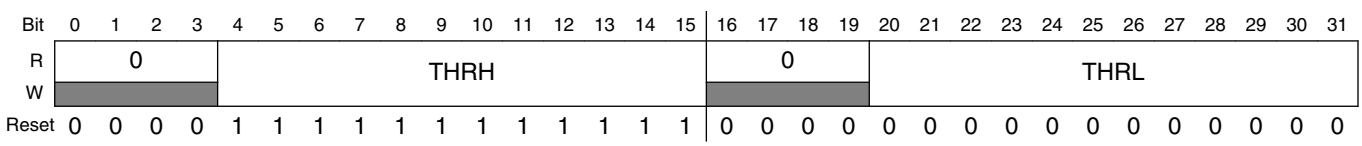
Table continues on the next page...

ADC_DMAR0 field descriptions (continued)

Field	Description
	When set, transferring data in DMA mode is enabled for channel 9.
23 DMA8	DMA enable for channel 8. When set, transferring data in DMA mode is enabled for channel 8.
24 DMA7	DMA enable for channel 7. When set, transferring data in DMA mode is enabled for channel 7.
25 DMA6	DMA enable for channel 6. When set, transferring data in DMA mode is enabled for channel 6.
26 DMA5	DMA enable for channel 5. When set, transferring data in DMA mode is enabled for channel 5.
27 DMA4	DMA enable for channel 4. When set, transferring data in DMA mode is enabled for channel 4.
28 DMA3	DMA enable for channel 3. When set, transferring data in DMA mode is enabled for channel 3.
29 DMA2	DMA enable for channel 2. When set, transferring data in DMA mode is enabled for channel 2.
30 DMA1	DMA enable for channel 1. When set, transferring data in DMA mode is enabled for channel 1.
31 DMA0	DMA enable for channel 0. When set, transferring data in DMA mode is enabled for channel 0.

43.5.11 Threshold Register (ADC_THRHLR*n*)

Address: 0h base + 60h offset + (4d × i), where i=0d to 3d



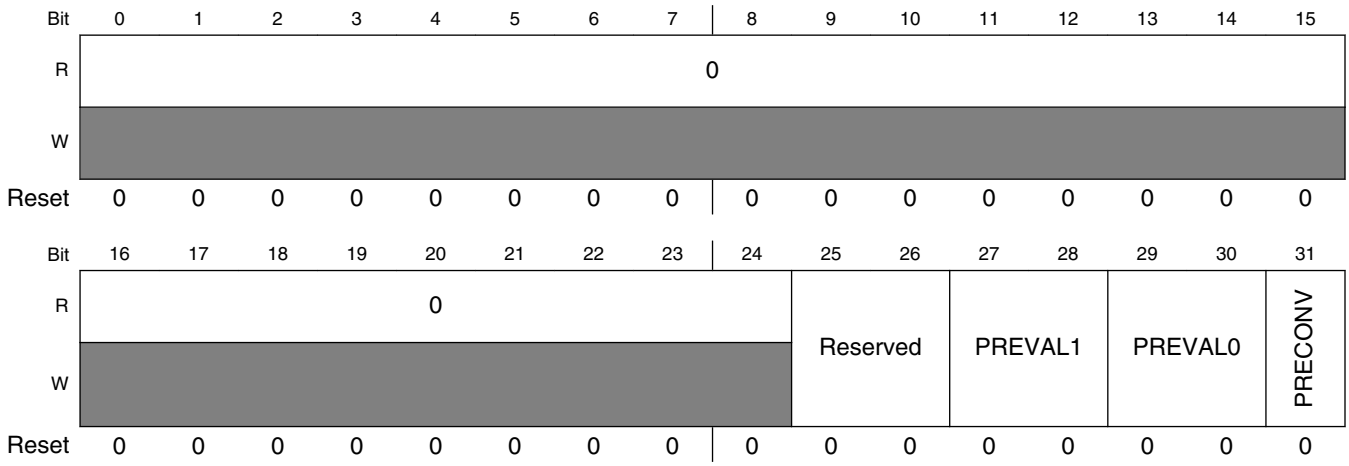
ADC_THRHLR*n* field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–15 THRH	High threshold value for watchdog n.
16–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 THRL	Low threshold value for watchdog n.

43.5.12 Presampling Control Register (ADC_PSCR)

See the chip configuration details for the availability of this register.

Address: 0h base + 80h offset = 80h



ADC_PSCR field descriptions

Field	Description
0–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–26 Reserved	This field is reserved.
27–28 PREVAL1	Internal voltage selection for Presampling. These two bits select analog input voltage for presampling from the available internal voltages using internal extended channels (channel 32 to 63). This is used for temperature sensor also. Refer to Presampling channel enable.
29–30 PREVAL0	Internal voltage selection for Presampling. These two bits select analog input voltage for presampling from the available four internal voltages for Internal precision channels (Channel 0 to 31). Refer to Presampling channel enable.
31 PRECONV	Convert Presampled value If bit PRECONV is set, presampling is followed by the conversion. Sampling will be bypassed and conversion of presampled data will be done. This bit has no effect on conversion of a channel when presampling on that channel is disabled (for example, PSR*x*[PRES*y*] = 0 , where *x* = register index and *y* = channel number).

43.5.13 Presampling register 0 (ADC_PSR0)

See the chip configuration details for the availability of this register.

Address: 0h base + 84h offset = 84h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ADC_PSR0 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 PRES15	Presampling enable for channel 15. When set, presampling is enabled for channel 15.
17 PRES14	Presampling enable for channel 14. When set, presampling is enabled for channel 14.
18 PRES13	Presampling enable for channel 13. When set, presampling is enabled for channel 13.
19 PRES12	Presampling enable for channel 12. When set, presampling is enabled for channel 12.
20 PRES11	Presampling enable for channel 11. When set, presampling is enabled for channel 11.
21 PRES10	Presampling enable for channel 10. When set, presampling is enabled for channel 10.
22 PRES9	Presampling enable for channel 9. When set, presampling is enabled for channel 9.
23 PRES8	Presampling enable for channel 8. When set, presampling is enabled for channel 8.

Table continues on the next page...

ADC_PSR0 field descriptions (continued)

Field	Description
24 PRES7	Presampling enable for channel 7. When set, presampling is enabled for channel 7.
25 PRES6	Presampling enable for channel 6. When set, presampling is enabled for channel 6.
26 PRES5	Presampling enable for channel 5. When set, presampling is enabled for channel 5.
27 PRES4	Presampling enable for channel 4. When set, presampling is enabled for channel 4.
28 PRES3	Presampling enable for channel 3. When set, presampling is enabled for channel 3.
29 PRES2	Presampling enable for channel 2. When set, presampling is enabled for channel 2.
30 PRES1	Presampling enable for channel 1. When set, presampling is enabled for channel 1.
31 PRES0	Presampling enable for channel 0. When set, presampling is enabled for channel 0.

43.5.14 Conversion Timing Register 0 (ADC_CTR0)

Conversion timing register. CTR0 is associated with channels 0 to 31.

NOTE

This register may contain fields for channels that have not been implemented. See the chip-specific information to find which channels are applicable.

Address: 0h base + 94h offset = 94h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

ADC_CTR0 field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 INPSAMP	Configuration of sampling phase duration.

Table continues on the next page...

ADC_CTR0 field descriptions (continued)

Field	Description
	This value tells the sample period duration in terms of the SAR Controller operating clock. The minimum acceptable value is 8. Setting a lower value automatically takes 8 cycles. **NOTE:** The Bandgap voltage sampling time is controlled by CTR0[INPSAMP]. CTR0[INPSAMP] is also used for the external channel sample time. When the user software needs to sample the Bandgap voltage, it must change the CTR0[INPSAMP] value to allow for a longer time while the Bandgap is being sampled, then change its value back to the normal value for sampling external channels.

43.5.15 Conversion Timing Register 1 (ADC_CTR1)

Please see the chip-specific configuration information as all channels may not be available in all ADC instances.

Address: 0h base + 98h offset = 98h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																								INPSAMP

ADC_NCMR0 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 CH15	Normal sampling enable for channel 15. When set, normal sampling is enabled for channel 15.
17 CH14	Normal sampling enable for channel 14. When set, normal sampling is enabled for channel 14.
18 CH13	Normal sampling enable for channel 13. When set, normal sampling is enabled for channel 13.
19 CH12	Normal sampling enable for channel 12. When set, normal sampling is enabled for channel 12.
20 CH11	Normal sampling enable for channel 11. When set, normal sampling is enabled for channel 11.
21 CH10	Normal sampling enable for channel 10. When set, normal sampling is enabled for channel 10.
22 CH9	Normal sampling enable for channel 9.

Table continues on the next page...

ADC_NCMR0 field descriptions (continued)

Field	Description
	When set, normal sampling is enabled for channel 9.
23 CH8	Normal sampling enable for channel 8. When set, normal sampling is enabled for channel 8.
24 CH7	Normal sampling enable for channel 7. When set, normal sampling is enabled for channel 7.
25 CH6	Normal sampling enable for channel 6. When set, normal sampling is enabled for channel 6.
26 CH5	Normal sampling enable for channel 5. When set, normal sampling is enabled for channel 5.
27 CH4	Normal sampling enable for channel 4. When set, normal sampling is enabled for channel 4.
28 CH3	Normal sampling enable for channel 3. When set, normal sampling is enabled for channel 3.
29 CH2	Normal sampling enable for channel 2. When set, normal sampling is enabled for channel 2.
30 CH1	Normal sampling enable for channel 1. When set, normal sampling is enabled for channel 1.
31 CH0	Normal sampling enable for channel 0. When set, normal sampling is enabled for channel 0.

43.5.17 Injected Conversion Mask Register 0 (ADC_JCMR0)

Enable bits of Injected Sampling for channel 0 to 31.

NOTE

This register may contain fields for channels that have not been implemented. See the chip-specific information to find which channels are applicable.

Address: 0h base + B4h offset = B4h

ADC_JCMR0 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 CH15	Injected sampling enable for channel 15. When set, injected sampling is enabled for channel 15.
17 CH14	Injected sampling enable for channel 14. When set, injected sampling is enabled for channel 14.
18 CH13	Injected sampling enable for channel 13. When set, injected sampling is enabled for channel 13.
19 CH12	Injected sampling enable for channel 12. When set, injected sampling is enabled for channel 12.
20 CH11	Injected sampling enable for channel 11. When set, injected sampling is enabled for channel 11.
21 CH10	Injected sampling enable for channel 10. When set, injected sampling is enabled for channel 10.
22 CH9	Injected sampling enable for channel 9. When set, injected sampling is enabled for channel 9.
23 CH8	Injected sampling enable for channel 8. When set, injected sampling is enabled for channel 8.
24 CH7	Injected sampling enable for channel 7. When set, injected sampling is enabled for channel 7.
25 CH6	Injected sampling enable for channel 6. When set, injected sampling is enabled for channel 6.
26 CH5	Injected sampling enable for channel 5. When set, injected sampling is enabled for channel 5.
27 CH4	Injected sampling enable for channel 4. When set, injected sampling is enabled for channel 4.
28 CH3	Injected sampling enable for channel 3. When set, injected sampling is enabled for channel 3.
29 CH2	Injected sampling enable for channel 2. When set, injected sampling is enabled for channel 2.

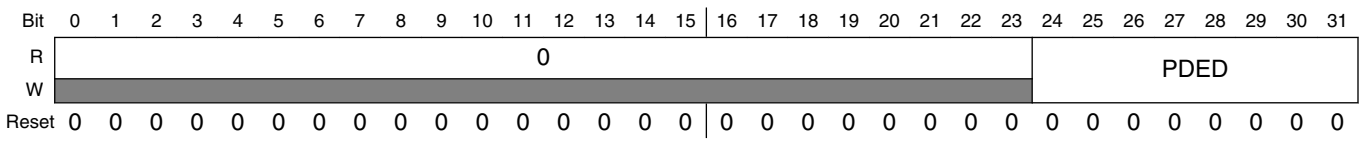
Table continues on the next page...

ADC_JCMR0 field descriptions (continued)

Field	Description
30 CH1	Injected sampling enable for channel 1. When set, injected sampling is enabled for channel 1.
31 CH0	Injected sampling enable for channel 0. When set, injected sampling is enabled for channel 0.

43.5.18 Power Down Exit Delay Register (ADC_PDEDR)

Address: 0h base + C8h offset = C8h



ADC_PDEDR field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 PDED	The delay between the power down bit reset and the start of conversion. The power down delay is calculated as (PDED x 1/[ADC_clock_frequency]).

43.5.19 Channel Data Register *n* (Precision Channels) (ADC_CDR*n*)

Note

It is important to note that the content of the CDATA field is affected by the setting of the ADC_MCR[WLSIDE] field, which controls whether the data is left aligned or right aligned. When ADC_MCR[WLSIDE]=1 (data to be left aligned), the CDATA field is left aligned from bit 16 to bit (16 + resolution - 1). When ADC_MCR[WLSIDE]=0 (data to be right aligned), the CDATA field is right aligned from bit (32-resolution) to bit 31. All other fields are unaffected.

Address: 0h base + 100h offset + (4d × i), where i=0d to 15d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0												VALID	OVERW	RESULT	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	CDATA															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ADC_CDR*n* field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 VALID	Used to notify when the data is valid (a new value has been written). It is automatically cleared when data is read.

Table continues on the next page...

ADC_CDR*n* field descriptions (continued)

Field	Description
13 OVERW	Overwrite data Used to notify when a conversion data is overwritten by a newer result. The new data is written or discarded according to the OWREN bit of MCR register.
14–15 RESULT	These two bits reflect the mode of conversion for the corresponding channel. 00 Data is a result of Normal conversion mode 01 Data is a result of Injected conversion mode 10 Data is a result of CTU conversion mode 11 Reserved
16–31 CDATA	Converted Data 11:0. **Note:** It is important to note that the content of the CDATA field is affected by the setting of the ADC_MCR[WLSIDE] field, which controls whether the data is left aligned or right aligned. When ADC_MCR[WLSIDE]=1 (data to be left aligned), the CDATA field is left aligned from bit 16 to bit (16 + resolution - 1). When ADC_MCR[WLSIDE]=0 (data to be right aligned), the CDATA field is right aligned from bit (32-resolution) to bit 31. All other fields are unaffected.

43.5.20 Threshold Register (ADC_THRHLR*n*)

Address: 0h base + 280h offset + (4d × i), where i=0d to 11d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0				THRH												0				THRL

ADC_THRHLR*n* field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–15 THRH	High threshold value for channel x.
16–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 THRL	Low threshold value for channel x.

43.5.21 Channel Watchdog Select Register 0 (ADC_CWSELR0)

WSEL_CHn[3:0] bit field: Selects the threshold register which provides the values to be used for upper and lower thresholds for channel n.

NOTE

This register may contain fields for channels that have not been implemented. See the chip-specific information to find which channels are applicable.

Address: 0h base + 2B0h offset = 2B0h

Bit	0–3	4–7	8–11	12–15	16–19	20–23	24–27	28–31

ADC_AWORR0 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 AWOR_CH15	Analog watchdog out of range for channel 15. When set, indicates the converted data is out of range for channel 15.
17 AWOR_CH14	Analog watchdog out of range for channel 14. When set, indicates the converted data is out of range for channel 14.
18 AWOR_CH13	Analog watchdog out of range for channel 13. When set, indicates the converted data is out of range for channel 13.
19 AWOR_CH12	Analog watchdog out of range for channel 12. When set, indicates the converted data is out of range for channel 12.
20 AWOR_CH11	Analog watchdog out of range for channel 11. When set, indicates the converted data is out of range for channel 11.
21 AWOR_CH10	Analog watchdog out of range for channel 10. When set, indicates the converted data is out of range for channel 10.
22 AWOR_CH9	Analog watchdog out of range for channel 9. When set, indicates the converted data is out of range for channel 9.
23 AWOR_CH8	Analog watchdog out of range for channel 8. When set, indicates the converted data is out of range for channel 8.
24 AWOR_CH7	Analog watchdog out of range for channel 7. When set, indicates the converted data is out of range for channel 7.
25 AWOR_CH6	Analog watchdog out of range for channel 6. When set, indicates the converted data is out of range for channel 6.
26 AWOR_CH5	Analog watchdog out of range for channel 5. When set, indicates the converted data is out of range for channel 5.
27 AWOR_CH4	Analog watchdog out of range for channel 4. When set, indicates the converted data is out of range for channel 4.

Table continues on the next page...

ADC_AWORR0 field descriptions (continued)

Field	Description
28 AWOR_CH3	Analog watchdog out of range for channel 3. When set, indicates the converted data is out of range for channel 3.
29 AWOR_CH2	Analog watchdog out of range for channel 2. When set, indicates the converted data is out of range for channel 2.
30 AWOR_CH1	Analog watchdog out of range for channel 1. When set, indicates the converted data is out of range for channel 1.
31 AWOR_CH0	Analog watchdog out of range for channel 0. When set, indicates the converted data is out of range for channel 0.

43.5.25 Self Test Configuration Register 1 (ADC_STCR1)

Address: 0h base + 340h offset = 340h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

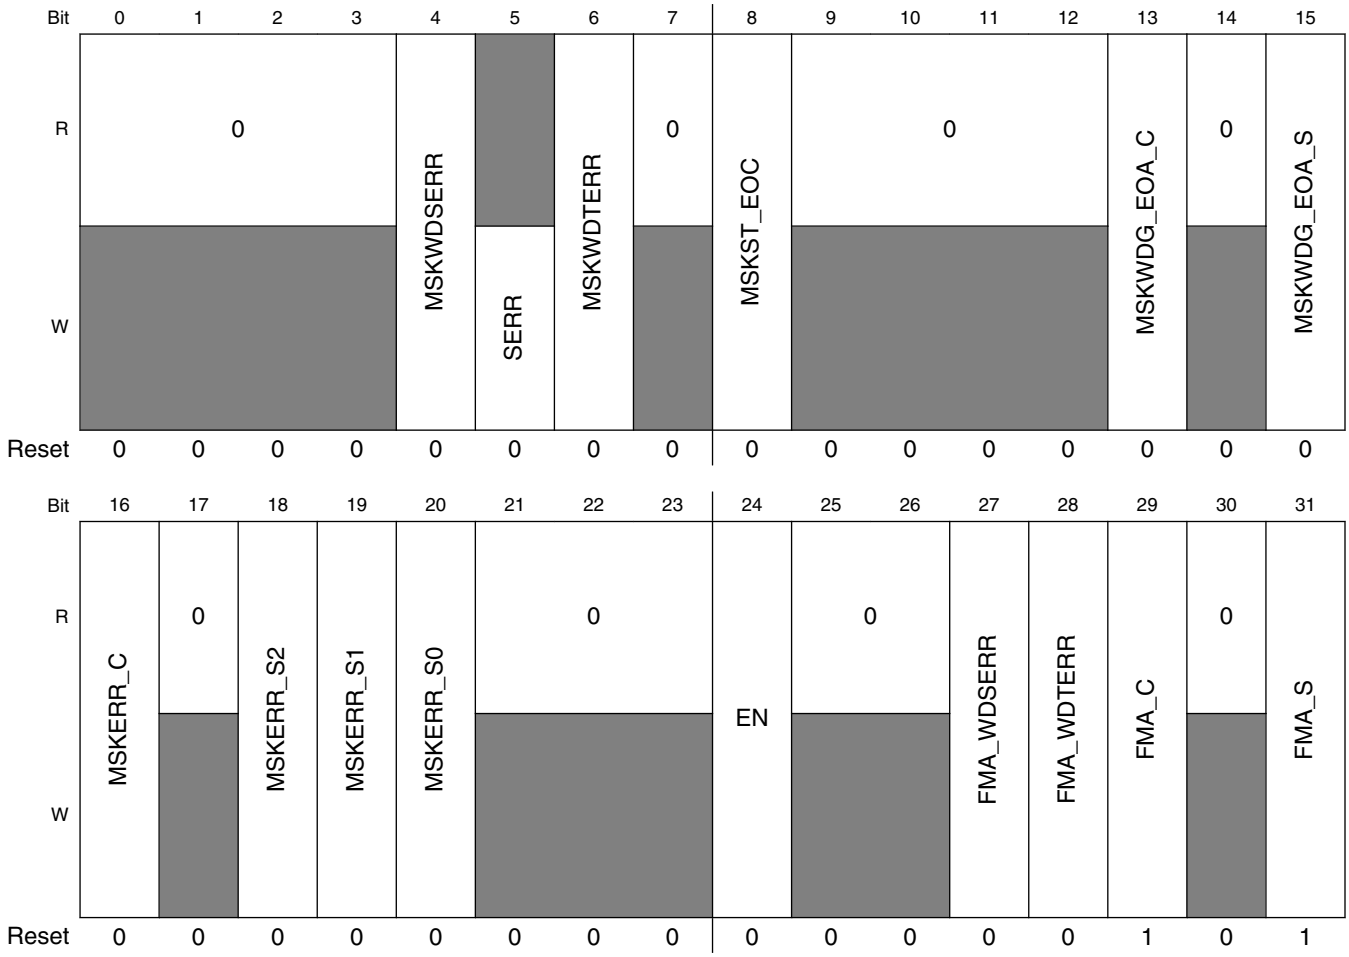
ADC_STCR1 field descriptions

Field	Description
0–7 INPSAMP_C	Sampling phase duration for the test conversions related to self test algorithm C. Minimum value should be set as per default (18h). Maximum can be FFh.
8–15 Reserved	This field is reserved.
16–23 INPSAMP_S	Sampling phase duration for the test conversions related to self test algorithm S. Minimum value should be set as per default (25h). Maximum can be FFh.
24–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 Reserved	This field is reserved.

43.5.26 Self Test Configuration Register 2 (ADC_STCR2)

Address: 0h base + 344h offset = 344h



ADC_STCR2 field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 MSKWDSERR	Interrupt enable (STSR1[WDSERR] status bit) 0 Interrupt disabled 1 Enables the STSR1[WDSERR] status bit to generate an interrupt indication.
5 SERR	Error fault injection bit (write only). Writing 1 to this bit sets the STSR1[ERRx] status bits once only. Reading always returns 0. Setting this bit does not affect any of the self test data registers.
6 MSKWDTERR	Interrupt enable (STSR[WDTERR] status bit) 0 Interrupt disabled 1 Enables the STSR1[WDTERR] status bit to generate an interrupt indication.

Table continues on the next page...

ADC_STCR2 field descriptions (continued)

Field	Description
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 MSKST_EOC	Interrupt Enable bit for STSR2[ST_EOC] 0 Interrupt disabled 1 Enables the STSR1[ST_EOC] status bit to generate an interrupt indication. (IMR[MSKEOC] must also be enabled.)
9–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 MSKWDG_EOA_C	Interrupt enable (WDG_EOA_C status bit) 0 Interrupt disabled 1 Enables the STSR1[WDG_EOA_C] status bit to generate an interrupt indication.
14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 MSKWDG_EOA_S	Interrupt enable (WDG_EOA_S status bit) 0 Interrupt disabled 1 Enables the STSR1[WDG_EOA_S] status bit to generate an interrupt indication.
16 MSKERR_C	Interrupt enable (ERR_C status bit) 0 Interrupt disabled 1 Enables the STSR1[ERR_C] status bit to generate an interrupt indication.
17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 MSKERR_S2	Interrupt enable (ERR_S2 status bit) 0 Interrupt disabled 1 Enables the STSR1[ERR_S2] status bit to generate an interrupt indication.
19 MSKERR_S1	Interrupt enable (ERR_S1 status bit) 0 Interrupt disabled 1 Enables the STSR1[ERR_S1] status bit to generate an interrupt indication.
20 MSKERR_S0	Interrupt enable (ERR_S0 status bit) 0 Interrupt disabled 1 Enables the STSR1[ERR_S0] status bit to generate an interrupt indication.
21–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 EN	Self testing channel enable. The TEST conversions are enabled. Enables the TEST channel only in CPU mode. This bit should be set before starting the normal conversion and should not be changed while conversion is ongoing. This bit should be reset only after end of conversion for the last self test channel has been received. 0 Disabled 1 Enabled
25–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

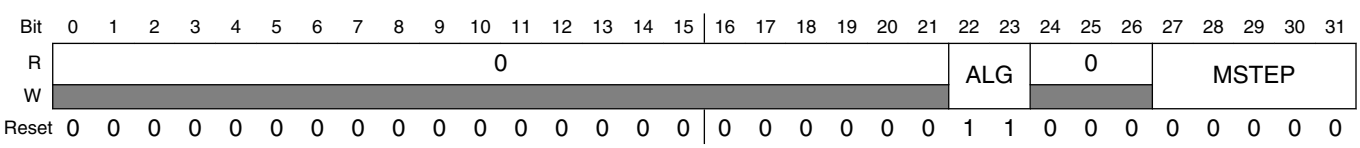
ADC_STCR2 field descriptions (continued)

Field	Description
27 FMA_WDSERR	Fault mapping for the Watchdog Sequence error. By default a failure on the watchdog sequence is mapped on the NCF fault line. 0 NCF mapping 1 CF mapping
28 FMA_WDTERR	Fault mapping for the Watchdog Timer error. By default a failure on the watchdog sequence is mapped on the NCF fault line. 0 NCF mapping 1 CF mapping
29 FMA_C	Fault mapping for self test algorithm C. By default a failure on the self test C algorithm is mapped on the CF fault line. 0 NCF mapping 1 CF mapping
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 FMA_S	Fault mapping for the self test algorithm BGAP. By default a failure on the Supply algorithm is mapped on the CF fault line. 0 NCF mapping 1 CF mapping

43.5.27 Self Test Configuration Register 3 (ADC_STCR3)

This register defines ADC self testing capabilities in CPU mode or CTU mode.

Address: 0h base + 348h offset = 348h



ADC_STCR3 field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–23 ALG	Algorithm scheduling. ONE-SHOT mode algorithm scheduling:

Table continues on the next page...

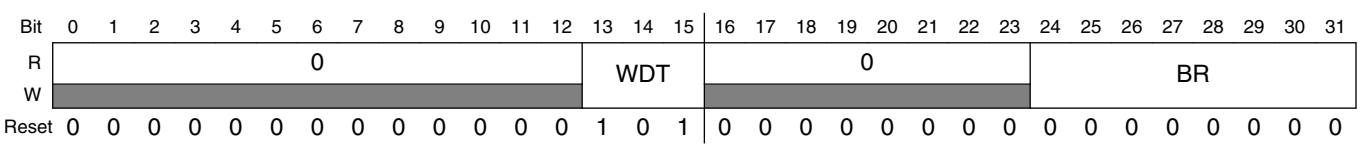
ADC_STCR3 field descriptions (continued)

Field	Description
	• 00: Algorithm S (single step=MSTEP) • 01: Reserved • 10: Algorithm C (single step=MSTEP) • 11: Algorithm S (default) For test/debug purposes. SCAN mode algorithm scheduling: • 00: Algorithm S • 01: Reserved • 10: Algorithm C • 11: Algorithm S + Algorithm C (default) The baud rate for the execution of the selected algorithm is defined by the STBRR register.
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 MSTEP	One shot mode: Current step for Algorithm S or Algorithm C. • MSTEP = 0 to (NUM_SUPPLY_STEPS-1) for algorithm S • MSTEP = 0 to (NUM_C_STEPS-1) for algorithm C Scan mode: This field is not used in scan mode as always single step execution (interleaved mode) is performed. It should be programmed to zero in scan mode. **NOTE:** All unused valued are RESERVED and should not be used.

43.5.28 Self Test Baud Rate Register (ADC_STBRR)

Used to set the baud rate for the selected baud rate in SCAN mode as well as the watchdog timer value.

Address: 0h base + 34Ch offset = 34Ch



ADC_STBRR field descriptions

Field	Description
0–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–15 WDT	The watchdog timer value is used to monitor that the algorithm sequence is correctly executed within the safe time period. The self testing watchdog is enabled setting the STAWxR[WDTE] control bits. Default value is 10 ms. A fixed pre-scaler runs on the ADCdig clock (80 MHz). (Prescaler value is fixed at 1024). 000 0.1 ms ((0008h * Prescaler) cycles at 80 MHz) 001 0.5 ms ((0027h * Prescaler) cycles at 80 MHz)

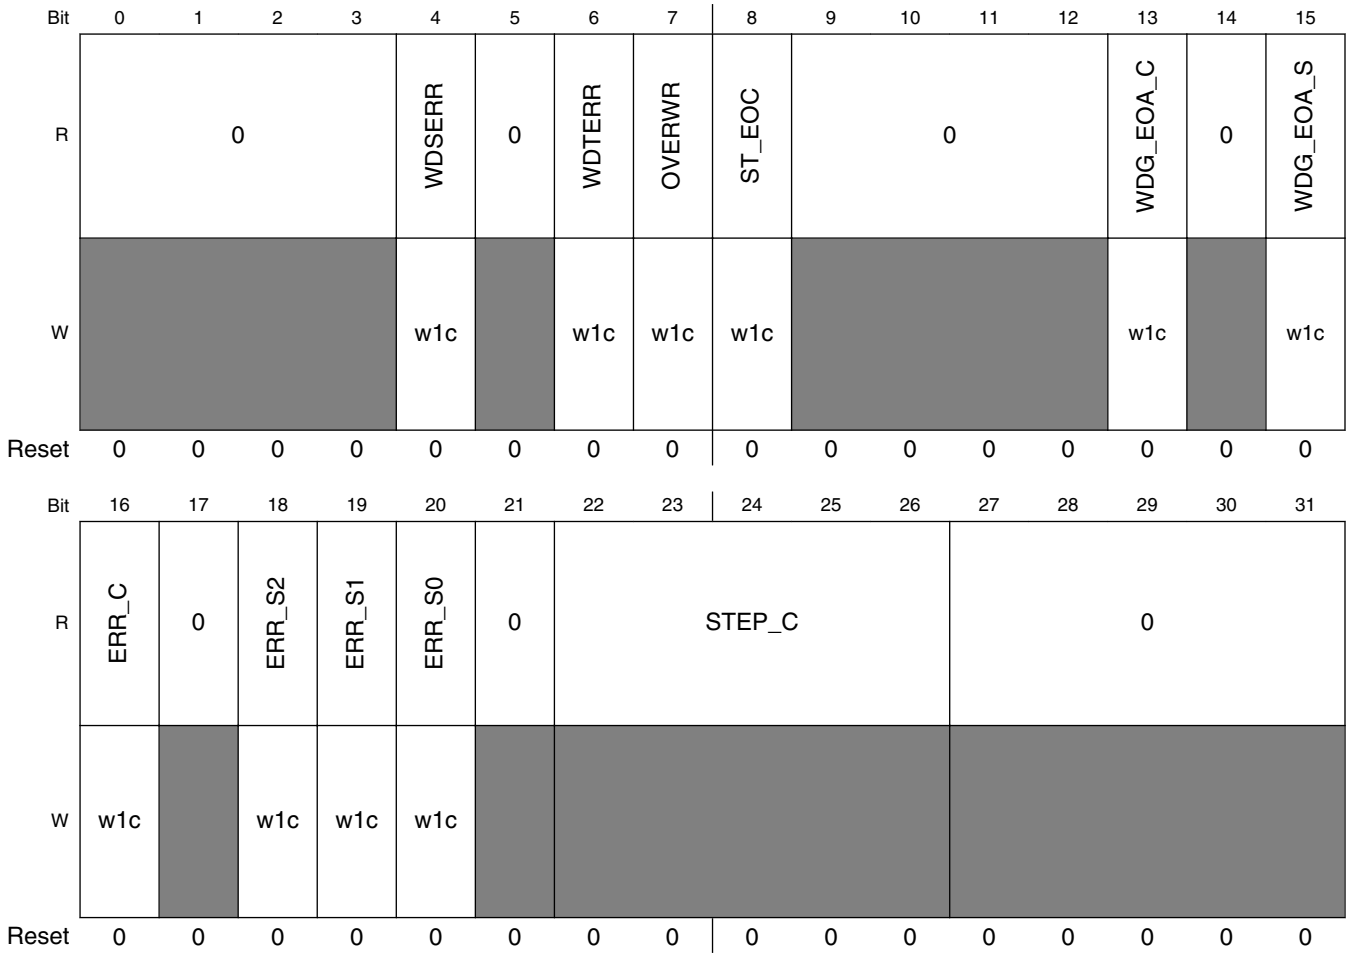
Table continues on the next page...

ADC_STBRR field descriptions (continued)

Field	Description
	010 1 ms ((004Eh * Prescaler) cycles at 80 MHz) 011 2 ms ((009Ch * Prescaler) cycles at 80 MHz) 100 5 ms ((0187h * Prescaler) cycles at 80 MHz) 101 10 ms ((030Dh * Prescaler) cycles at 80 MHz) 110 20 ms ((061Ah * Prescaler) cycles at 80 MHz) 111 50 ms ((0F42h * Prescaler) cycles at 80 MHz)
16–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 BR	Baud rate for the selected algorithm in SCAN mode (MCR[MODE] = 1). 00h Max scheduling rate (NOMINAL rate) ... FFh Min scheduling rate (NOMINAL rate scaled by 255) This field should be programmed when ST_EN is zero i.e. before enabling self test channel.

43.5.29 Self Test Status Register 1 (ADC_STSR1)

Address: 0h base + 350h offset = 350h



ADC_STSR1 field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 WDSERR	Watchdog sequence error of the ADC sub-system (check for algorithm step sequence). The WDSERR status bit is cleared writing 1. A 0 write is an invariant operation. It generates an interrupt if enabled (STCR2[MSKWDSERR] = 1). It provides the fault indication to an outside module such as the FCCU, asserting the Critical type or Non-Critical type lines according to the STCR2[FMA_WDSERR] mapping. **NOTE:** This bit is set only if STAWxR[WDTE] = '1'. 0 No failure 1 Failure occurred
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

ADC_STSR1 field descriptions (continued)

Field	Description
6 WDTERR	Watchdog timer error of the ADC sub-system (algorithm check for completion within safe time). The WDTERR status bit is cleared writing 1. A 0 write is an invariant operation. It generates an interrupt if enabled (STCR2[MSKWDTERR] = 1). It provides the fault indication to an outside module such as the FCCU, asserting the Critical type or Non-Critical type lines according to the STCR2[FMA_WDTERR] mapping. 0 No failure 1 Failure occurred
7 OVERWR	Overwrite error. Used to notify when the STSR1[ERRx] bit is overwritten by a newer one. The OVERWR status bit is cleared writing 1. A 0 write is an invariant operation. The new error status is written or discarded according to the MCR[OWREN] bit value. To avoid OVERWR indication, the ERRx status bit must be cleared (via software).
8 ST_EOC	Self Test EOC Bit. This bit is set along with EOC bit when end_of_conversion signal is received from ADC analog for self test channel. The ST_EOC status bit is cleared by writing 1b. A 0b write is an invariant operation. It generates an interrupt if enabled by STCR2[MSKST_EOC]. (Also, IMR[MSKEOC] has to be enabled.)
9–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 WDG_EOA_C	This bit indicates that Algorithm C has been completed. This bit is generated after the last STEP of algorithm C is executed. The WDG_EOA_C status bit is cleared by writing 1. A 0 write is an invariant operation. It generates an interrupt if enabled (STCR2[MSKWDG_EOA_C] = 1). This bit is set only if STAW4R[WDTE] = 1. For CTU conversions, this bit is significant only for Burst mode of operation.
14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 WDG_EOA_S	This bit indicates that Algorithm S has been completed. This bit is generated after the last STEP of algorithm S is executed. The WDG_EOA_S status bit is cleared writing 1. A 0 write is an invariant operation. It generates an interrupt if enabled (STCR2[MSKWDG_EOA_S] = 1). This bit is set only if STAW0R[WDTE] = ‘1’. For CTU conversions, this bit is significant only for Burst mode of operation.
16 ERR_C	Indicates an error on the self testing channel (algorithm C). The ERR_C status bit is cleared writing 1b. A 0b write is an invariant operation. It generates an interrupt if enabled (STCR2[MSKERR_C] = 1). It provides the fault indication to an outside module such as the FCCU, asserting the programmed fault line (STCR2[FMAx]). The ERR_C bit can be also set via SW (fault injection) writing 1b into the STCR2[SERR] bit. In this case the Critical type or Non-Critical type lines are asserted according to the STCR2[FMAx] mapping. 0 No C-algorithm ERROR 1 C-algorithm ERROR occurred
17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 ERR_S2	Indicates an error on the self testing channel (algorithm SUPPLY, step2). The ERR_S2 status bit is cleared by writing a 1b. A 0b write is an invariant operation. It generates an interrupt (“ipi_int_er” line) if enabled (STCR2[MSKERR_S2] = 1). It provides the fault indication to an outside module such as the FCCU, asserting the programmed fault line (STCR2[FMAx]). The ERR_S2 bit can be also set via SW (fault injection) writing 1b into the STCR2[SERR] bit. In this case the Critical / Non-Critical lines are asserted according to the STCR2[FMAx] mapping. 0 No ERROR occurred on the sampled signal 1 ERROR occurred on the sampled signal

Table continues on the next page...

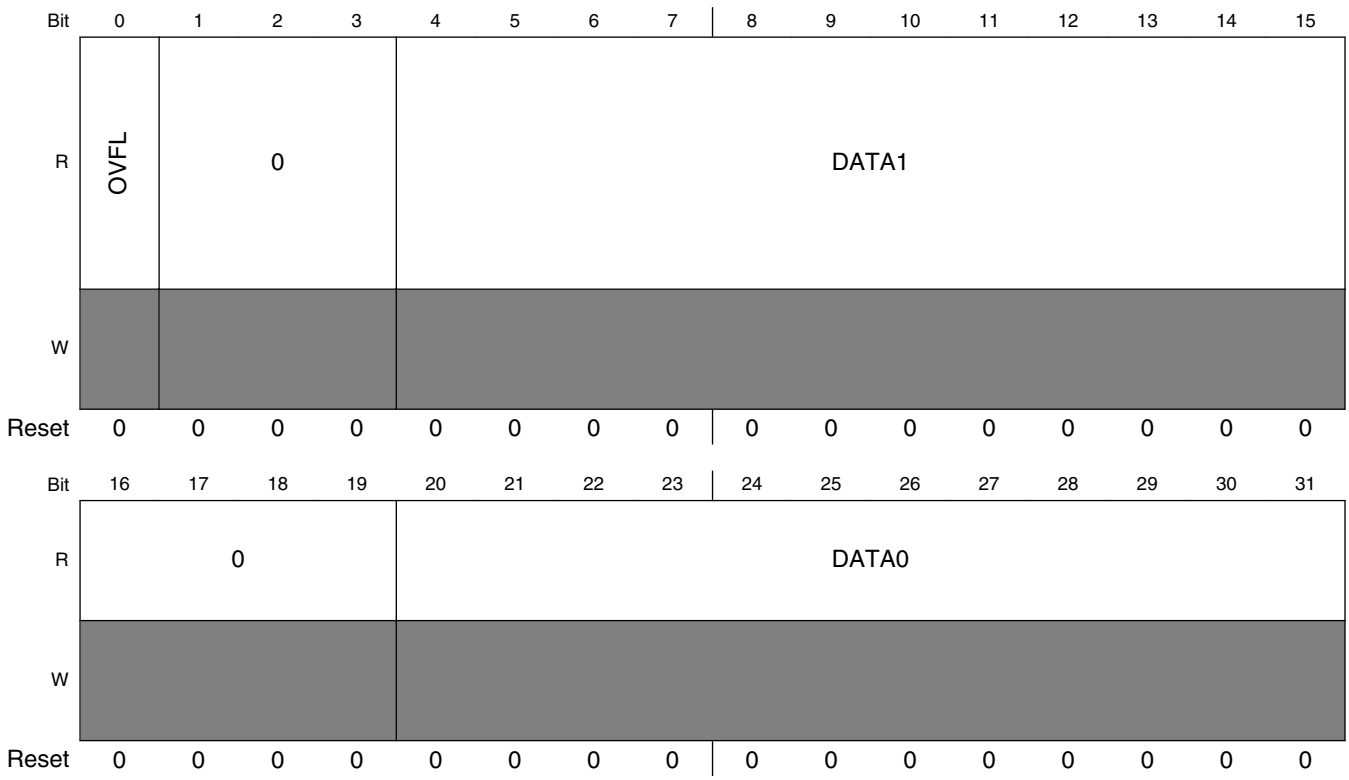
ADC_STSR1 field descriptions (continued)

Field	Description
19 ERR_S1	Indicates an error on the self testing channel (algorithm SUPPLY, step1). The ERR_S1 status bit is cleared writing 1. A 0 write is an invariant operation. It generates an interrupt if enabled (STCR2[MSKERR_S1] = 1). It provides the fault indication to an outside module such as the FCCU, asserting the programmed fault line (STCR2[FMAx]). The ERR_S1 bit can be also set via SW (fault injection) writing 1b into the STCR2[SERR] bit. In this case the Critical / Non-Critical lines are asserted according to the STCR2[FMAx] mapping. 0 No VDD ERROR 1 VDD ERROR occurred
20 ERR_S0	Indicates an error on the self testing channel (algorithm SUPPLY, step0). The ERR_S0 status bit is cleared writing 1. A 0 write is an invariant operation. It generates an interrupt if enabled (STCR2[MSKERR_S0] = 1). It provides the fault indication to an outside module such as the FCCU, asserting the programmed fault line (STCR2[FMAx]). The ERR_S0 bit can be also set via SW (fault injection) writing 1b into the STCR2[SERR] bit. In this case the Critical / Non-Critical type fault lines are asserted according to the STCR2[FMAx] mapping. 0 No VREF ERROR 1 VREF ERROR occurred
21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–26 STEP_C	Step of the algorithm C when an ERR_C has occurred. 0.. (NUM_C_STEPS-1) => algorithm C
27–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

43.5.30 Self Test Status Register 2 (ADC_STSR2)

If MCR[OVERWR] bit is set, registers STSR2-4 are overwritten if another error occurs.

Address: 0h base + 354h offset = 354h



ADC_STSR2 field descriptions

Field	Description
0 OVFL	Overflow Bit This bit is set when the divisor is zero. Also, the STSR1[ERR_S1] bit is set if overflow occurs.
1–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–15 DATA1	Test channel converted data when the ERR_S1 has occurred. Algorithm S (step1) => fractional part of the ratio TEST(step1)/TEST (step0) = VDD/VBGAP
16–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 DATA0	Test channel converted data when the ERR_S1 has occurred. Algorithm S (step1) => integer part of the ratio TEST(step1)/TEST (step0) = VDD/VBGAP

43.5.31 Self Test Status Register 3 (ADC_STSR3)

If MCR[OVERWR] bit is set, registers STSR2-4 are overwritten if another error occurs.

Address: 0h base + 358h offset = 358h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

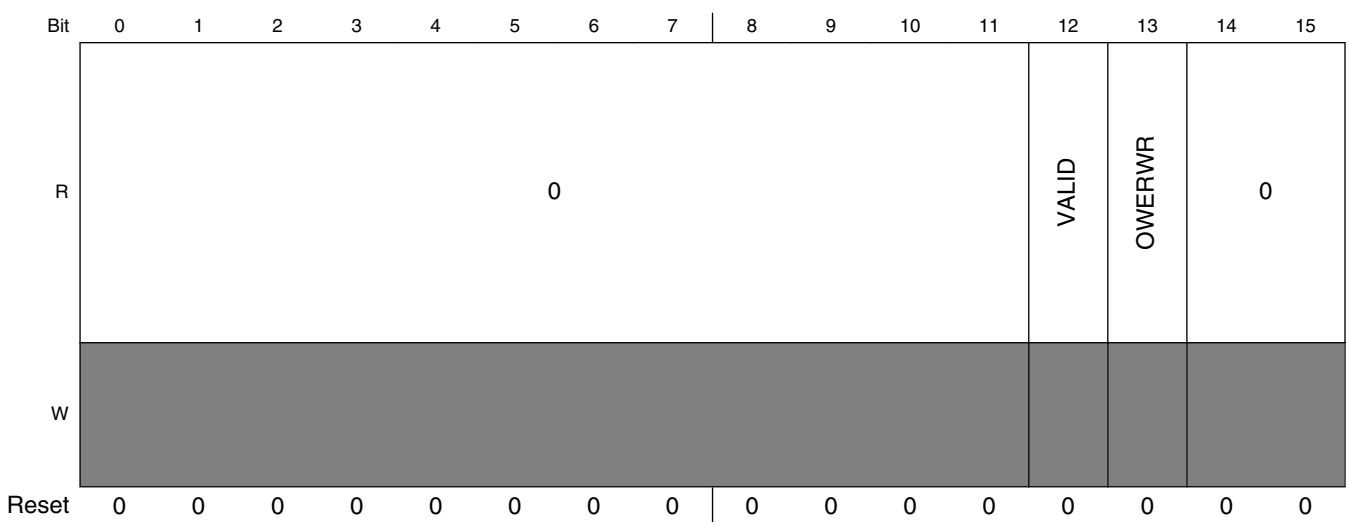
43.5.33 Self Test Data Register 1 (ADC_STDR1)

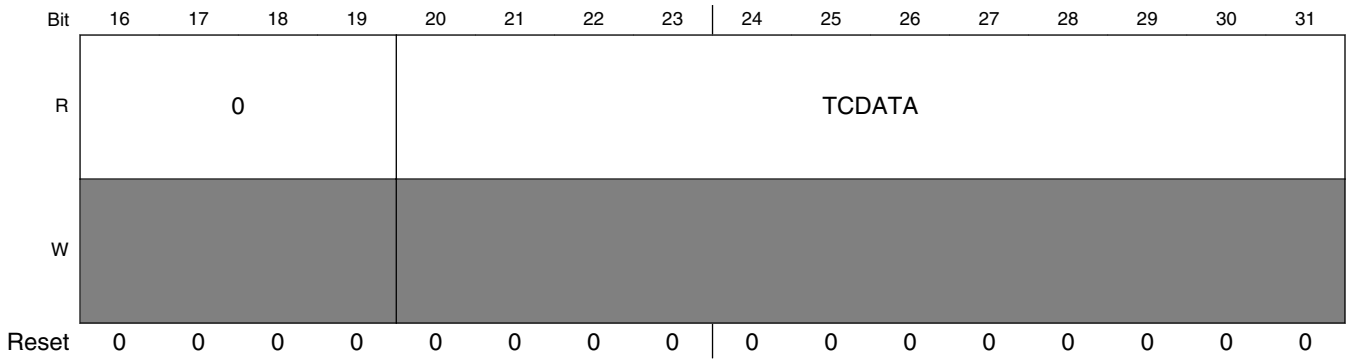
The ADC_STDR1 register contains the most current result data for conversions executed during ADC self test. Additionally, the register contains status bits to indicate whether result data has been read and whether existing conversion data has been overwritten by a newer result.

NOTE

- For Algorithm S step 1, the result data contained in this register is not the final step 1 result. The step 1 data is the conversion of the analog supply (VDDA). This VDDA conversion result is divided by the Algorithm S step 0 conversion data and the result is written to the ADC_STDR2 register.
- The conversion performed in Algorithm S Step 1 is not on the full scale analog supply. Instead, the voltage sampled is VDDA / 8. The pre-scaling is done to avoid issues that can occur in the analog portion of the ADC when VREFH = VDDA = 3.3 V, or VDDA is slightly higher than VREFH. The conversion result is multiplied by 8 at the internal stage of data processing before being written to this register to scale the result to the expected level.

Address: 0h base + 370h offset = 370h





ADC_STDR1 field descriptions

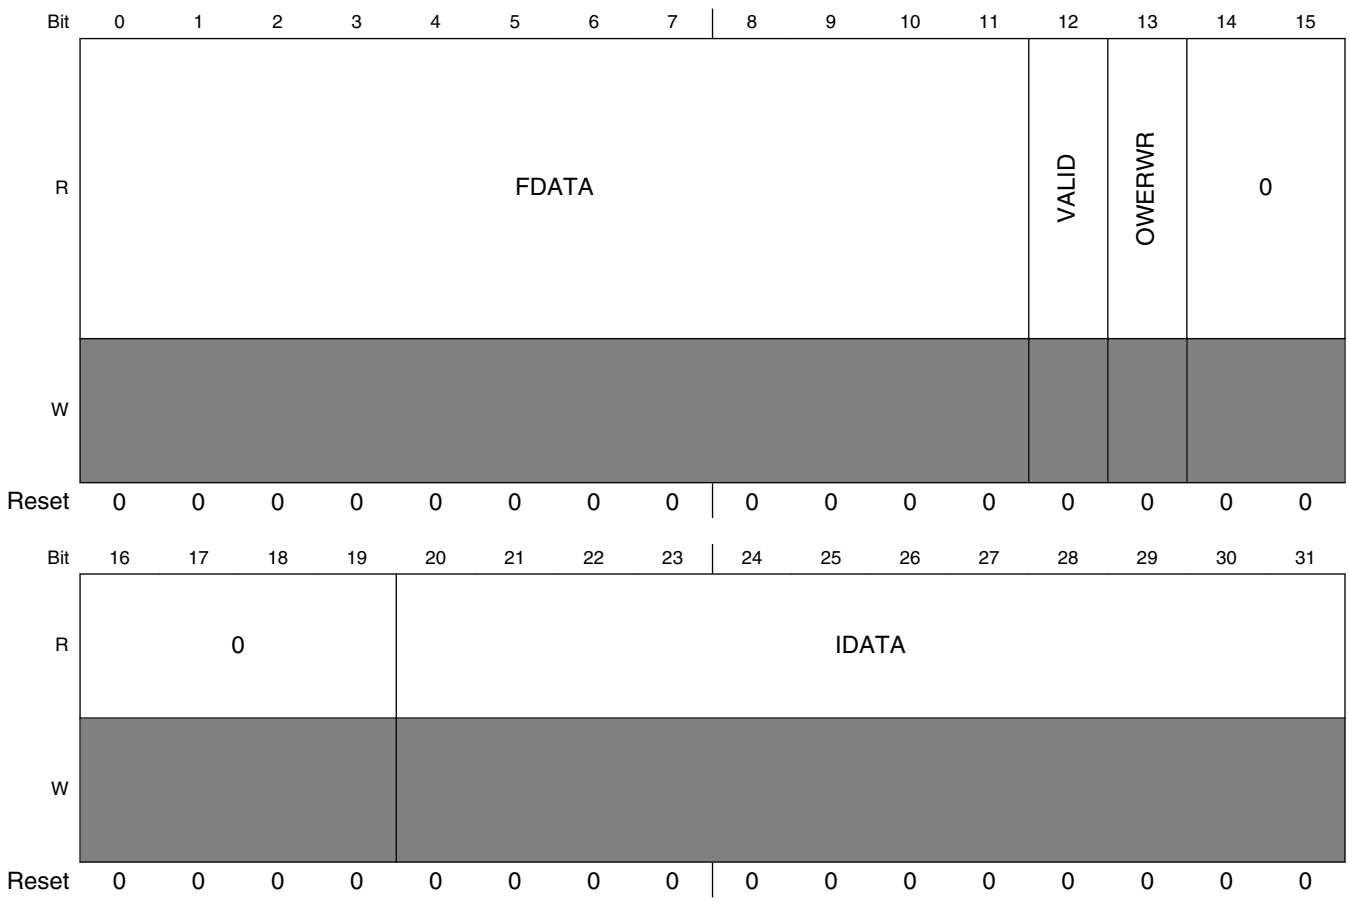
Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 VALID	Valid data. Used to notify when the data is valid (a new value has been written). It is automatically cleared when data is read.
13 OWERWR	Overwrite data. Used to notify when a conversion data is overwritten by a newer result. The new data is written or discarded according to the MCR[OWREN] bit value.
14–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 TCDATA	Test channel converted data. - Unsigned format for Supply Self test - 2's complement for Capacitive Self test

43.5.34 Self Test Data Register 2 (ADC_STDR2)

NOTE

If overflow error occurs for STEP1 of Algorithm-S, STDR2 is not written.

Address: 0h base + 374h offset = 374h



ADC_STDR2 field descriptions

Field	Description
0–11 FDATA	Fractional part of the ratio TEST(step1)/TEST (step0) = VDD/VBGAP for the algorithm S.
12 VALID	Valid data. Used to notify when the data is valid (a new value has been written). It is automatically cleared when data is read.
13 OWERWR	Overwrite data.

Table continues on the next page...

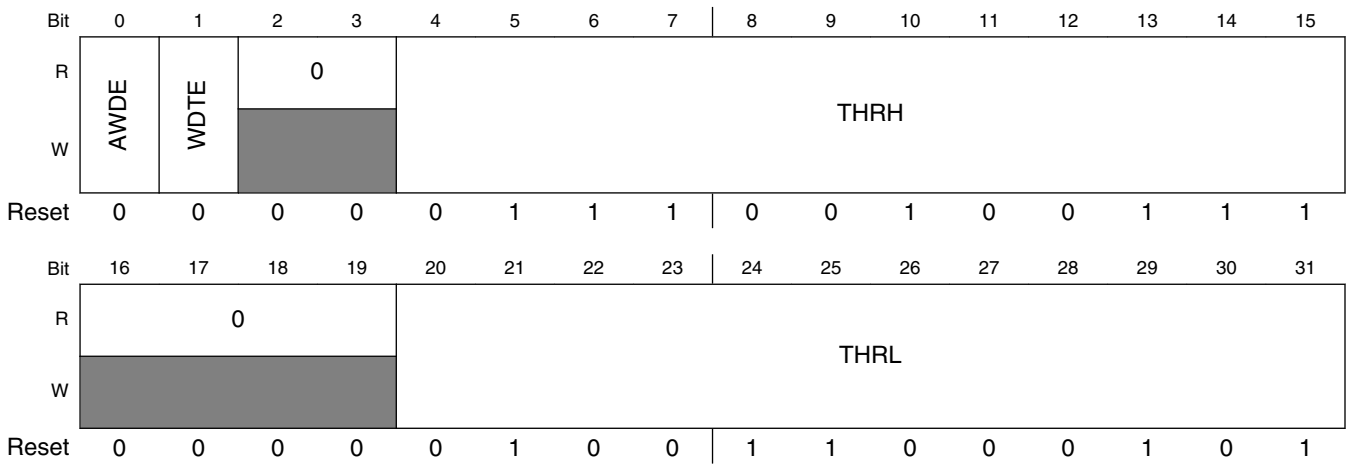
ADC_STDR2 field descriptions (continued)

Field	Description
	Used to notify when a conversion data is overwritten by a newer result. The new data is written or discarded according to the MCR[OWREN] bit value.
14–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 IDATA	Integer part of the ratio TEST(step1)/TEST (step0) = VDD/VBGAP for the algorithm S.

43.5.35 Self Test Analog Watchdog Register 0 (ADC_STAW0R)

This register provides control values associated with the ADC's supply self test step 0, which samples bandgap voltage.

Address: 0h base + 380h offset = 380h



ADC_STAW0R field descriptions

Field	Description
0 AWDE	Analog watchdog enable (related to the algorithm S (step 0)) Enables/disables the comparison of the conversion result from the ADC's supply self test step 0 to the thresholds contained in this register (THRH and THRL) 0 Disabled 1 Enabled
1 WDTE	Watchdog timer enable (related to the algorithm S) Enables/disables the watchdog timer monitoring function for all ADC supply self test steps. The watchdog timer verifies: • Correct sequence of the algorithm (step sequence) • Execution of the algorithm within the safe time period as defined by STBRR[WDT] As soon as the watchdog timer is enabled the algorithm execution must be detected within the safe time period. The watchdog timer is reset each time the algorithm restarts. This bit should be set only in scan mode.

Table continues on the next page...

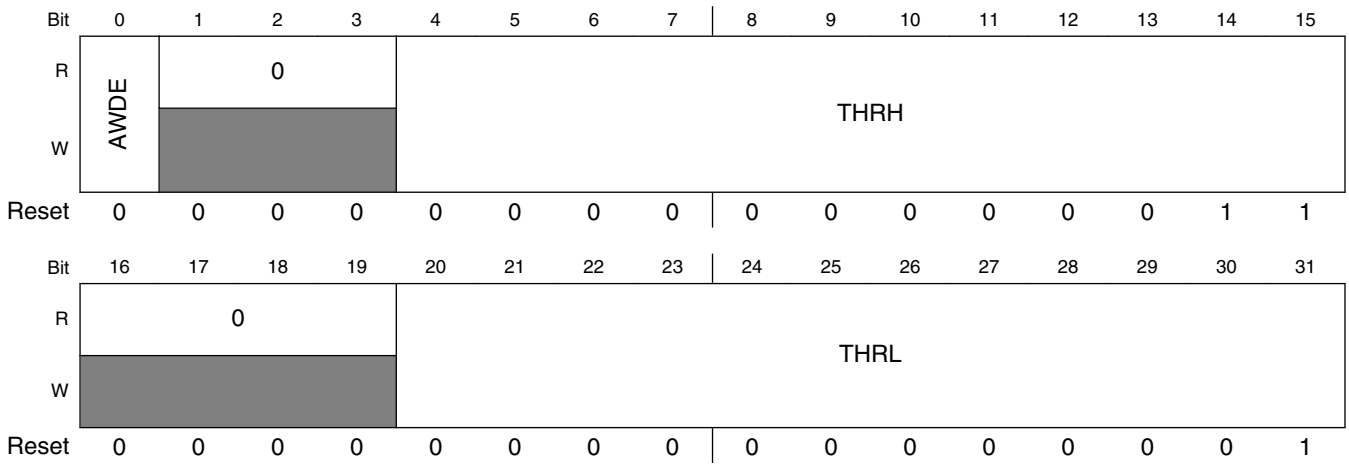
ADC_STAW0R field descriptions (continued)

Field	Description
	0 Disabled 1 Enabled
2–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–15 THRH	High threshold value for Algorithm S step 0 If the analog watchdog is enabled, the STSR1[ERRx] status bit is set if STDR1[TCDATA]) > THRH. **NOTE:** The recommended watchdog threshold values are set according to expected and tested results in a noise-controlled environment, i.e., introduction of noise from outside of the device minimized. The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments.
16–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 THRL	Low threshold value for Algorithm S step 0 If the analog watchdog is enabled, the STSR1[ERRx] status bit is set if STDR1[TCDATA]) < THRL. **NOTE:** The recommended watchdog threshold values are set according to expected and tested results in a noise-controlled environment, i.e., introduction of noise from outside of the device minimized. The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments.

43.5.36 Self Test Analog Watchdog Register 1A (ADC_STAW1AR)

This register contains values associated with the ADC's supply self test step 1, in which the analog supply (VDDA) is sampled and a fixed point division is performed, dividing the conversion result by the result from step 0 (bandgap voltage). The integer portion of the result is handled separately from the fractional part, i.e., they have separate data registers and threshold fields. Thresholds in this register are applied to the integer portion of the result. Thresholds in the ADC_STAW1BR register are applied to the fractional portion of the result.

Address: 0h base + 384h offset = 384h



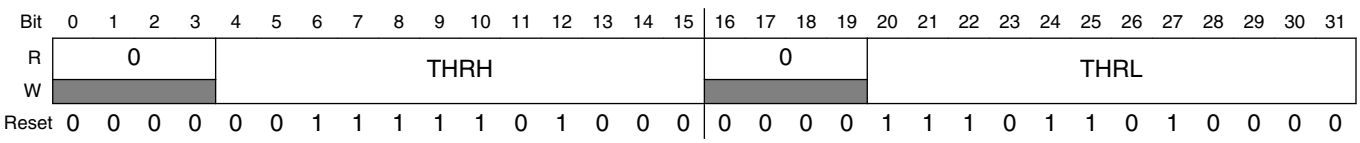
ADC_STAW1AR field descriptions

Field	Description
0 AWDE	Analog watchdog enable related to the algorithm S (step1).
1–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–15 THRH	High threshold value (integer part) for test channel for algorithm S (step 1) (unsigned coding). **NOTE:** The recommended watchdog threshold values are set according to expected and tested results in a noise-controlled environment, i.e., introduction of noise from outside of the device minimized. The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments.
16–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 THRL	Low threshold value (integer part) for test channel for algorithm S (step 1) (unsigned coding). **NOTE:** The recommended watchdog threshold values are set according to expected and tested results in a noise-controlled environment, i.e., introduction of noise from outside of the device minimized. The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments.

43.5.37 Self Test Analog Watchdog Register 1B (ADC_STAW1BR)

This register contains values associated with the ADC's supply self test step 1, in which the analog supply (VDDA) is sampled and a fixed point division is performed, dividing the conversion result by the result from step 0 (bandgap voltage). The integer portion of the result is handled separately from the fractional part, i.e., they have separate data registers and threshold fields. Thresholds in this register are applied to the fractional portion of the result. Thresholds in the ADC_STAW1AR register are applied to the integer portion of the result.

Address: 0h base + 388h offset = 388h



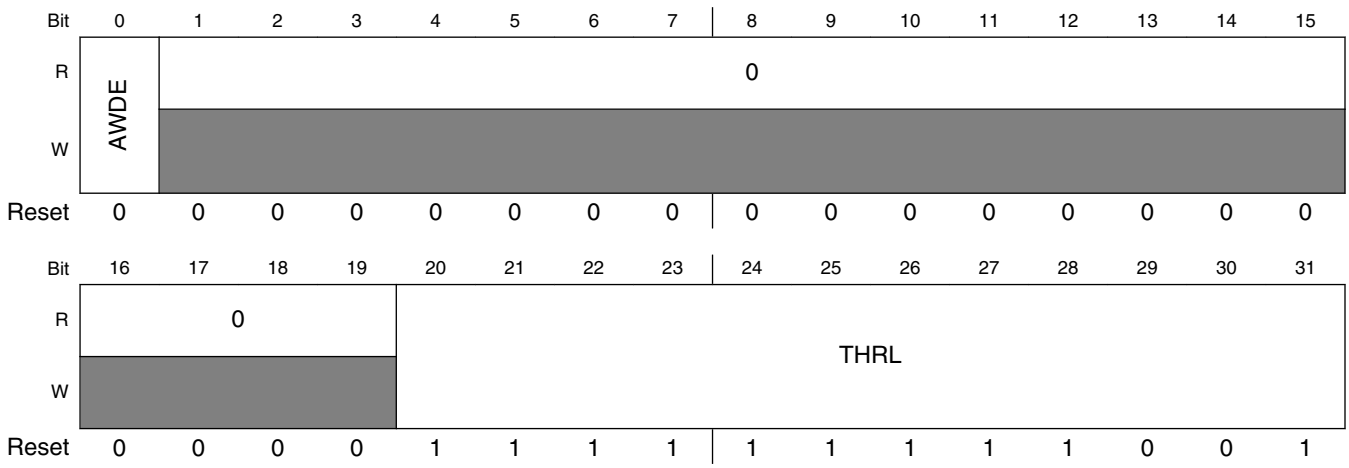
ADC_STAW1BR field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–15 THRH	High threshold value (fractional part) for test channel for algorithm S (step 1)(unsigned coding). **NOTE:** The recommended watchdog threshold values are set according to expected and tested results in a noise-controlled environment, i.e., introduction of noise from outside of the device minimized. The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments.
16–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 THRL	Low threshold value (fractional part) for test channel for algorithm S (step 1) (unsigned coding). **NOTE:** The recommended watchdog threshold values are set according to expected and tested results in a noise-controlled environment, i.e., introduction of noise from outside of the device minimized. The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments.

43.5.38 Self Test Analog Watchdog Register 2 (ADC_STAW2R)

This register contains control values associated with the ADC's supply self test step 2, in which the ADC's high reference voltage is sampled and converted. Note that there is no upper threshold value in this register since the conversion result should ideally be FFFh (12-bit) or 3FF (10-bit).

Address: 0h base + 38Ch offset = 38Ch



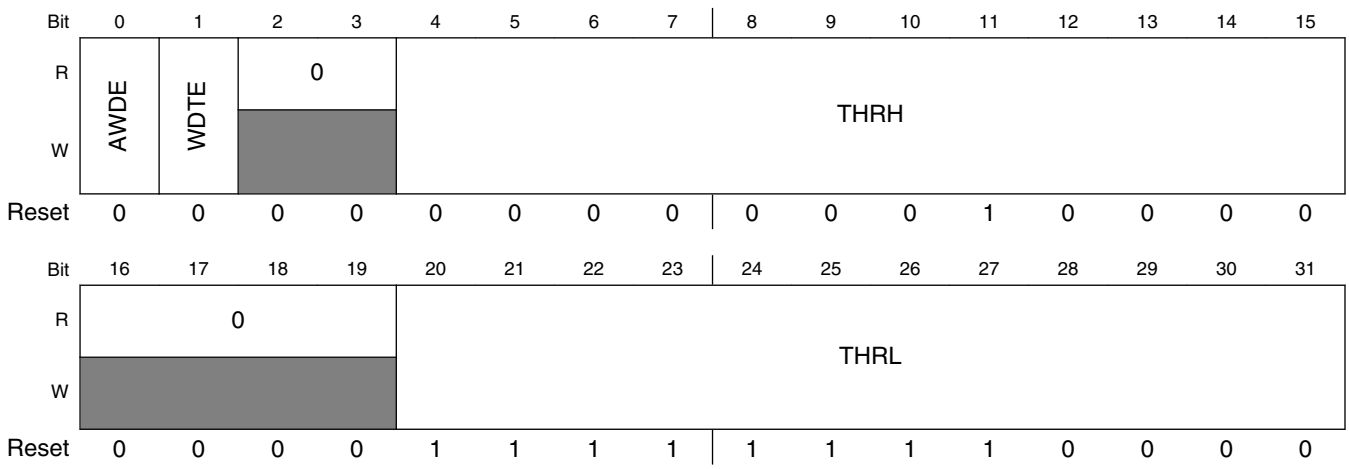
ADC_STAW2R field descriptions

Field	Description
0 AWDE	Analog watchdog enable related to the algorithm S (step2).
1–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 THRL	Low threshold value for channel x (unsigned coding). If the analog watchdog is enabled, the STSR1[ERR_S2] status bit is set if STDR1[TCDATA] < THRL. **NOTE:** The recommended watchdog threshold values are set according to expected and tested results in a noise-controlled environment, i.e., introduction of noise from outside of the device minimized. The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments.

43.5.39 Self Test Analog Watchdog Register 4 (ADC_STAW4R)

This register contains ADC self test configuration controls associated with the ADC's capacitive self test (also referred to as "Algorithm C") sequence, which samples voltages from the ADC's internal capacitor array. The watchdog enable fields (AWDE and WDTE) affect all Algorithm C steps; the threshold fields (THRH and THRL) fields are specific to Algorithm C Step 0.

Address: 0h base + 394h offset = 394h



ADC_STAW4R field descriptions

Field	Description
0 AWDE	Analog watchdog enable (related to the algorithm C) Enables/disables the analog watchdog monitoring function for all ADC capacitive self test steps. 0 Disabled 1 Enabled
1 WDTE	Watchdog timer enable (related to the algorithm C). Enables/disables the watchdog timer monitoring function for all ADC capacitive self test steps. The watchdog timer verifies: • Correct sequence of the algorithm (step sequence) • Execution of the algorithm within the safe time period as defined by STBRR[WDT] As soon as the watchdog timer is enabled, execution must be detected within the safe time period. The watchdog timer is reset each time the algorithm restarts. This bit should be set only in scan mode. 0 Disabled 1 Enabled
2–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–15 THRH	High threshold value for step 0 of C algorithm.

Table continues on the next page...

ADC_STAW4R field descriptions (continued)

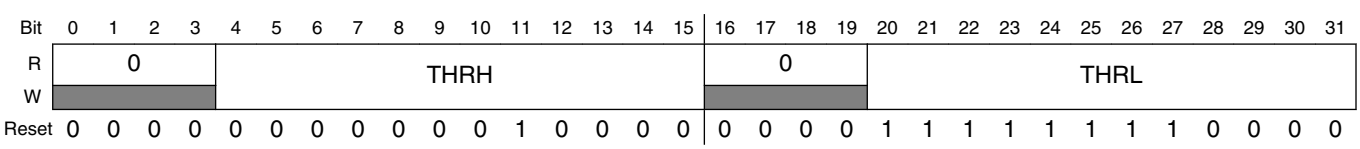
Field	Description
	This value is read by the ADC as twos-complement, but should be written positive. If the watchdog is enabled (STAW4R[AWDE] = 1) and STDR1[TCDATA] > STAW4R[THRH], then STSR1[ERR_C] is set. **NOTE:** The recommended watchdog threshold values are set according to expected and tested results in a noise-controlled environment (for example, introduction of noise from outside of the device minimized). The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments.
16–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 THRL	Low threshold value for step 0 of C algorithm. This value is read by the ADC as twos-complement, and it should be the negative of STAW4R[THRH]. If the watchdog is enabled (STAW4R[AWDE] = 1) and STDR1[TCDATA] < STAW4R[THRL], then STSR1[ERR_C] is set. **NOTE:** The settings in this register are applicable only to step 0 of the ADC's capacitive self test. Refer to the ADC_STAW5R register for settings applicable to other capacitive self test steps. The recommended watchdog threshold values are set according to expected and tested results in a noise-controlled environment (for example, introduction of noise from outside of the device minimized). The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments.

43.5.40 Self Test Analog Watchdog Register 5 (ADC_STAW5R)

This register contains ADC self test threshold values associated with all capacitive self test (also referred to as "Algorithm C") steps other than Step 0, which is controlled by fields in the ADC_STAW4R register.

Note that the threshold values in this register are distinctly different than those in the ADC_STAW4R register. The threshold values in this register do not represent a voltage conversion value relative to the ADC high reference voltage, but instead represent the upper and lower thresholds for the absolute difference between the voltage sampled and converted in an Algorithm C step and the voltage sampled and converted in Algorithm C Step 0. Ideally, the difference will be zero.

Address: 0h base + 398h offset = 398h



ADC_STAW5R field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–15 THRH	High threshold value for step N of C algorithm (N = 1 to CS-1). This value is read by the ADC as twos-complement, but should be written positive. If the watchdog is enabled (STAW4R[AWDE] = 1) and (STDR1[TCDATA] (step-N) – STDR1[TCDATA] (step-0)) > STAW5R[THRH], then STSR1[ERR_C] is set. **NOTE:** The recommended watchdog threshold values are set according to expected and tested results in a noise-controlled environment (for example, introduction of noise from outside of the device minimized). The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments.
16–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 THRL	Low threshold value for step 0 of C algorithm. This value is read by the ADC as twos-complement, and it should be the negative of STAW5R[THRH]. If the watchdog is enabled (STAW4R[AWDE = 1]) and (STDR1[TCDATA] (step-N) – STDR1[TCDATA] (step-0)) < STAW5R[THRL], then STSR1[ERR_C] is set. **NOTE:** The recommended watchdog threshold values are set according to expected and tested results in a noise-controlled environment (for example, introduction of noise from outside of the device minimized). The setting may need to be adjusted to prevent a given threshold value from falsely reporting fault detections in applications operating in noisier environments.

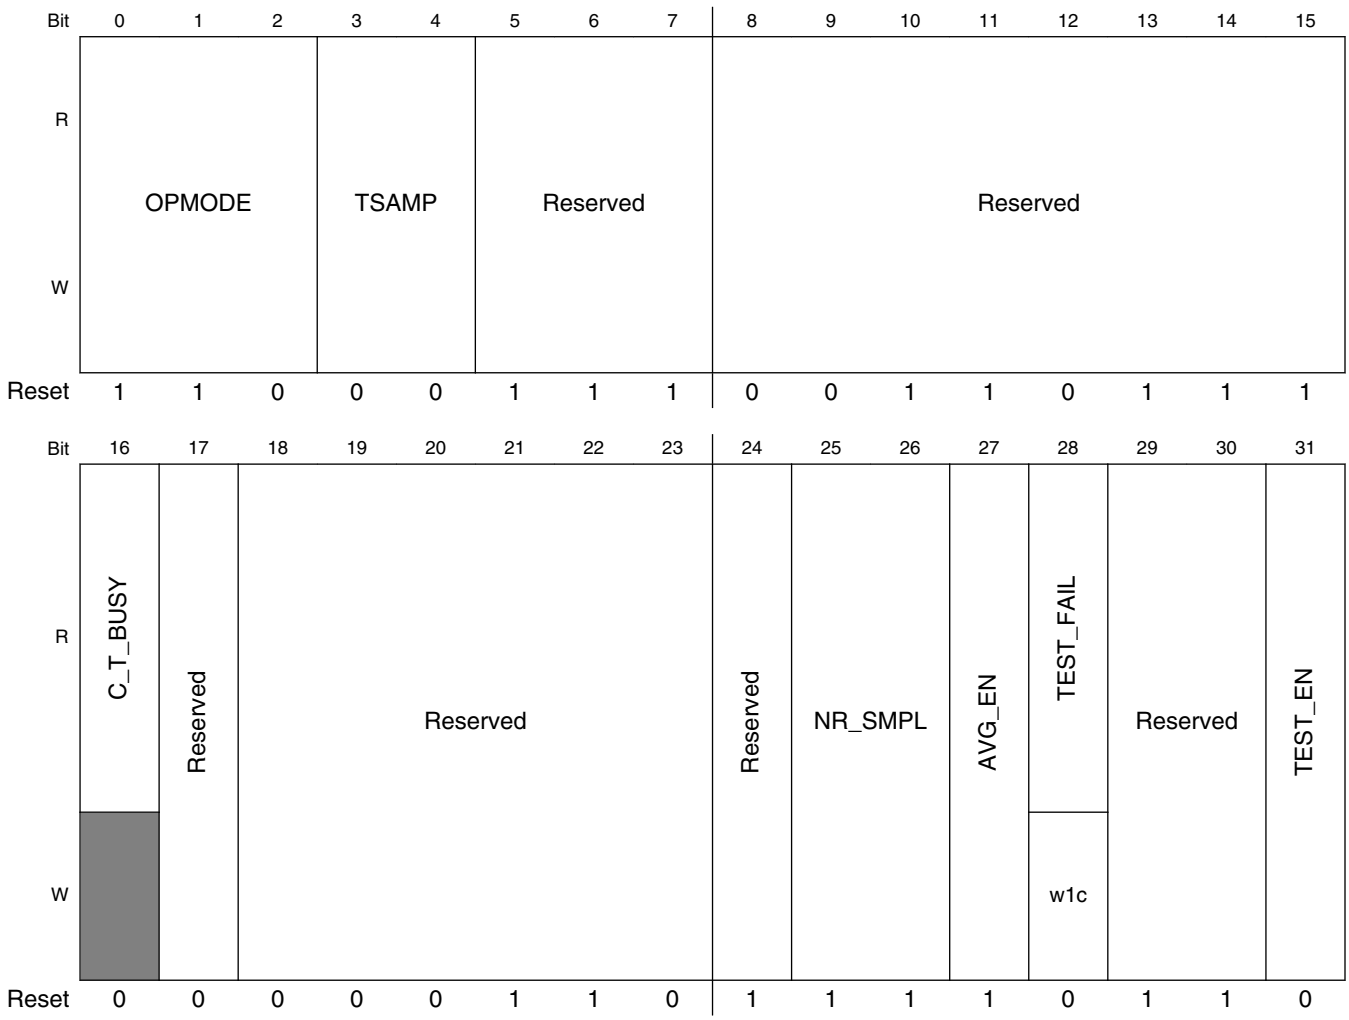
43.5.41 Calibration, BIST Control and status Register (ADC_CALBISTREG)

This register controls the Offset calculation, Calibration and BIST functionality with Averaging option. The averaging function has no effect in other conversion modes.

NOTE

CALBISTREG retains value after all Long Functional Resets except the one caused by an external reset event. It also retains value after Short Functional Resets.

Address: 0h base + 3A0h offset = 3A0h



ADC_CALBISTREG field descriptions

Field	Description
0–2 OPMODE	This field specifies the operating mode of the ADC (normal/high accuracy). The high accuracy mode comes at a cost of 4 additional ADC cycles (80 MHz/40 MHz). In order to keep the same total conversion time as normal mode, the sample time has to be reduced. 000 Reserved 001 12-bit operating mode (normal) 010 Reserved 011 Reserved 100 Reserved 101 Reserved 110 12-bit operating mode (high accuracy, recommended) 111 Reserved
3–4 TSAMP	Test Sample period in Calibration, BIST and Offset calculation process. 00 22 cycles of ADC clk 01 8 cycles of ADC clk

Table continues on the next page...

ADC_CALBISTREG field descriptions (continued)

Field	Description
	10 16 cycle of ADC clk 11 32 cycle of ADC clk
5–7 Reserved	This field is reserved.
8–15 Reserved	This field is reserved. When writing to this register, do not change the default value of this field.
16 C_T_BUSY	This bit indicates that ADC is doing internal operations for BIST or Calibration. This is set when the TEST_EN bit is set. 0 ADC is ready for use 1 ADC is busy in calibration or test operation
17 Reserved	This field is reserved.
18–23 Reserved	This field is reserved. When writing to this register, do not change the default value of this field.
24 Reserved	This field is reserved. The default value must not change. Always write the default value to this field.
25–26 NR_SMPL	Number of Samples for averaging. **NOTE:** The sample setting is providing a trade-off between calibration time and accuracy. For best accuracy 512 samples are recommended. The 16 sample setting shall only be used for applications which require very fast calibration time at the expense of accuracy. 00 16 samples 01 32 samples 10 128 samples 11 512 samples
27 AVG_EN	Average Enable (for Calibration only). 0 Disable 1 Enable
28 TEST_FAIL	Test Fail. This bit indicates the status of Calibration output. This bit sets automatically if tests are aborted prematurely by any normal conversion or tests complete but one of them fails. This bit is cleared by writing 1 to it or on restarting of test by writing 1 to TEST_EN 0 Test passed 1 Test failed
29–30 Reserved	This field is reserved.
31 TEST_EN	Enable the test. 0 Disable the test 1 Enable the test (self clearing) (once set it cannot be overwritten till it resets)

43.5.42 Offset and Gain User Register (ADC_OFSGNUSR)

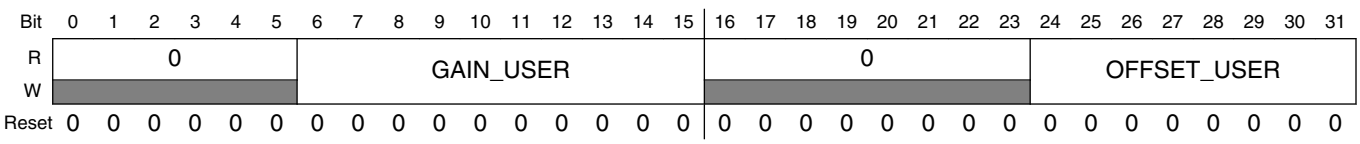
This register contains the user configured offset and Gain values used by ADC for data processing and have all the bits valid (MSB through LSB).

OFFSET and Gain Calibration values can be either positive or negative, so they need to be in 2's complement format with MSB as sign bit.

NOTE

OFSGNUSR retains value after all Long Functional Resets except the one caused by an external reset event. It also retains value after Short Functional Resets.

Address: 0h base + 3A8h offset = 3A8h



ADC_OFSGNUSR field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–15 GAIN_USER	Gain User (2's complement format)
16–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 OFFSET_USER	Offset User (2's complement format)

43.6 Functional description

The following sections detail the ADCD interfaces as well as the functionality of this module.

43.6.1 Conversion

After power-up or reset, the ADC is in power-down mode until the MCR[PWDN] field is written. There are some configurations, listed below, available only in power-down mode, that must be handled before exiting power down.

- Clock selection for SAR Controller (AD_clk): MCR [ADCLKSEL]

After the above configurations, ADC need to be taken out from power-down mode by writing '0' into MCR [PWDN], Conversions can be initiated now in the following modes:

- Normal
- Injected
- CTU Triggered

43.6.1.1 Normal conversion

The conversion mode generally used to convert channels is called normal conversion. Programming the available Normal Conversion Mask Register(s) (ADC_NCMR*n*) selects the channel(s). Each channel can be individually enabled by setting a bit in the corresponding field of the NCMR*n* register.

- NCMR0 serves *precision* channels:
  - 0 - 15 (ADC0)
  - 0 - 15 (ADC1)

The mask register(s) must be programmed before starting the conversion and cannot be changed until the conversion of all the selected channels ends. Conversion always starts from the lowest channel number selected and sequentially goes to the highest number.

43.6.1.1.1 Starting a normal conversion

After programming the MCR and NCMR0*n* register(s), a normal conversion is started via *software* by setting the MCR[NSTART] bit.

43.6.1.2 Normal conversion operating modes

Two operating modes are available for normal conversion:

- One-Shot mode
- Scan mode

The MCR[MODE] bit determines which mode is used during a normal conversion. The first phase of the conversion process involves sampling the analog channel. The next phase is the conversion phase, during which the sampled analog value is converted to digital as shown in the figure below.

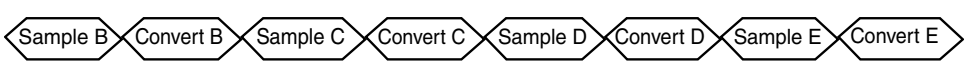


Figure 43-2. Normal conversion flow

43.6.1.2.1 One shot mode

In one shot mode (MCR[MODE] = 0) a sequential conversion specified in the following mask register(s) is performed only once:

- NCMR0

At the end of each conversion, the digital result of the conversion is stored into the corresponding data register(CDRx, x = channel number).

For example: Channels A-B-C-D-E-F-G-H are present in the device where channels B-D-E are to be converted in One-Shot mode. Conversion starts with channel B, followed by the conversion of channels D and E. At the end of conversion of channel E, the scanning of channels will stop.

The MSR[NSTART] status bit is automatically set when the normal conversion starts. At the same time, MCR[NSTART]is reset by hardware, allowing the software to program a new start of conversion in advance. In this case, the newly requested conversion starts after completing the running/current conversion. However, for the sake of simplicity and straightforwardness, it is advisable to program the NSTART bit for the new conversion only after the completion of the running conversion. To know the end of conversion of running chain, application will either wait for an End of Chain (ECH) Interrupt or check the status of MSR[NSTART] prior to setting MCR[NSTART] again.

43.6.1.2.2 Scan mode

In scan mode (MCR[MODE] = 1), a sequential conversion of *n* channels specified in the NCMR*n* register(s) is continuously performed. At the end of each conversion, the converted result is stored into the corresponding data registers, as in One-Shot mode.

The MSR[NSTART] status bit is automatically set when the normal conversion starts. Unlike One-Shot mode, the MCR[NSTART] bit is not reset automatically in Scan mode. It can be reset by software when you need to stop Scan mode. In that case, the ADC completes the current chain and, after the last conversion, resets MSR[NSTART].

For example: Channels A-B-C-D-E-F-G-H are present in the device where channels B-D-E are to be converted in Scan mode. MCR[MODE] = 1 is set for Scan mode. Conversion starts from channel B, followed by the conversion of channels D and E. At the end of the conversion of channel E, the conversion of channel B starts again, followed by the conversion of channels D and E. This sequence repeats itself until MCR[NSTART] is reset by software.

This scan chain can be stopped by writing 0 to MCR[NSTART]. The conversion stops when the ongoing chain is finished.

43.6.1.2.3 End of conversion

In both modes, at the end of each conversion an end-of-conversion (EOC) interrupt is issued if enabled by the corresponding mask bit in the following register(s):

- CIMR0

Additionally, the EOC interrupt must enabled in the IMR register. After the conversion of all the channels selected in the NCMR*n* register(s) is completed and the conversion operation is considered finished, ISR[ECH] is set and an end-of-chain (ECH) interrupt is issued (if enabled in IMR[MSKECH]). The corresponding channel bit within the appropriate CEOCFR*n* register is updated to indicate that data is available on the data register (CDR*n*) of the respective channel. If there is no channel selected in the NCMR*n* register(s) and there is a start of conversion trigger, then ISR[ECH] is set and an ECH interrupt is immediately issued (if enabled).

NOTE

To add or remove channels to/from the ongoing chain:

1. Clear the MCR[NSTART] bit
2. Set/clear mask bit for the needed channels in NCMR*n*
3. Set the MCR[NSTART] bit

43.6.1.3 Injected conversion

An injected conversion is a conversion chain that can be injected at any time, including into an ongoing normal conversion chain. To do so, configure the injected mask register(s):

- JCMR0

As in a normal conversion, each internal or external channel can be individually selected for injected conversion.

- JCMR0 controls *precision* channels:
  - 0 - 15 (ADC0)
  - 0 - 15 (ADC1)

Injected conversion can only be run in One-Shot mode, and can only interrupt a normal conversion. Please note, that a CTU conversion cannot be interrupted by an injected conversion. In this case, the injected conversion is discarded. When an injected chain is inserted into an ongoing normal chain, the ongoing normal channel is suspended and the injected channel request is processed. After completing the last channel in the injected chain, normal conversion resumes from the channel at which it was suspended as shown in the following figure.

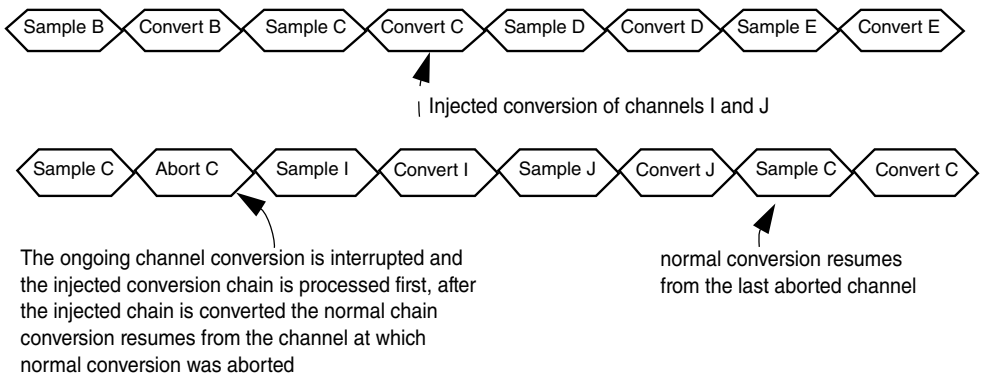

Figure 43-3. Injected sample/conversion sequence

43.6.1.3.1 Starting injected conversion

The injected conversion can be started via *software* by setting the MCR[JSTART] bit to start an injected conversion; the current normal conversion is suspended and the injected chain is converted.

To start an injected conversion via *external trigger*, enable external triggering by setting MCR[JTRGEN]=1. A programmed event (rising/falling edge depending on MCR[JEDGE] bit) on the injection trigger input starts the injected conversion.

The MSR[JSTART] status bit is automatically set when the injected conversion starts. At the same time, the MCR[JSTART] bit is reset, allowing software to program a new start of conversion in advance. In that case, the new requested conversion starts after the running conversion is completed.

At the end of each conversion, an End Of Injected Conversion (JEOC) interrupt is issued (if enabled by the corresponding mask bit in IMR) and at the end of the chain an End Of Injected Chain (JECH) interrupt is issued (if enabled by the corresponding mask bit in IMR). The status bit ISR[JECH] is also set.

If the content of all the injected conversion mask registers (JCMRn) is zero (i.e., no channel is selected) the interrupt JECH is immediately issued to resume normal operation or conversion mode.

The corresponding channel bit in the appropriate CEOCFR*n* register is updated to indicate that data is available in the data register (CDR) of the respective channel.

Once started, injected chain conversion cannot be interrupted by Normal or another Injected conversion. A CTU trigger has the higher priority; injected conversion has a lower priority. Therefore, only a CTU trigger can interrupt an ongoing injected conversion. In this case, the injected conversion will be discarded.

43.6.1.4 Aborting conversions

Two different abort functions are provided:

- A single channel abort
- A chain abort

You can abort the ongoing conversion by setting the MCR[ABORT] bit. The current conversion is aborted and the conversion of the next channel of the chain is immediately started. The abort action may take 1 to 4 cycles of the bus clock to abort the current conversion depending on the state of the conversion. At the start of any conversion and at the end of a particular conversion, when internal state counters are changing, then abort is delayed by a maximum of 3 cycles to take all states in stable condition. Abort also should not be programmed along with and within 3 cycles of programming the MCR[NSTART] or MCR[JSTART]. This may not have a significant impact from software point of view since on any SoC the next write access comes only after a minimum of 3 clock cycles.

NOTE

Programming Abort or Abort chain with NSTART or JSTART in idle condition has no effect.

For a Normal conversion chain having only one channel:

1. Abort re-runs the conversion again from the Abort point

In the case of an abort operation, the MSR[NSTART/JSTART] bit remains set, if not in last channel of chain, and the MCR[ABORT] bit is reset as soon as the channel is aborted. The EOC corresponding to the aborted channel is not generated. This behavior is true for Normal or Injected conversion modes. If the last channel of a chain is aborted, the end of chain is reported by generating an ECH interrupt.

It is also possible to abort the current chain of conversions by setting the MCR[ABORTCHAIN] bit. In that case, the behavior of the ADC depends on the MCR[MODE] bit (One-Shot/Scan) for Normal conversion. In One-Shot mode, MSR[NSTART] is automatically reset together with the MCR[ABORTCHAIN]. Otherwise, in Scan mode, a new chain is started, and the current chain is aborted. The EOC of the current aborted conversion is not generated, but an ECH interrupt is generated to signal the end of the chain. For Injected conversion, the behavior of ABORTCHAIN is same as for One-shot Normal conversion. In this case, MSR[JSTART] is automatically reset together with the MCR[ABORTCHAIN].

When an ABORTCHAIN is requested while an injected chain is running over a suspended normal chain, both injected and normal chains are aborted; both MSR[NSTART] and MSR[JSTART] are reset. ABORT and ABORTCHAIN requests are ignored during CTU conversion. ABORT requests are also discarded during Self-Test conversion.

43.6.2 Crosstriggering Unit interface

The Crosstriggering Unit (CTU) interface enhances the injected conversion capability of the ADC. The CTU contains multiple event inputs that can be used to select the channels to be converted from the appropriate event configuration register. The CTU/ADC interface is shown in the figure below. The CTU generates a trigger and a channel number to be converted. A single channel is converted for each request. After performing the conversion, the ADC returns the result.

The conversion result is also saved in the corresponding data register and it is compared with watchdog thresholds if requested. DMA and interrupt feature of ADC can also be used during CTU conversion.

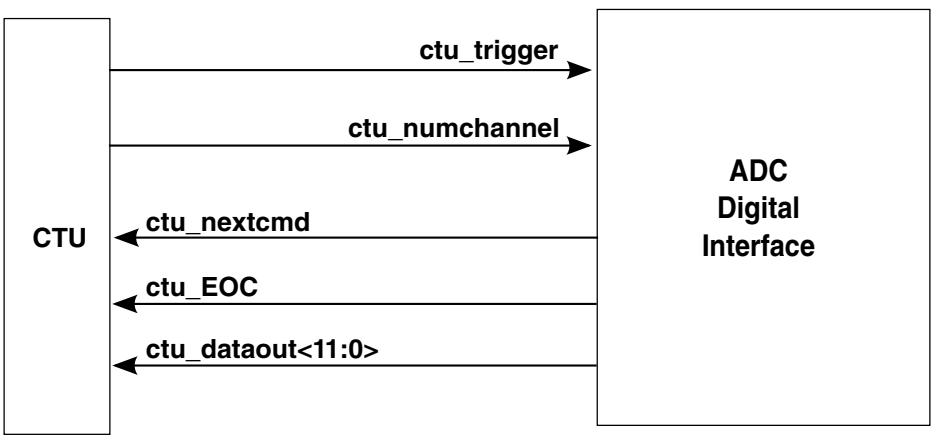

Figure 43-4. ADC Crosstriggering Unit

The CTU interface has one mode of operation, Control.

The CTU interface is enabled by programming the MCR[CTUEN] bit.

43.6.2.1 CTU Control mode

In CTU Control mode, if enabled via MCR[CTUEN], the CPU is able to write in the ADC registers, but it cannot start a conversion. Conversion requests can be generated only by a CTU trigger. If a normal or injected conversion is requested when the CTU is enabled (MCR[CTUEN]), it will be automatically discarded.

Along with CTU trigger the ctu_numchannel is taken as channel and CTU conversion starts. MSR[CTUSTART]is set automatically at this point and it remains set unless the CTU is disabled by resetting MCR[CTUEN].

CTU conversions must be requested when calibration is over. If a CTU trigger is received during calibration, the calibration stops immediately in order to satisfy the CTU request. Calibration will fail in this case.

43.6.3 ADC clock prescaler and sample time settings

The clock (AD_clk) provided to the ADC's SAR controller, which controls the ADCA, must satisfy particular conditions of frequency and duty cycle. The maximum acceptable frequency is 80 MHz with a duty cycle equal to 50% (±5%).

The AD_clk frequency can be scaled by programming the MCR[ADCLKSEL] bit. If this bit is set, AD_clk frequency is the same as the bus clock. Otherwise, AD_clk frequency is half of the bus clock. MCR[ADCLKSEL] can only be written in power-down, when MCR[PWDN] = 1.

Sampling times are controlled by settings in the Conversion Timing Register (CTR*n*).

- CTR0 controls sampling time for *precision* channels:
  - 0 - 15 (ADC0)
  - 0 - 15 (ADC1)

The exception is the Temperature Sensor channel, which always uses the CTR1 value. See Conversion Timing Register 1 (ADC_CTR1) for details.

43.6.4 Presampling

Presampling allows the ADC internal capacitor to precharge or discharge to a defined level before it starts the actual sampling/conversion of the analog input coming from the pads. This is useful for resetting information (history effect/offset) regarding the last converted data. During presampling, the ADC samples the internally generated voltage while, during sampling, the ADC samples the analog input coming from the pads.

Presampling can be enabled/disabled on an individual channel by setting the corresponding bit in the applicable PSR*n* register.

- PSR0 controls precision channels

After enabling the presampling for a channel, the normal sequence of operation is presampling + sampling + evaluation for that channel. Sampling of the channel can be bypassed by setting PSCR[PRECONV]. When sampling of a channel is bypassed, the presampled voltage will be converted.

See Conversion time for the conversion's timing equation.

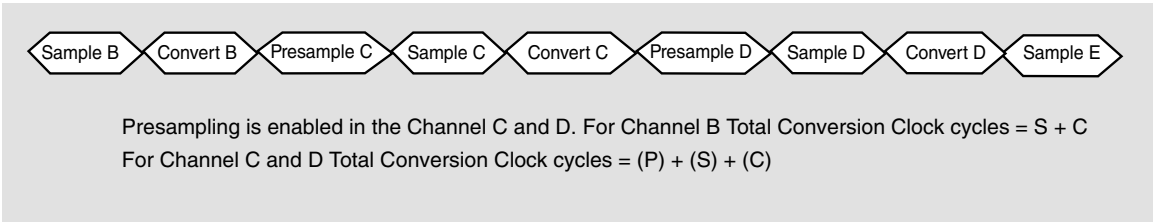

Figure 43-5. Presampling sequence

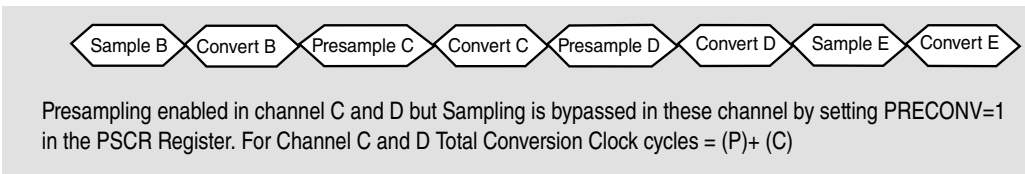

Figure 43-6. Presampling sequence with PRECONV = 1

43.6.4.1 Presampling channel enable

The presampling channels are selected by programming the presampling register (Presampling Control Register (ADC_PSCR)). These are used to enable analog switches that samples an internally generated voltage. It is possible to select presample voltage from four internally available voltages depending on the value of PREVAL*x* [*x* = 0,1,2] fields in the PSCR register as given in Table 43-4.

Table 43-4. Presample voltage selection

PREVAL*n*	Presampling voltage
00b	Presample voltage 1: VSS_HV_ADC (SAR ADC ground)
01b[1]	Presample voltage 2: VDD_HV_ADC/8 (SAR ADC supply divided by 8)
10b	Presample voltage 3: VSS_HV_ADCREF0/1, VSS_HV_ADCREF0/1 (SAR ADC reference ground)
11b	Presample voltage 4: VDD_HV_ADCREF0/1, VDD_HV_ADCREF0/1 (SAR ADC reference supply)

1. The voltage sampled inside ADCA is always (analog supply) / 8 for PSCR[PREVAL*n*] = 01b. However, when sampling is bypassed (PSCR[PRECONV] = 1), ADCD multiplies the conversion result by 8 to make the conversion result equal to the analog supply, or maximum value possible during saturation.

   So, for an open or short circuit test on any channel with presampling feature and PSCR[PRECONV] = 0b, user should expect conversion results as shown below:
   - Equal to Vin of the channel (if there is no open or short defect)
   - Close to (analog supply) / 8 if the channel is open (not connected to any voltage source, internally or externally)
   - Close to 0 V if the channel has a short to ground (analog ground, either internally or externally).
   - Close to the analog supply if the channel has a short to supply (analog supply, either internally or externally).

The PREVAL*n* fields are associated with specific channels, as shown in Table 43-5.

Table 43-5. PREVAL*n* channel association

Field	Channels
PREVAL0	• 0 - 15 (ADC0) • 0 - 15 (ADC1)

The temperature sensor channel is an exception. It can be mapped with any of the channels, but it uses the PREVAL1 value to select the presample voltage because its physical properties may be different than the other internal precision channels.

43.6.5 Programmable analog watchdog

NOTE

The number of analog watchdogs and channels may vary depending on the ADC instance on your chip. Please see the chip-specific section for how many are available on each instance.

The analog watchdogs are used for determining whether the result of a conversion lies within a given guard area (as shown in Figure 43-7) specified by an upper and a lower threshold value named THRH and THRL, respectively.

After the conversion of the selected channel, a comparison is performed between the converted value and the threshold values. If the converted value lies outside the guard area, then the corresponding threshold violation interrupt is generated.

The comparison result is stored as WTISR[WDGxH] and WTISR[WDGxL], as explained in the following table. Depending on the WTIMR[MSKWDGxL] and WTIMR[MSKWDGxH] mask bits, an interrupt is generated upon threshold violation.

Table 43-6. Values of WDGxH and WDGxL fields

WDGxH	WDGxL	Converted data
1	0	converted data > THRH
0	1	converted data < THRL
0	0	THRH ≤ converted data ≤ THRL

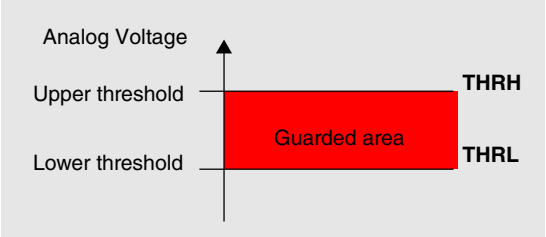

Figure 43-7. Guarded Area

43.6.5.1 Analog watchdog setting

For each watchdog there is one Threshold value (Low and High) Register (THRHLR).

The analog watchdog for each channel can be enabled independently by programming CWENR*n* register bits.

- CWENR0 controls *precision* channels:
  - 0 - 15 (ADC0)
  - 0 - 15 (ADC1)

The availability of these registers depends on device configuration.

Threshold values for each channel can be selected independently from a maximum of 16 threshold registers (THRHLRx,(x=0..15)) by the WSEL_CHx field of CWSELRx (x=0..11) register.

Each CWSELRx register holds selection for 8 consecutive channels. CWSELR0 holds 8 WSEL_CH fields for channel 0 to 7. Likewise CWSELR1 is for channel 8 to 15 and so on. The availability of fields and registers depends on device configuration.

If the converted value for a particular channel lies outside the range specified by threshold values, then the corresponding bit is set in the Analog Watchdog Out of Range Register (AWORR).

For example, if channel number 12 is to be monitored with the threshold values in register THRHLR3, then CWSELR1[WSEL_CH4] needs to be programmed with 3. The enabling will be done by setting the bit corresponding to channel 12 in the CWENR0 register.

A set of threshold values (THRHLRx) can be linked to several ADC channels. The threshold values to be selected for a channel needs be programmed only once in the CWSELRx register.

43.6.6 DMA functionality

Conversion data of any channel can be transferred from register to system memory via Direct Memory Access (DMA). The DMA transfers can be enabled by setting ADC_DMAE[DMAEN]. Once enabled, the on chip DMA controller can get DMA requests after the conversion of every channel by setting the respective masking bit in the DMAR*n* registers. The DMA masking registers must be programmed before starting any conversion.

The DMA request to DMA controller can be cleared at different times in two modes:

MODE-1: Clearing of DMA request on Acknowledgement from DMA controller (ADC_DMAE [DCLR] = 0)

MODE-2: Clearing of DMA request on Read to data registers (ADC_DMAE [DCLR] = 1)

The figures below shows DMA operation in two modes (cycle counts are typical values).

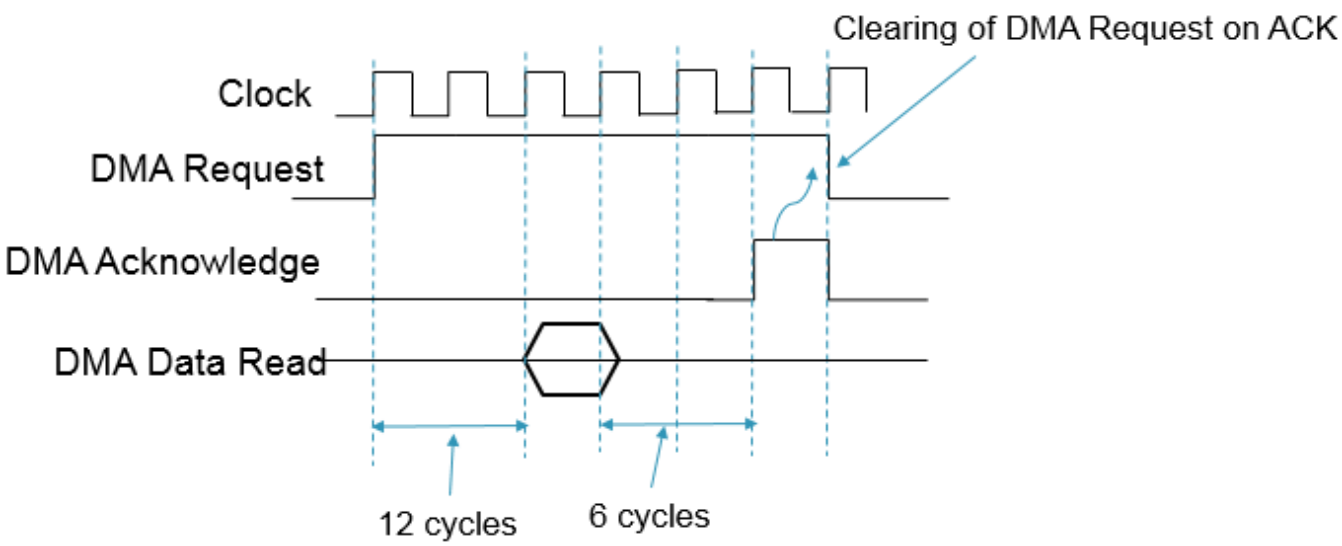

Figure 43-8. DMA operation MODE – 1 (DMAE [DCLR] = 0)

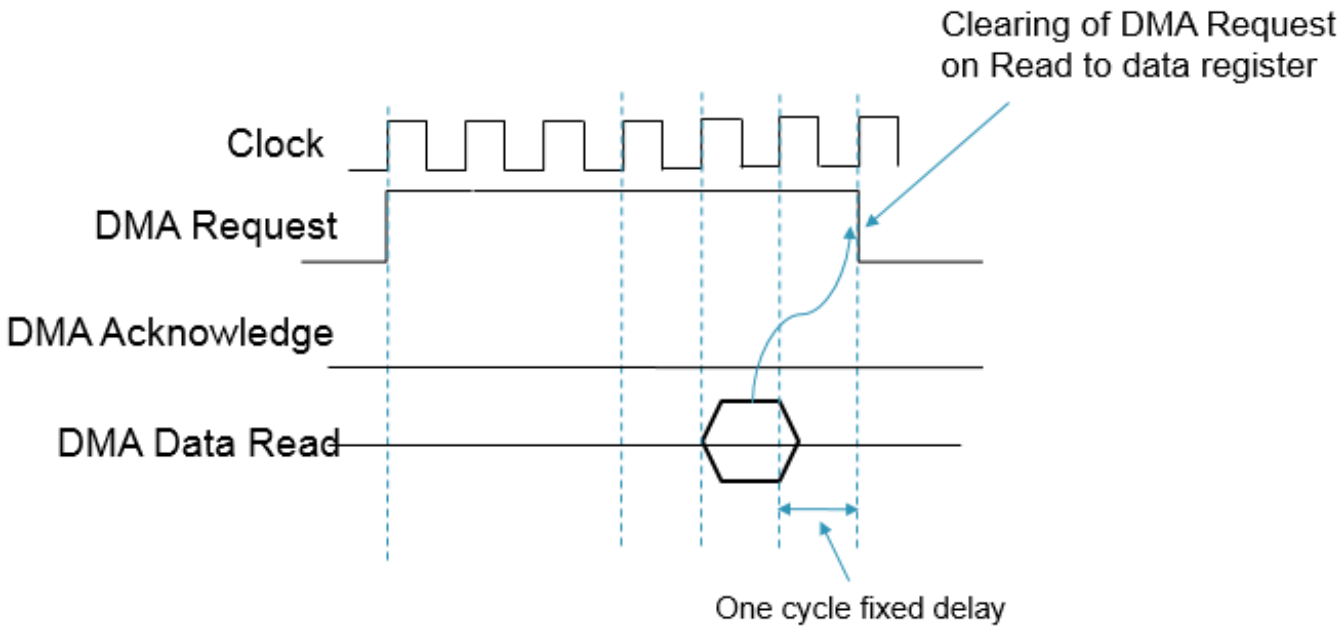

Figure 43-9. DMA operation MODE – 2 (DMAE [DCLR] = 1)

43.6.7 Interrupts

ADC generates the following maskable interrupt signals:

- End-of-conversion interrupt (EOC) request
- End-of-chain interrupt (ECH) request
- End-of-injected conversion interrupt (JEOC) request
- End-of-injected chain interrupt (JECH) request
- End-of-CTU conversion interrupt (EOCTU) request
- Watchdog threshold interrupt (WDGxL and WDGxH) requests

Interrupts are generated during the conversion process to signal events, like the end of a conversion, as explained in the register description for the Interrupt Status Register (ISR). The ISR and the Interrupt Mask Register (IMR) allow you to check and enable the interrupt request.

Interrupts can be individually enabled on a channel-by-channel basis by programming the Channel Interrupt Mask Register (CIMR).

A Channel Pending Register (CEOCFR*n*) is also provided in order to signal which of the channels' measurement has been completed.

Analog Watchdog interrupts are enabled by Watchdog Threshold Interrupt Mask Register (WTIMR) and the status can be checked at Watchdog Threshold Interrupt Status Register (WTISR). The watchdog interrupt source sets two fields, WDGxH and WDGxL, for each channel monitored in the WTISR.

In particular, the EOC, ECH, EOCTU, JEOC, and JECH interrupt lines are combined (OR-ed) on the same line. The EOC interrupt request is cleared by clearing either ISR[EOC] or all bits of CEOCFR. The JEOC interrupt request is cleared by clearing either ISR[JEOC] or all bits of CEOCFR. The EOCTU interrupt request is cleared by clearing either ISR[EOCTU] or all bits of CEOCFR. Also, the self-test end of algorithm interrupts STSR1[WDG_EOA_S] and STSR1[WDG_EOA_C] are combined.

All WDGxH and WDGxL requests are combined on the second line.

Another interrupt on the third line is a combination of WDSERR, WDTERR, ERR_S0, ERR_S1, ERR_S2, and ERR_C in STSR1.

The ISR register contains the interrupt pending request status. If you want to clear a particular interrupt event status, then writing a 1 to the corresponding status bit will clear the pending interrupt flag. (At this write operation, all the other bits of the ISR register must be programmed to 0.)

43.6.8 Power-Down mode

The analog part of the ADC can be put in Power-Down mode by setting the MCR[PWDN] bit, which shuts off the ADCA and stops the clock in the SAR controller. After power-on or device reset, the ADCA is kept in Power-Down mode by default, so this state must be exited before starting any operation by resetting the MCR[PWDN] bit. In Power-Down mode, no conversion and calibration can be started. Trigger from CTU during power down is discarded. In the ADC power-down mode, the CTU must not start any conversion.

The MCR[PWDN] bit may be programmed high at any time. However, if a conversion is ongoing, then the ADCA cannot be sent immediately into Power-down mode. In fact, the ADC enters Power-down mode only after completing the ongoing conversion. Otherwise, the ongoing operation should be aborted manually by resetting the NSTART bit and using the ABORTCHAIN function.

The ADC status in MSR[ADCSTATUS] field shows Power-down status only when ADC enters in Power-down mode.

If CTU is enabled and MSR[CTUSTART] is 1, then the MCR[PWDN] bit cannot be set. When CTU Control mode is enabled, the application needs to reset the CTUEN bit before entering Power-Down mode.

After the power-down phase is complete, the process ongoing before the power-down phase must be restarted manually .

NOTE

Resetting the MCR[PWDN] bit and setting the MCR[NSTART] or MCR[JSTART] bit during the same cycle is forbidden.

43.6.9 Auto-Clock-Off mode

To reduce power consumption in Idle mode (without going into Power-Down mode), an auto-clock-off feature can be enabled by setting MCR[ACKO]. When enabled, the analog clock is automatically switched off when no operation is ongoing (that is, when no conversion has been programmed).

NOTE

This feature must remain off during calibration.

43.6.10 Calibration and Self Test

The ADC is calibrated and tested runtime through the same set of test conversions. The test result is used for computation and stored during the calibration process and only checked in self test. The two modes of running tests are as follows:

1. High-Accuracy mode/Calibration. Needs to be run after power-on reset and whenever required in runtime operation. Calibrates the ADC and updates calibration-related registers.
2. Quick-Check mode/Self-Test. Used for runtime functional self-tests to improve reliability. Catches any runtime fault or accuracy shift from previously calibrated values. Please see the chip-specific configuration information as self-test may not be available in all ADC instances.

The following sections describe both and the steps for executing them.

43.6.10.1 Calibration (High Accuracy mode)

The functioning of the analog block of ADC depends on the accuracy of values of its various parts and parameters, such as the value of capacitors, the gain of the amplifier, and so on. Due to variations in manufacturing and various runtime environmental effects, the actual values may differ from the ideal values for which the ADC is targeted.

Because of these deviations, the ADC's converted values contain errors. To eliminate these errors, the ADC must be calibrated prior to any conversion.

In the calibration process, a fixed known reference voltage (VrefH) is sampled many times and converted under various controlled conditions to check for deviations between these converted values and predefined values.

The deviations, known as offsets or modified values, are used to eliminate errors during the data processing of normal conversions.

Note

The ADC must be recalibrated if the operating conditions (particularly VrefH) change significantly. Calibration should also be performed again if the Self-Test indicates that a recalibration is needed.

Recommended settings:

- Clock frequency = 40 MHz
- Averging – Maximum (512)

The calibration process will take ~12ms of time with the above recommended settings.

NOTE

If the ADC clock frequency is > 40MHz during calibration, the accuracy of the calibration process will be compromised, hence the performance of the ADC. Thus, it is strongly recommended to run the calibration with 40 MHz clock.

As calibration is a time consuming process, it can be performed after a long interval – probably several hours of operation – but it is not necessary to recalibrate frequently. The goal is to maximize the possible accuracy delivered from conversion and to catch any structural fault to flag the error.

The calibration routine sets the fail flag (CALBISTREG[TEST_FAIL]) to indicate:

- A fault in ADC
- A premature abort of the calibration

Calibration is aborted if a normal conversion is initiated during calibration; this is called *premature termination*. The terminating conversion and the immediate next one to it will have invalid result in this case.

CALBISTREG[TEST_FAIL] = 1 indicates that the ADC health is not good and that it will not meet specifications.

To execute this routine, follow these steps:

1. Configure the ADC to 40 MHz.
   - Put the ADC in power down mode: set MCR[PWDN]
   - Configure clock divider selection: reset MCR[ADCLKSEL]
   - Power-up the ADC: reset MCR[PWDN]
2. Configure the Calibration, BIST Control, and Status Register (CALBISTREG). The default values are set for maximum accuracy (recommended).
3. Start calibration: set CALBISTREG[TEST_EN].
4. Wait for calibration to complete. Check MSR[ADCSTATUS] or till CALBISTREG[C_T_BUSY] becomes 0.
5. Check the value of MSR[CALIBRTD] to determine whether calibration was successful.
6. If MSR[CALIBRTD] = 1, calibration was successful; otherwise, it failed, and CALBISTREG[TEST_FAIL] = 1.
7. If required, reconfigure the ADC clock frequency for normal operation.

43.6.10.2 Self test (Quick-Check/Safety mode)

For devices used for very critical applications requiring high reliability it is important to check at regular intervals if the ADC is functioning correctly. For this purpose, Self Testing feature (Quick Check) has been incorporated inside ADC.

The following testing algorithms are available for checking:

- Supply Self test: algorithm S. It includes the conversion of the bandgap, supply and VREF voltages. It includes a sequence of three test conversions (steps). The supply test conversions must be an atomic operation (no functional conversions interleaved).
- Capacitive Self test: algorithm C. It includes a sequence of 12 test conversions (steps) to check the capacitive array.

The capacitive test of ADC requires only 12 steps to test itself.

The capacitive array is used as DA converter to generate from V_{REFH} 12 different voltages by distributing and partially discharging portions of the capacity array. These 12 voltages are sampled using some redundant capacities. C algorithm may be compared to providing 12 different voltages to ADC and validate the conversion result.

Two kinds of tests are performed in this mode, as shown in the following table.

Table 43-7. Quick-Check mode tests

STCR3 [ALG]	STCR3 [MSTEP]	Description	Outcome	Comment
00 supply test	0	Supply self-test (band gap voltage)	Measures the internal band gap voltage	—
	1	Supply self-test (analog supply)	Measures the analog supply voltage (VDDA) and divides the result by the bandgap voltage (result from Algorithm S step 0). The VDDA conversion result is written to ADC_STDR1[TCDATA]. The final result (after division) consists of an integer portion and a fractional portion, both of which are written to the ADC_STDR2 register.	The conversion performed in Algorithm S Step 1 is not the full scale analog supply. Instead, the sampled voltage is VDDA / 8. Prescaling is done to avoid issues that can occur in the analog portion of the ADC when VREFH = VDDA = 3.3 V, or VDDA is slightly higher than VREFH. The conversion result is multiplied by 8 in the digital part of the ADC to scale the result to the expected level.
	2	Supply self-test (reference voltage high)	Measures the high reference voltage of the ADC	—
01	Reserved	—	—	—
10 capacitive test	0–11	One of the ADC-BIST steps is being run	The difference or error of individual value from the previously calibrated value is being returned (unsigned) as an ADC result that is compared with a programmed value in the analog watchdog register(s) to detect any fault. The difference or error may be caused by any runtime fault, runtime accuracy shift, or device noise.	Ideally, the result value is expected to be 0. If the returned value is higher, this indicates runtime fault or accuracy shift. This indicates that ADC should be recalibrated in High-Accuracy mode to check whether the reported error can be handled by recalibrating or whether permanent damage to ADC has occurred.
11	Supply test followed by Capacitive test in same sequence as shown above	—	—	—

This mode is described in the following sections.

43.6.10.2.1 Self test initialization and application information

ADC samples the internal V_{REFH} for the C algorithm and samples different supplies (bandgap, V_{DD} and V_{REFH}) for the supply algorithm. It also provides signals for the following:

- Scheduling self-testing algorithms using configuration registers

- Monitoring the converted data using analog watchdog registers
- Flagging the error to FCCU in case a failure occurs in any of the algorithms

ADC mode	TEST channel (ADCdig)	TEST channel (CTU)
CPU mode (MCR[CTUEN] = 0)	Yes • One-Shot mode • Scan mode	No
CTU Control mode	No	Yes

43.6.10.2.2 CPU mode

In this case, the test channel works similarly to a normal conversion. The test channel is enabled by setting STCR2[EN].

Self-test conversions are executed by interleaving the Normal conversions. The sequencing of steps of the selected algorithm for test channel depends on the operating mode of normal conversion, selected by MCR[MODE].

In One-Shot mode, if the test channel is enabled, only one step of the selected self-testing algorithm is executed at the end of the chain. The step number and algorithm to be executed are programmed in the STCR3 register. So, in One-Shot mode, the sequence is as follows:

1. Program NCMR*n* register(s) to select channels to be converted for normal conversion.
2. Modify the Sample period of normal conversion to 20 d cycles, write ADC_CTRx[INPSAMP] = 20 d (for 1 MSPS operation)
3. Program MCR[MODE] = 0 to select One-Shot mode.
4. Program sampling duration for self test conversion in STCR1[INPSAMPx].
5. Select the self-testing algorithm in STCR3[ALG]. The default is algorithm S.
6. Enable the self-testing channel by setting STCR2[EN].
7. Start the normal conversion by setting MCR[NSTART].
8. All normal conversions are executed as usual.
9. At the end of all normal conversions, the step number programmed in STCR3[MSTEP] of the self-testing algorithm selected by STCR3[ALG] is executed similar to a normal functional channel.
10. On receiving an end-of-conversion for the test channel, the digital result is written in STDR1[TCDATA] andSTDR1[VALID] is set. Also, ISR[EOC], ISR[ECH], and STSR1[ST_EOC] are set. See the register descriptions (Self Test Data Register 1 (ADC_STDR1), Interrupt Status Register (ADC_ISR), and Self Test Status Register 1 (ADC_STSR1)) for details of settings for each test.
11. The state machine returns to the Idle state.

For example: in a device with channels A-B-C-D-E-F-G-H, channels B-D-E are to be converted in One-Shot mode. MODE = 0 is set for One-Shot mode. Refer to Conversion. Conversion for channels B-D-E are done. After channel E test channel conversion is done and ISR[ECH] and ISR[EOC] are set.

MSR[NSTART] is automatically set when the normal conversion starts; it is reset at the end of conversion for the test channel.

In Scan mode, the consecutive steps of the selected self test algorithm are converted continuously at the end of each chain of normal conversions. The number of channels converted at the end of each chain is 1 (except for algorithm S, in which all the steps are performed at once without any functional conversion interleaved). So, in Scan mode the sequence is as follows:

1. Program the NCMR*n* registers to select channels to be converted for normal conversion.
2. Modify the Sample period of normal conversion to 20 d cycles, write ADC_CTRx[INPSAMP] = 20 d (for 1 MSPS operation)
3. Program MCR[MODE] = 1 to select Scan mode.
4. Program sampling duration for self test conversion in STCR1[INPSAMPx].
5. Select the self-testing algorithm in STCR3[ALG]. By default, all algorithms are selected (that is, all algorithms are executed step-by-step one after the other).
6. Enable the self-testing channel by setting STCR2[EN].
7. Start the normal conversion by setting MCR[NSTART].
8. All normal conversions are executed as usual.
9. At the end of chain for the normal conversions (assuming a default value of STCR3[ALG]), all steps of algorithm S are performed (as algorithm S is always atomic). MSR[SELF_TEST_S] is set.
10. At the end of conversion of test channel for the last step of algorithm S, the digital result is written in STDR1[TCDATA] and STDR1[VALID] is set. At the same time, MSR[SELF_TEST_S] is reset. For step 1, the integral part and fractional part are written in STDR2[IDATA] and STDR2[FDATA]. Also, ISR[EOC], ISR[ECH], and STSR2[ST_EOC] are set.
11. The next normal conversion chain starts.
12. At the end of the normal conversion chain, Step0 of the C algorithm is executed.
13. At the end of conversion of test channel for Step0 of the C algorithm, the digital result is stored in STDR1[TCDATA] and STDR1[VALID] is set (if MCR[OVERWR] is set). Also, ISR[EOC], ISR[ECH], andSTSR2[ST_EOC] are set.
14. The next normal conversion chain starts.
15. At the end of the normal conversion chain, step1 of C algorithm is executed.
16. This process continues for all steps of all algorithms.
17. The state machine returns to the Idle state when MCR[NSTART] is written to 0.

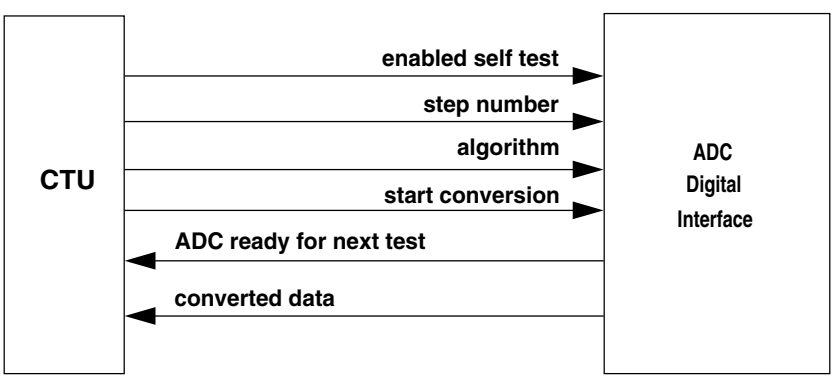
NOTE

- Test channel conversion is not performed during injected conversions. It is performed only during normal conversions.
- If, during a test channel conversion, injection conversion arrives, then the test channel is aborted (just as a normal functional channel) and injected conversions are done. After injected conversions are completed, the test channel resumes from the step at which it was aborted. In this case, MSR.SELF_TEST_S remains high during the injected conversion.
- For self testing, MCR[MODE]should be programmed at least one cycle *before* setting MCR[NSTART]. It should not be changed thereafter until a conversion is ongoing.

43.6.10.2.3 CTU mode

For this chip, the operating mode is CTU Control mode.

When MCR[CTUEN] is set, the test channel conversion can be started only by the CTU interface; software cannot start it. STCR2[EN] does not have any effect in CTU mode. The CTUEN bit should not be changed while normal conversion is ongoing. The interface between the CTU and ADCD (for self test) is shown here:



For self testing conversions in CTU mode, the CTU asserts an indication that enables self test along with the CTU trigger that starts the self test conversion. The algorithm and the step number to be executed is put on the interface respectively.

NOTE

As already mentioned for algorithm S, the three steps must be atomic. In CTU mode, this is managed by the CTU itself; that is, the CTU has to send three triggers (one for each step)

asserting the indication that enables self test and updating the step number for each step.

43.6.10.2.4 Abort and Abort Chain for self-test channel

Setting MCR[ABORT] during self-test channel has no effect.

In One-Shot mode, if MCR[ABORTCHAIN] is set when the test channel conversion is ongoing, the test channel is aborted and ECH is set. In this case, EOC for the test channel is not generated.

In Scan mode, if MCR[ABORTCHAIN] is set when test channel STEP N is ongoing, then the test channel STEP N is aborted and the next chain conversion starts. At the end of this chain, STEP N conversion is performed again. (If algorithm S is ongoing, the full algorithm is executed again.)

43.6.10.2.5 Self-test analog watchdog

ADCD also provides a monitor for the values returned by the ADC analog macro for self-test algorithms. The analog watchdogs are used to determine whether the result of conversion for self-test algorithms lie in a particular guard area. For this purpose, separate Self-Test Analog Watchdog Registers are provided for each algorithm.

If the analog watchdog feature is enabled (STAWxR[AWDE] = 1), a comparison is performed between the converted value and the threshold values after the conversion of each step of an algorithm. If the converted value does not lie between the upper and lower threshold values specified by the Analog Watchdog Register of the particular algorithm, the corresponding error bit (STSR1[ERR_x]) is set and the step number during which the error occurred is updated in STSR1[STEP_x] (in case of the C algorithm) and erroneous data is written in STSR4[DATAx]. STSR1[ERR_x] generates an interrupt if enabled by the corresponding mask bit in STCR2. The fault indication is also given to the FCCU via the Critical and Non-Critical fault lines, so that necessary action can be taken at chip level.

The analog watchdog feature works differently in the case of algorithm S. As already mentioned, algorithm S is always an atomic operation. So, separate error bits are provided in STSR1 for each step of algorithm S to avoid an overwrite in case an error occurs in more than one step. Hence, there are separate mask bits for each step in STCR1. For the same reason, separate fields in the status registers (STSR2 and STSR3) exist to store erroneous data for each step.

In step 0 of supply algorithm, ADC measures the band gap voltage (+1.2V), which is assumed to be stable with very little variation (up to +/- 1.5%). The converted data of step 0 is measured with high (THRH) and low (THRL) threshold defined in STAW0R if enabled (STAW0R[AWDE]). The STSR1[ERR_S0] is set to '1' if threshold is violated; once set, it is cleared to '0' by writing '1' to it.

In step 1 of supply algorithm, ADC measures the Analog supply (Vdda) for the ADC, and then a fixed point division is performed with the result of step 1 (ADC supply voltage) and step 0 (band gap voltage). It takes around 26 cycles after EOC for step 1 to get a divided value, and it is the divided value on which analog watchdog checks are applied. So, the value to be compared for step 1 contains the integer as well as fractional part; two registers (STAW1AR and STAW1BR) are provided for this. The comparison is done first for the integer part using the threshold values programmed in STAW1AR. If the integer part lies in the range, the fractional part comparison is skipped; otherwise, it is compared with the values programmed in STAW1BR. The following table summarizes this feature for step 1.

Table 43-8. Algorithm S (step 1) threshold comparison

STDR2[IDATA] (integer part)	STDR2[FDATA] (fractional part)	STSR1[ERR_S1]
> STAW1AR[THRH]	Any value	Set
< STAW1AR[THRL]	Any value	Set
== STAW1AR[THRH]	> STAW1BR.THRH	Set
== STAW1AR[THRL]	< STAW1BR.THRL	Set

In step 2 of supply algorithm, ADC measures the High Reference voltage (Vrh); (VREF/VREF) is measured in order to check the integrity of sampling signal. For this particular conversion, no higher threshold value is required as the ideal value is 0xFFF. Only the lower threshold value is programmed in STAW2R.

In the supply self-test algorithm, the band gap is measured with regard to the reference voltage (Vrh) in step 0. The result is capable of catching mismatches between them. Step 1 measures the supply with regard to reference (Vrh), and the result is taken to do a ratio (Vdda/Vbg). If the band gap voltage remains within +/-1.25% of its ideal value of 1.2 V, then by setting appropriate values of THRH and THRL in watchdog registers, the ADC self-test can catch more than 4% variation in supply and reference faithfully.

Algorithm C has total 12 steps. Output data of step 0 is compared with the threshold values stored in STAW4R, if enabled in the same register. The result of step 0 is used as an offset for rest of the steps (step 1 to 11). The absolute difference between the converted data of each of the steps (1 to 11) with the data of step 0 are compared with the threshold values of STAW5R, if enabled in STAW4R. Error in any step is indicated by STSR1[ERR_C] and the data in error case is captured in STSR4.

Calculation of Threshold values:

S1 Algorithm: Calculated voltage comparison method:

The user software can implement a method of calculating S1 algorithm IDATA, FDATA, the THRH values, and the THRL values to voltages and then perform a comparison of the calculated voltage to the calculated THRH voltage and calculated THRL voltage.

The steps involved in this method are as follows:

1. Calculate the high threshold voltage:

   (STAW1AR [THRH] + (STAW1BR [THRH] / 4096)) * Vbandgap

2. Calculate the low threshold voltage:

   (STAW1AR [THRL] + (STAW1BR [THRL] / 4096)) * Vbandgap

3. Calculate the converted results to voltage:

   (STDR2 [IDATA] + (STDR2 [FDATA] / 4096)) * Vbandgap

4. Compare result from step 3 to THRH and THRL.S1 algorithm passes

   If (low threshold voltage <= converted voltage <= high threshold voltage).

43.6.10.2.6 Watchdog timer

The watchdog timer is an additional check that monitors the sequence of the self-testing algorithm implemented and checks that the algorithm completes within a safe time period. Watchdog timers can be enabled for CPU as well as CTU conversions. Each algorithm has a different watchdog timer that runs independently of the other. The watchdog timer for a particular algorithm can be enabled by setting STAWxR[WDTE]. The safe time value can be programmed in STBRR[WDT] (the default value is 10 ms, assuming an 80 MHz clock).

The safe time is measured starting from step 0 of the algorithm (including all normal chain conversions in between) to the point at which step 0 of the same algorithm starts again.

The sequence is as follows:

1. Program NCMR0 to select channels to be converted for normal conversion in Scan mode (MODE = 1).
2. Modify the Sample period of normal conversion to 20 d cycles, write ADC_CTRx[INPSAMP] = 20 d (14 h) (for 1 MSPS operation)

3. Select the self-testing algorithm in STCR3[ALG]. By default, all algorithms are selected; that is, all algorithms will be executed step-by-step, one after the other.
4. Enable the self-testing channel by setting STCR2[EN].
5. Program the safe period value in STBRR[WDT].
6. Enable the watchdog timer by setting STAWxR[WDTE]. Assume the setting of WDTE to be t0. (It is important to do all the programming first and to then enable WDTE as the safe time check is also performed between the setting of WDTE and the start of step 0 to check that algorithm has started within the safe time).
7. Start the normal conversion by setting MCR[NSTART].
8. After first chain conversion ends, step 0 of algorithm S is executed. Lets assume the start of STEP0 to be t1.
9. Step 1 and step 2 of algorithm S are executed.
10. The next chain conversions are performed.
11. When chain conversion completes, step 0 of C algorithm is performed.
12. After each chain conversion, a consecutive step of the C algorithm is performed. A similar sequence follows for algorithm C.
13. After the last step of the C algorithm is performed, another chain conversion is executed. At the end of this chain conversion, step 0 of algorithm S starts, repeating the whole sequence. Let's assume this time (starting of step 0) to be t2.
14. For algorithm S, if (t1 – t0) > Safe Period, or if (t2 – t1) > Safe Period, then the watchdog timer flags an error and STSR1[WDTERR] is set. A critical fault is asserted and an interrupt is also generated if enabled by STCR2[MSKWDTERR]. Otherwise, the watchdog timer counter is reset and starts again to monitor the same for the next sequence.
15. A similar sequence is followed for watchdog timers for algorithm C.

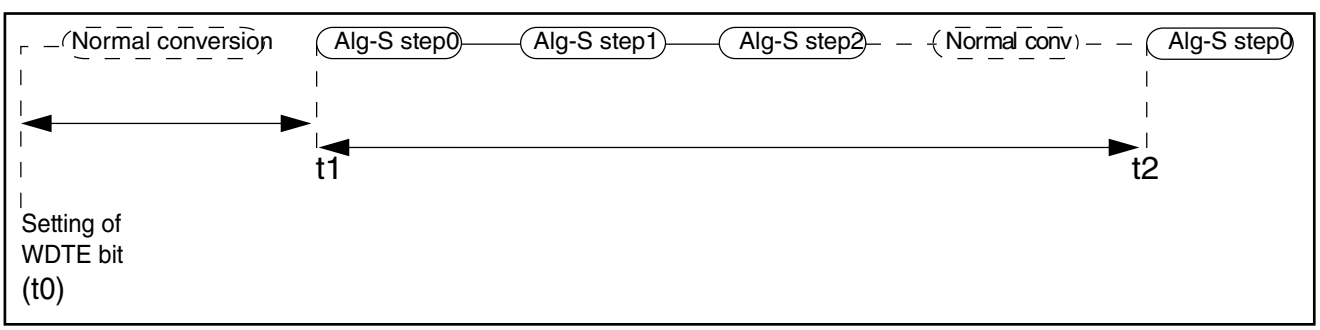


Figure 43-10. Watchdog timer monitor for algorithm S

Notes:

- As CTU does not incorporate any safe period checking mechanism, the watchdog timers can also be enabled for CTU conversions.
- Take care not to enable the watchdog timer for an algorithm that is not to be executed.

43.6.10.2.6.1 Watchdog sequence checking

The watchdog timer also incorporates sequence checking features that check the order of a particular algorithm's steps. If the steps are not in order, then an error is flagged by setting the STSR1[WDSERR]. A critical fault is asserted and an interrupt is also generated if enabled by STCR2[MSKWDSERR].

A watchdog sequence error is flagged in the following cases:

- If the steps of any algorithm are not executed in the proper order.
- If an abort chain occurs during a test channel conversion, that step has to be repeated at the end of the next chain. This will give a sequence error as soon as test channel conversion starts again.
  - Exception: If an abort chain occurs during the last step of algorithm S, then sequence errors are not flagged as the whole algorithm has to be repeated again.
- If, for CTU conversions, the step numbers provided by the CTU are not in order. Watchdog sequence checking is significant for CTU burst mode only.

If injected conversion occurs during the test channel, watchdog sequence errors are *not* flagged although the ongoing step number is aborted and repeated again.

Note

The watchdog timer feature is applicable only for Scan mode, not for One-Shot mode.

43.6.10.2.7 Baud rate control for test channel

It defines the scheduling of the test channel between normal conversions. The scheduling rate is specified by STBRR[BR].

By default, if the test channel is enabled, one step of the selected algorithm is executed after every chain of normal conversion. The bandwidth consumed by the test channel depends on the number of channels in a normal chain. For example, if there are 100 normal conversions in a chain, then the test channel consumes only 1% of the total bandwidth, which is very small. However, if the number decreases to just four channels, then the bandwidth consumed by the test channel is 25%, which is significant (and may not be desirable as it slows down the normal conversion rate).

STBRR[BR] provides flexibility by scheduling the test channel conversion to be performed, not at the end of every chain, but at the end of BR + 1 number of chains. For example, if BR = 5, a single step of the selected algorithm for the test channel is performed after six chain conversions, then the next step is performed at end of the next six chain conversions, and so on. By default, the value of BR is 0.

Notes:

- This feature is applicable only for Scan mode, not for One-Shot mode. STBRR[BR] should be set to 0 for one shot mode.
- To use the baud rate feature in Scan mode, the NCMR register should have nonzero value.

43.6.10.2.7.1 Abort chain when baud rate is non-zero

As previously described, a nonzero value of STBRR[BR] means that the test channel conversion is performed at the end of BR + 1 number of chains. If an abort chain occurs during the chain in which the test channel is scheduled to be converted, then the test channel is converted after the next BR + 1 number of chains.

For example, if STBRR[BR] is programmed to 2, the sequence will be two normal chains (without any test channel conversion) followed by a chain with the test channel converted at the end. Now, if an abort chain occurs during first two chains it is treated as a normal chain abort and the test channel is converted at the end of the third chain only (as the case without any abort chain). But if the abort chain occurs during the third chain in which the test channel is scheduled to be converted, then the test channel is converted after next three chains (that is, at the end of sixth chain, counting from the beginning).

43.6.11 Conversion time

Total conversion time depends on ADC-SAR controller's operating clock. This clock can be prescaled to bus clock ÷ 2. The ADC-SAR operating clock (AD_clk) is always synchronous with bus clock. The frequency of AD_clk is dependent on settings of ADC_MCR[ADCLKSEL].

If ADC_MCR[ADCLKSEL] = 0, then AD_clk = (bus clock ÷ 2)

If ADC_MCR[ADCLKSEL] = 1, then AD_clk = bus clock

The various components of conversion time and affecting configurations are shown and described in Figure 43-11.

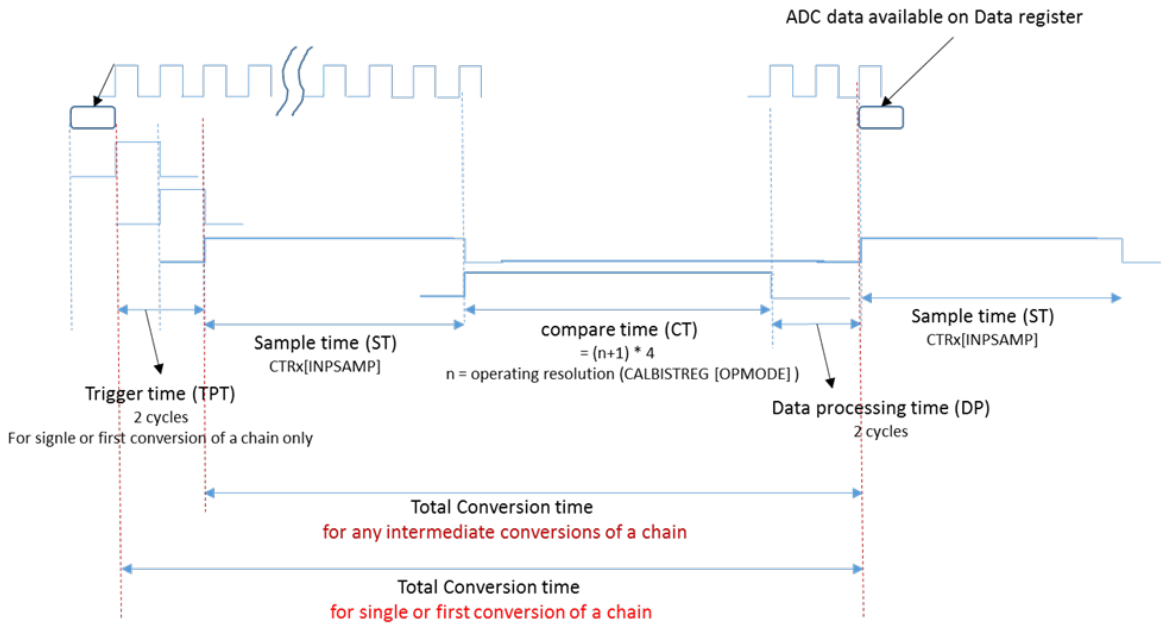

Figure 43-11. Conversion time

- Trigger processing time (TPT):

  To prepare the channel and start the operation, two clock cycles of bus clock is required by the ADC for the first conversion and for subsequent conversions in a chain, or for a continuous conversion, this time is not required as it is hidden in the pipeline operation. Triggers from Synchronous CTU interface requires two cycle of bus clock for first conversion and for back-to-back CTU conversions it takes only one cycle for trigger processing as the other cycle is hidden in pipeline operation. Triggers from Asynchronous CTU interface requires three cycles of bus clock for synchronization and processing.
- Sample phase time (ST):

  Sample time duration is controlled by the INPSAMP[7:0] field of Conversion timing Registers ADC_CTR*x* (*x* = 0...2) for different types of channels. Value in each register affects the sample time in similar way. The value in the register represents units of cycle of the AD_clk. The minimum value of sample time is 8. If the value programmed is less than 8, then it has no effect on sample time duration and in this case sample time will be 8 AD_clk cycles.
- Compare phase time (CT):

  The compare phase of the ADC is dependent on the resolution setting. It takes $((n + 1) \times 4)$ cycles of AD_clk, where n is the resolution setting configured in CALBISTREG[OPMODE].

- Data processing time (DP):

The ADC takes 2 cycles of AD_clk to post process and load the data int registers.

- Total Conversion Time:

  The total time required for single or first conversion is [TPT+ST+CT+DP] cycles of AD_clk and for subsequent conversion is a chain or continuous conversion is [ST+CT+DP] cycles of AD_clk.

  Examples:

  - CALBISTREG[OPMODE] = 110b; CTR*x*[INPSAMP] = 20d; software/hardware triggered (NSTART):
    - Single/First Conversion: 2 + 20 + ((13 + 1) × 4) + 2 = 2 + 20 + 56 + 2 = 80 cycles of AD_clk
    - Subsequent/continuous conversion: 20 + ((13 + 1) × 4) + 2 = 20 + 56 + 2 = 78 cycles of AD_clk
  - CALBISTREG[OPMODE] = 001b; CTR*x*[INPSAMP] = 22d; software/hardware triggered (NSTART):
    - Single/First Conversion: 2 + 22 + ((12 + 1) × 4) + 2 = 2 + 22 + 52 + 2 = 78 cycles of AD_clk
    - Subsequent/continuous conversion: 22 + ((12 + 1) × 4) + 2 = 22 + 52 + 2 = 76 cycles of AD_clk
  - CALBISTREG[OPMODE] = 110b; CTR*x*[INPSAMP] = 20d; CTU triggered:
    - Single/First Conversion: 2 + 20 + ((13 + 1) × 4) + 2 = 2 + 20 + 56 + 2 = 80 cycles of AD_clk
    - Subsequent/continuous conversion: 1 + 20 + ((13 + 1) × 4) + 2 = 1 + 20 + 56 + 2 = 79 cycles of AD_clk
  - CALBISTREG[OPMODE] = 001b; CTR*x*[INPSAMP] = 22d; CTU triggered:
    - Single/First Conversion: 2 + 22 + ((12 + 1) × 4) + 2 = 2 + 22 + 52 + 2 = 78 cycles of AD_clk
    - Subsequent/continuous conversion: 1 + 22 + ((12 + 1) × 4) + 2 = 1 + 22 + 52 + 2 = 77 cycles of AD_clk

- Pre-Sampling:

  When pre-sampling is enabled, the ADC does pre-sampling prior to starting the actual channel sampling as described in pre-sampling section. This phase takes CTR*x*[INPSAMP] cycles of AD_clk. Additionally, to switch from pre-sample phase to actual channel sampling phase, it takes another two cycles of AD_clk. So, total CTR*x*[INPSAMP] + 2 cycles additionally required for a conversion to be completed. Thus, in case of pre-sample, all the equations and examples above are valid with the addition of (CTR*x*[INPSAMP] + 2) cycles.

43.6.11.1 Conversion time for CTU interface

The CTU works in the same clock domain of the ADC operating clock allowing the conversion time to be similar to normal conversion time previously discussed.

43.6.12 Conversion data processing

The raw converted ADC data contains many types of errors such as offset, gain, DC bias, and so on. Thus, to generate error-free results, raw converted data is processed before it is written to a result register. The process of error correction goes bit-by-bit during conversion with the values generated during the offset calculation and calibration process. This helps in reducing final data processing time as only one addition/addition (2's complement) is performed simultaneously with conversion.

43.7 Clock frequency

The ADC internal blocks are designed to work with an 80 MHz clock. Thus, the specified speed can be met with this clock frequency. If the clock is faster than this, ADCA cannot work properly and the ADC may malfunction. If the clock is slower, then the ADC speed will be lower, but it will work properly. It should be noted that there is an absolute maximum value of the sampling time that the analog portion of the ADC can support. For slower clocks, the sampling clock count will need to be programmed accordingly.

CTU, which talks to the ADC digital part, may run in different clock domain. For such usages, a clock domain synchronizer is placed at the interface of ADC digital and CTU. The loss is of 2-extra clock cycles due to synchronization; thus overall speed need to be achieved by reduced cycles for samples.

Chapter 44
Temperature Sensor (TSENS)

44.1 Introduction

The device includes two on-chip temperature sensors. The temperature sensor module monitors device temperature and delivers one analog output signal and two digital output signals each (under- and over-temperature flags). The analog output consists of a voltage signal directly proportional to the internal junction temperature. The analog output is connected to an input channel of an ADC on the device (see the ADC details for the channel number). The internal junction temperature must be calculated by software based on the sampled temperature sensor voltage; sampled bandgap reference voltage, which comes from another module; and calibration parameter values stored in internal flash memory. The two digital outputs, connected to the PMC module, are used to signal under- and over-temperature operating conditions.

The digital outputs signal when the junction temperature drifts below the low temperature threshold or above the high temperature threshold. These signals notify the device to take action to appropriately adjust the device temperature in response to an out-of-specification low or high temperature operating condition. Calibration parameter values associated with the temperature threshold detection feature are determined and stored in internal flash memory during production testing at the factory.

44.2 Functional Description

The temperature sensor generates one analog output voltage, $V_{TSENS}(T)$, which is proportional to the absolute current junction temperature of the device, and two digital outputs that signal whether the junction temperature has reached either a pre-set low temperature threshold or a pre-set high temperature threshold.

An on-chip ADC module is used to convert the analog output voltage, as well as the bandgap reference voltage, into a digital representation. These values, along with parameter values stored in on-chip flash memory, are used by software to calculate the device junction temperature.

44.2.1 Temperature threshold detection (digital output generation)

Temperature threshold trimming values are adjusted through calibration during factory test and stored in on-chip flash memory. Refer to "Software-controlled temperature sensor trim adjustment" in Chip-specific power management controller (PMC) information.

When the temperature threshold detection feature is enabled, the temperature sensor monitors the internal junction temperature of the chip and asserts a signal if any of the following temperature thresholds are crossed.

- The low temperature digital output signals if the junction temperature falls below the low temperature threshold (-40°C).
- The high temperature digital output signals if the junction temperature rises above the high temperature threshold (150°C).

The threshold detection circuit is calibrated with respect to the factory-test temperatures: the low temperature threshold is trimmed to match the cold insertion test temperature (nominally equal to –40°C), and the high temperature threshold is trimmed to match the hot insertion test temperature (nominally equal to 150°C). In other words, the thresholds are not trimmed to absolute values of temperature but to the specific temperatures for which the device is validated during factory test.

Hysteresis is applied whenever outputs transition to a logic level low in order to eliminate spurious toggling. Digital output behavior is illustrated on Figure 44-1.

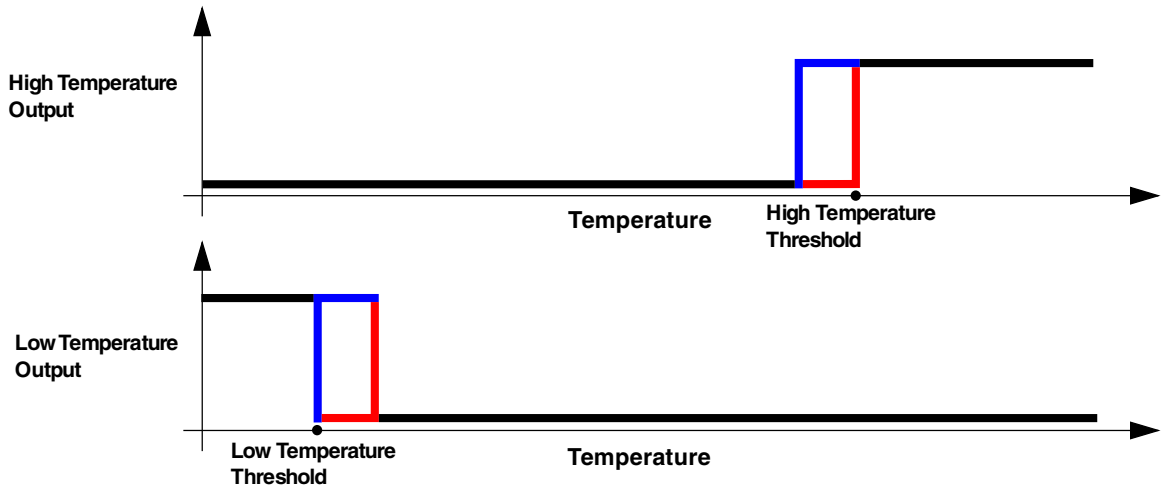

Figure 44-1. Digital output behavior with temperature

44.2.2 Linear temperature sensor (analog output generation)

When analog output generation is enabled, the temperature sensor outputs a voltage proportional to the internal junction temperature of the chip. This analog voltage signal is converted into a digital code by an on-chip ADC. The temperature value is obtained from a linear voltage-temperature relation with coefficients adjusted by calibration parameters extracted during factory test and programmed into flash memory.

44.3 Temperature formula

The system chain that translates device junction temperature into a digital variable is composed of the temperature sensor, a bandgap reference voltage source and the on-chip ADC. Both analog output voltages of the temperature sensor and the bandgap reference voltage source must be converted by the ADC into digital codes to obtain the device junction temperature. The temperature formula shown in Figure 44-2 is used to calculate internal device junction temperature.

$$T \times 2^2 = \frac{(K_1 \times V_{BG\_CODE}(T)) \times 2^{-1} + (K_2 \times V_{TSENS\_CODE}(T)) \times 2^3}{[(K_3 \times V_{BG\_CODE}(T)) \times 2^2 + (K_4 \times V_{TSENS\_CODE}(T))] \times 2^{-10}} \quad [K]$$

$$V_{TSENS\_CODE}(T) = \frac{V_{TSENS}(T)}{V_{ref}} \times 2^{12} \qquad V_{BG\_CODE}(T) = \frac{V_{BG}(T)}{V_{ref}} \times 2^{12}$$

- T is the internal junction temperature in Kelvin
- $V_{TSENS}(T)$ is the temperature sensor output sampled by the ADC
- $V_{BG}(T)$ is the bandgap reference voltage sampled by the ADC
- V_{ref} is the ADC reference voltage in normal usage of the device
- K1, K2, K3, and K4 are 16-bit signed integer constants in two's-complement representation stored in flash memory (obtained from factory calibration)

Figure 44-2. Temperature formula

Parameters K1, K2, K3, and K4 are 16-bit signed integer constants in two's-complement representation that are stored in flash memory during factory test and calibration. These constants must be used in the temperature formula to calculate device junction temperature.

44.4 Calculating device temperature

Software must perform the following steps in order to calculate device temperature.

1. Measure the bandgap reference voltage using the on-chip ADC module and calculate $V_{BG\_CODE}(T)$ according to the formula shown in Figure 44-2.
2. Measure the temperature sensor output voltage using the on-chip ADC module and calculate $V_{TSENS\_CODE}(T)$ according to the formula shown in Figure 44-2
3. Retrieve parameters K1, K2, K3, and K4 from flash memory.
4. Calculate T according to the formula shown in Figure 44-2.

Note

Temperature Formula may be calculated using signed 32-bit (integer) operations showing negligible precision loss.

Chapter 45
Signal Processing Toolbox (SPT)

45.1 Chip-specific SPT information

The following table gives the defined sample rates for SPT-MIPICSI2 interactions as per the 1 Gbps limitation from MIPICSI2 and 20 MSPS limitation from SPT.

Table 45-1. SPT-MIPICSI2 sample rate

Data Type	Data Mode	5th channel	Sampla rate per chanel (MSPS)	Sampla rate 5th chanel (MSPS)
RAW8/10/12	REAL (A-D)	OFF	2.5 - 20	N.A.
RAW14	REAL (A-D)	OFF	2.5 - 1 8	N.A.
RAW8/10/12	COMPLEX (A-H)	OFF	2.5 - 10	N.A.
RAW14	COMPLEX (A-H)	OFF	2.5 - 9	N.A.
RAW8/10/12	REAL (A-D)	ON	10	10
RAW8/10/12/14	REAL (A-D)	ON	5	10
RAW8/10/12/14	REAL (A-D)	ON	2.5	10
RAW8/10/12/14	REAL (A-D)	ON	6.67	13.33
RAW8/10/12	COMPLEX (A-H)	ON	5	10

NOTE

The ‘CPU VERSION Registers’ mentioned in Interrupts, corresponds to ‘System Version Register’ of Z7 Cores in this device.

45.1.1 Time Period of calculation of Throughput in various modes of PDMA

The Table 45-73 uses the following time periods for its calculations.

In this device

- spt_clock_period is the time period of SPT_CLK.

- ahb_clock_period is the time period of SYS_CLK.
- ipg_clock_period is the time period of PBRIDGE_n_CLK.

45.2 Introduction

The Signal Processing Toolbox (SPT) contains all the hardware modules required for processing of the sampled RADAR signals. It is a powerful processing engine containing high-performance signal processing operations, driven by a specific use-oriented instruction set. The programmability ensures flexibility for modifications of signal processing. The CPU is removed from frequent scheduling of hardware operations, but still controls and interacts with the processing flow.

45.3 Block diagram

The SPT is connected to the device by an advanced high performance master bus and a peripheral bus.

The system bus master interface performs fast data transfers between external memory and local RAM.

The purpose of the peripheral interface is to set configuration, get status information and basic control of SPT (start/stop, program pointer) and to trigger interrupts. It can also be used to exchange small amounts of the data between the CPU and the SPT, such as constant operands.

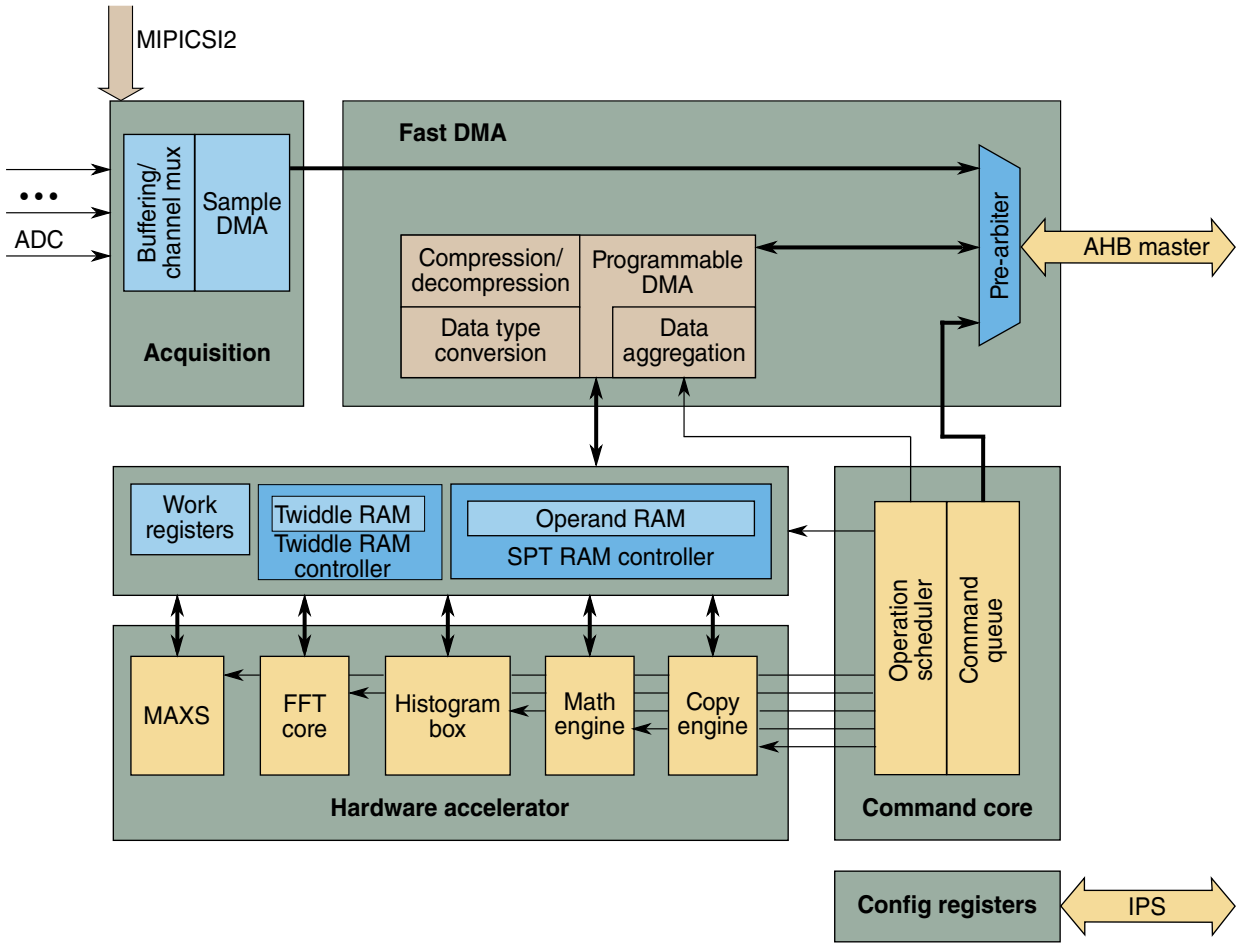

Figure 45-1. SPT Block Diagram

45.4 Features

- Acquisition of ADC samples
  - Capturing of ADC samples within programmed window
  - On-the fly statistical computation
  - Supports MIPICSI2 interface
- Provides HW acceleration for
  - FFT (8 - 4096 point)
  - Histogram calculation
  - Maximum and peak search
  - Mathematical operations on vector data
- High-speed DMA data transfer
  - Supports system RAM, TCM and Flash memory transfers
  - Includes compression/decompression capability for reduction of storage footprint
- Instruction based program flow

    - High-level commands for signal processing operations
    - Simple control commands
    - Local instruction buffer
    - Automatic instruction fetch from main memory
    - CPU interaction possible
- CPU interrupt notification
- Watchdog
- Debug Support - Single Stepping and Jamming Mode

45.5 SPT modes of operation

The following sections provide information about the modes in which SPT module can be used.

45.5.1 STOP Mode

When STOP mode request arrives, the command sequencer goes to the ASYNCSTOP state. The current SDMA, PDMA, or CSDMA burst is completed and reset is applied to SPT clock domain modules (which includes all modules except ACQ, SDMA and DMA arbiter). Also, the DMA arbiter does not request any further bursts on the System bus (though the acquisition module continues to receive data from the ADC). At this point acknowledge to this stop request is given. Thereafter ADC, SPT and AHB clock are stopped.

While exiting from the STOP mode, for proper operation, the acquisition module shall be restarted by resetting and then again setting the ACQ_EN signal. After that, the command sequencer can be restarted by setting the SPT_GBL_CTRL[PG_ST_CTRL] bit. Note that for proper sync after STOP mode exit, all the modules interacting with SPT, like CTE, WGM, MIPICSI2 receiver and transmitter, etc need to be restarted as well.

45.5.2 System Debug mode

When system enters debug mode and requests SPT to go to debug mode then the command sequencer goes to the debug state only after the current instruction has completed execution. This debug mode is mainly for the CPU, and it works in conjunction with another field SPT_CS_MODE_CTRL[CS_SYS_DEBUG]. If this field is zero then the command sequencer ignores the system debug entry request, else it goes to the debug state.

Also note that since the sequencer enters the debug state only at the end of the current instruction, the CPU must wait till the present instruction is completed before it tries to debug errors inside the SPT.

Note that ACQ and SDMA continue working in debug mode.

45.5.3 Normal Mode

The detailed functioning of this mode is provided in the Functional Description section.

45.6 SPT Operation Model

The SPT executes a list of instructions. These commands contain all the information to perform signal processing operations on data vectors consisting of a set of numbers. The instruction list is provided by the CPU in a memory buffer (SRAM or flash) and read by the SPT with autonomous triggered DMA operations. Preparation of command scripts is performed off-line during development on a different system, such as a PC.

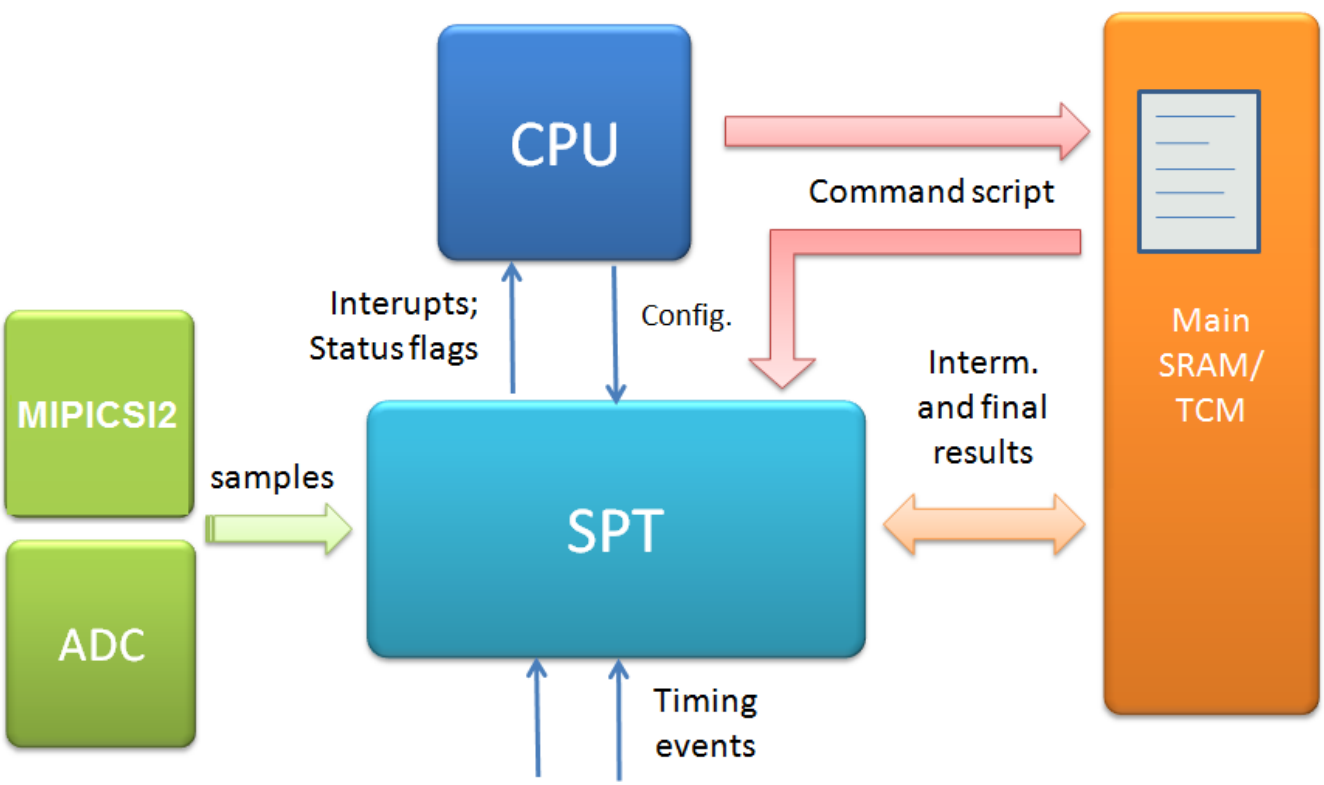

Figure 45-2. SPT Operation Model

Data as results or inputs of signal processing operations can be transferred between operand/twiddle RAM and system RAM or TCM by DMA operations. These kind of DMA operations are also scheduled by commands in the script.

CPU application software functions may be invoked between signal processing operations. In order to synchronize these SW functions with the processing flow, interrupts and polling flags are provided, which may be activated as a result of specific commands. In the same way, eDMA operations can be triggered from the SPT. The data transfer descriptors need to be prepared by application software.

To enable advanced and precisely timed pipelining of HW assisted operations, SPT command execution can also be synchronized with or triggered by events from CTE or MIPICSI2.

The SPT also performs initial, on-the-fly processing for ADC samples to generate statistical results in advance and compensate offsets.

45.6.1 Program Execution

Program execution is performed by a dedicated register machine. The program execution may be stalled at the end of each command and can be synchronized with events provided by the CTE or MIPICSI2. The CPU can stop and release program execution and execute its own instructions in the mean time.

The SPT command sequence is provided by CPU SW and written to a buffer in the system RAM or flash, where CSDMA fetches or alternatively transfers the list of instructions to the command queue.

The program is executed sequentially, one command following the next in the chain with the exception being loops and asynchronous PDMA instruction. The end of a sequence is marked with a specific termination command. The start address of the instruction sequence is configured by application software using the peripheral interface.

The command queue stores a number of instructions to be executed, which may be a shorter sequence than the complete instruction list. It maintains an instruction pointer to the current executed operation, which is incremented when the current operation is completed. This instruction pointer indicates the position in the complete instruction list sequence relative to the first instruction.

Loop instructions are special cases, the program sequence may continue with a lower address depending on the state of the loop counter. The start and next command address of the loops are saved in special registers. Up to four nested loops are supported.

Jump instructions or branch instructions are another case where the program may cause the program to branch to a non-contiguous address location. It is the responsibility of the assembler to ensure that the sanity of the program structure is not violated i.e. infinite loops, jumping into or out of a loop, etc.

The commands are stored in the system RAM or flash in a big endian format i.e. MSB in lower memory byte and LSB in higher memory byte. Table 45-2 shows the organization of a command word in the memory.

Table 45-2. Command word organization in memory

Memory Address	Instruction Bit Range
0x0	[127:120]
0x1	[119:112]
0x2	[111:104]
0x3	[103:96]
0x4	[95:88]
0x5	[87:80]
0x6	[79:72]
0x7	[71:64]
0x8	[63:56]
0x9	[55:48]
0xa	[47:40]
0xb	[39:32]
0xc	[31:24]
0xd	[23:16]
0xe	[15:8]
0xf	[7:0]

45.6.2 Instruction Fetch

SPT instructions are fetched from system RAM when the command queue is empty at the start of a program or when the last instruction in the queue starts during program execution, or even when a command close to the last instruction is being executed and the remaining commands are not loop-end commands. The command queue is filled by means of a SPT DMA operation. The instruction fetcher also handles loads from lower than the current addresses, in case a loop command branches to a lower address or an instruction load from a higher or lower address is required when a jump instruction causes program flow to go to a non-contiguous address. A specific branch prediction for performance increase is not performed. It is assumed that an execution stall due to instruction fetch only takes a few bus cycles and only happens when the longest command chain in a loop does not fit in the queue.

45.6.3 Watchdog

Some signal processing operations may have a limited time budget. A watchdog is available to monitor the processing time of a sequence of commands and raise a flag when a command sequence has taken too long.

The watchdog is armed by an SPT command configuring the initial timer value it can also stop or reset the watchdog. The watchdog works in two modes, count mode and event mode. In count mode the timer counts down using the SPT clock till it reaches zero. In the event mode the watchdog can be reset to zero with any CTE or MIPICSI2 event signal. Hence, in event mode the CTE or MIPICSI2 events can serve as a timing reference.

The current watchdog value can be read by application software. An interrupt may be issued to the CPU if the watchdog counter reaches zero in count mode. Alternatively the application software may read the watchdog value to identify if exceeding the timing budget, which is the case if read value is zero.

45.7 SPT internal memory map

SPT contains internal memory resources namely, Operand RAM, Twiddle RAM and work registers. Out of these, only the work registers can be directly accessed via the peripheral interface and are visible on the SPT external memory map.

The CPU can access these internal memory resources via the hardware accelerators. The instruction bitfields SRC_ADD and DEST_ADD point to these memories.

The two MSB bits of the address define the memory type. Table 45-3 shows the mapping of these address bits to the different memory resources in SPT. The figure below shows the memory map view.

Table 45-3. Memory type address decoding

Address bit value	Memory type	Comments
00b	Work registers	48 Work registers of word width of 48 bits each
01b	Twiddle RAM	512 x 8 locations of 36 bits each
10b	Operand RAM	512 x 8 x 4 locations of 52 bits each
11b	Reserved	Future Operand RAM expansion - Address wrapped around to point to Operand RAM

The Twiddle RAM extends from location 0x4000 to 0x4FFF. However the area from 0x5000 to 0x7FFF is aliased to the Twiddle RAM i.e. it wraps around to point to the Twiddle RAM. It should be noted that the memory accesses to the Twiddle RAM should not cross the area from 0x4000 to 0x7FFF.

The Operand RAM extends from location 0x8000 to 0xBFFF. But the area from 0xC000 to 0xFFFF is aliased to the Operand RAM. The memory accesses to the Operand RAM should not cross the area from 0x8000 to 0xFFFF.

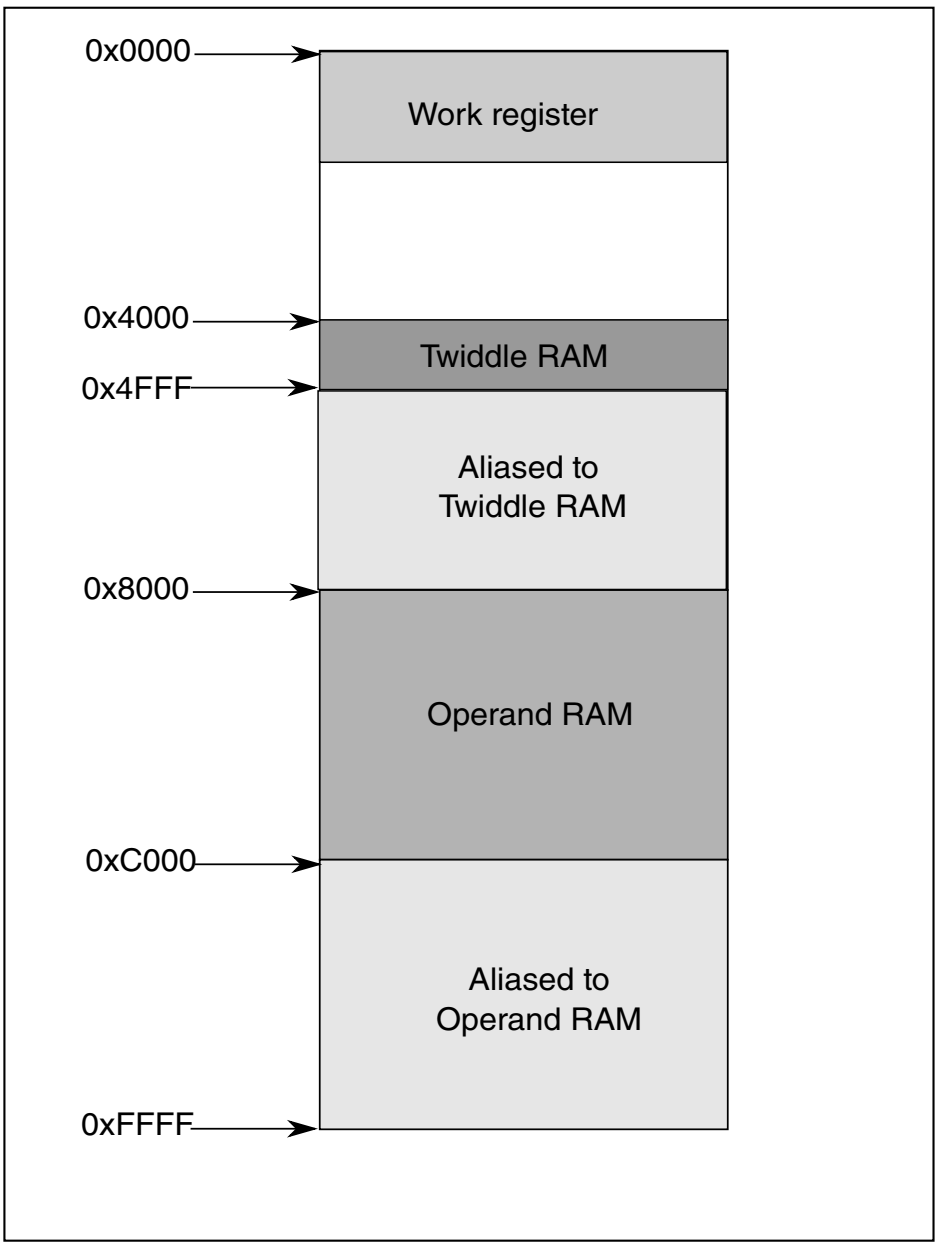

Figure 45-3. Memory Map view

45.8 Memory map and register description

NOTE

Transfer error will not be generated at offset 0x3E0, 0x3E4, 0x3E8 and 0x3EC

The following table shows the SPT detailed memory map:

SPT memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	SPT Global Control Register (SPT_GBL_CTRL)	32	R/W	0000_0008h	45.8.1/1783
4	Acquisition Global Control Register (SPT_ACQ_GBL_CTRL_0)	32	R/W	0000_0000h	45.8.2/1784

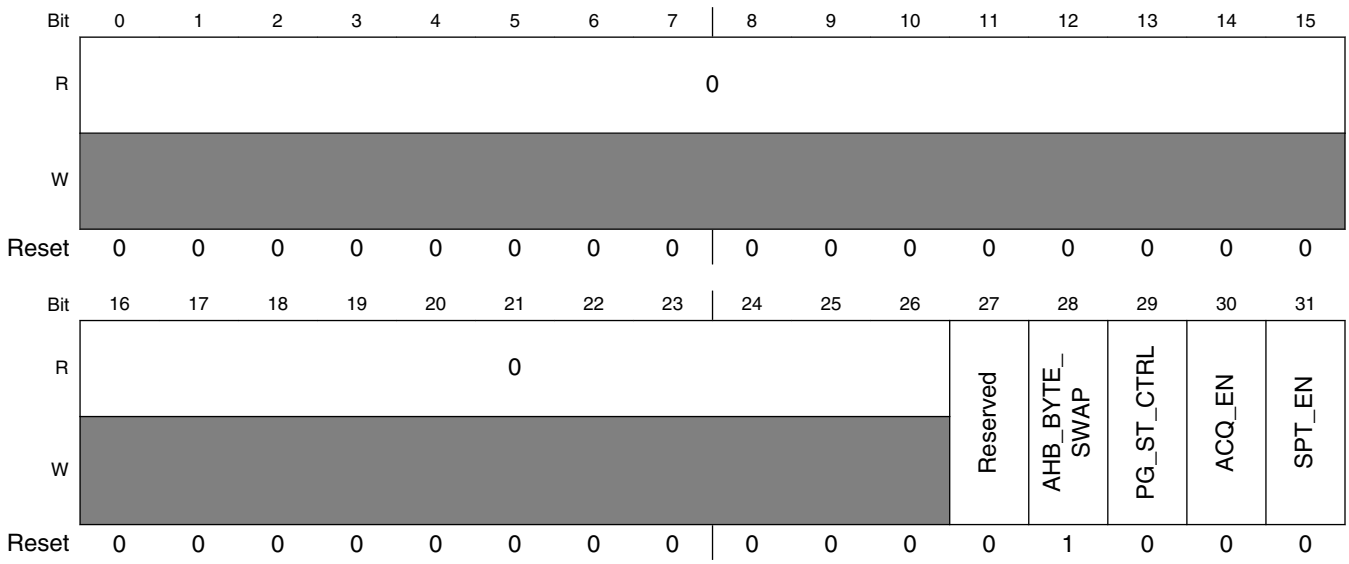
45.8.1 SPT Global Control Register (SPT_GBL_CTRL)

This register allows user to configure various control fields as described below.

Address: 0h base + 0h offset = 0h



SPT_GBL_CTRL field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 Reserved	This field is reserved.
28 AHB_BYTE_ SWAP	Bit to control data byte swapping on the AHB interface. 1 - Swap(required). This bit is Reserved and always write as 1.
29 PG_ST_CTRL	Program start control Program execution starts only after this bit is set. When this bit is set the command sequencer in the START state checks if there is any residual instruction fetch operation still going on. If no such operation is going on then the sequencer moves to the SETUP state and this bit is internally cleared. This bit should be set when SPT_EN is high. When set, user should wait for PG_ST_CTRL to be 0 to ensure that all status are cleared properly.
30 ACQ_EN	Acquisition Enable. This field enables the Acquisition module. This field must be asserted only after all other Acquisition and SDMA register fields have been programmed. This bit should be set after IPS programming is done for the SPT domain modules. When this bit is cleared, it will reset all the ACQ and SDMA modules after any on-going AHB burst is completed. ACQ_EN and SPT_EN bit can be used independently. Before changing the configuration for Acquisition ACQ_EN should be deasserted. Note: There must be a gap of atleast 10 AFE/MIPICSI2 interface clock cycles between setting this bit and subsequently asserting of frame start signal. There must be a gap of atleast 100 AFE/MIPICSI2 interface clock cycles between resetting this bit and subsequently setting it; so that there is enough time for any on-going AHB burst to complete and for ACQ and SDMA modules to be reset.

Table continues on the next page...

SPT_GBL_CTRL field descriptions (continued)

Field	Description
	0 Acquisition module is disabled. Acquisition and SDMA registers can now be programmed. 1 Acquisition module is enabled. ADC samples can now be collected by acquisition block which are processed and transferred to System RAM by SDMA via AHB bus.
31 SPT_EN	SPT Enable This bit should be set after IPS programming is done for the SPT domain modules. When reset, any on-going CSDMA or PDMA burst is completed and thereafter it will reset all the SPT domain modules (which is all modules except ACQ, SDMA and AHB Arbiter). This bit can be used independently from ACQ_EN. Note: There must be a gap of atleast 100 AHB interface clock cycles between resetting this bit and setting it again; so that there is enough time for any on-going AHB burst to complete and for SPT domain modules to be reset. Also, please note that this bit should be reset only when the command sequencer FSM is in the start state (One way to ensure this is by setting the SPT_CS_MODE_CTRL[CFG_STOP] or SPT_CS_MODE_CTRL[ASYNCSTOP] bit and then poll the SPT_CS_STATUS3[PROC_STATE] field). 0 SPT is disabled 1 SPT is enabled.

45.8.2 Acquisition Global Control Register (SPT_ACQ_GBL_CTRL_0)

This register allows user to configure various control fields as described below.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	CH_H_SEL		CH_G_SEL		CH_F_SEL		CH_E_SEL		CH_D_SEL		CH_C_SEL		CH_B_SEL		CH_A_SEL	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	CSI_ADC_SEL	INF_CHRPS	INF_SMPLS	ADC_SWAP_SEL	0											
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SPT_ACQ_GBL_CTRL_0 field descriptions

Field	Description
0–1 CH_H_SEL	Channel H Select This field is used to disable or swap channel H. If the MIPICSI2 path is enabled, the channel can only be disabled and not swapped. This field should be set to zero if its real data mode or 4ADC mode.

Table continues on the next page...

SPT_ACQ_GBL_CTRL_0 field descriptions (continued)

Field	Description
	00 Channel Disabled 01 No Swap - Channel H 10 Swaps to Channel A 11 Swaps to Channel G
2–3 CH_G_SEL	Channel G Select This field is used to disable or swap channel G. If the MIPICSI2 path is enabled, the channel can only be disabled and not swapped.This field should be set to zero if its real data mode or 4ADC mode. 00 Channel Disabled 01 No Swap - Channel G 10 Swaps to Channel B 11 Swaps to Channel H
4–5 CH_F_SEL	Channel F Select This field is used to disable or swap channel F. If the MIPICSI2 path is enabled, the channel can only be disabled and not swapped. This field should be set to zero if its real data mode or 4ADC mode. 00 Channel Disabled 01 No Swap - Channel F 10 Swaps to Channel C 11 Swaps to Channel E
6–7 CH_E_SEL	Channel E Select This field is used to disable or swap channel E. If the MIPICSI2 path is enabled, the channel can only be disabled and not swapped. This field should be set to zero if its real data mode or 4ADC mode. 00 Channel Disabled 01 No Swap - Channel E 10 Swaps to Channel D 11 Swaps to Channel F
8–9 CH_D_SEL	Channel D Select This field is used to disable or swap channel D for ADC data. The channel swapping varies from 4 to 8 ADC channels, given by ADC_SWAP_SEL If the MIPICSI2 path is enabled, the channel can only be disabled and not swapped. 00 Channel Disabled 01 No Swap - Channel D 10 Swaps to Channel C 11 Swaps to Channel E for 8ADCs, swaps to Channel A for 4ADCs
10–11 CH_C_SEL	Channel C Select This field is used to disable or swap channel C for ADC data. The channel swapping varies from 4 to 8 ADC channels, given by ADC_SWAP_SEL If the MIPICSI2 path is enabled, the channel can only be disabled and not swapped.

Table continues on the next page...

SPT_ACQ_GBL_CTRL_0 field descriptions (continued)

Field	Description
	00 Channel Disabled 01 No Swap - Channel C 10 Swaps to Channel DReserved 11 Swaps to Channel F for 8ADCs, swaps to channel B for 4ADCs
12–13 CH_B_SEL	Channel B Select This field is used to disable or swap channel B for ADC data.The channel swapping varies from 4 to 8 ADC channels, given by ADC_SWAP_SEL If the MIPICSI2 path is enabled, the channel can only be disabled and not swapped. 00 Channel Disabled 01 No Swap - Channel B 10 Swaps to Channel A 11 Swaps to Channel G for 8ADCs, swaps to channel C for 4ADCs
14–15 CH_A_SEL	Channel A Select This field can be used to disable or swap channel A for ADC data.The channel swapping varies from 4 to 8 ADC channels, given by ADC_SWAP_SEL If the MIPICSI2 path is enabled, the channel can only be disabled and not swapped. 00 Channel Disabled 01 No Swap - Channel A 10 Swaps to Channel B 11 Swaps to Channel H for 8ADCs, swaps to channel D for 4ADCs
16 CSI_ADC_SEL	CSI/ADC Select This field decides between using ADC data or MIPICSI2 data as source for Acquisition. 0 Acquisition source is ADC data 1 acquisition source is MIPICSI2 data
17 INF_CHRPS	Infinite Chirps in a Frame This field allows user to override ACQ_GBL_CTRL_1[NUM_CHRP] value and allows infinite chirps in a frame. Asserting this field prevents end of frame from being detected, thus preventing GBL_STA[FRM_ACQ_DONE] from asserting. User must wait for GBL_STA[CHRP_ACQ_DONE] after last chirp in the frame has been processed, before performing a read on any statistics present on Acquisition Status registers. 0 The number of chirps within a frame is limited and is programmable via ACQ_GBL_CTRL_1[NUM_CHRP] field. 1 The number of chirps within a frame is unlimited.
18 INF_SMPLS	Infinite Samples in a Chirp This field allows user to override ACQ_GBL_CTRL_1[NUM_SMPL] value and allows infinite samples in a chirp. If asserted, the acquisition window signal from CTE/MIPICSI2 solely decides the window for acquisition within a chirp. It is however expected that the acquisition window will be deasserted only after equal samples of all channels have been acquired. 0 The number of samples within a chirp is limited and is programmable via ACQ_GBL_CTRL_1[NUM_SMPL] field. 1 The number of samples within a chirp is unlimited.

Table continues on the next page...

SPT_ACQ_GBL_CTRL_0 field descriptions (continued)

Field	Description
19 ADC_SWAP_SEL	ADC Swap select Channel Swap select for 4 or 8 ADCs. **NOTE:** Recommended setting of ADC_SWAP_SEL is 1, as SDADC has 4 channels. 0 8 ADC channel swapping 1 4 ADC channel swapping
20–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

45.8.3 Acquisition Global Control Register 1 (SPT_ACQ_GBL_CTRL_1)

This register allows user to configure various control fields as described below.

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	NUM_SMPL																NUM_CHRP															
Reset	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1

SPT_ACQ_GBL_CTRL_1 field descriptions

Field	Description
0–15 NUM_SMPL	Number of Samples in a Chirp This value is given by (NUM_SMPL + 1)*8 for each channel, hence configuring this field to 0 results in 8 samples per chirp. Similarly the default value of 31 corresponds to 256 samples per chirp. Maximum value of 65,535 corresponds to 524,288 samples per chirp. This field is invalid if ACQ_GBL_CTRL_0[INF_SMPLS] is asserted.
16–31 NUM_CHRP	Number of chirps in a frame The number of chirps in a frame is given directly by this field Configuring this field to 0 results in 0 chirps per frame. Similarly the default value of 31 corresponds to 31 chirps per frame. This field can be configured upto a maximum of 65,535 chirps per frame. The chirp count remains the same for both SDMAs. This field is invalid if ACQ_GBL_CTRL_0[INF_CHRPS] is asserted.

45.8.4 Acquisition Control 0 Register (SPT_ACQ_CTRL0)

Gives offset compensation values for channels A and B.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	CH_A_DC

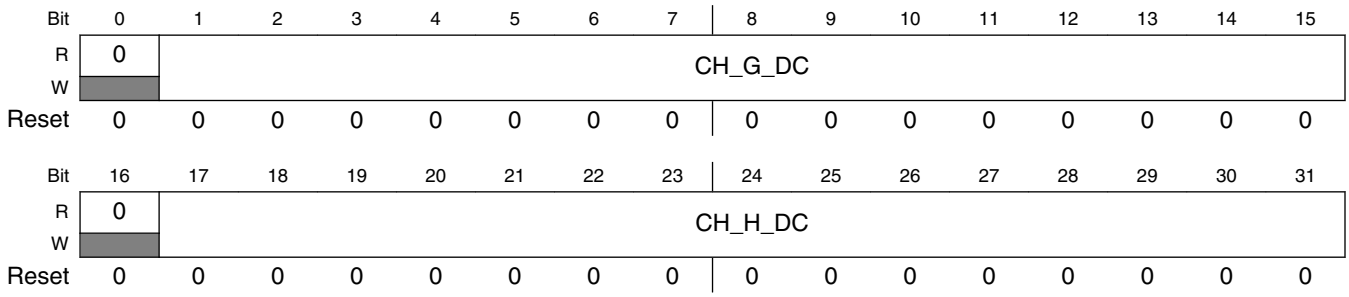
SPT_ACQ_CTRL2 field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–15 CH_E_DC	Channel E Offset Compensation value This is a signed 15-bit value
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–31 CH_F_DC	Channel F Offset Compensation value This is a signed 15-bit value

45.8.7 Acquisition Control 3 Register (SPT_ACQ_CTRL3)

Gives offset Compensation values for channels G and H.

Address: 0h base + 1Ch offset = 1Ch

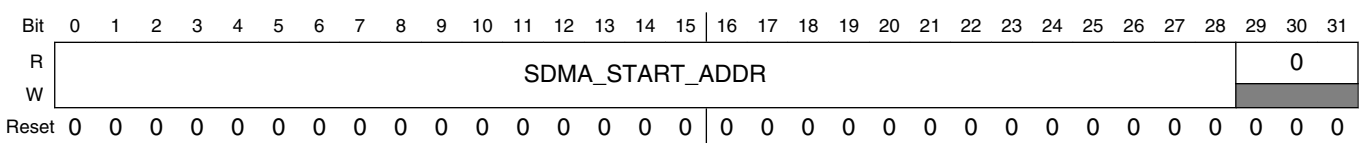


SPT_ACQ_CTRL3 field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–15 CH_G_DC	Channel G Offset Compensation value This is a signed 15-bit value
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–31 CH_H_DC	Channel H Offset Compensation value This is a signed 15-bit value

45.8.8 SDMA Control 0 Register (SPT_SDMA_CTRL0)

Address: 0h base + 20h offset = 20h

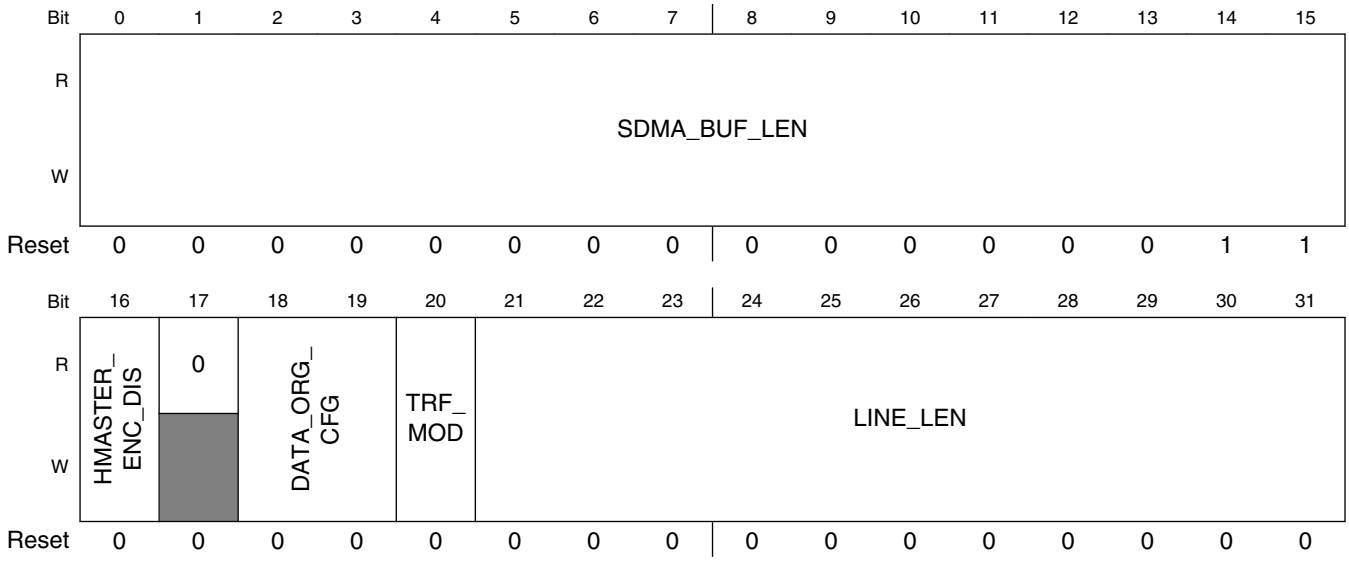


SPT_SDMA_CTRL0 field descriptions

Field	Description
0–28 SDMA_START_ADDR	SDMA Start Address All 32 bits in this register together provide the System RAM address from which SDMA starts writing ADC packets. The 3 LSB's of this address are restricted to zero, since this address must be a multiple of 8.
29–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

45.8.9 SDMA Control 1 Register (SPT_SDMA_CTRL1)

Address: 0h base + 24h offset = 24h



SPT_SDMA_CTRL1 field descriptions

Field	Description
0–15 SDMA_BUF_ LEN	SDMA Buffer Length This field provides the number of chirps in which samples received can be stored in System RAM continuously without being over-written. Once this is done, wrap-around occurs and previous samples in System RAM will be over-written. The default value of this field is 3. A value of 0 is invalid and hence should not be programmed in this field. For example, if this field is set to 2, then samples received from first 2 chirps are stored in SRAM one after the other depending on the active SDMA addressing mode. The SDMA write address resets to SPT_SDMA_CTRL0[SDMA_START_ADDRESS] from 3'rd chirp onwards, over-writing samples from previous two chirps with samples from 3'rd and 4'th chirps respectively.
16 HMASTER_ ENC_DIS	AHB Master ID generation disable Note: If SPT_SDMA_CTRL1[HMASTER_ENC_DIS] bit is 1, then the Duplicate Master ID will be 0xE when regular SDMA is giving out its burst and will 0xA when the Bypass SDMA is giving out its data. If SPT_SDMA_CTRL1[HMASTER_ENC_DIS] bit is 0, then whenever SDMA transfer is ongoing the Duplicate Master ID can be used to decode which ADC or MIPICSI2 source's data is being transferred in the transaction. If Interleaved mode is selected, the Duplicate Master ID will be: • 0x0 => First 4 channel's data in the transaction. • 0x1 => Last 4 channel's data in the transaction. If Tile-4 or Tile-8 mode is selected, the MasterID will be: • 0x0 => 1st enabled channel. • 0x1 => 2nd enabled channel. • 0x2 => 3rd enabled channel. • 0x3 => 4th enabled channel. • 0x8 => 5th enabled channel. • 0x9 => 6th enabled channel.

Table continues on the next page...

SPT_SDMA_CTRL1 field descriptions (continued)

Field	Description
	• 0xA => 7th enabled channel. • 0xB => 8th enabled channel. For MIPICSI2 real data, first 4 channels are used and for MIPICSI2 complex data all 8 channels are used. For bypass SDMA, the duplicate Master ID is 0xF. Note that the Crossbar Master ID is not affected by SPT_SDMA_CTRL1[HMASTER_ENC_DIS]; only the Duplicate Master ID is affected. The Duplicate Master ID encoding is only for the debugger to receive via NXMC. The PDMA and CSDMA master IDs are not affected by this bit. They will be 0x6 and 0xD respectively. 0 Duplicate AHB Master ID generated. In this case the Duplicate AHB Master ID at the top shows a value different from the Crossbar Master ID 1 Duplicate AHB Master ID not generated. In this case the Duplicate AHB Master ID at the top shows the same value as the Crossbar Master ID
17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–19 DATA_ORG_CFG	Data Organization Configuration This field selects between various configuration options by which regular SDMA places the ADC data in its internal buffer. The bypass SDMA always places the data in interleaved mode for both 5th channel and image data formats irrespective of this bitfield. 00 Interleaved Mode 01 Tile 4 Mode 10 Tile 8 Mode 11 Reserved
20 TRF_MOD	Transfer Mode This Field is used to select between 1D (Linear) and 2D (Orthogonal) modes for SDMA transfer. 0 Selects Linear (1D) Mode 1 Selects Orthogonal (2D) Mode
21–31 LINE_LEN	Line Length This field is utilized when SDMA_CTRL1[TRF_MOD] = 1; i.e. 2D Mode is selected. The value of line length is given by (LINE_LEN + 1)*8 Hence configuring this field to 0 results in line length of 8. Similarly a value of 31 corresponds to line length of 256. Maximum value of 2047 corresponds to line length of 16384.

45.8.10 Acquisition Status Register A0 (SPT_ACQ_STATUS_A0)

Address: 0h base + 44h offset = 44h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Field	Description
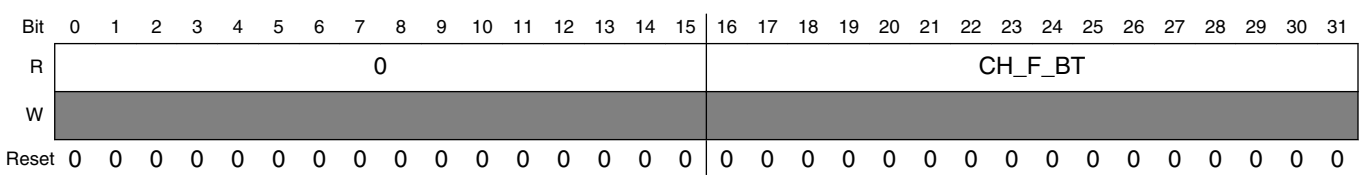
0–15 CH_F_MAX	Channel F Maximum This field provides the global (signed) maximum of all samples received from channel F within the acquisition window during the Frame. It is valid to be read only between frames; i.e the period between assertion of GBL_STA[FRM_ACQ_DONE] (or assertion of GBL_STA[CHRP_ACQ_DONE] after last chirp in frame has arrived) and the next RFS occurrence.
16–31 CH_F_MIN	Channel F Minimum This field provides the global (signed) minimum of all samples received from channel F within the acquisition window during the Frame. It is valid to be read only between frames; i.e the period between assertion of GBL_STA[FRM_ACQ_DONE] (or assertion of GBL_STA[CHRP_ACQ_DONE] after last chirp in frame has arrived) and the next RFS occurrence.

45.8.27 Acquisition Status Register F2 (SPT_ACQ_STATUS_F2)

Address: 0h base + 88h offset = 88h



SPT_ACQ_STATUS_F2 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 CH_F_BT	Channel F Bit Toggle

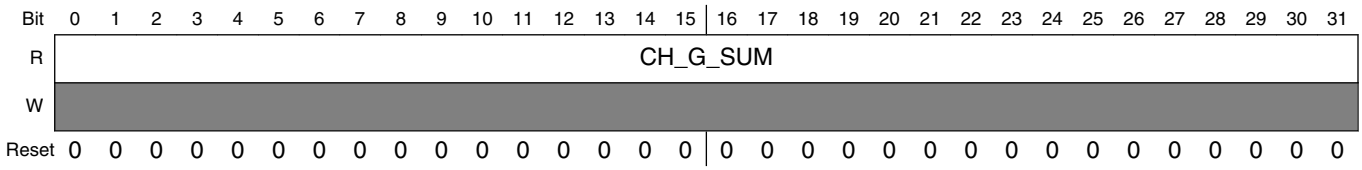
Table continues on the next page...

SPT_ACQ_STATUS_F2 field descriptions (continued)

Field	Description
	In this context, toggle is defined as detection of a '1 to 0' transition and a '0 to 1' transition. This field shows toggle status of Channel F input by scanning all samples received from channel F within the acquisition window during the Frame. It is valid to be read only between frames; i.e the period between assertion of GBL_STA[FRM_ACQ_DONE] (or assertion of GBL_STA[CHRP_ACQ_DONE] after last chirp in frame has arrived) and the next RFS occurrence. The input sample toggle status is MSB aligned. Unused LSB bits will be padded with zeros. 0 The corresponding bit did not toggle. 1 The corresponding bit has toggled.

45.8.28 Acquisition Status Register G0 (SPT_ACQ_STATUS_G0)

Address: 0h base + 8Ch offset = 8Ch

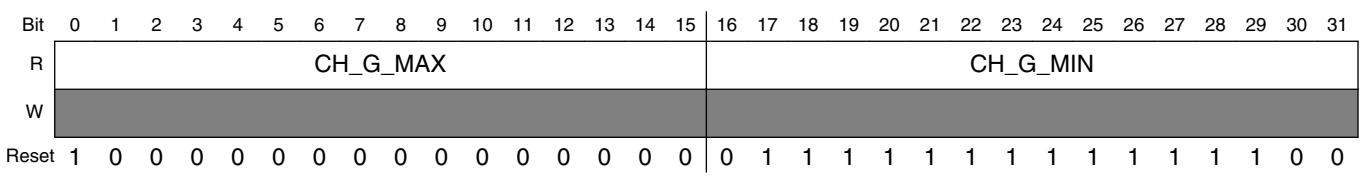


SPT_ACQ_STATUS_G0 field descriptions

Field	Description
0–31 CH_G_SUM	Channel G Sum This field provides the signed sum of all samples received by channel G within the acquisition window during the Frame. It is valid to be read only between frames; i.e the period between assertion of GBL_STA[FRM_ACQ_DONE] (or assertion of GBL_STA[CHRP_ACQ_DONE] after last chirp in frame has arrived) and the next RFS occurrence.

45.8.29 Acquisition Status Register G1 (SPT_ACQ_STATUS_G1)

Address: 0h base + 90h offset = 90h



SPT_ACQ_STATUS_G1 field descriptions

Field	Description
0–15 CH_G_MAX	Channel G Maximum This field provides the global (signed) maximum of all samples received from channel G within the acquisition window during the Frame. It is valid to be read only between frames; i.e the period between

Table continues on the next page...

0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 CH_H_BT	Channel H Bit Toggle

Table continues on the next page...

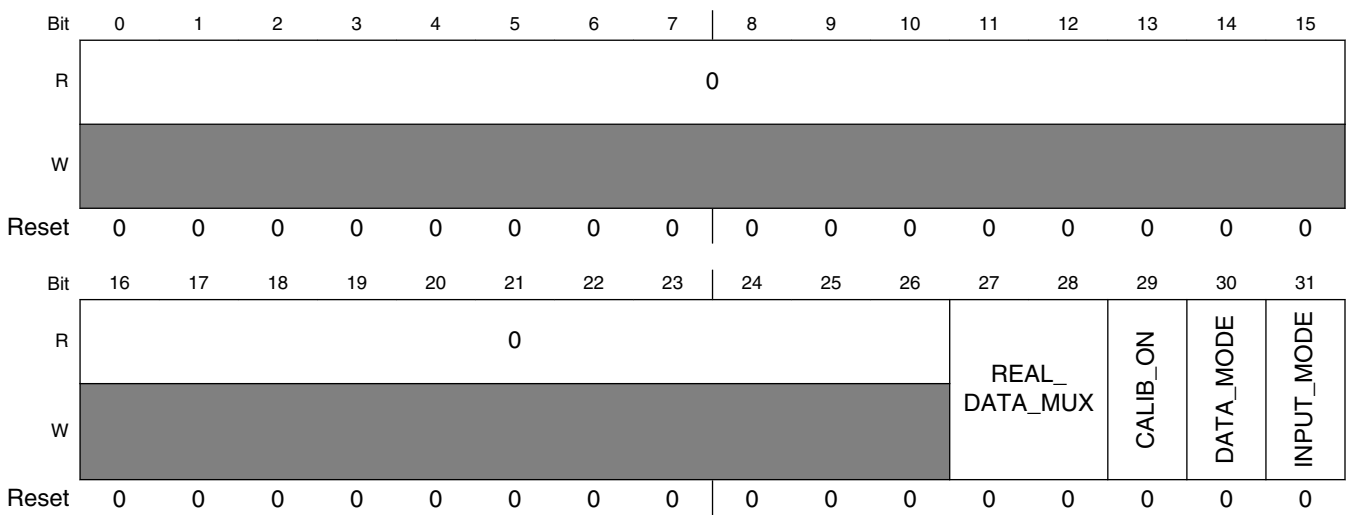
SPT_ACQ_STATUS_H2 field descriptions (continued)

Field	Description
	In this context, toggle is defined as detection of a '1 to 0' transition and a '0 to 1' transition. This field shows toggle status of Channel H input by scanning all samples received from channel H within the acquisition window during the Frame. It is valid to be read only between frames; i.e the period between assertion of GBL_STA[FRM_ACQ_DONE] (or assertion of GBL_STA[CHRP_ACQ_DONE] after last chirp in frame has arrived) and the next RFS occurrence. The input sample toggle status is MSB aligned. Unused LSB bits will be padded with zeros. 0 The corresponding bit did not toggle. 1 The corresponding bit has toggled.

45.8.34 Acquisition MIPICSI2 control register (SPT_ACQ_CSI_CTRL)

This register allows user to configure various control fields as described below only when MIPICSI2 is giving RAW data to Acquisition. No need to configure this for other image formats.

Address: 0h base + A4h offset = A4h



SPT_ACQ_CSI_CTRL field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–28 REAL_DATA_ MUX	Configures the sequence of data when channel 5 is on This register tells the sample rate of each channel data from MIPICSI2. This bit field is used only when calib_on is set to 1. It tells us the sequence of incoming data and repetition of channel 5 data. 00 Channel A-D at 10MSPS and channel E at 10MSPS. RAW14 does not support this mode. 01 Channel A-D at 5MSPS and channel E at 10MSPS.

Table continues on the next page...

SPT_ACQ_CSI_CTRL field descriptions (continued)

Field	Description
	10 Channel A-D at 2.5MSPS and channel E at 10MSPS. 11 Channel A-D at 6.667MSPS and channel E at 13.33MSPS.
29 CALIB_ON	Enables the fifth channel This bit field enables the calibration channel that is the fifth channel (channel E in diagrams). The input mode cannot be tile4 if this bit field is high. 0 calibration channel off 1 calibration channel on
30 DATA_MODE	Defines the type of data. This bit field selects whether the data is Real or complex. If the data is real then only 4 channels are used, else 8 channels are used to store the respective real and imaginary part of each channel. The real and imaginary data come in two consecutive valid clock cycles. 0 Input data is Real only. 1 Input data is complex (Real and Imaginary)
31 INPUT_MODE	Input Mode select This field is used to select input mode as interleaved or tile4 for data from MIPICSI2. Tile4 mode is not supported with data mode as complex. Image data type is always in Interleaved input mode irrespective of this bitfield. 0 Input data is in Tile4 format. Each channel receives 4 consecutive valid data. 1 Input data in Interleaved format. Each channel receives 1 valid data at a time.

45.8.35 Bypass SDMA Control 0 (SPT_SDMA_BYP_CTRL0)

Address: 0h base + A8h offset = A8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SPT_SDMA_BYP_CTRL0 field descriptions

Field	Description
0–28 SDMA_START_ADDR_BYP	Bypass SDMA Start Address All 32 bits in this register together provide the System RAM address from which Bypass SDMA starts writing ADC packets. The 3 LSB's of this address are restricted to zero, since this address must be a multiple of 8.
29–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

45.8.36 Bypass SDMA Control 1 Register (SPT_SDMA_BYP_CTRL1)

Address: 0h base + ACh offset = ACh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	SDMA_BUF_LEN_BYP																0					LINE_LEN_BYP									
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SPT_SDMA_BYP_CTRL1 field descriptions

Field	Description
0–15 SDMA_BUF_ LEN_BYP	Bypass SDMA Buffer Length This field provides the number of chirps in which samples received can be stored in System RAM continuously without being over-written. Once this is done, wrap-around occurs and previous samples in System RAM will be over-written. The default value of this field is 3. A value of 0 is invalid and hence should not be programmed in this field. For example, if this field is set to 2, then samples received from first 2 chirps are stored in SRAM one after the other depending on the active SDMA addressing mode. The SDMA write address resets to SPT_SDMA_BYP_CTRL0[SDMA_START_ADDR_BYP] from 3'rd chirp onwards, over-writing samples from previous two chirps with samples from 3'rd and 4'th chirps respectively.
16–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–31 LINE_LEN_BYP	Line Length Bypass This field is utilized when SDMA_CTRL1[TRF_MOD] = 1; i.e. 2D Mode is selected. The value of line length is given by (LINE_LEN_BYP + 1)*8 Hence configuring this field to 0 results in line length of 8. Similarly a value of 31 corresponds to line length of 256. Maximum value of 2047 corresponds to line length of 16384.

45.8.37 Acquisition Bypass Control Register (SPT_ACQ_BYP_CTRL)

This register allows user to configure various control fields as described below for bypass mode of ACQ in case of MIPICSI2 as input.

Address: 0h base + B0h offset = B0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	NUM_SMPL_BYP																0															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SPT_ACQ_BYP_CTRL field descriptions

Field	Description
0–15 NUM_SMPL_ BYP	Number of Samples in a Chirp This value is given by (NUM_SMPL_BYP + 1)*8 Hence configuring this field to 0 results in 8 samples per chirp. Similarly the default value of 31 corresponds to 256 samples per chirp. Maximum value of 65,535 corresponds to 524,288 samples per chirp. This field is programmed when the SPT_ACQ_CSI_CTRL[CALIB_ON] is enabled or the data type from MIPICSI2 is not RAW. This field is invalid if ACQ_GBL_CTRL_0[INF_SMPLS] is asserted.
16–31 Reserved	reserved This field is reserved. This read-only field is reserved and always has the value 0.

45.8.38 Program Start Addr Register (SPT_CS_PG_ST_ADDR)

Address: 0h base + C0h offset = C0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	PG_ST_ADDR

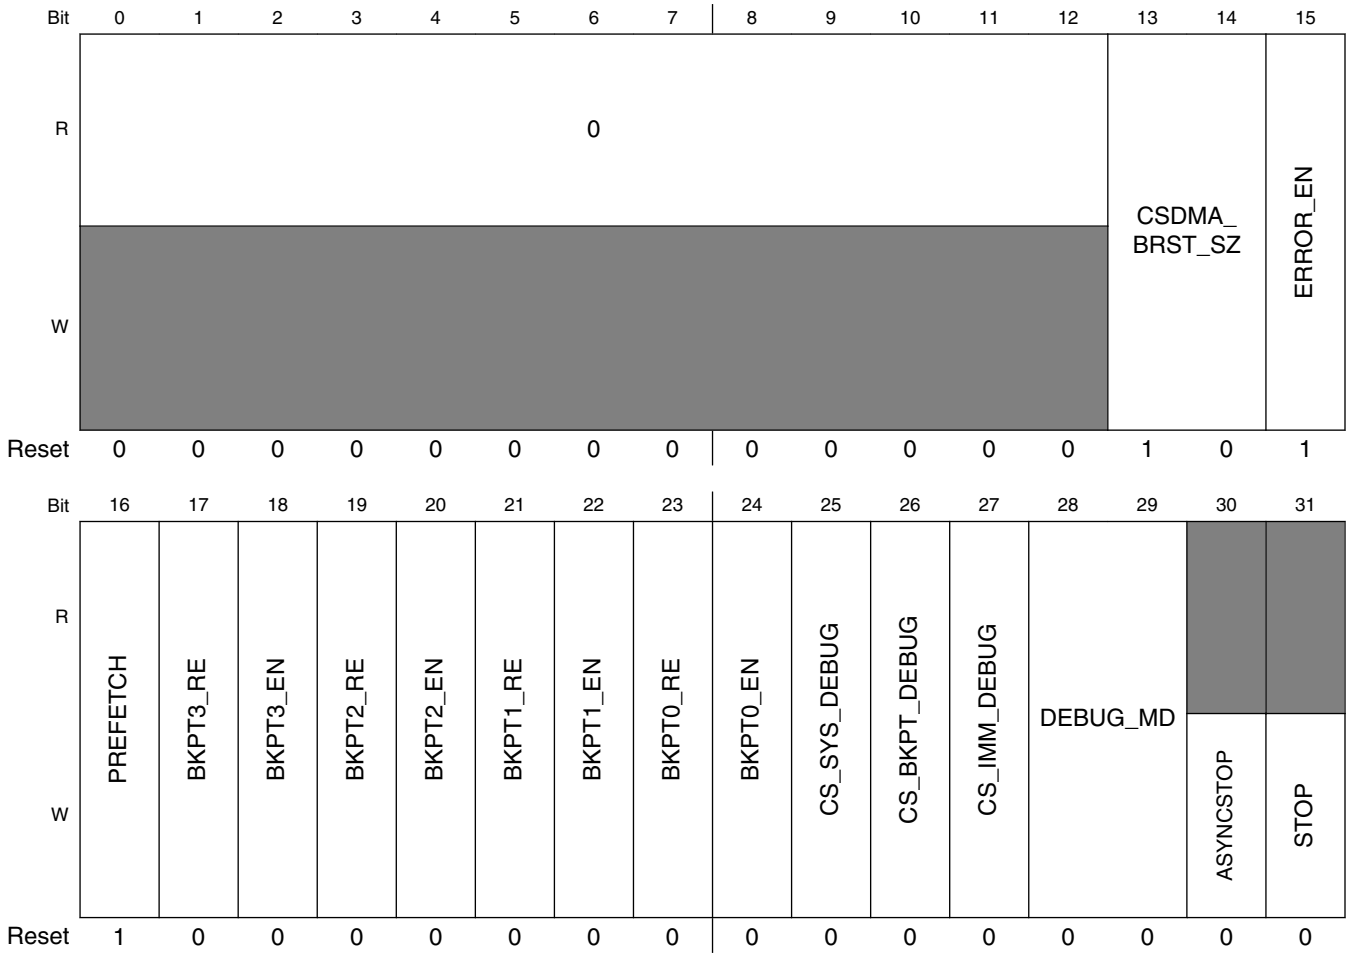
SPT_CS_PG_ST_ADDR field descriptions

Field	Description
0–31 PG_ST_ADDR	Program start address Gives the starting address for program execution. This is the fetch address of instructions from system memory. This address should be a multiple of 8. This address should be written before setting the SPT_GBL_CTRL[PG_ST_CTRL] field.

45.8.39 Mode Control Register (SPT_CS_MODE_CTRL)

Address: 0h base + C4h offset = C4h



SPT_CS_MODE_CTRL field descriptions

Field	Description
0–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–14 CSDMA_BRST_SZ	Command Sequencer DMA Burst Size This field allows the user to choose the size of the command sequencer DMA burst 00 The burst size is INCR4 01 The burst size is INCR8 1X The burst size is INCR16
15 ERROR_EN	Error Enable If this bit is set then a command error causes the command sequencer to go to the ASYNCSTOP state. If it is reset then the command sequencer ignores the error and moves to the subsequent instruction. However it should be noted that the loop error (more than 4 loops), next error (NEXT instruction fired

Table continues on the next page...

SPT_CS_MODE_CTRL field descriptions (continued)

Field	Description
	before LOOP instruction), iteration error (loop of zero iteration) and opcode error (illegal opcode value) always cause the sequencer to go to the ASYNCSTOP state. The ERROR_EN bit has no effect on these errors.
16 PREFETCH	Early Pre-fetch Enable This bit controls the early pre-fetch option of the command sequencer. 0 Early pre-fetch option disabled. 1 Early pre-fetch option enabled.
17 BKPT3_RE	Breakpoint 3 remains enabled If set then the breakpoint 3 remains enabled after sequencer has hit this breakpoint, else it is disabled.
18 BKPT3_EN	Breakpoint 3 enabled If set then the breakpoint 3 is enabled
19 BKPT2_RE	Breakpoint 2 remains enabled If set then the breakpoint 2 remains enabled after sequencer has hit this breakpoint, else it is disabled.
20 BKPT2_EN	Breakpoint 2 enabled If set then the breakpoint 2 is enabled
21 BKPT1_RE	Breakpoint 1 remains enabled If set then the breakpoint 1 remains enabled after sequencer has hit this breakpoint, else it is disabled.
22 BKPT1_EN	Breakpoint 1 enabled If set then the breakpoint 1 is enabled
23 BKPT0_RE	Breakpoint 0 remains enabled If set then the breakpoint 0 remains enabled after sequencer has hit this breakpoint, else it is disabled.
24 BKPT0_EN	Breakpoint 0 enabled If set then the breakpoint 0 is enabled
25 CS_SYS_ DEBUG	System debug enable If set along with the 'system debug' input signal it causes the command sequencer to go into the DEBUG state at the end of the current instruction. If not set and the 'system debug' input signal is HIGH, then the command sequencer just ignores the signal.
26 CS_BKPT_ DEBUG	Breakpoint debug enable If set then sequencer goes from RUN state to DEBUG state when an enabled breakpoint is hit
27 CS_IMM_ DEBUG	IMM DEBUG enable If set then the sequencer goes from RUN state to the DEBUG state at the end of execution of current instruction.
28–29 DEBUG_MD	DEBUG MODE control This field decides the mode of debug when the command sequencer enters the DEBUG state. 00 - halt mode. The command sequencer remains halted. 01 - step once mode. The sequencer steps one instruction ahead at a time. 10 - step jump mode. The sequencer keeps executing instructions till it hits an enabled breakpoint. 11 - instruction jamming mode. The sequencer enters the instruction jamming mode.

Table continues on the next page...

SPT_CS_MODE_CTRL field descriptions (continued)

Field	Description
30 ASYNCSTOP	Asynchronous STOP bit If set it causes the sequencer (either in RUN, DEBUG or WAIT state) to go to the ASYNCSTOP state immediately. It is set by SW and is reset internally in the next cycle.
31 STOP	STOP bit If set it causes the sequencer (either in RUN, DEBUG or WAIT state) to go to the STOP state at the end of execution of the present instruction. It is set by SW and is reset internally in the next cycle.

45.8.40 Watchdog Counter Register (SPT_CS_WD_COUNT)

Address: 0h base + C8h offset = C8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SPT_CS_JAM_INST2 field descriptions

Field	Description
0–31 JAM_INST_63_32	Jamming instruction bits 63:32 Bits 63:32 of the 128-bit register which holds the instruction to be executed in the instruction jamming mode. This field should be written before clearing the SPT_CS_STATUS0[JAM_OVR] field.

45.8.48 Jamming Instruction3 Register (SPT_CS_JAM_INST3)

Address: 0h base + E8h offset = E8h

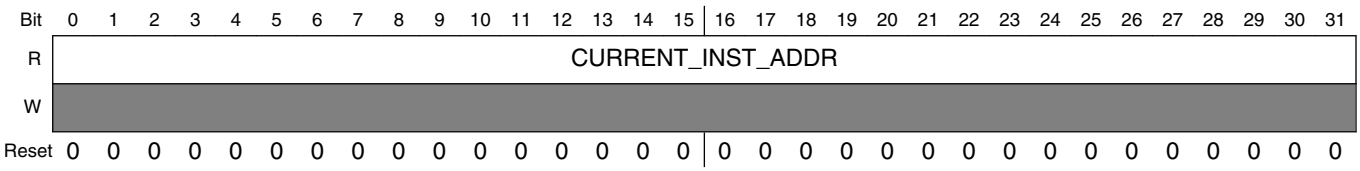
Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	JAM_INST_31_0																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SPT_CS_JAM_INST3 field descriptions

Field	Description
0–31 JAM_INST_31_0	Jamming instruction bits 31:0 Bits 31:0 of the 128-bit register which holds the instruction to be executed in the instruction jamming mode. This field should be written before clearing the SPT_CS_STATUS0[JAM_OVR] field.

45.8.49 Current Instruction Addr Register (SPT_CS_CURR_INST_ADDR)

Address: 0h base + ECh offset = ECh

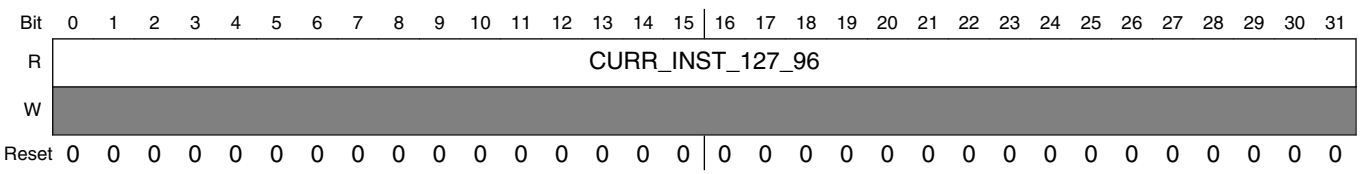


SPT_CS_CURR_INST_ADDR field descriptions

Field	Description
0–31 CURRENT_ INST_ADDR	Current instruction pointer Gives the address (corresponding to the system memory) of the instruction being executed. The current instruction pointer value propagates from the SPT domain to the slower peripheral interface and thus a synchronous read is not possible. It is refreshed every 32 clock cycles of the SPT domain.

45.8.50 Current Instruction0 Register (SPT_CS_CURR_INST0)

Address: 0h base + F0h offset = F0h

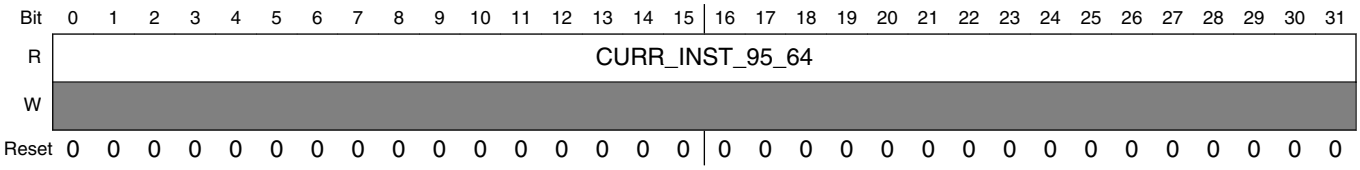


SPT_CS_CURR_INST0 field descriptions

Field	Description
0–31 CURR_INST_ 127_96	Current instruction bits 127:96 Bits 127:96 of the 128-bit status register which gives the actual instruction being currently executed. It should be noted that SW needs to perform 4 read operations on SPT_CS_CURR_INST0, SPT_CS_CURR_INST1, SPT_CS_CURR_INST2 and SPT_CS_CURR_INST3 to get the entire instruction's contents. Thus a synchronous read out is not guaranteed unless the command sequencer is in the HALT mode of the DEBUG state. Also it must be noted that the current instruction value propagates from the SPT domain to the slower peripheral interface and hence also a synchronous read is not possible. It is refreshed every 32 clock cycles of the SPT domain.

45.8.51 Current Instruction1 Register (SPT_CS_CURR_INST1)

Address: 0h base + F4h offset = F4h

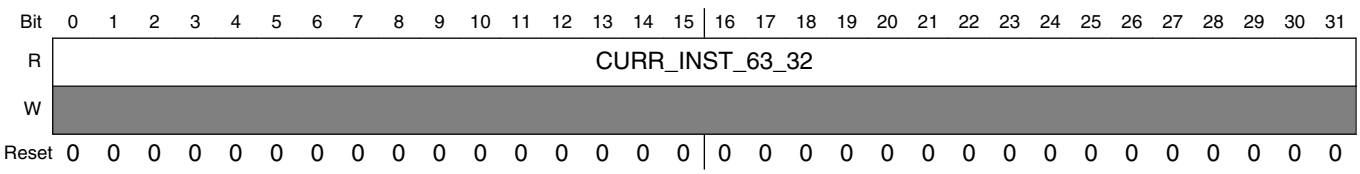


SPT_CS_CURR_INST1 field descriptions

Field	Description
0–31 CURR_INST_ 95_64	Current instruction bits 95:64 Bits 95:64 of the 128-bit status register which gives the actual instruction being currently executed.

45.8.52 Current Instruction2 Register (SPT_CS_CURR_INST2)

Address: 0h base + F8h offset = F8h

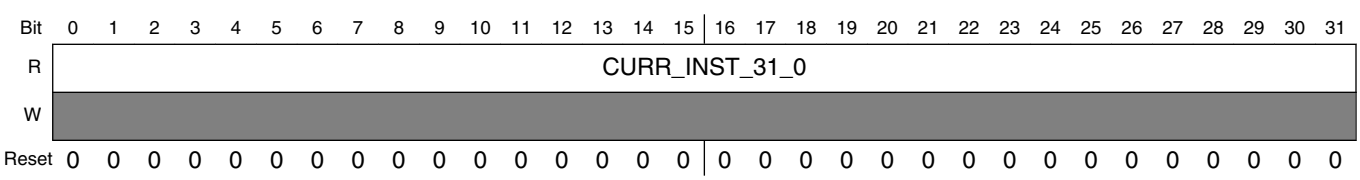


SPT_CS_CURR_INST2 field descriptions

Field	Description
0–31 CURR_INST_ 63_32	Current instruction bits 63:32 Bits 63:32 of the 128-bit status register which gives the actual instruction being currently executed.

45.8.53 Current Instruction3 Register (SPT_CS_CURR_INST3)

Address: 0h base + FCh offset = FCh



SPT_CS_CURR_INST3 field descriptions

Field	Description
0–31 CURR_INST_ 31_0	Current instruction bits 31:0 Bits 31:0 of the 128-bit status register which gives the actual instruction being currently executed.

45.8.54 Loop Counter 0 and 1 Register (SPT_CS_LOOPCNTR01)

Address: 0h base + 100h offset = 100h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	LOOP_CNTR1																LOOP_CNTR0															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SPT_CS_LOOPCNTR01 field descriptions

Field	Description
0–15 LOOP_CNTR1	Loop count of counter 1 Gives the count of the loop counter 1. The counter counts down to zero. The counter value propagates from the SPT domain to the slower peripheral interface and thus a synchronous read is not possible. It is refreshed every 32 clock cycles of the SPT domain.
16–31 LOOP_CNTR0	Loop count of counter 0 Gives the count of the loop counter 0. The counter counts down to zero. The counter value propagates from the SPT domain to the slower peripheral interface and thus a synchronous read is not possible. It is refreshed every 32 clock cycles of the SPT domain.

45.8.55 Loop Counter 2 and 3 Register (SPT_CS_LOOPCNTR23)

Address: 0h base + 104h offset = 104h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	LOOP_CNTR3																LOOP_CNTR2															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SPT_CS_LOOPCNTR23 field descriptions

Field	Description
0–15 LOOP_CNTR3	Loop count of counter 3 Gives the count of the loop counter 3. The counter counts down to zero. The counter value propagates from the SPT domain to the slower peripheral interface and thus a synchronous read is not possible. It is refreshed every 32 clock cycles of the SPT domain.

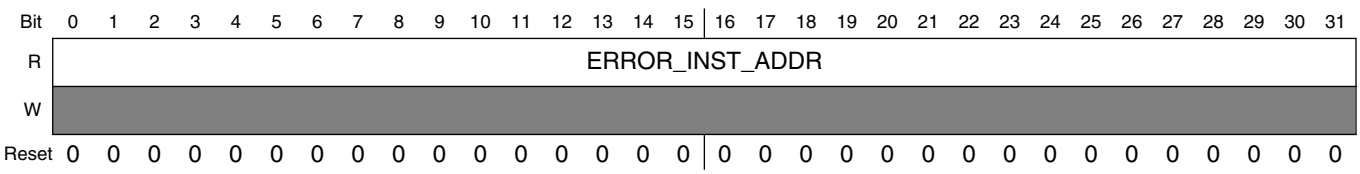
Table continues on the next page...

SPT_CS_LOOPCNTR23 field descriptions (continued)

Field	Description
16–31 LOOP_CNTR2	Loop count of counter 2 Gives the count of the loop counter 2. The counter counts down to zero. The counter value propagates from the SPT domain to the slower peripheral interface and thus a synchronous read is not possible. It is refreshed every 32 clock cycles of the SPT domain.

45.8.56 Error Instruction Addr Register (SPT_CS_ERR_INST_ADDR)

Address: 0h base + 108h offset = 108h

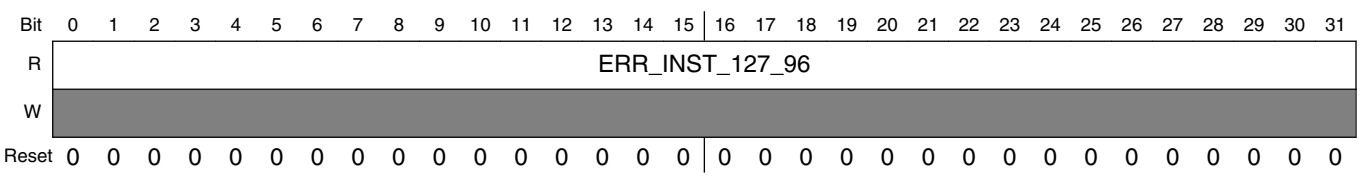


SPT_CS_ERR_INST_ADDR field descriptions

Field	Description
0–31 ERROR_INST_ ADDR	Error instruction pointer Gives the address (corresponding to the system memory) of the instruction which caused the command error.

45.8.57 Error Instruction 0 Register (SPT_CS_ERR_INST0)

Address: 0h base + 10Ch offset = 10Ch

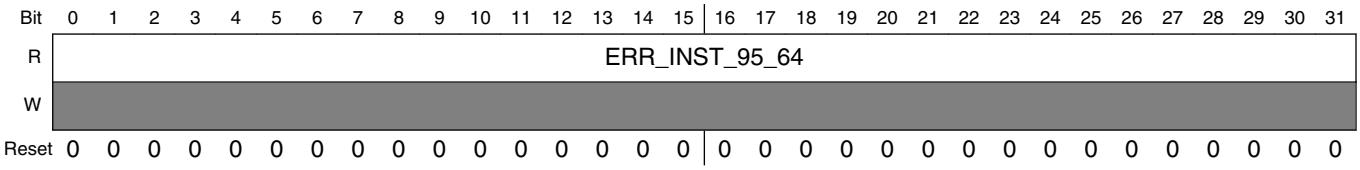


SPT_CS_ERR_INST0 field descriptions

Field	Description
0–31 ERR_INST_127_ 96	Error instruction bits 127:96 Bits 127:96 of the 128-bit status register which gives the actual instruction which caused the error.

45.8.58 Error Instruction 1 Register (SPT_CS_ERR_INST1)

Address: 0h base + 110h offset = 110h

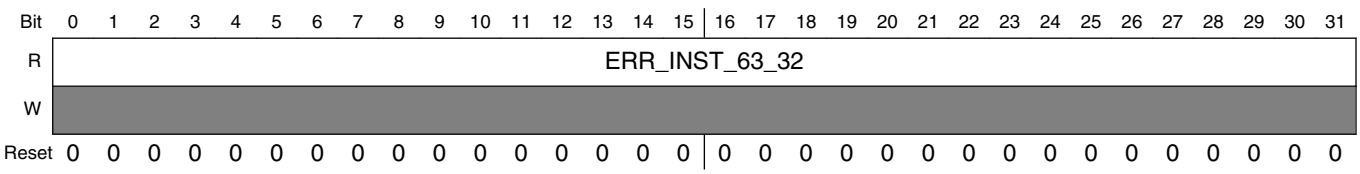


SPT_CS_ERR_INST1 field descriptions

Field	Description
0–31 ERR_INST_95_64	Error instruction bits 95:64 Bits 95:64 of the 128-bit status register which gives the actual instruction which caused the error.

45.8.59 Error Instruction 2 Register (SPT_CS_ERR_INST2)

Address: 0h base + 114h offset = 114h

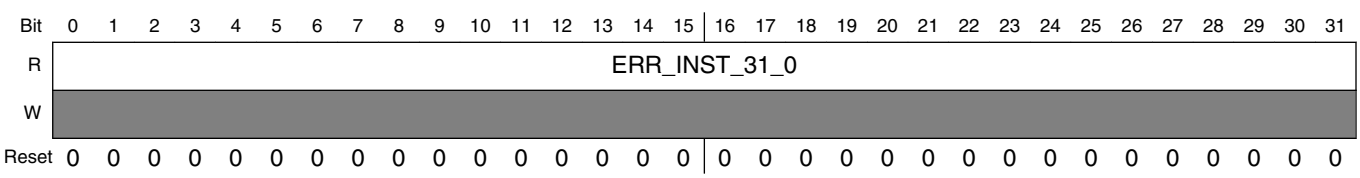


SPT_CS_ERR_INST2 field descriptions

Field	Description
0–31 ERR_INST_63_32	Error instruction bits 63:32 Bits 63:32 of the 128-bit status register which gives the actual instruction which caused the error.

45.8.60 Error Instruction 3 Register (SPT_CS_ERR_INST3)

Address: 0h base + 118h offset = 118h

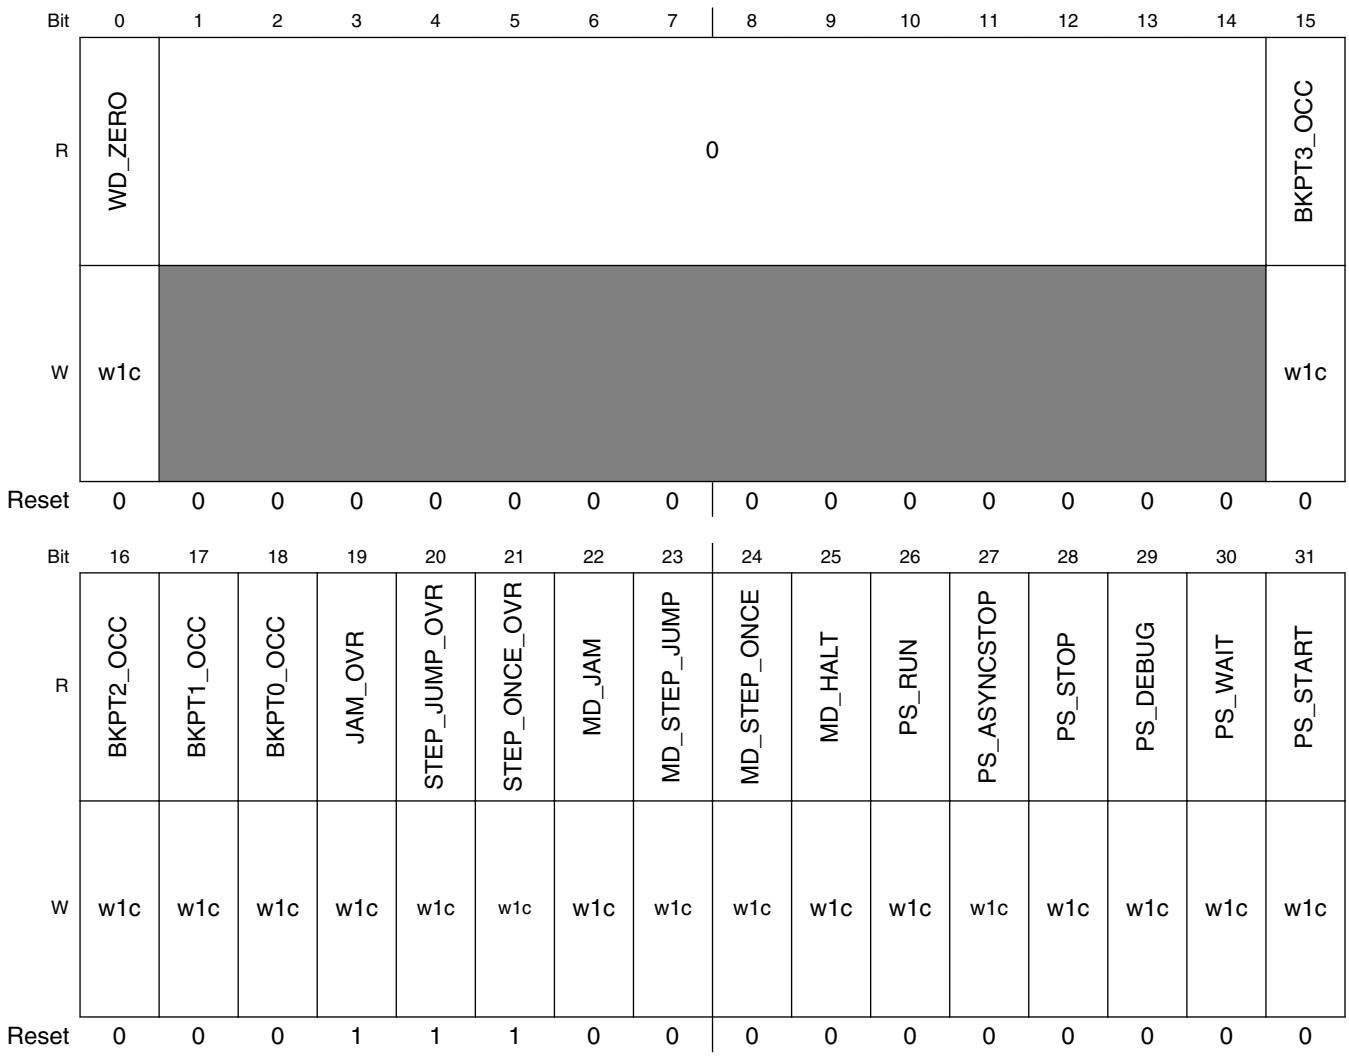


SPT_CS_ERR_INST3 field descriptions

Field	Description
0–31 ERR_INST_31_0	Error instruction bits 31:0 Bits 31:0 of the 128-bit status register which gives the actual instruction which caused the error.

45.8.61 General Status 0 Register (SPT_CS_STATUS0)

Address: 0h base + 11Ch offset = 11Ch



SPT_CS_STATUS0 field descriptions

Field	Description
0 WD_ZERO	Watchdog timer reached zero This field is set when the watchdog timer goes to zero in the count mode. Is internally reset in the SETUP state

Table continues on the next page...

SPT_CS_STATUS0 field descriptions (continued)

Field	Description
1–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 BKPT3_OCC	'Breakpoint 3 hit' indication Set when the command sequencer hits the breakpoint 3 in the STEP JUMP mode and there is no ongoing asynchronous PDMA instruction. Is internally reset in the SETUP state
16 BKPT2_OCC	'Breakpoint 2 hit' indication Set when the command sequencer hits the breakpoint 2 in the STEP JUMP mode and there is no ongoing asynchronous PDMA instruction. Is internally reset in the SETUP state
17 BKPT1_OCC	'Breakpoint 1 hit' indication Set when the command sequencer hits the breakpoint 1 in the STEP JUMP mode and there is no ongoing asynchronous PDMA instruction. Is internally reset in the SETUP state
18 BKPT0_OCC	'Breakpoint 0 hit' indication Set when the command sequencer hits the breakpoint 0 in the STEP JUMP mode and there is no ongoing asynchronous PDMA instruction. Is internally reset in the SETUP state
19 JAM_OVR	Jamming mode instruction completion indication This field is set when program execution starts. When a '1' is written to it then the field gets reset and if the command sequencer is in the instruction jamming mode then a new instruction is executed. It gets set when an instruction is completed in the instruction jamming mode.
20 STEP_JUMP_ OVR	STEP JUMP mode break indication This field is set when program execution starts. When a '1' is written to it then the field gets reset and if the command sequencer is in STEP JUMP mode it starts executing instructions. It gets set in the STEP JUMP mode when a breakpoint is hit (at the end of execution of the instruction) and there is no ongoing asynchronous PDMA instruction
21 STEP_ONCE_ OVR	STEP ONCE mode instruction completion indication This field is set when program execution starts. When a '1' is written to it then the field gets reset and if the command sequencer is in the STEP ONCE mode it executes a single instruction. It gets set when an instruction is completed in the STEP ONCE mode.
22 MD_JAM	INSTRUCTION JAMMING mode indicator Set when the command sequencer enters the instruction jamming mode. Is internally reset in the SETUP state
23 MD_STEP_ JUMP	STEP JUMP mode indicator Is set when the sequencer enters the DEBUG state's STEP JUMP mode. Is internally reset in the SETUP state
24 MD_STEP_ ONCE	STEP ONCE mode indicator Is set when the sequencer enters the DEBUG state's STEP ONCE mode. Is internally reset in the SETUP state
25 MD_HALT	HALT MODE indicator Is set when the sequencer enters the DEBUG state's halt mode. Is internally reset in the SETUP state
26 PS_RUN	RUN state indicator

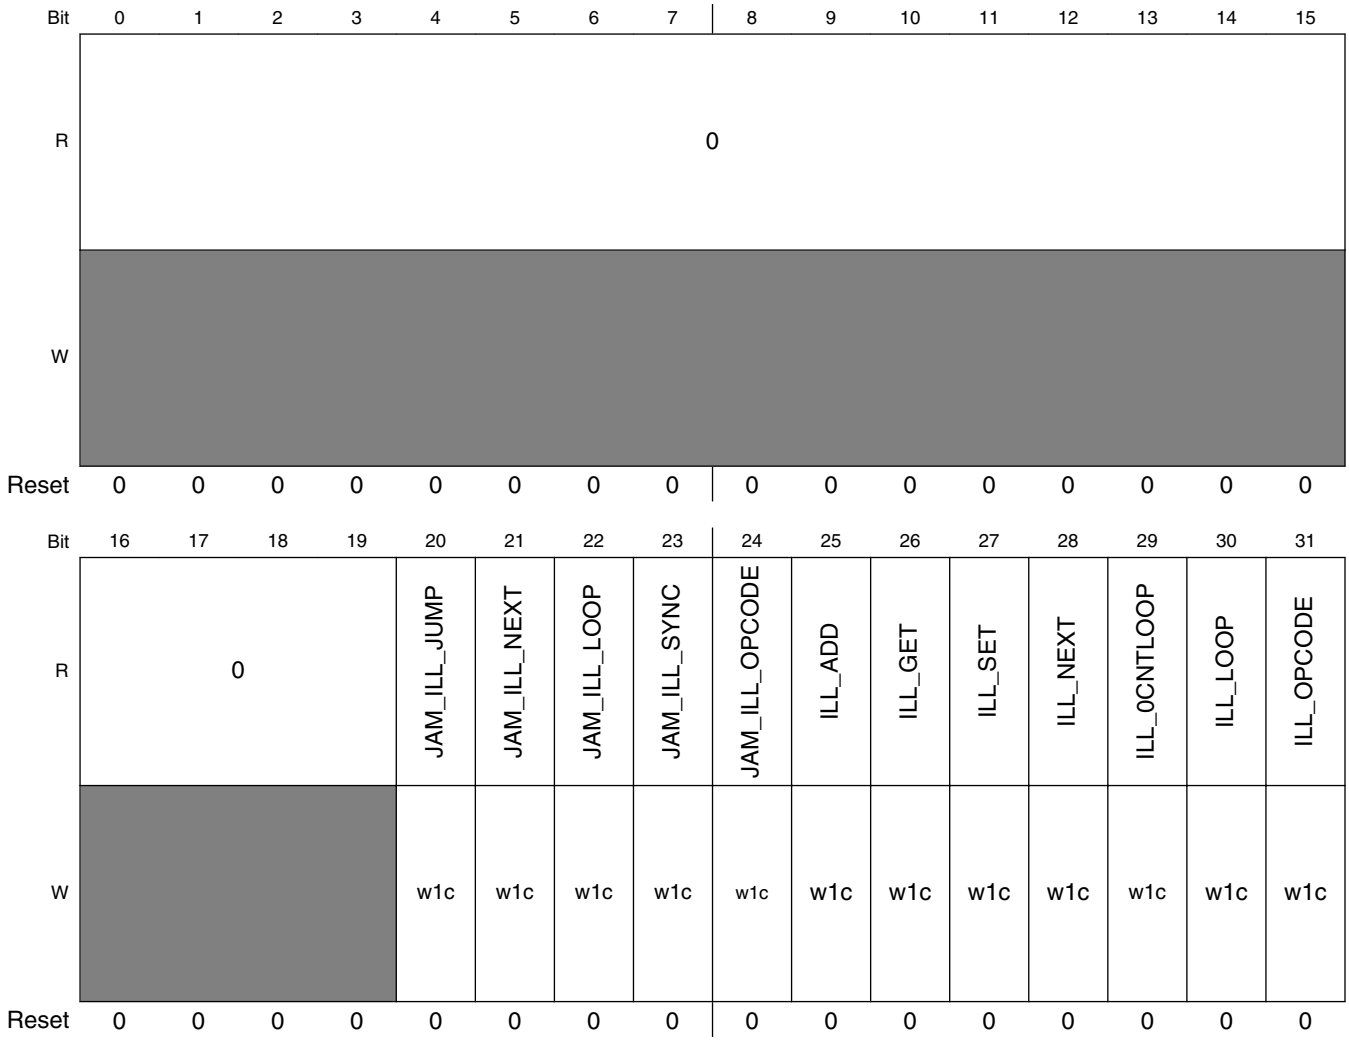
Table continues on the next page...

SPT_CS_STATUS0 field descriptions (continued)

Field	Description
	Set when the command sequencer enters the RUN state. Is internally reset in the SETUP state
27 PS_ ASYNCSTOP	ASYNCSTOP state indicator Set when the command sequencer enters the ASYNCSTOP state. Is internally reset in the SETUP state
28 PS_STOP	STOP state indicator Set when the command sequencer enters the STOP state. Is internally reset in the SETUP state
29 PS_DEBUG	DEBUG state indicator Set when the command sequencer enters the DEBUG state. Is internally reset in the SETUP state
30 PS_WAIT	WAIT state indicator Set when the command sequencer enters the WAIT state. Is internally reset in the SETUP state
31 PS_START	START state indicator Set when the command sequencer enters the START state. Is internally reset in the SETUP state

45.8.62 General Status 1 Register (SPT_CS_STATUS1)

Address: 0h base + 120h offset = 120h



SPT_CS_STATUS1 field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 JAM_ILL_JUMP	Illegal JUMP in jamming mode Indicates that 'JUMP' instruction was fired, which is illegal in the instruction jamming mode. Is internally reset in the SETUP state.
21 JAM_ILL_NEXT	Illegal NEXT in jamming mode Indicates that 'NEXT' instruction was fired, which is illegal in the instruction jamming mode. Is internally reset in the SETUP state.

Table continues on the next page...

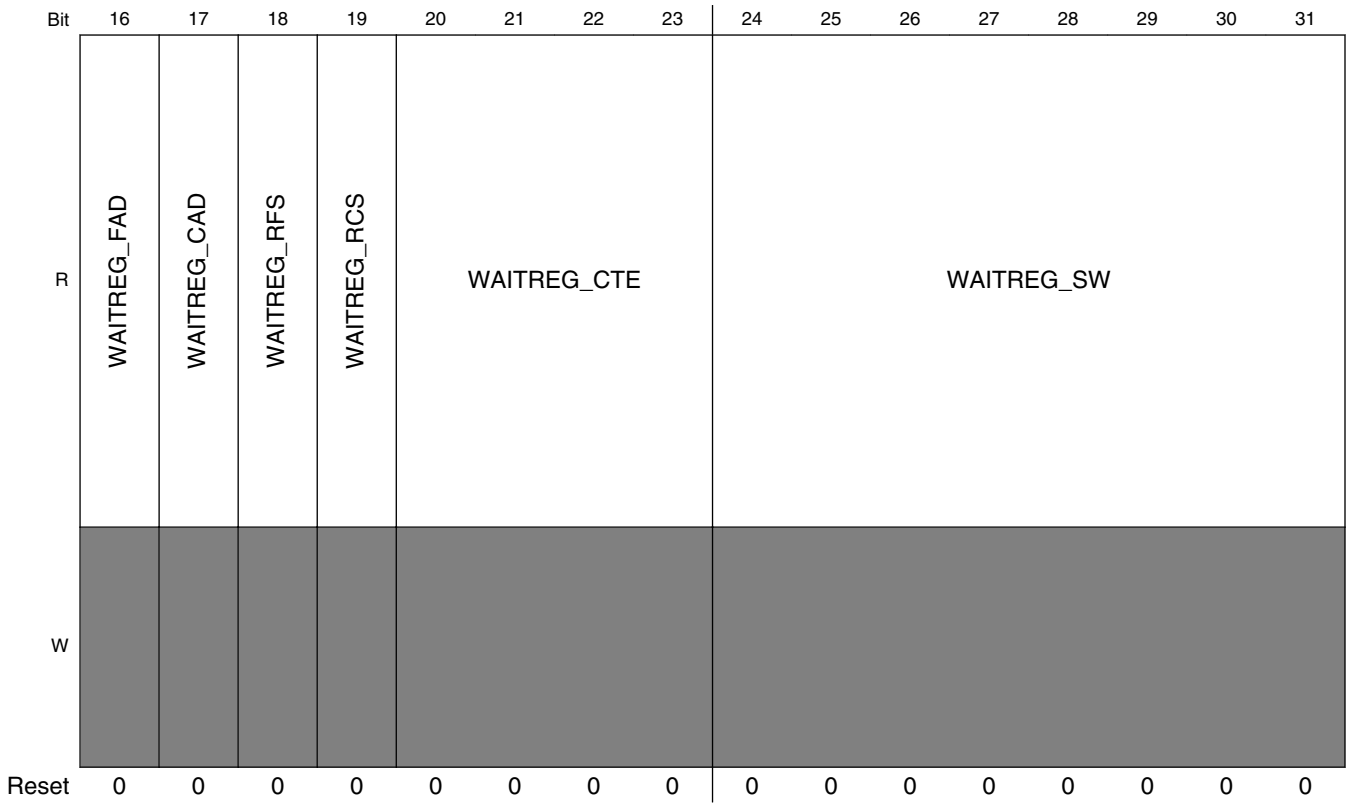
SPT_CS_STATUS1 field descriptions (continued)

Field	Description
22 JAM_ILL_LOOP	Illegal LOOP in jamming mode Indicates that 'LOOP' instruction was fired, which is illegal in the instruction jamming mode. Is internally reset in the SETUP state.
23 JAM_ILL_SYNC	Illegal SYNC in jamming mode Indicates that 'SYNC' instruction was fired, which is illegal in the instruction jamming mode. Is internally reset in the SETUP state.
24 JAM_ILL_ OPCODE	Illegal opcode in jamming mode Indicates that an illegal instruction opcode was fired while in the instruction jamming mode. Is internally reset in the SETUP state.
25 ILL_ADD	Illegal ADD Indicates that an illegal 'ADD' or illegal 'SUB' or illegal 'CMP' or illegal 'SEL' command instruction was fired. Is internally reset in the SETUP state. The user can also check the SPT_CS_ERR_INST_ADDR register to see which instruction caused the error. It is not set in the jamming mode in debug state.
26 ILL_GET	Illegal GET Indicates that an illegal 'GET' instruction was fired. It is not set in the jamming mode in debug state. Is internally reset in the SETUP state.
27 ILL_SET	Illegal SET Indicates that an illegal 'SET' instruction was fired. It is not set in the jamming mode in debug state. Is internally reset in the SETUP state.
28 ILL_NEXT	Illegal NEXT Indicates that a NEXT instruction was fired though there was no loop in progress. Is internally reset in the SETUP state. It is not set in the jamming mode in debug state.
29 ILL_0CNTLOOP	Illegal loop count error Indicates that a LOOP instruction with zero iterations was fired. Is internally reset in the SETUP state. It is not set in the jamming mode in debug state.
30 ILL_LOOP	illegal LOOP Indicates that a LOOP instruction was fired to start a fifth loop, and only four are allowed. Is internally reset in the SETUP state. It is not set in the jamming mode in debug state.
31 ILL_OPCODE	Illegal opcode Indicates that an illegal instruction opcode was fired. Is internally reset in the SETUP state. It is not set in the jamming mode in debug state.

45.8.63 General Status2 Register (SPT_CS_STATUS2)

Address: 0h base + 124h offset = 124h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0					WD_WAITREG_TR		WD_WAITREG_RFS	WD_WAITREG_RCS	WD_WAITREG_CTE				WAITREG_TR		WAITREG_PXD
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0



SPT_CS_STATUS2 field descriptions

Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–6 WD_WAITREG_TR	Event trigger type for WATCHDOG timer Specifies whether the awaited event is level-0 triggered, level-1 triggered, posedge triggered or negedge triggered. 00 – level-0 triggered; 01 – level-1 triggered; 10 – posedge triggered; 11 – negedge triggered;
7 WD_WAITREG_RFS	Watchdog waits for cte_rfs or csi_vsync signal If set then indicates that the watchdog waits for event on cte_rfs or csi_vsync signal. At any given time only one bit of SPT_CS_STATUS2[WD_WAITREG_RFS], SPT_CS_STATUS2[WD_WAITREG_RCS] and SPT_CS_STATUS2[WD_WAITREG_CTE] is set.
8 WD_WAITREG_RCS	Watchdog waits for cte_rcs or csi_hsync signal If set then indicates that the watchdog waits for event on cte_rcs or csi_hsync signal
9–12 WD_WAITREG_CTE	Watchdog waits for CTE
13–14 WAITREG_TR	Event trigger type Specifies whether the awaited event is level-0 triggered, level-1 triggered, posedge triggered or negedge triggered. 00 – level-0 triggered; 01 – level-1 triggered; 10 – posedge triggered; 11 – negedge triggered;
15 WAITREG_PXD	WAIT status for 'pdma transfer done' signal

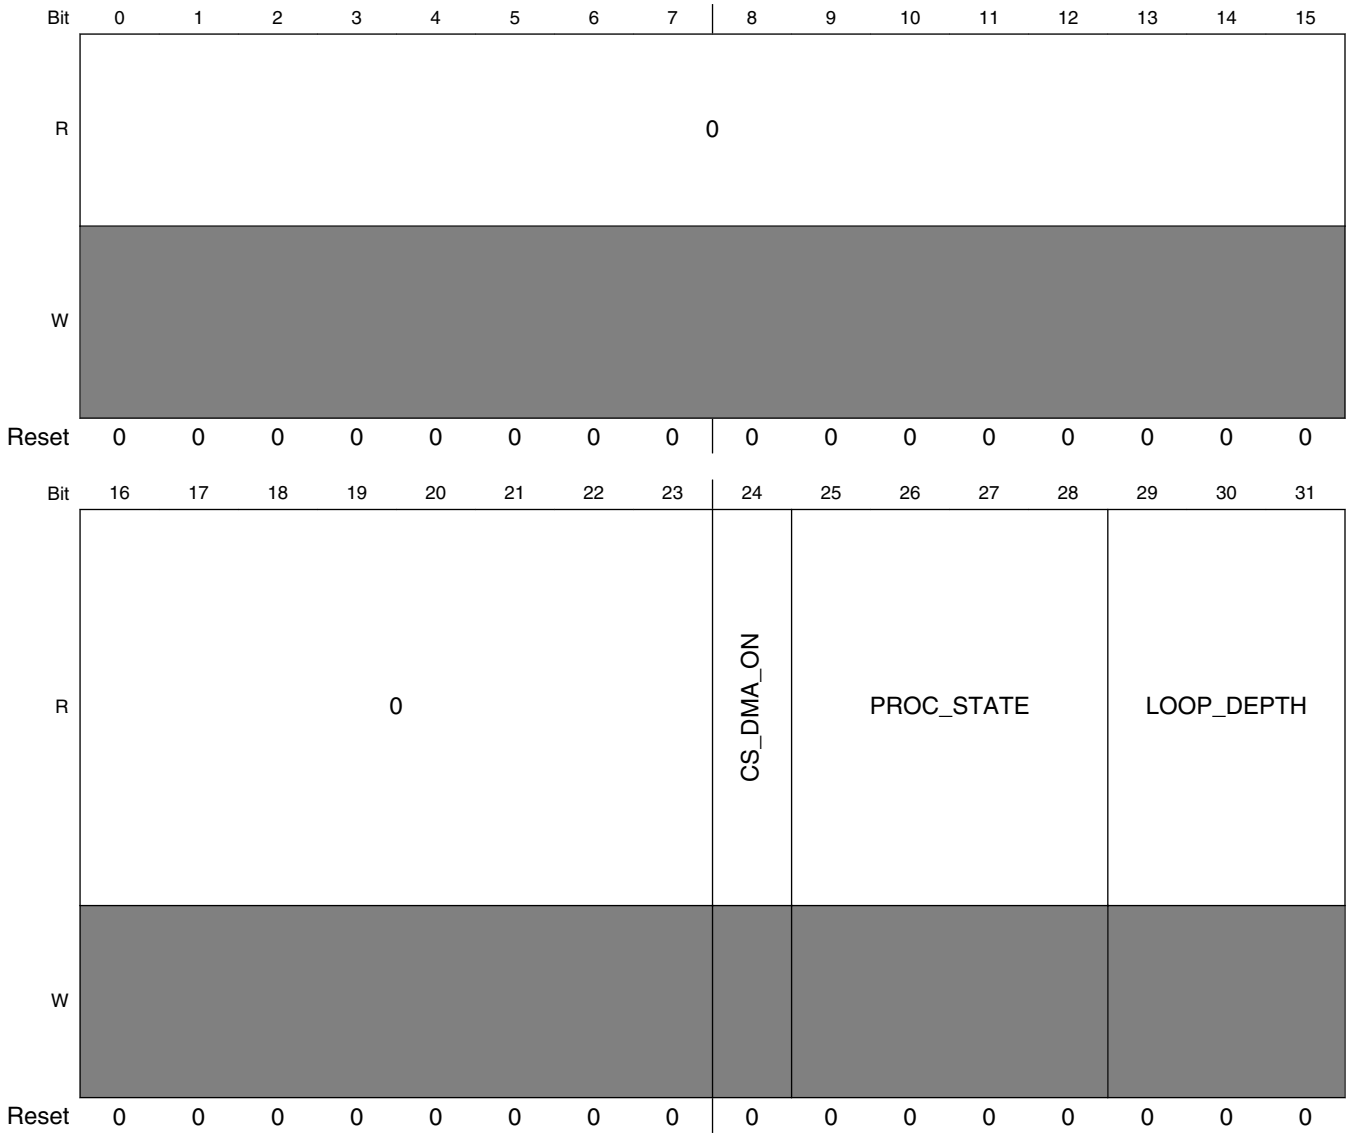
Table continues on the next page...

SPT_CS_STATUS2 field descriptions (continued)

Field	Description
	If set then indicates that the sequencer is waiting for event on 'pdma transfer done' signal. At any given time only 1 bit of SPT_CS_STATUS2[WAITREG_PXD], SPT_CS_STATUS2[WAITREG_FAD], SPT_CS_STATUS2[WAITREG_CAD], SPT_CS_STATUS2[WAITREG_RFS], SPT_CS_STATUS2[WAITREG_RCS], SPT_CS_STATUS2[WAITREG_CTE] or SPT_CS_STATUS2[WAITREG_SW] is set.
16 WAITREG_FAD	WAIT status for 'frame acquisition done' signal If set then indicates that the sequencer is waiting for event on 'frame acquisition done' signal.
17 WAITREG_CAD	WAIT status for 'chirp acquisition done' signal If set then indicates that the sequencer is waiting for event on 'chirp acquisition done' signal.
18 WAITREG_RFS	WAIT status for cte_rfs If set then indicates that the sequencer is waiting for event on cte_rfs or csi_vsync signal.
19 WAITREG_RCS	WAIT status for cte_rcs If set then indicates that the sequencer is waiting for event on cte_rcs or csi_hsync signal.
20–23 WAITREG_CTE	WAIT status for CTE event If any bit is set then it indicates that sequencer is waiting for the corresponding bit of cte_evt[3:0] 1000- Waits for event on cte_evt[3] 0100- Waits for event on cte_evt[2] 0010- Waits for event on cte_evt[1] 0001- Waits for event on cte_evt[0]
24–31 WAITREG_SW	WAIT status for SW-enforced event If any bit is set then it indicates that sequencer is waiting for the corresponding bit of the SW-enforced event 00000001- Waits for event triggered on SPT_CS_SW_EVTREG[SW_EVTREG[0]] 00000010- Waits for event triggered on SPT_CS_SW_EVTREG[SW_EVTREG[1]] 00000100- Waits for event triggered on SPT_CS_SW_EVTREG[SW_EVTREG[2]] 00001000- Waits for event triggered on SPT_CS_SW_EVTREG[SW_EVTREG[3]] 00010000- Waits for event triggered on SPT_CS_SW_EVTREG[SW_EVTREG[4]] 00100000- Waits for event triggered on SPT_CS_SW_EVTREG[SW_EVTREG[5]] 01000000- Waits for event triggered on SPT_CS_SW_EVTREG[SW_EVTREG[6]] 10000000- Waits for event triggered on SPT_CS_SW_EVTREG[SW_EVTREG[7]]

45.8.64 General Status 3 Register (SPT_CS_STATUS3)

Address: 0h base + 128h offset = 128h



SPT_CS_STATUS3 field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 CS_DMA_ON	Command sequencer DMA ON Provides the status that command sequencer is accessing the AHB bus
25–28 PROC_STATE	Processing state

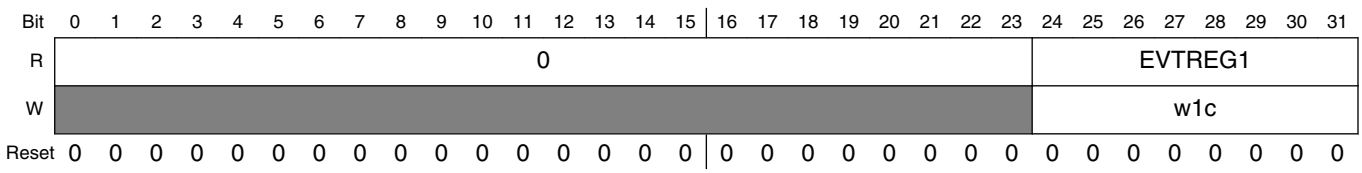
Table continues on the next page...

SPT_CS_STATUS3 field descriptions (continued)

Field	Description
	Gives the present processing state of the command sequencer FSM. RST = 0000b. START = 0001b. SETUP = 0010b. RUN = 0011b. WAIT = 0100b. DEBUG = 0101b. STOP = 0110b. ASYNCSTOP = 0111b. The processing state value propagates from the SPT domain to the slower peripheral interface and thus a synchronous read is not possible. It is refreshed every 32 clock cycles of the SPT domain.
29–31 LOOP_DEPTH	Loop depth Gives the depth of the command sequencer loop being executed. A value of 0 means that no loop is being executed. The loop depth value propagates from the SPT domain to the slower peripheral interface and thus a synchronous read is not possible. The loop depth value is refreshed every 32 clock cycles of the SPT domain.

45.8.65 EVT1 Status Register (SPT_CS_EVTREG1)

Address: 0h base + 12Ch offset = 12Ch

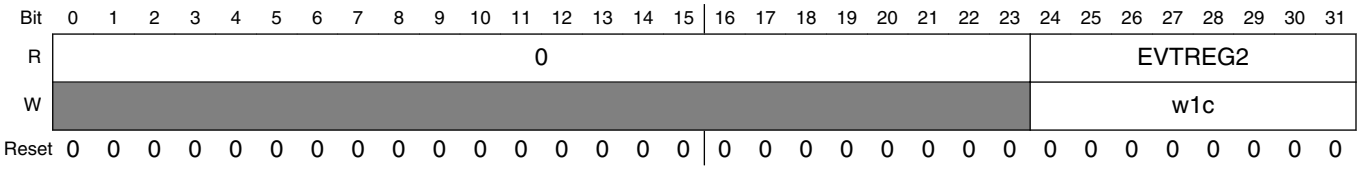


SPT_CS_EVTREG1 field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 EVTREG1	EVT1 register Each bit corresponds to an event. Whenever an EVT command occurs a bit corresponding to the specified event (given in the command word by the field name 'EV') is set when 'EV_LVL' field in the command word is 1 or reset when 'EV_LVL' is 0. This field is internally reset in the SETUP state. Value '000' in EV field corresponds to '00000001' in SPT_CS_EVTREG1[EVTREG1] Value '001' in EV field corresponds to '00000010' in SPT_CS_EVTREG1[EVTREG1] Value '010' in EV field corresponds to '00000100' in SPT_CS_EVTREG1[EVTREG1] Value '011' in EV field corresponds to '00001000' in SPT_CS_EVTREG1[EVTREG1] Value '100' in EV field corresponds to '00010000' in SPT_CS_EVTREG1[EVTREG1] Value '101' in EV field corresponds to '00100000' in SPT_CS_EVTREG1[EVTREG1] Value '110' in EV field corresponds to '01000000' in SPT_CS_EVTREG1[EVTREG1] Value '111' in EV field corresponds to '10000000' in SPT_CS_EVTREG1[EVTREG1]

45.8.66 EVT2 Status Register (SPT_CS_EVTREG2)

Address: 0h base + 130h offset = 130h

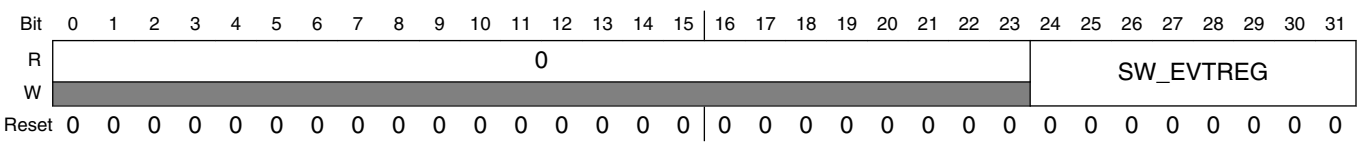


SPT_CS_EVTREG2 field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 EVTREG2	EVT2 register Each bit corresponds to an event. Whenever an EVT command occurs a bit corresponding to the specified event (given in the command word by the field name 'EV') is set when the field 'EV_LVL' in the command word is 1 or reset when 'EV_LVL' is 0. This field is internally reset in the SETUP state. Value '000' in EV field corresponds to '00000001' in SPT_CS_EVTREG2[EVTREG2] Value '001' in EV field corresponds to '00000010' in SPT_CS_EVTREG2[EVTREG2] Value '010' in EV field corresponds to '00000100' in SPT_CS_EVTREG2[EVTREG2] Value '011' in EV field corresponds to '00001000' in SPT_CS_EVTREG2[EVTREG2] Value '100' in EV field corresponds to '00010000' in SPT_CS_EVTREG2[EVTREG2] Value '101' in EV field corresponds to '00100000' in SPT_CS_EVTREG2[EVTREG2] Value '110' in EV field corresponds to '01000000' in SPT_CS_EVTREG2[EVTREG2] Value '111' in EV field corresponds to '10000000' in SPT_CS_EVTREG2[EVTREG2]

45.8.67 SW Event Trigger Register (SPT_CS_SW_EVTREG)

Address: 0h base + 134h offset = 134h

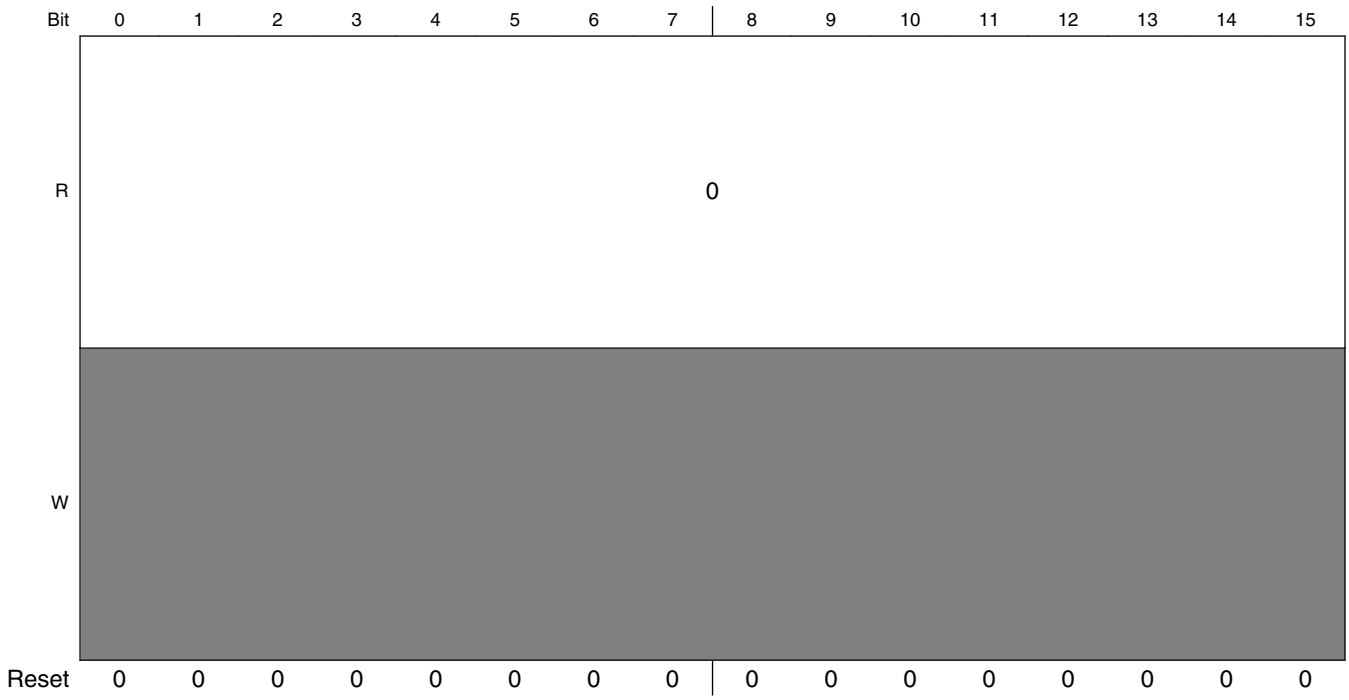


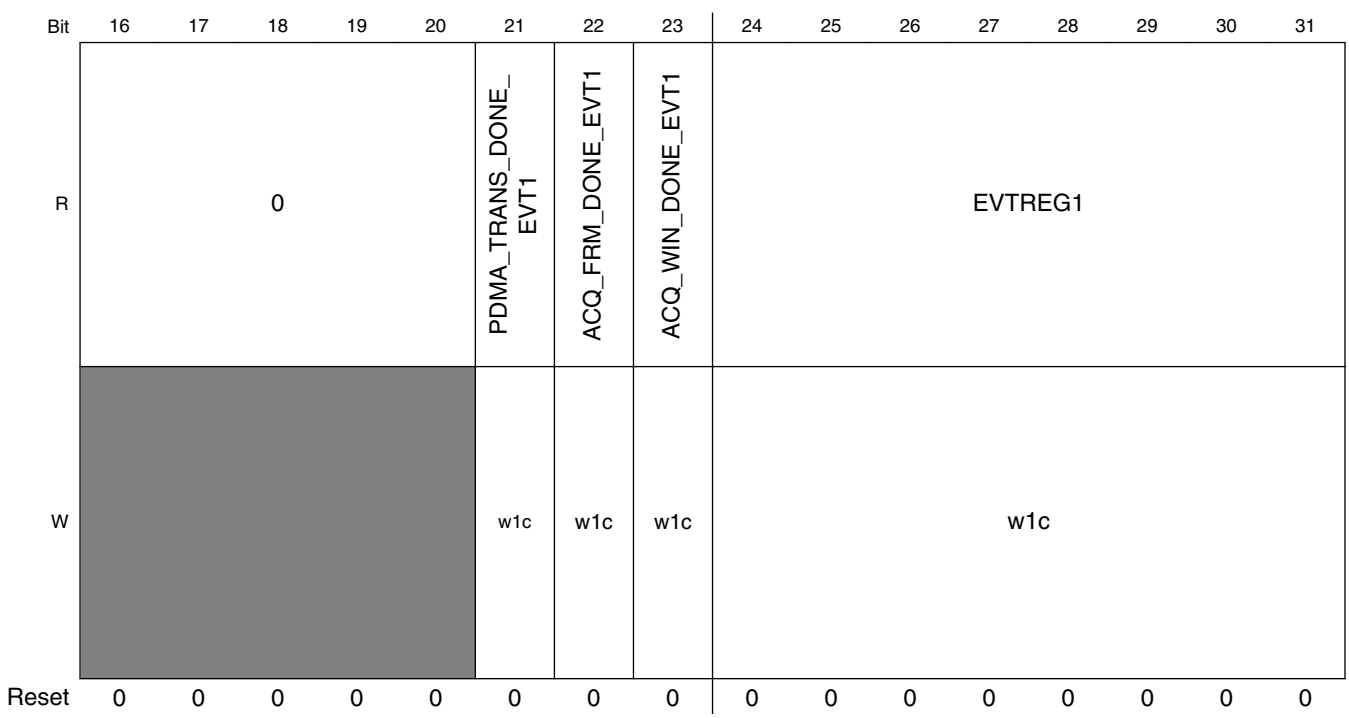
SPT_CS_SW_EVTREG field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 SW_EVTREG	SW event trigger SW can trigger an event on any of the 8 bits, to be used by WAIT command. After WAIT on these events is over they are reset internally., and hence these events can only be positive-edge triggered or positive-level triggered They are also internally reset in the SETUP state

45.8.68 Core 1 Version Register Events (SPT_CORE1_VER_EVT)

Address: 0h base + 138h offset = 138h





SPT_CORE1_VER_EVT field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 PDMA_TRANS_ DONE_EVT1	Event for PDMA transfer done for CPU core 1 This field is internally reset in the SETUP state.
22 ACQ_FRM_ DONE_EVT1	Event for acquisition frame done for CPU core 1 This field is internally reset in the SETUP state.
23 ACQ_WIN_ DONE_EVT1	Event for acquisition window finished for CPU core 1 This field is internally reset in the SETUP state.
24–31 EVTREG1	EVT1 register Each bit corresponds to an event. Whenever an EVT command occurs a bit corresponding to the specified event (given in the command word by the field name 'EV') is set when the field 'EV_LVL' in the command word is 1 or reset when 'EV_LVL' is 0. This field is internally reset in the SETUP state. Value '000' in EV field corresponds to '00000001' in SPT_CS_EVTREG1[EVTREG1] Value '001' in EV field corresponds to '00000010' in SPT_CS_EVTREG1[EVTREG1] Value '010' in EV field corresponds to '00000100' in SPT_CS_EVTREG1[EVTREG1] Value '011' in EV field corresponds to '00001000' in SPT_CS_EVTREG1[EVTREG1] Value '100' in EV field corresponds to '00010000' in SPT_CS_EVTREG1[EVTREG1] Value '101' in EV field corresponds to '00100000' in SPT_CS_EVTREG1[EVTREG1] Value '110' in EV field corresponds to '01000000' in SPT_CS_EVTREG1[EVTREG1] Value '111' in EV field corresponds to '10000000' in SPT_CS_EVTREG1[EVTREG1].

45.8.69 Core 2 Version Register Events (SPT_CORE2_VER_EVT)

Address: 0h base + 13Ch offset = 13Ch

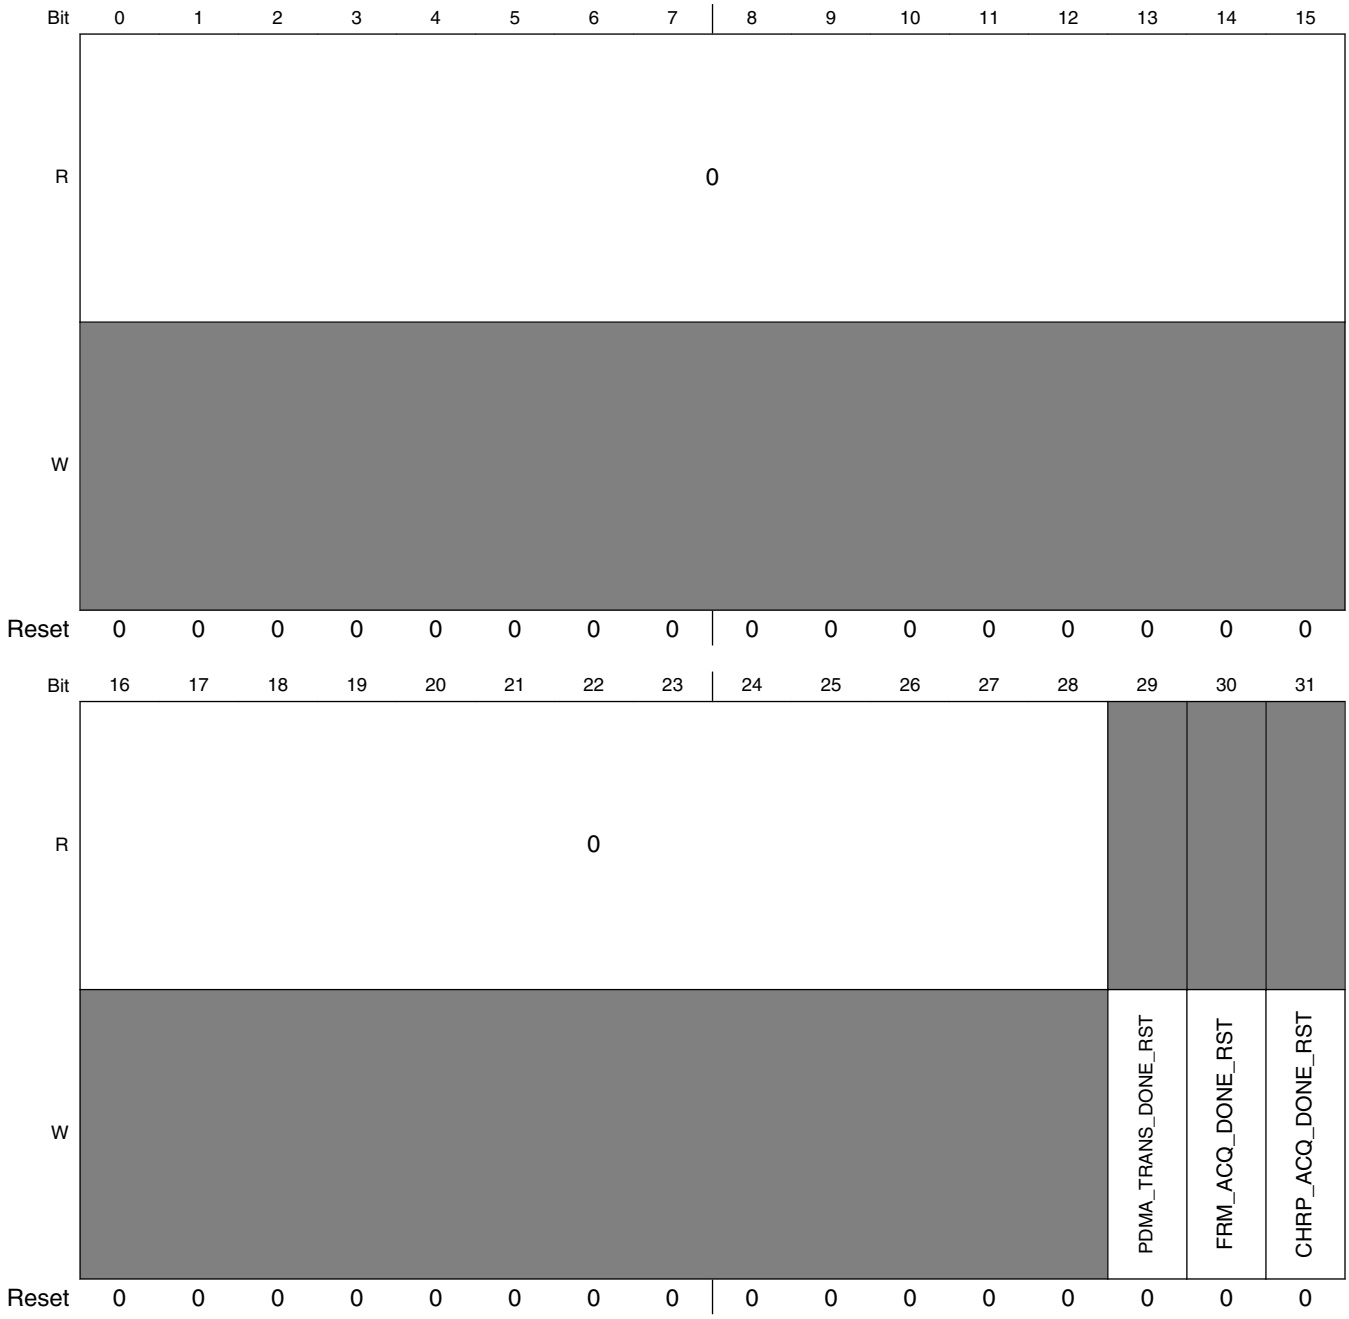
SPT_CORE2_VER_EVT field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 PDMA_TRANS_ DONE_EVT2	Event for PDMA transfer done for CPU core 2 This field is internally reset in the SETUP state.
22 ACQ_FRM_ DONE_EVT2	Event for acquisition frame done for CPU core 2 This field is internally reset in the SETUP state.
23 ACQ_WIN_ DONE_EVT2	Event for acquisition window finished for CPU core 2 This field is internally reset in the SETUP state.
24–31 EVTREG2	EVT2 register Each bit corresponds to an event. Whenever an EVT command occurs a bit corresponding to the specified event (given in the command word by the field name 'EV') is set when the field 'EV_LVL' in the command word is 1 or reset when 'EV_LVL' is 0. This field is internally reset in the SETUP state. Value '000' in EV field corresponds to '00000001' in SPT_CS_EVTREG2[EVTREG2] Value '001' in EV field corresponds to '00000010' in SPT_CS_EVTREG2[EVTREG2] Value '010' in EV field corresponds to '00000100' in SPT_CS_EVTREG2[EVTREG2] Value '011' in EV field corresponds to '00001000' in SPT_CS_EVTREG2[EVTREG2] Value '100' in EV field corresponds to '00010000' in SPT_CS_EVTREG2[EVTREG2] Value '101' in EV field corresponds to '00100000' in SPT_CS_EVTREG2[EVTREG2] Value '110' in EV field corresponds to '01000000' in SPT_CS_EVTREG2[EVTREG2] Value '111' in EV field corresponds to '10000000' in SPT_CS_EVTREG2[EVTREG2].

45.8.70 SPT Event Reset Control Register (SPT_EVENT_RST_CTRL)

Address: 0h base + 140h offset = 140h



SPT_EVENT_RST_CTRL field descriptions

Field	Description
0–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

SPT_EVENT_RST_CTRL field descriptions (continued)

Field	Description
29 PDMA_TRANS_ DONE_RST	When a 1 is written to this bit it causes the registered PDMA Transfer Done event inside the WAIT module to be reset. This bit auto-resets the next cycle.
30 FRM_ACQ_ DONE_RST	When a 1 is written to this bit it causes the registered Frame Acquisition Done event inside the WAIT module to be reset. This bit auto-resets the next cycle.
31 CHRP_ACQ_ DONE_RST	When a 1 is written to this bit it causes the registered Chirp Acquisition Done event inside the WAIT module to be reset. This bit auto-resets the next cycle.

45.8.71 LFSR Load High Value (SPT_PDMA_LFSR_LOAD_VAL_HIGH)

Address: 0h base + 180h offset = 180h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	PDMA_LFSR_LOAD_VAL_HIGH																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SPT_PDMA_LFSR_LOAD_VAL_HIGH field descriptions

Field	Description
0–31 PDMA_LFSR_ LOAD_VAL_ HIGH	LFSR High value [63:32] for compression

45.8.72 LFSR Load Low Value (SPT_PDMA_LFSR_LOAD_VAL_LOW)

Address: 0h base + 184h offset = 184h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	PDMA_LFSR_LOAD_VAL_LOW																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SPT_PDMA_LFSR_LOAD_VAL_LOW field descriptions

Field	Description
0–31 PDMA_LFSR_ LOAD_VAL_ LOW	LFSR Low Value [31:0] for compression

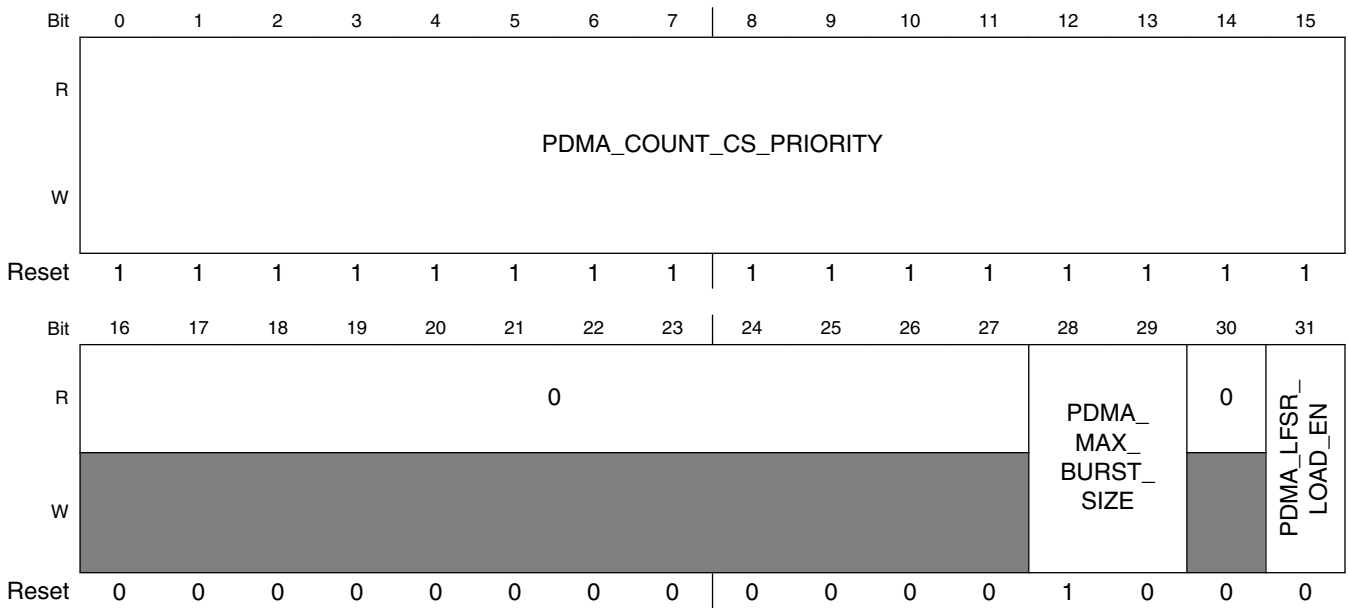
45.8.73 PDMA Control Register (SPT_PDMA_CONTROL)

This register controls the PDMA instruction processing.

NOTE

The minimum value of 'PDMA_COUNT_CS_PRIORITY' field is 0x10. Writing less than 0x10 to PDMA_COUNT_CS_PRIORITY field take value 0x10.

Address: 0h base + 188h offset = 188h



SPT_PDMA_CONTROL field descriptions

Field	Description
0–15 PDMA_COUNT_CS_PRIORITY	PDMA Count register for Command sequencer to get priority Count value in terms of clock cycles that should be loaded after which the command sequencer will get access on the AHB bus
16–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–29 PDMA_MAX_BURST_SIZE	Maximum AHB burst size Controls the size of burst that is initiated on the AHB side. 00b - INCR4,01b - INCR8, 10b - INCR16
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 PDMA_LFSR_LOAD_EN	LFSR load enable bit Enables loading LFSR with register values

45.8.74 PDMA Transfer Count Status (SPT_PDMA_TRANSFER_COUNT_STATUS)

Address: 0h base + 1C0h offset = 1C0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	AGGR_DATA_COUNT																TRANSFER_COUNT															
W

SPT_PDMA_TRANSFER_COUNT_STATUS field descriptions

Field	Description
0–15 AGGR_DATA_COUNT	Aggregation Data Count Specifies the number of aggregated data after performing aggregation operation.
16–31 TRANSFER_COUNT	Number of words transferred via PDMA Number of words transferred in current cycle. This is automatically cleared on the next instruction start.

45.8.75 PDMA formatB Exponent Address status Register (SPT_PDMA_FMTB_EXP_ADDR_STATUS)

Address: 0h base + 1C4h offset = 1C4h

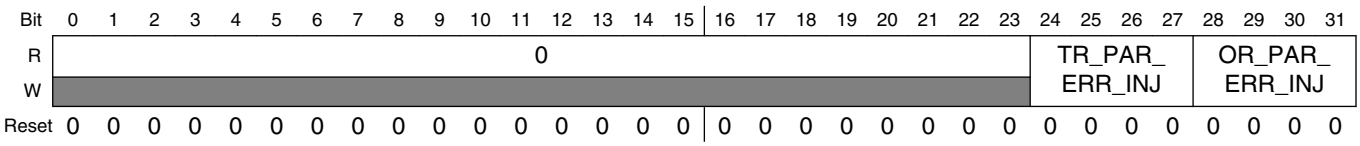
Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	EXPN_ADDR																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SPT_PDMA_FMTB_EXP_ADDR_STATUS field descriptions

Field	Description
0–31 EXPN_ADDR	Exponent Address First exponent Address for FormatB Compression and Decompression modes

45.8.76 Memory Error Injection Register (SPT_MEM_ERR_INJECT_CTRL)

Address: 0h base + 1FCh offset = 1FCh

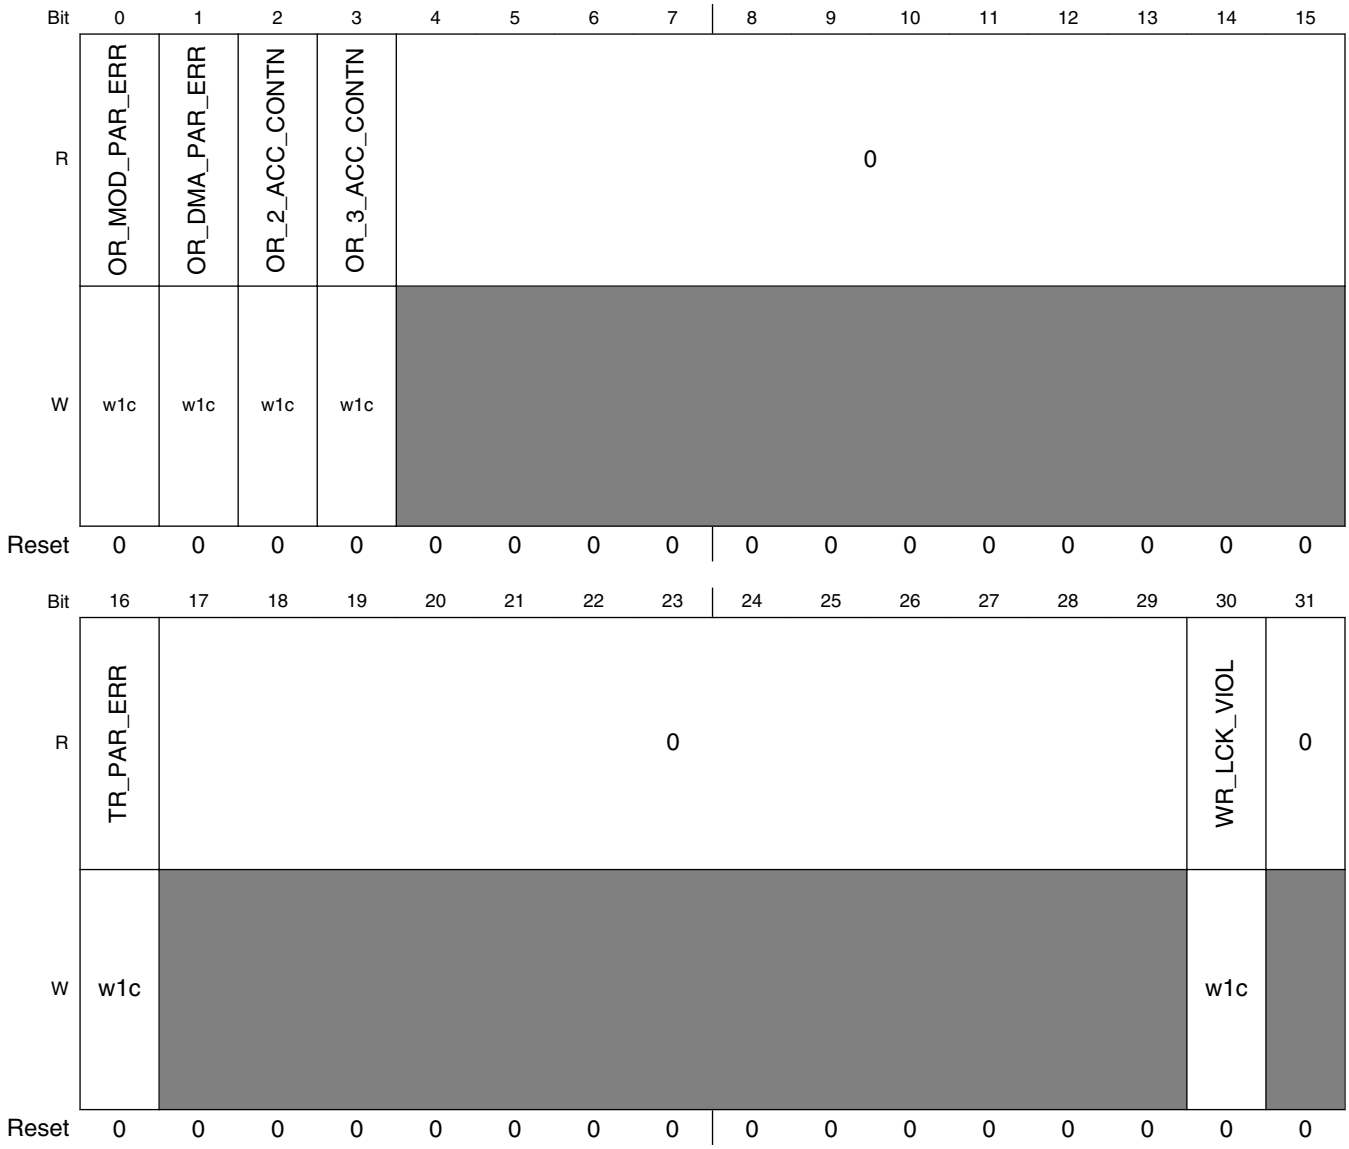


SPT_MEM_ERR_INJECT_CTRL field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–27 TR_PAR_ERR_ INJ	Twiddle RAM parity error Injection This field can be used to inject error in the parity bits in the TRAM. There are 4 bits (1 bit for each parity bit) to invert the actual parity during the data write to the memory. Anyone or all the bits can be set to inject parity error in the corresponding parity bit.
28–31 OR_PAR_ERR_ INJ	Operand RAM parity error Injection This field can be used to inject error in the parity bits in the ORAM. There are 4 bits (1 bit for each parity bit) to invert the actual parity during the data write to the memory. Anyone or all the bits can be set to inject parity error in the corresponding parity bit.

45.8.77 Memory Error Status Register (SPT_MEM_ERR_STATUS)

Address: 0h base + 200h offset = 200h



SPT_MEM_ERR_STATUS field descriptions

Field	Description
0 OR_MOD_PAR_ERR	Operand RAM module parity error Set when read data requested by any of the modules (hardware accelerators) has a parity error
1 OR_DMA_PAR_ERR	Operand RAM DMA parity error Set when read data requested by PDMA has a parity error

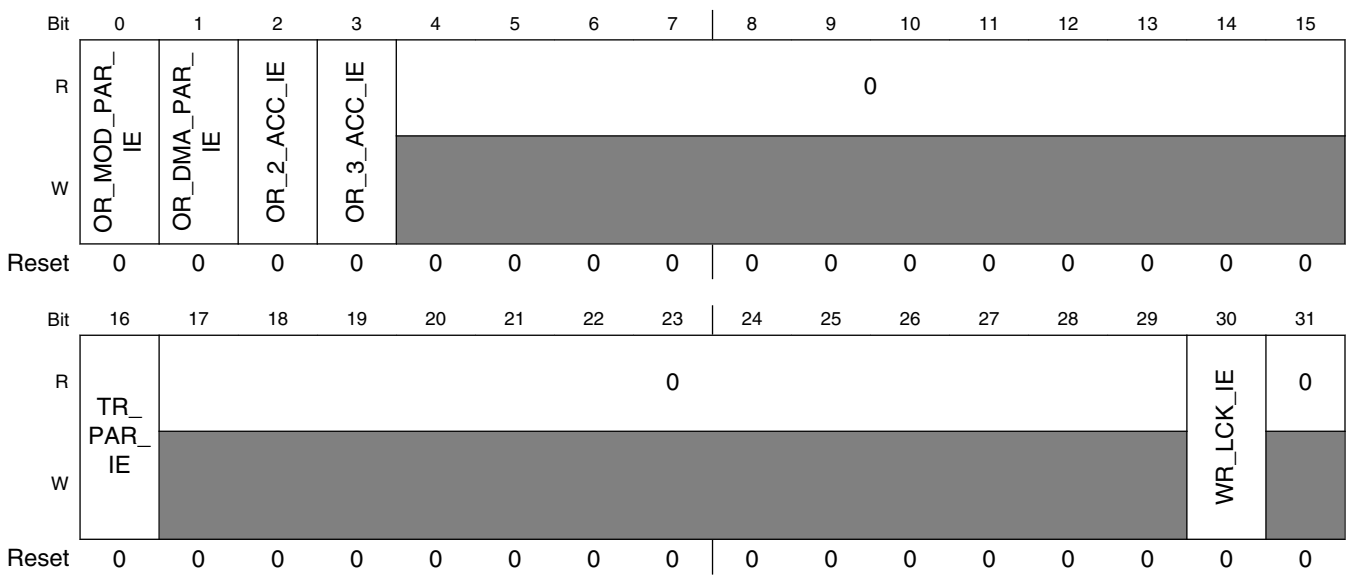
Table continues on the next page...

SPT_MEM_ERR_STATUS field descriptions (continued)

Field	Description
2 OR_2_ACC_CONTN	Operand RAM two access contention Set when two accesses are made on the same operand RAM bank.
3 OR_3_ACC_CONTN	Operand RAM three access contention Set when three accesses are made on the same operand RAM bank.
4–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 TR_PAR_ERR	Twiddle RAM parity error Set when any read access has a parity error
17–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 WR_LCK_VIOL	Work register lock violation Set when SPT writes to a work register locked for CPU
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

45.8.78 Memory Interrupt Enable register (SPT_MEM_ERR_INT_EN)

Address: 0h base + 204h offset = 204h



SPT_MEM_ERR_INT_EN field descriptions

Field	Description
0 OR_MOD_PAR_IE	Operand RAM module parity interrupt enable

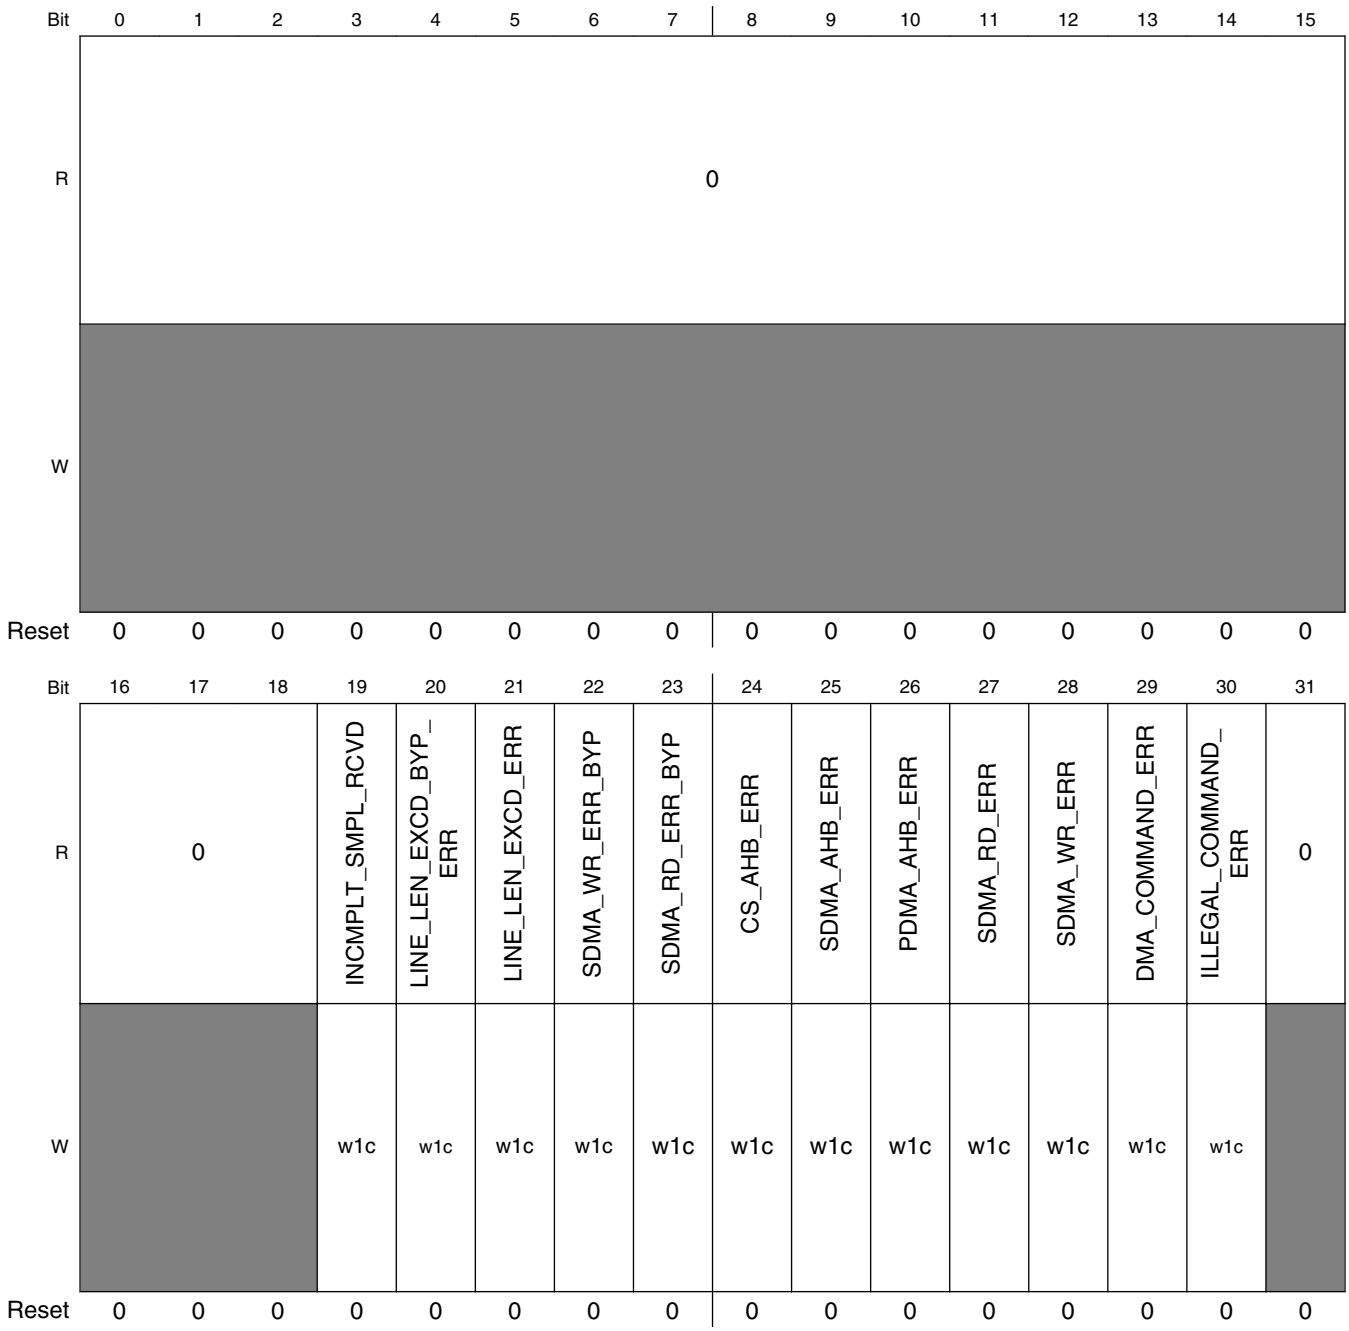
Table continues on the next page...

SPT_MEM_ERR_INT_EN field descriptions (continued)

Field	Description
	Enables the interrupt for MEM_ERR_REG[OP_MOD_PAR_ERR]. Interrupt generated when OP_MOD_PAR_ERR is set.
1 OR_DMA_PAR_IE	Operand RAM DMA parity interrupt enable Enables the interrupt for MEM_ERR_REG[OP_DMA_PAR_ERR]. Interrupt generated when OP_DMA_PAR_ERR is set.
2 OR_2_ACC_IE	Operand RAM two access contention interrupt enable Enables the interrupt for MEM_ERR_REG[OP_2_ACC_CONTN]. Interrupt generated when OP_2_ACC_CONTN is set.
3 OR_3_ACC_IE	Operand RAM three access contention interrupt enable Enables the interrupt for MEM_ERR_REG[OP_3_ACC_CONTN]. Interrupt generated when OP_3_ACC_CONTN is set.
4–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 TR_PAR_IE	Twiddle RAM parity error interrupt enable Enables the interrupt for MEM_ERR_REG[TR_PAR_ERR]. Interrupt generated when TR_PAR_ERR is set.
17–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 WR_LCK_IE	Work register lock interrupt enable Enables the interrupt for MEM_ERR_REG[WR_LCK_VIOL]. Interrupt generated when WR_LCK_VIOL is set.
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

45.8.79 DMA Error Status Register (SPT_DMA_ERR_STATUS)

Address: 0h base + 208h offset = 208h



SPT_DMA_ERR_STATUS field descriptions

Field	Description
0–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

SPT_DMA_ERR_STATUS field descriptions (continued)

Field	Description
19 INCMPLT_ SMPL_RCVD	Incomplete sample received An exception is generated when the acquisition window deasserts before the number of samples programmed for regular SDMA or bypass SDMA is achieved. The acquisition block will continue working and no interrupt is generated corresponding to this exception.
20 LINE_LEN_ EXCD_BYP_ ERR	Bypass SDMA line length exceeded This error is asserted when cfg_trf_mode is high, that is 2D mode in acquisition, if the incrementing address exceeds the base address of next chirp. **NOTE:** W1C should be performed between the subsequent chirp start pulse and the acquisition window start to avoid setting of the error bit again. Also, it is expected that the line length is reprogrammed if such an error occurs.
21 LINE_LEN_ EXCD_ERR	Line Length Exceeded This error is asserted when cfg_trf_mode is high, that is 2D mode in acquisition, if the incrementing address exceeds the base address of next chirp. **NOTE:** W1C should be performed between the subsequent chirp start pulse and the acquisition window start to avoid setting of the error bit again. Also, it is expected that the line length is reprogrammed if such an error occurs.
22 SDMA_WR_ ERR_BYP	Bypass SDMA write error Generated if the Bypass SDMA internal buffer was full (due to arbiter being busy) and Acquisition data write was performed.
23 SDMA_RD_ ERR_BYP	Bypass SDMA read error Generated if the Bypass SDMA internal buffer was empty and arbiter tries to perform SRAM write via SDMA.
24 CS_AHB_ERR	Command Sequencer AHB error Response Generated if there is an AHB error response for Command Sequencer access. In case of access to a protected region of memory it is possible that this error indication may not be given, but an error status will be given on SPT_CS_STATUS1[ILL_OPCODE] status bit and corresponding interrupt can be enabled in SPT_CS_INTEN1. It is also recommended that the user check the slave memory controller error indication.
25 SDMA_AHB_ ERR	SDMA AHB Error Response Generated if there is an AHB error response for SDMA access
26 PDMA_AHB_ ERR	PDMA AHB Error Generated if there is an AHB error response for PDMA access
27 SDMA_RD_ERR	SDMA Read Error Generated if the SDMA internal buffer was empty and arbiter tries to perform SRAM write via SDMA.
28 SDMA_WR_ERR	SDMA Write Error Generated if the SDMA internal buffer was full (due to arbiter being busy) and Acquisition data write was performed.

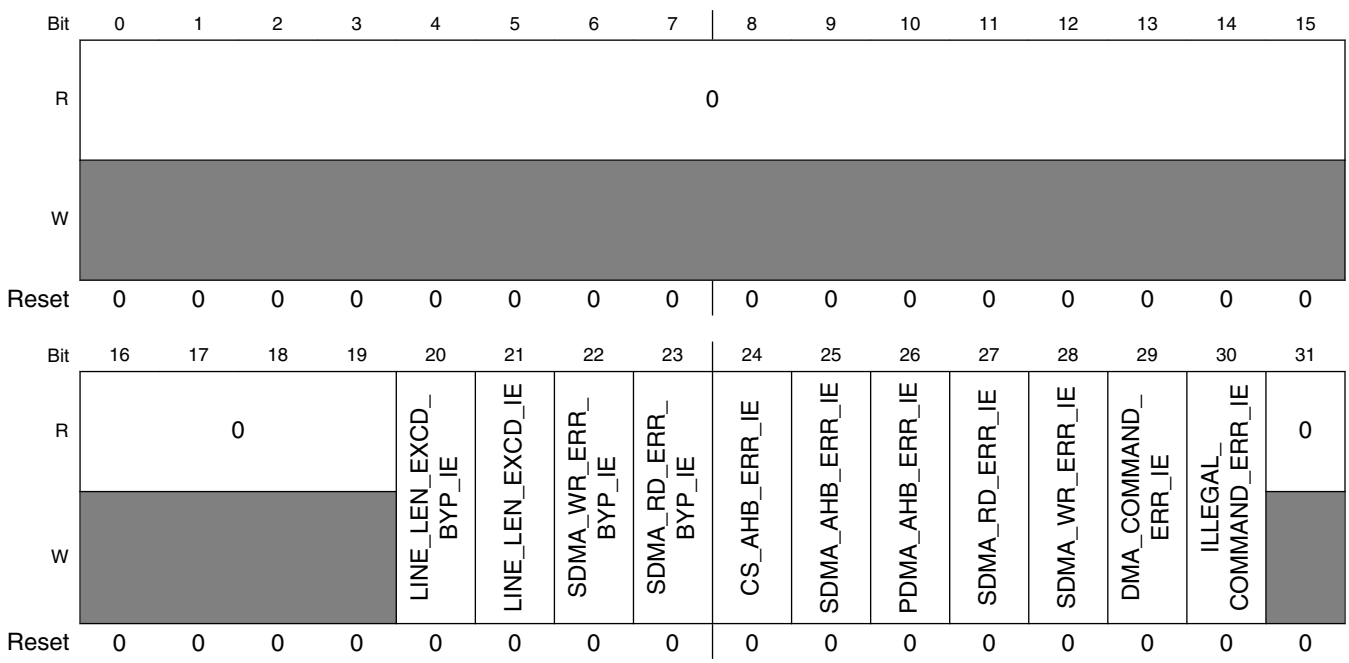
Table continues on the next page...

SPT_DMA_ERR_STATUS field descriptions (continued)

Field	Description
29 DMA_ COMMAND_ERR	Generated if the transfer size is more than the maximum value possible
30 ILLEGAL_ COMMAND_ ERR	Generated if proprietary functionality is tried being used by user.
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

45.8.80 Interrupt Enable for DMA_ERROR_STATUS (SPT_DMA_ERR_INT_EN)

Address: 0h base + 20Ch offset = 20Ch



SPT_DMA_ERR_INT_EN field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 LINE_LEN_ EXCD_BYP_IE	Bypass SDMA line length exceeded interrupt Enables or disables interrupt generation 0 Interrupt generation disabled 1 Interrupt generation enabled

Table continues on the next page...

SPT_DMA_ERR_INT_EN field descriptions (continued)

Field	Description
21 LINE_LEN_ EXCD_IE	Line length exceeded interrupt Enables or disables interrupt generation 0 Interrupt generation disabled 1 Interrupt generation enabled
22 SDMA_WR_ ERR_BYP_IE	Bypass SDMA write error interrupt Enables or disables interrupt generation 0 Interrupt generation disabled 1 Interrupt generation enabled
23 SDMA_RD_ ERR_BYP_IE	Bypass SDMA read error interrupt Enables or disables interrupt generation. 0 Interrupt generation disabled 1 Interrupt generation enabled
24 CS_AHB_ERR_ IE	Command Sequencer AHB Interrupt Enable Enables or disables interrupt generation.
25 SDMA_AHB_ ERR_IE	SDMA AHB Error Interrupt Enable Enables or disables interrupt generation.
26 PDMA_AHB_ ERR_IE	Interrupt Enable for PDMA AHB Error Enables or disables interrupt generation.
27 SDMA_RD_ ERR_IE	SDMA Read Error Interrupt Enable Enables or disables interrupt generation. 0 Interrupt generation disabled. 1 Interrupt generation enabled.
28 SDMA_WR_ ERR_IE	SDMA Write Error Interrupt Enable Enables or disables interrupt generation. 0 Interrupt generation disabled. 1 Interrupt generation enabled.
29 DMA_ COMMAND_ ERR_IE	Generated if the transfer size is more than the maximum value possible
30 ILLEGAL_ COMMAND_ ERR_IE	Generated if proprietary functionality is tried being used by user.
31 Reserved	Interrupt Enable bit This field is reserved. This read-only field is reserved and always has the value 0.

45.8.81 Global Status Register (SPT_GBL_STATUS)

GBL_STATUS is a w1c register but should only be written to as a full register, never as single bits. This is because a single bit write is compiled into a read-modify-write instruction sequence that clears the other bits simultaneously. Clearing by writing the full register with a mask avoids this situation. All the bits in this register are reset in SETUP state.

Address: 0h base + 210h offset = 210h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

W														w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SPT_GBL_STATUS field descriptions

Field	Description
0–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 PDMA_TRANS_DONE	PDMA transfer done
30 FRM_ACQ_DONE	Frame Acquisition Done This status field is set when a Frame has completed and acquisition of all chirps within this frame are done and have been transferred to System RAM. All statistics for this frame are stable and can be read. Refer to explanation added in interrupts section. This status will never set if ACQ_GBL_CTRL_0[INF_CHRPS] is set. 0 Frame Acquisition is not done 1 Frame Acquisition is done
31 CHRP_ACQ_DONE	Chirp Acquisition Done This status field is set when a chirp has completed and acquisition of all samples within this chirp are done and have been transferred to System RAM. All statistics for this chirp are now stable and can be read. An internal chirp counter is used to detect the last chirp in a frame based on the programmed value of ACQ_GBL_CTRL_1[NUM_CHRP]. This counter decrements every time acquisition window within a given chirp de-asserts, thus signifying end of acquisition for that chirp. 0 Chirp Acquisition is not done 1 Chirp acquisition is done

45.8.82 Global Status Interrupt Enable Register (SPT_GBL_STATUS_IE)

Address: 0h base + 214h offset = 214h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

SPT_HW_ACC_ERR_STATUS field descriptions

Field	Description
0 FFT_RDX2_RND_ERR	FFT Radix2 Round Error This bit is set if an invalid value of RDX2 round is provided for a given vector length
1 FFT_OPR_ADDR_ERR	Operand Address Error This bit indicates source or destination address for FFT Core Operands are not from OPRAM
2 FFT_MULT_COEF2_ERR	FFT MULT Co-efficient 2 Error This field is set if MULT_COEF_ADDR is ORAM for Windowing operation with MULT_MODE = 1.
3 FFT_MULT_COEF1_ERR	FFT MULT Co-efficient 1 Error This field is set if MULT_COEF_ADDR / TAP_COEF_ADDR is not TRAM for the following: a) Non-Windowing operation b) Windowing operation with MULT_MODE = 2
4 FFT_TW_OVS_ERR	FFT Twiddle Oversampling Error This bit is set when an invalid twiddle oversampling option is selected. The invalid scenarios are: Vector length = 32 and twiddle oversampling factor field value > 7 Vector length = 64 and twiddle oversampling factor field value > 6 Vector length = 128 and twiddle oversampling factor field value > 5 Vector length = 256 and twiddle oversampling factor field value > 4 Vector length = 512 and twiddle oversampling factor field value > 3 Vector length = 1024 and twiddle oversampling factor field value > 2 Vector length = 2048 and twiddle oversampling factor field value > 1 Vector length = 4096 and twiddle oversampling factor field value > 0

Table continues on the next page...

SPT_HW_ACC_ERR_STATUS field descriptions (continued)

Field	Description
5 FFT_QE_VL_ OVS_ERR	Quadrature Extension Vector Length Oversampling Error This bit is set if QE is not enabled for the vector length and Twiddle oversampling field combinations which require QE to be enabled. This bit is set if : Vector length = 16 and twiddle oversampling factor field value > 5 Vector length = 32 and twiddle oversampling factor field value > 4 Vector length = 64 and twiddle oversampling factor field value > 3 Vector length = 128 and twiddle oversampling factor field value > 2 Vector length = 256 and twiddle oversampling factor field value > 1 Vector length = 512 and twiddle oversampling factor field value > 0
6 FFT_RDX4_ RND_ERR	FFT Radix4 Round Error This bit is set if an invalid value of RDX4 round is provided for a given vector length
7 FFT_WIN_RND_ ERR	FFT Window Round Error This bit indicates if Round is greater than 0 in Radix4 Command with WIN bit high.
8 MAXS_IP_CMD_ ERR	MAXS input command error Asserted when there is an error in the incoming instruction 0 No command error 1 Asserted when any of the following errors are encountered in the incoming instruction. Refer Error scenarios
9–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 COPY_IP_CMD_ ERR	COPY input command error Asserted when there is an error in the incoming instruction 0 No command error 1 Asserted when any of the following command errors are encountered: 1.In in_dattyp = CMPLX and preproc = 0 (no preproc) 2.If in_dattyp != CMPLX and preproc = 2 (MAG) 3.If (src_add[15:14] = WREG_ADD or dest_add[15:14] = WREG_ADD) 4.In_dattyp == 11b (RESERVED) 5.Preproc == 11b (RESERVED) 6.Cp_type >= 1100b 7.Cp_type == CP_TRNSPOSE and vec_sz[5:0] != 0 8.Vec_sz[3:0] != 0 9.Cp_type == CP_SHFT AND dest_add[3:0] == 0 // copy shift with 0 shift not allowed
13–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 FFT_ILL_ SHFTVAL	FFT Illegal Shift Value error This bit is raised when the mult_mode=0 and pre-shift value comes from WR.
17–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 HST_ DESTADDR_ NOT_MULTOF8_ ERR	Destination address not multiple of 8 error It is set when the destination address value for HIST instruction is not a multiple of 8. This condition is checked only when destination is either operand RAM or twiddle RAM. This field is internally reset in SETUP state.
22 HST_ SRCADDR_ NOT_MULTOF8_ ERR	Source address not multiple of 8 error It is set when the source address value for HIST instruction is not a multiple of 8. This condition is not checked for 'write only' operation mode. This field is internally reset in SETUP state.

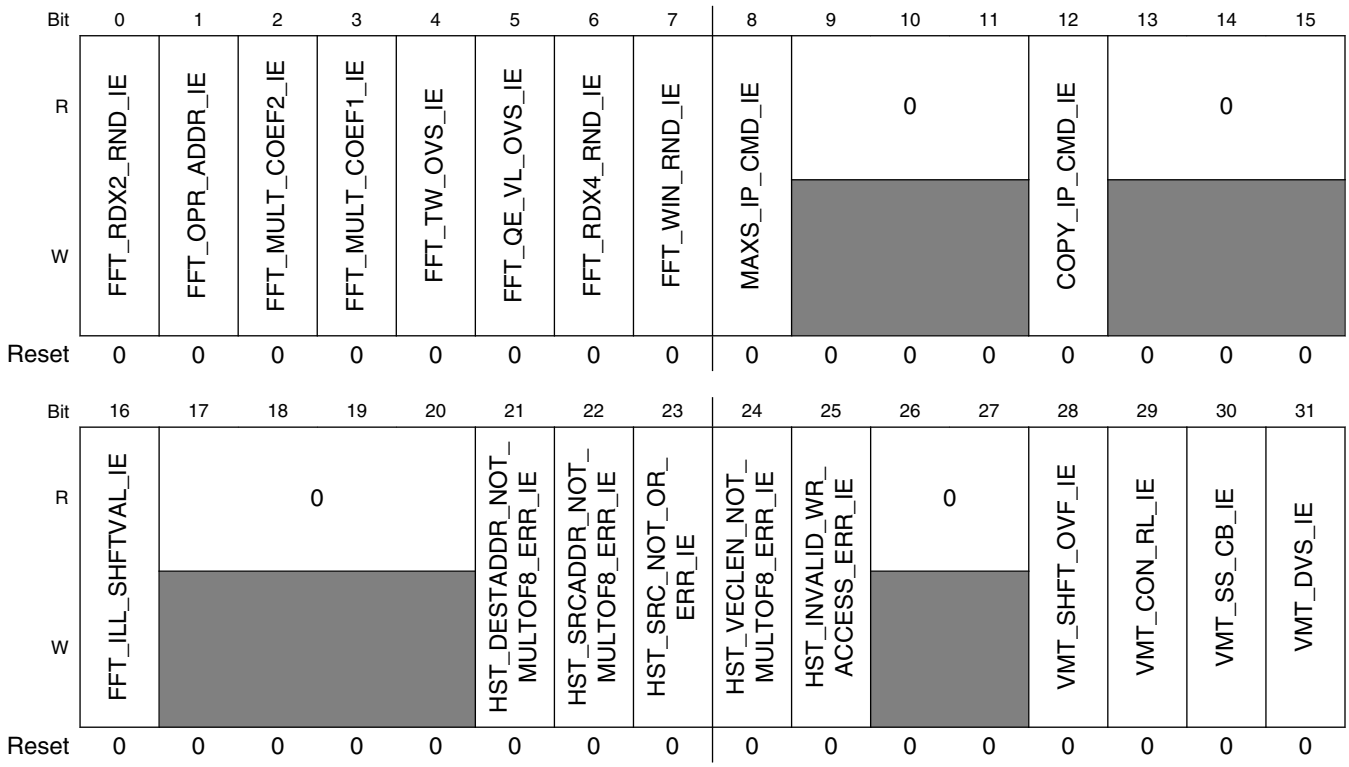
Table continues on the next page...

SPT_HW_ACC_ERR_STATUS field descriptions (continued)

Field	Description
23 HST_SRC_NOT_OR_ERR	Source not Operand RAM error It is set when the source address for the HIST instruction is any other than that of Operand RAM. This condition is not checked for the 'write only' operation mode. This field is internally reset in SETUP state.
24 HST_VECLEN_NOT_MULTOF8_ERR	Vector length not multiple of 8 error It is set when the vector length for HIST instruction is not a multiple of 8. This field is internally reset in SETUP state.
25 HST_INVALID_WR_ACCESS_ERR	HIST work register access error If the IMA bit is set in the HIST instruction and it points from work register number 48 to work register number 63 it is an access error condition. This field is internally reset in SETUP state.
26–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 VMT_SHFT_OVF_ERR	VMT Shift Overflow Error This field is set when in VMT, Vector Shift operation leads to saturation, due to overflow .However, this overflow condition does not cause the command sequencer to go to the ASYNCSTOP state; the sequencer continues in the same state. 0 No saturation condition hit 1 Saturation condition is hit
29 VMT_CON_RL_ERR	VMT Conjugate with Real Type Error This error field is set if in VMT, conjugate operation is selected when Vector type is Real. 0 No Error 1 Error condition is hit
30 VMT_SS_CB_ERR	VMT Sum Scale with Conjugate/Bypass Error This error status field is set if in VMT, sum and scale is selected along with conjugate or bypass with input type as complex. 0 No Error 1 Error condition is hit
31 VMT_DVS_ERR	VMT Dual vector sum error This error status field is set if in Dual Vector Sum operation of VMT, the first vector source (SRC_ADDR) is selected as TRAMor the second vector source (2ND_VEC_SRC) is selected as ORAM. 0 No Error 1 Error condition is hit

45.8.84 Hardware Accelerator Error Interrupt Enable Register (SPT_HW_ACC_ERR_IE)

Address: 0h base + 21Ch offset = 21Ch



SPT_HW_ACC_ERR_IE field descriptions

Field	Description
0 FFT_RDX2_RND_IE	FFT Radix2 Round Error Interrupt Enable Allows interrupt generation when HW_ACC_ERR_STATUS[FFT_RDX2_RND_ERR] is asserted.
1 FFT_OPR_ADDR_IE	Operand Address Interrupt Enable Allows interrupt generation when HW_ACC_ERR_STATUS[FFT_OPR_ADDR_ERR] is asserted. 0 Interrupt Disabled 1 Interrupt Enabled
2 FFT_MULT_COEF2_IE	FFT MULT Co-efficient 2 Interrupt Enable Allows interrupt generation when HW_ACC_ERR_STATUS[FFT_MULT_COEF2_ERR] is asserted. 0 Interrupt Disabled 1 Interrupt Enabled
3 FFT_MULT_COEF1_IE	FFT MULT Co-efficient 1 Interrupt Enable Allows interrupt generation when HW_ACC_ERR_STATUS[FFT_MULT_COEF1_ERR] is asserted.

Table continues on the next page...

Field	Description
	0 Interrupt Disabled 1 Interrupt Enabled
4 FFT_TW_OVS_IE	FFT Twiddle Oversampling Interrupt Enable Allows interrupt generation when HW_ACC_ERR_STATUS[FFT_TW_OVS_ERR] is asserted. 0 Interrupt Disabled 1 Interrupt Enabled
5 FFT_QE_VL_OVS_IE	Quadrature Extension Vector Length Oversampling Interrupt Enable Allows interrupt generation when HW_ACC_ERR_STATUS[FFT_QE_VL_OVS_ERR] is asserted. 0 Interrupt Disabled 1 Interrupt Enabled
6 FFT_RDX4_RND_IE	FFT Radix4 Round Error Interrupt Enable Allows interrupt generation when HW_ACC_ERR_STATUS[FFT_RDX4_RND_ERR] is asserted.
7 FFT_WIN_RND_IE	FFT Window Round Interrupt Enable Allows interrupt generation when HW_ACC_ERR_STATUS[FFT_WIN_RND_ERR] is asserted. 0 Interrupt Disabled 1 Interrupt Enabled
8 MAXS_IP_CMD_IE	MAXS input command interrupt enable If set, an interrupt is generated when the HW_ACC_ERR_STATUS[MAXS_IP_CMD_ERR] is asserted
9–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 COPY_IP_CMD_IE	COPY input command interrupt enable If set, an interrupt is generated when the HW_ACC_ERR_STATUS[COPY_IP_CMD_ERR] is asserted
13–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 FFT_ILL_SHFTVAL_IE	FFT Illegal Shift Value Error This is the interrupt enable for HW_ACC_ERR_STATUS[FFT_ILL_SHFTVAL].
17–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 HST_DESTADDR_NOT_MULTOF8_ERR_IE	Destination address not multiple of 8 error interrupt enable If set then an interrupt is issued if SPT_HW_ACC_ERR_STATUS[HST_DESTADDR_NOT_MULTOF8_ERR] is set
22 HST_SRCADDR_NOT_MULTOF8_ERR_IE	Source address not multiple of 8 error interrupt enable If set then an interrupt is issued if SPT_HW_ACC_ERR_STATUS[HST_SRCADDR_NOT_MULTOF8_ERR] is set

Table continues on the next page...

SPT_HW_ACC_ERR_IE field descriptions (continued)

Field	Description
23 HST_SRC_NOT_OR_ERR_IE	Source not Operand RAM error interrupt enable If set then an interrupt is issued when SPT_HW_ACC_ERR_STATUS[HST_SRC_NOT_OR_ERR] is set
24 HST_VECLEN_NOT_MULTOF8_ERR_IE	Vector length not multiple of 8 error interrupt enable If set then an interrupt is issued if SPT_HW_ACC_ERR_STATUS[HST_VECLEN_NOT_MULTOF8_ERR] is set
25 HST_INVALID_WR_ACCESS_ERR_IE	HIST work register access error interrupt enable If set then an interrupt is raised when SPT_HW_ACC_ERR_STATUS[HST_INVALID_WR_ACCESS_ERR] is set
26–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 VMT_SHFT_OVF_IE	VMT Shift Overflow Interrupt Enable. Allows interrupt generation when HW_ACC_ERR_STATUS[VMT_SHFT_OVF_ERR] is asserted. 0 Interrupt Disabled 1 Interrupt Enabled
29 VMT_CON_RL_IE	VMT Conjugate with Real Type Interrupt Enable Allows interrupt generation when HW_ACC_ERR_STATUS[VMT_CON_RL_ERR] is asserted. 0 Interrupt Disabled. 1 Interrupt Enabled
30 VMT_SS_CB_IE	VMT Sum Scale with Conjugate/Bypass Interrupt Enable Allows interrupt generation when HW_ACC_ERR_STATUS[VMT_SS_CB_ERR] is asserted. 0 Interrupt Disabled 1 Interrupt Enabled
31 VMT_DVS_IE	VMT Dual vector sum Interrupt Enable Allows interrupt generation when HW_ACC_ERR_STATUS[VMT_DVS_ERR] is asserted. 0 Interrupt Disabled 1 Interrupt Enabled

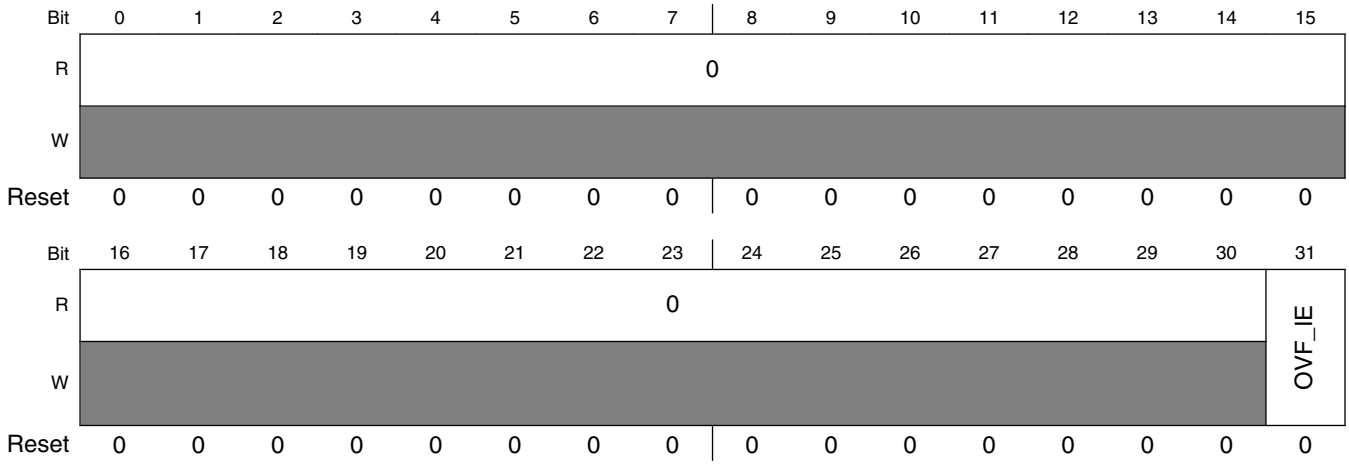
27 B36_OVF	Bin 36 overflow It is set if bin 36 in HIST overflows. Reset internally in SETUP state.
28 B35_OVF	Bin 35 overflow It is set if bin 35 in HIST overflows. Reset internally in SETUP state.
29 B34_OVF	Bin 34 overflow It is set if bin 34 in HIST overflows. Reset internally in SETUP state.
30 B33_OVF	Bin 33 overflow It is set if bin 33 in HIST overflows. Reset internally in SETUP state.
31 B32_OVF	Bin 32 overflow It is set if bin 32 in HIST overflows. Reset internally in SETUP state.

45.8.87 HIST Overflow Interrupt Enable Register (SPT_HIST_OVF_IE)

Address: 0h base + 228h offset = 228h

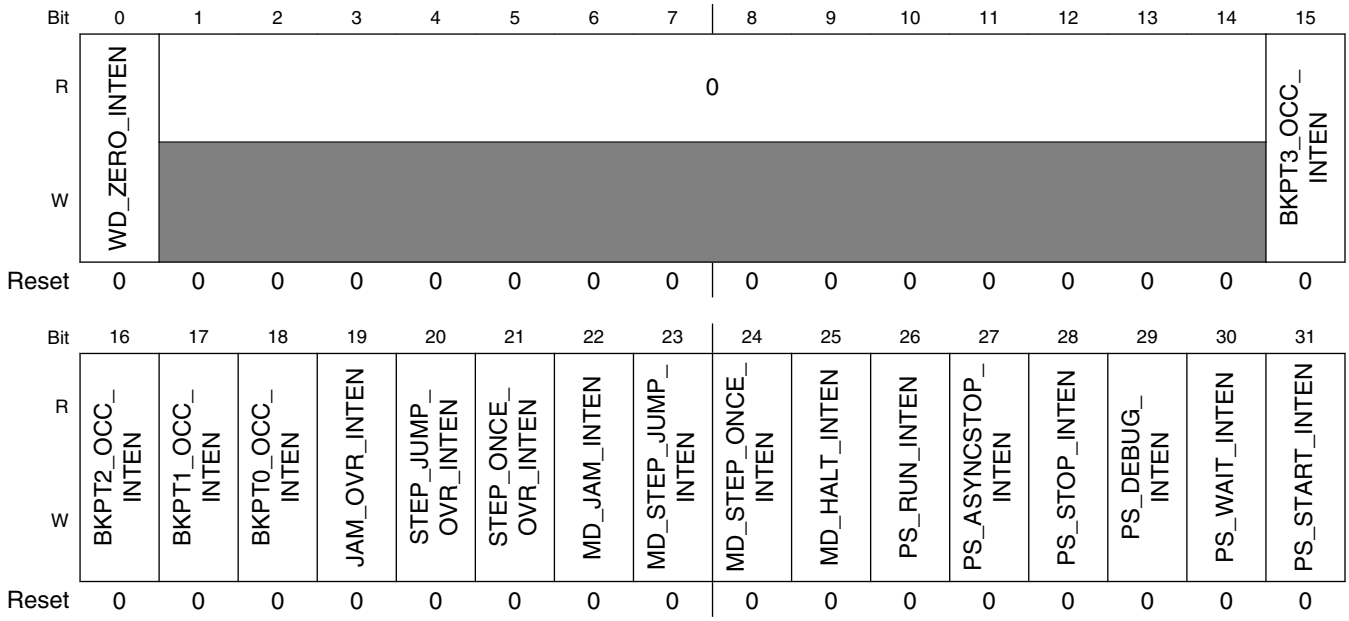


SPT_HIST_OVF_IE field descriptions

Field	Description
0–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 OVF_IE	HIST overflow interrupt enable If set then an interrupt is caused when any bit of SPT_HIST_OVF_STATUS0 and SPT_HIST_OVF_STATUS1 registers is set.

45.8.88 Interrupt Enable Register 0 (SPT_CS_INTEN0)

Address: 0h base + 22Ch offset = 22Ch



SPT_CS_INTEN0 field descriptions

Field	Description
0 WD_ZERO_INTEN	Watchdog reached zero interrupt enable If set then an interrupt is issued when the watchdog reaches zero in the count-down mode
1–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 BKPT3_OCC_INTEN	BKPT3 interrupt enable If set then an interrupt is issued when SPT_CS_STATUS0[BKPT3_OCC] is set
16 BKPT2_OCC_INTEN	BKPT2 interrupt enable If set then an interrupt is issued when SPT_CS_STATUS0[BKPT2_OCC] is set
17 BKPT1_OCC_INTEN	BKPT1 interrupt enable If set then an interrupt is issued when SPT_CS_STATUS0[BKPT1_OCC] is set
18 BKPT0_OCC_INTEN	BKPT0 interrupt enable If set then an interrupt is issued when SPT_CS_STATUS0[BKPT0_OCC] is set
19 JAM_OVR_INTEN	Jamming instruction over interrupt enable If set then an interrupt is issued when SPT_CS_STATUS0[JAM_OVR] gets set upon instruction completion
20 STEP_JUMP_OVR_INTEN	'Breakpoint hit in STEP JUMP mode' interrupt enable

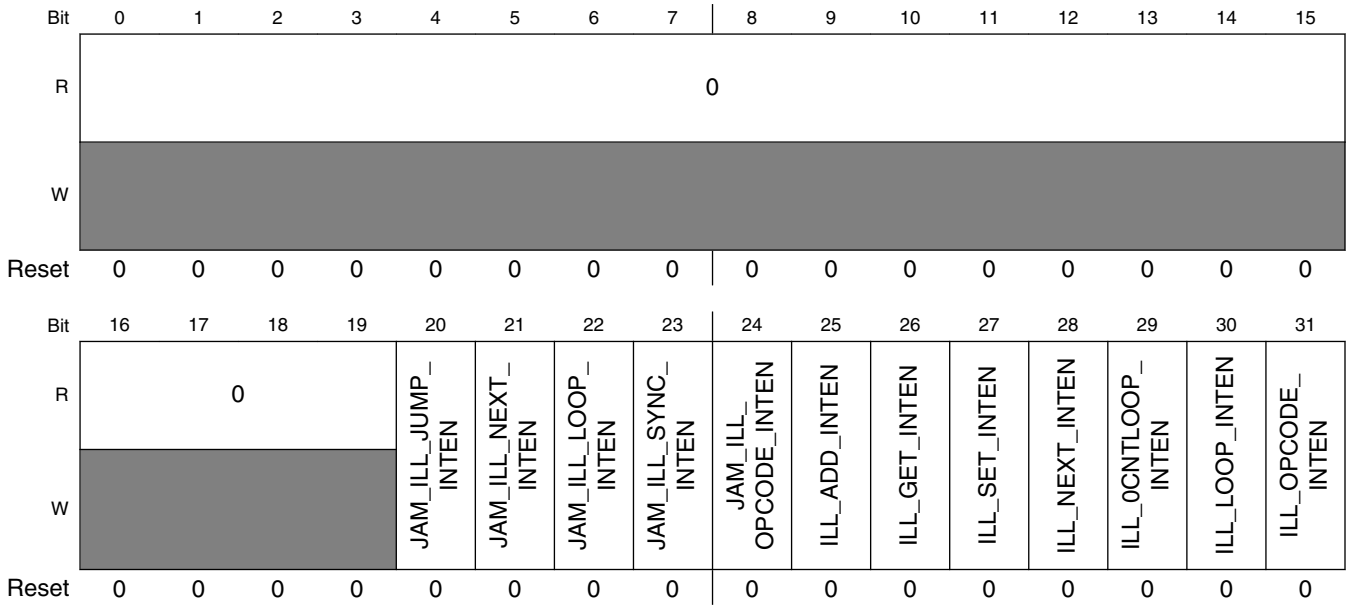
Table continues on the next page...

SPT_CS_INTEN0 field descriptions (continued)

Field	Description
	If set then an interrupt is issued when SPT_CS_STATUS0[STEP_JUMP_OVR] gets set on hitting a breakpoint
21 STEP_ONCE_ OVR_INTEN	STEP ONCE mode instruction over interrupt enable If set then an interrupt is issued when SPT_CS_STATUS0[STEP_ONCE_OVR] gets set upon instruction completion
22 MD_JAM_INTEN	Interrupt enable for instruction jamming mode If set then an interrupt is issued when SPT_CS_STATUS0[MD_JAM] gets set.
23 MD_STEP_ JUMP_INTEN	Interrupt enable for STEP JUMP mode If set then an interrupt is issued when SPT_CS_STATUS0[MD_STEP_JUMP] gets set.
24 MD_STEP_ ONCE_INTEN	Interrupt enable for STEP ONCE mode If set then an interrupt is issued when SPT_CS_STATUS0[MD_STEP_ONCE] gets set.
25 MD_HALT_ INTEN	Interrupt enable for HALT mode If set then an interrupt is issued when SPT_CS_STATUS0[MD_HALT] gets set.
26 PS_RUN_INTEN	Interrupt enable for RUN state If set then an interrupt is issued when SPT_CS_STATUS0[PS_RUN] gets set.
27 PS_ ASYNCSTOP_ INTEN	Interrupt enable for ASYNCSTOP state If set then an interrupt is issued when SPT_CS_STATUS0[PS_ASYNCSTOP] gets set.
28 PS_STOP_ INTEN	Interrupt enable for STOP state If set then an interrupt is issued when SPT_CS_STATUS0[PS_STOP] gets set.
29 PS_DEBUG_ INTEN	Interrupt enable for DEBUG state If set then an interrupt is issued when SPT_CS_STATUS0[PS_DEBUG] gets set.
30 PS_WAIT_INTEN	Interrupt enable for WAIT state If set then an interrupt is issued when SPT_CS_STATUS0[PS_WAIT] gets set.
31 PS_START_ INTEN	Interrupt enable for START state If set then an interrupt is issued when SPT_CS_STATUS0[PS_START] gets set.

45.8.89 Interrupt Enable Register 1 (SPT_CS_INTEN1)

Address: 0h base + 230h offset = 230h



SPT_CS_INTEN1 field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 JAM_ILL_JUMP_INTEN	Illegal JUMP in jamming mode interrupt enable If set then an interrupt is raised when the SPT_CS_STATUS1[JAM_ILL_JUMP] bit is set.
21 JAM_ILL_NEXT_INTEN	Illegal NEXT in jamming mode interrupt enable If set then an interrupt is raised when the SPT_CS_STATUS1[JAM_ILL_NEXT] bit is set.
22 JAM_ILL_LOOP_INTEN	Illegal LOOP in jamming mode interrupt enable If set then an interrupt is raised when the SPT_CS_STATUS1[JAM_ILL_LOOP] bit is set.
23 JAM_ILL_SYNC_INTEN	Illegal SYNC in jamming mode interrupt enable If set then an interrupt is raised when the SPT_CS_STATUS1[JAM_ILL_SYNC] bit is set.
24 JAM_ILL_OPCODE_INTEN	Illegal Opcode in jamming mode interrupt enable If set then an interrupt is raised when the SPT_CS_STATUS1[JAM_ILL_OPCODE] bit is set.
25 ILL_ADD_INTEN	Illegal ADD interrupt enable If set then an interrupt is raised when the SPT_CS_STATUS1[ILL_ADD] bit is set.
26 ILL_GET_INTEN	Illegal GET interrupt enable If set then an interrupt is raised when the SPT_CS_STATUS1[ILL_GET] bit is set.

Table continues on the next page...

SPT_CS_INTEN1 field descriptions (continued)

Field	Description
27 ILL_SET_INTEN	Illegal SET interrupt enable If set then an interrupt is raised when the SPT_CS_STATUS1[ILL_SET] bit is set.
28 ILL_NEXT_ INTEN	Illegal NEXT interrupt enable If set then an interrupt is raised when the SPT_CS_STATUS1[ILL_NEXT] bit is set.
29 ILL_0CNTLOOP_ INTEN	Illegal loop count error interrupt If set then an interrupt is raised when the SPT_CS_STATUS1[ILL_0CNTLOOP] bit is set.
30 ILL_LOOP_ INTEN	Illegal LOOP interrupt enable If set then an interrupt is raised when the SPT_CS_STATUS1[ILL_LOOP] bit is set.
31 ILL_OPCODE_ INTEN	Illegal Opcode interrupt enable If set then an interrupt is raised when the SPT_CS_STATUS1[ILL_OPCODE] bit is set.

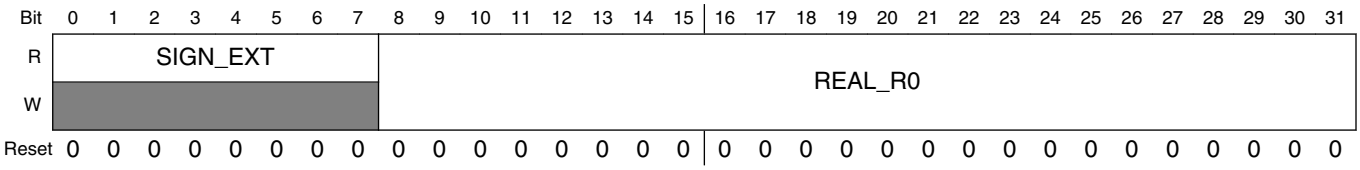
29 WR33_LCK	Work register 33 lock 1: Writes to WR_R33_RE and WR_R33_IM are locked. These registers written by either CPU or SPT as defined by WR33_ACC_CTRL bit. 0: Writes to WR_R33_RE and WR_R33_IM are unlocked. These registers can be written by CPU and SPT
30 WR32_ACC_ CTRL	Work register 32 access control 0: SPT has write access to WR_R32_RE and WR_R32_IM 1: CPU has write access to WR_R32_RE and WR_R32_IM
31 WR32_LCK	Work register 32 lock 1: Writes to WR_R32_RE and WR_R32_IM are locked. These registers written by either CPU or SPT as defined by WR32_ACC_CTRL bit. 0: Writes to WR_R32_RE and WR_R32_IM are unlocked. These registers can be written by CPU and SPT

45.8.95 Work Register R0 Real (SPT_WR_R0_RE)

Address: 0h base + 250h offset = 250h

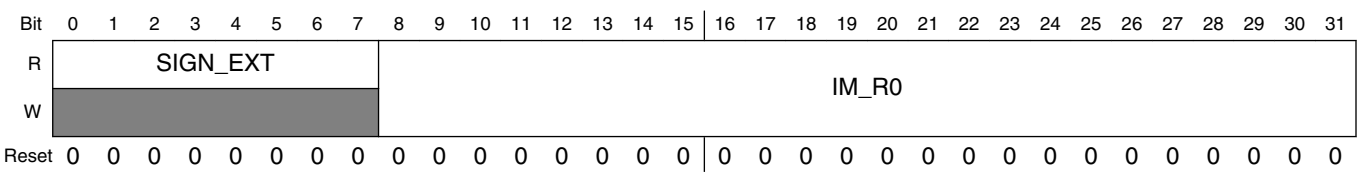


SPT_WR_R0_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R0	Real part of Work Register R0

45.8.96 Work Register R0 Imaginary (SPT_WR_R0_IM)

Address: 0h base + 254h offset = 254h

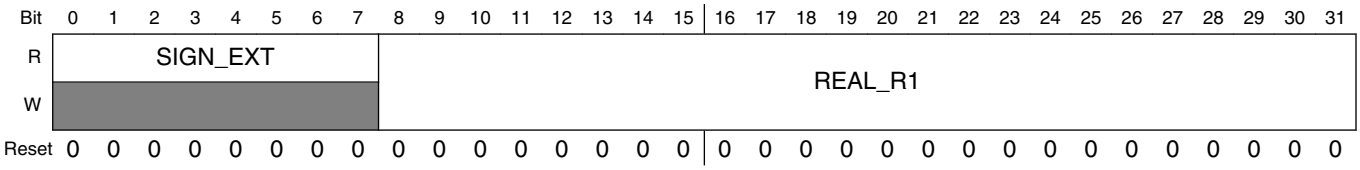


SPT_WR_R0_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R0	Imaginary part of Work Register R0

45.8.97 Work Register R1 Real (SPT_WR_R1_RE)

Address: 0h base + 258h offset = 258h

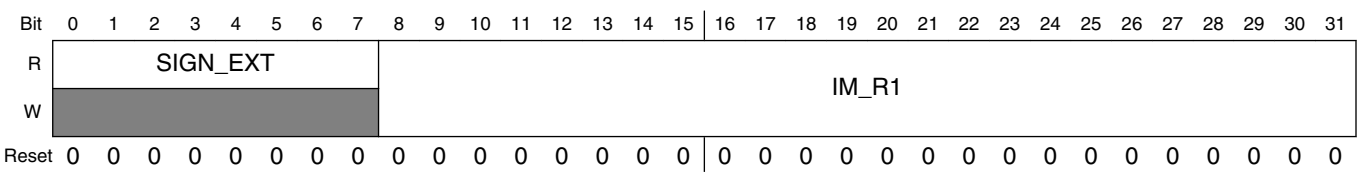


SPT_WR_R1_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R1	Real part of Work Register R1

45.8.98 Work Register R1 Imaginary (SPT_WR_R1_IM)

Address: 0h base + 25Ch offset = 25Ch

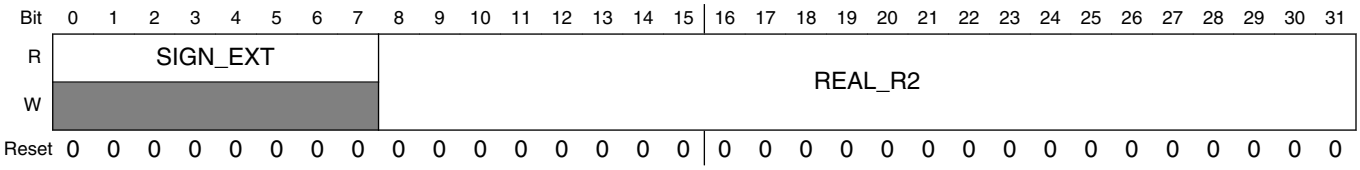


SPT_WR_R1_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R1	Imaginary part of Work Register R1

45.8.99 Work Register R0 Real (SPT_WR_R2_RE)

Address: 0h base + 260h offset = 260h

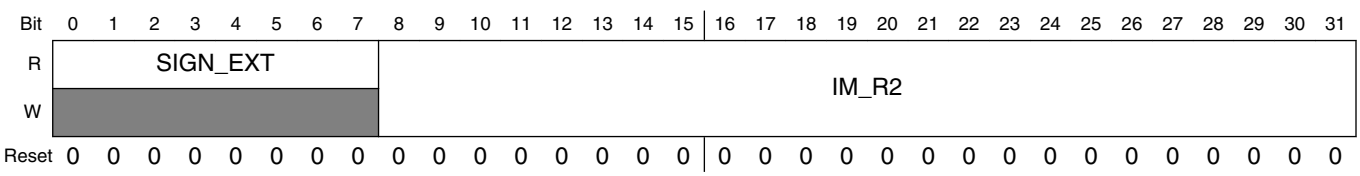


SPT_WR_R2_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R2	Real part of Work Register R2

45.8.100 Work Register R2 Imaginary (SPT_WR_R2_IM)

Address: 0h base + 264h offset = 264h

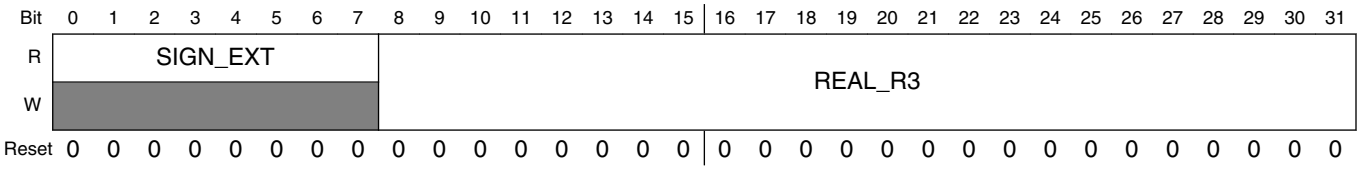


SPT_WR_R2_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R2	Imaginary part of Work Register R2

45.8.101 Work Register R3 Real (SPT_WR_R3_RE)

Address: 0h base + 268h offset = 268h

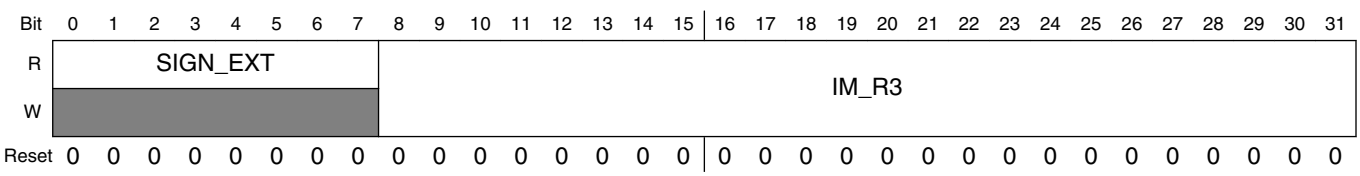


SPT_WR_R3_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R3	Real part of Work Register R3

45.8.102 Work Register R3 Imaginary (SPT_WR_R3_IM)

Address: 0h base + 26Ch offset = 26Ch

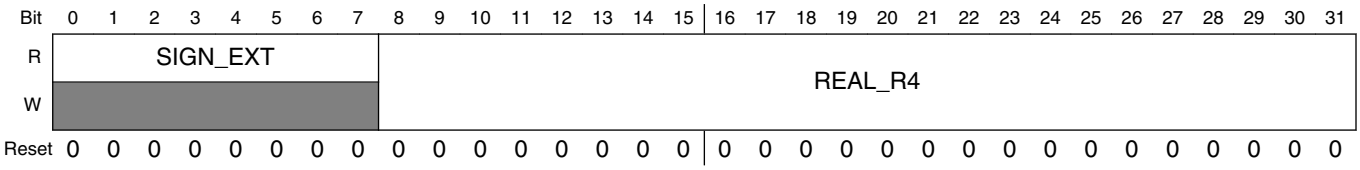


SPT_WR_R3_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R3	Imaginary part of Work Register R3

45.8.103 Work Register R4 Real (SPT_WR_R4_RE)

Address: 0h base + 270h offset = 270h

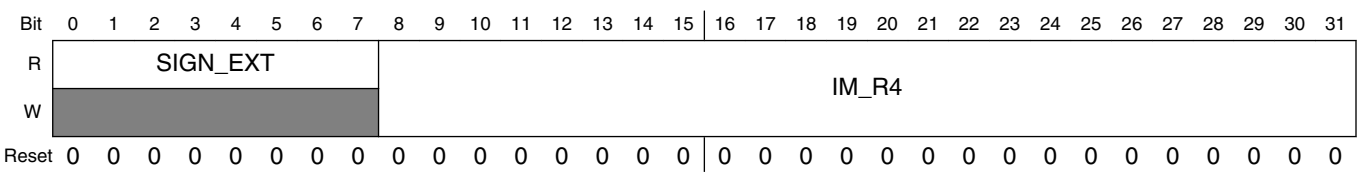


SPT_WR_R4_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R4	Real part of Work Register R4

45.8.104 Work Register R4 Imaginary (SPT_WR_R4_IM)

Address: 0h base + 274h offset = 274h

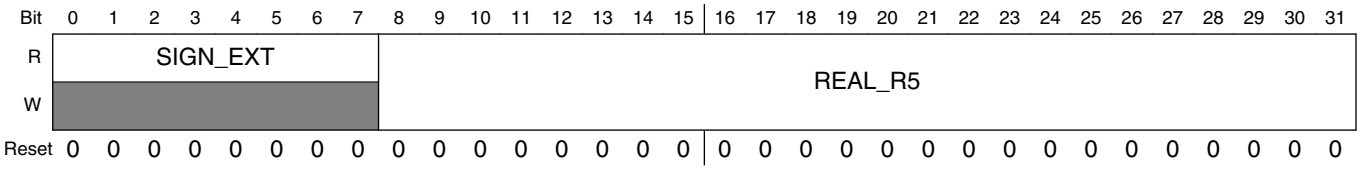


SPT_WR_R4_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R4	Imaginary part of Work Register R4

45.8.105 Work Register R5 Real (SPT_WR_R5_RE)

Address: 0h base + 278h offset = 278h

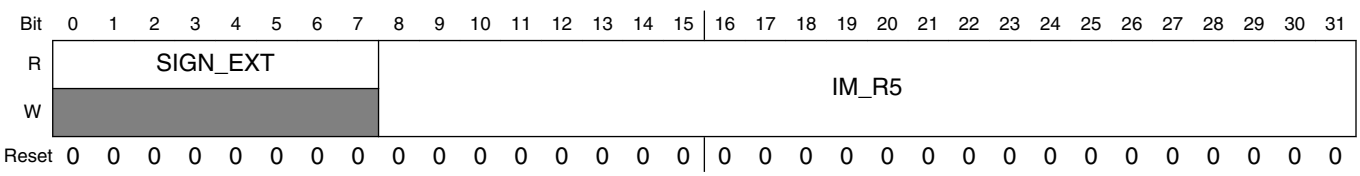


SPT_WR_R5_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R5	Real part of Work Register R5

45.8.106 Work Register R5 Imaginary (SPT_WR_R5_IM)

Address: 0h base + 27Ch offset = 27Ch

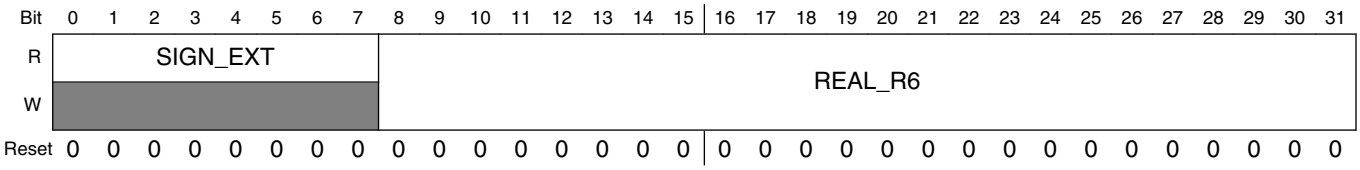


SPT_WR_R5_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R5	Imaginary part of Work Register R5

45.8.107 Work Register R6 Real (SPT_WR_R6_RE)

Address: 0h base + 280h offset = 280h

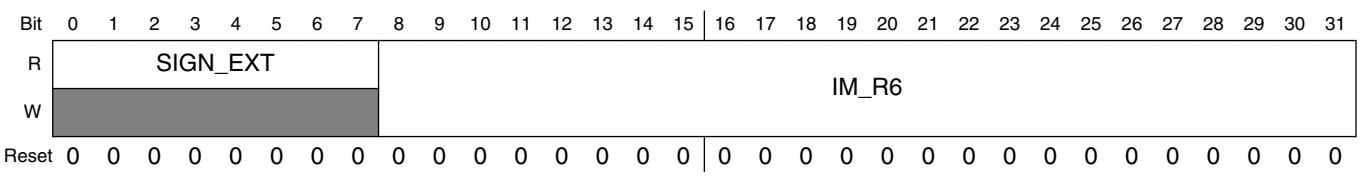


SPT_WR_R6_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R6	Real part of Work Register R6

45.8.108 Work Register R6 Imaginary (SPT_WR_R6_IM)

Address: 0h base + 284h offset = 284h

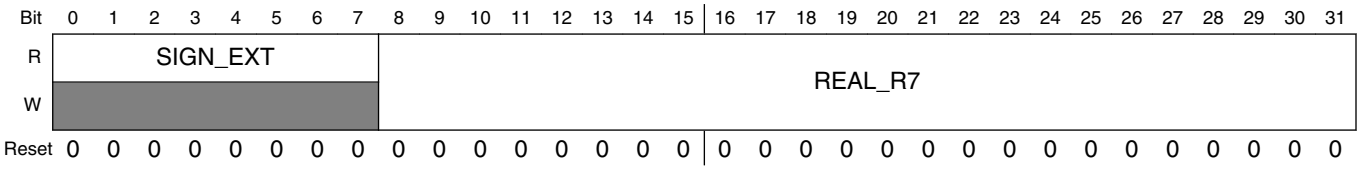


SPT_WR_R6_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R6	Imaginary part of Work Register R6

45.8.109 Work Register R7 Real (SPT_WR_R7_RE)

Address: 0h base + 288h offset = 288h

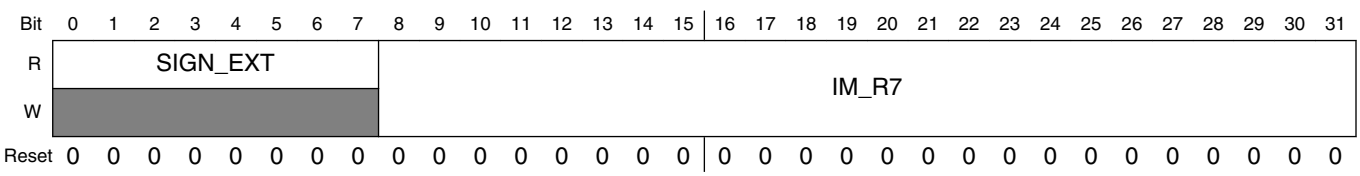


SPT_WR_R7_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R7	Real part of Work Register R7

45.8.110 Work Register R7 Imaginary (SPT_WR_R7_IM)

Address: 0h base + 28Ch offset = 28Ch

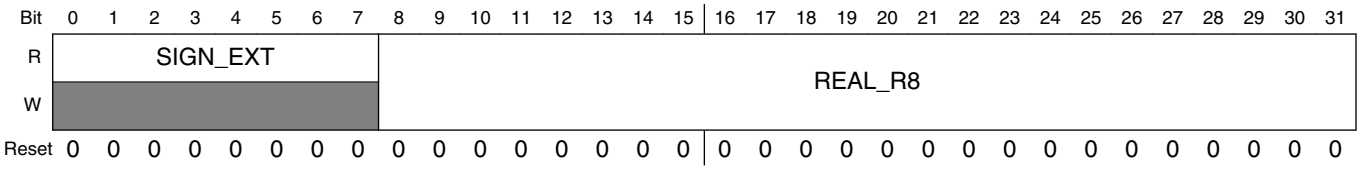


SPT_WR_R7_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R7	Imaginary part of Work Register R7

45.8.111 Work Register R8 Real (SPT_WR_R8_RE)

Address: 0h base + 290h offset = 290h

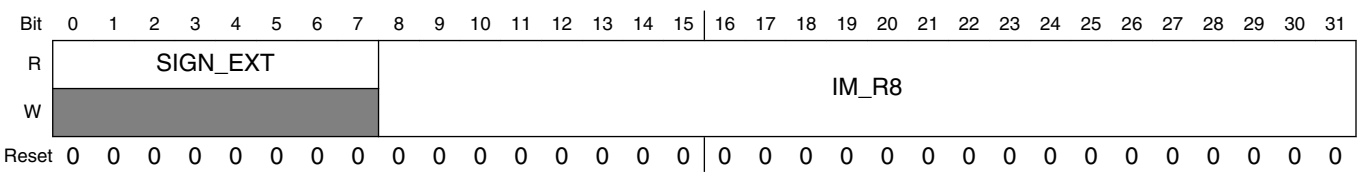


SPT_WR_R8_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R8	Real part of Work Register R8

45.8.112 Work Register R8 Imaginary (SPT_WR_R8_IM)

Address: 0h base + 294h offset = 294h

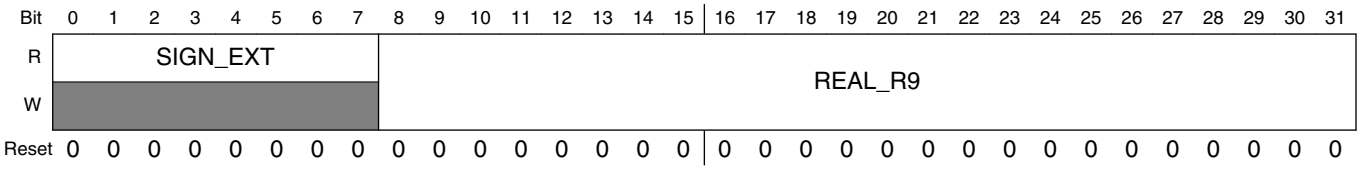


SPT_WR_R8_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R8	Imaginary part of Work Register R8

45.8.113 Work Register R9 Real (SPT_WR_R9_RE)

Address: 0h base + 298h offset = 298h

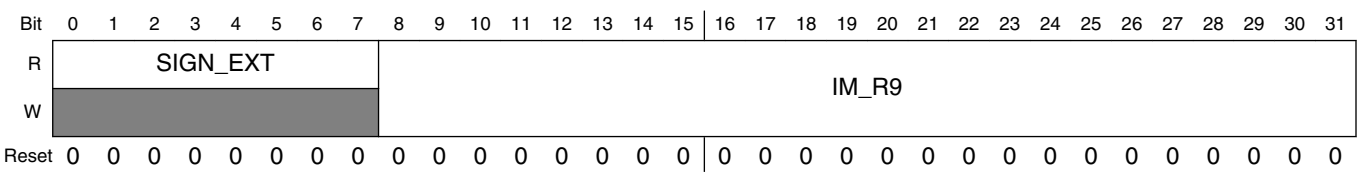


SPT_WR_R9_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R9	Real part of Work Register R9

45.8.114 Work Register R9 Imaginary (SPT_WR_R9_IM)

Address: 0h base + 29Ch offset = 29Ch

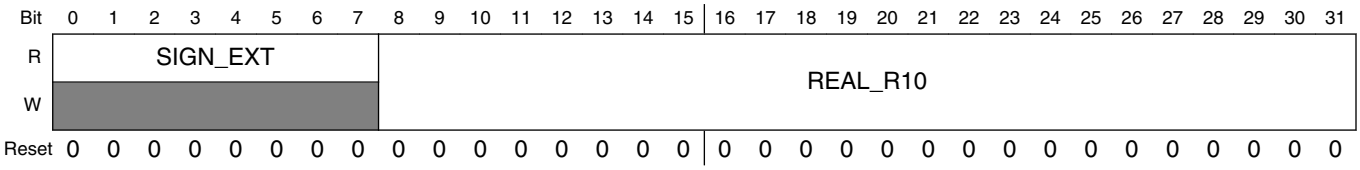


SPT_WR_R9_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R9	Imaginary part of Work Register R9

45.8.115 Work Register R10 Real (SPT_WR_R10_RE)

Address: 0h base + 2A0h offset = 2A0h

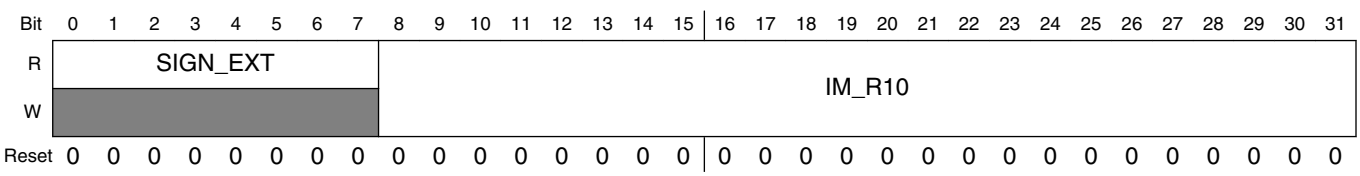


SPT_WR_R10_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R10	Real part of Work Register R10

45.8.116 Work Register R10 Imaginary (SPT_WR_R10_IM)

Address: 0h base + 2A4h offset = 2A4h

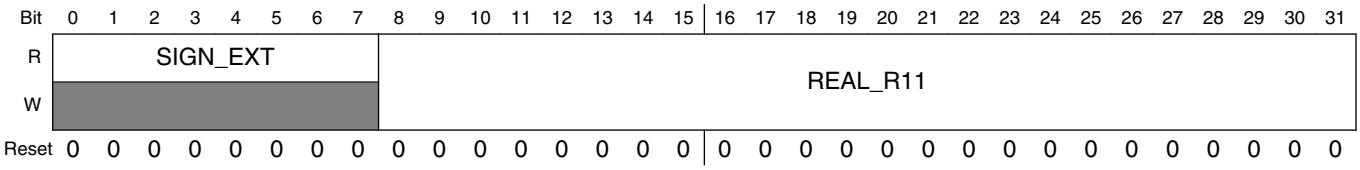


SPT_WR_R10_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R10	Imaginary part of Work Register R10

45.8.117 Work Register R11 Real (SPT_WR_R11_RE)

Address: 0h base + 2A8h offset = 2A8h

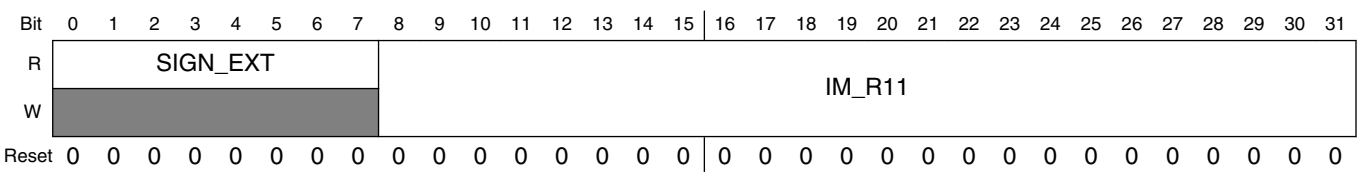


SPT_WR_R11_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R11	Real part of Work Register R11

45.8.118 Work Register R11 Imaginary (SPT_WR_R11_IM)

Address: 0h base + 2ACh offset = 2ACh

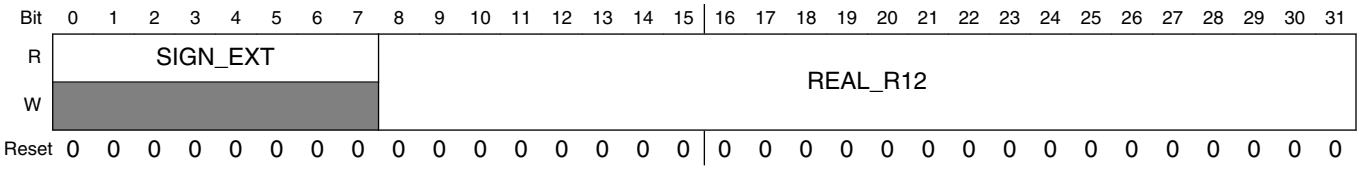


SPT_WR_R11_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R11	Imaginary part of Work Register R11

45.8.119 Work Register R12 Real (SPT_WR_R12_RE)

Address: 0h base + 2B0h offset = 2B0h

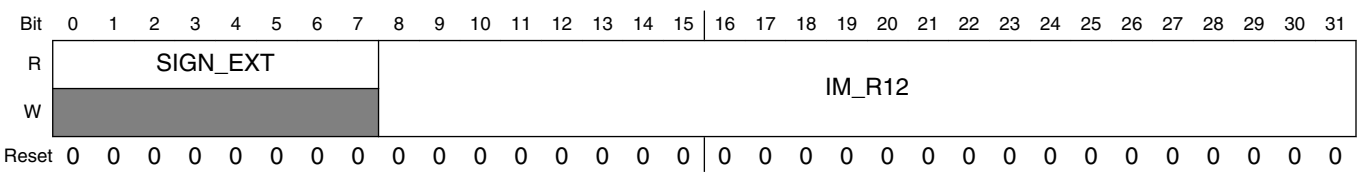


SPT_WR_R12_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R12	Real part of Work Register R12

45.8.120 Work Register R12 Imaginary (SPT_WR_R12_IM)

Address: 0h base + 2B4h offset = 2B4h

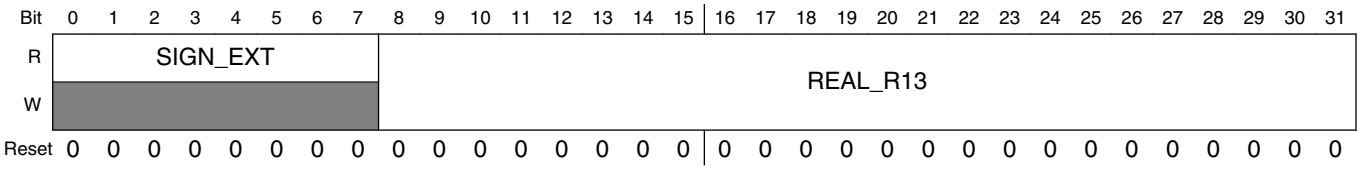


SPT_WR_R12_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R12	Imaginary part of Work Register R12

45.8.121 Work Register R13 Real (SPT_WR_R13_RE)

Address: 0h base + 2B8h offset = 2B8h

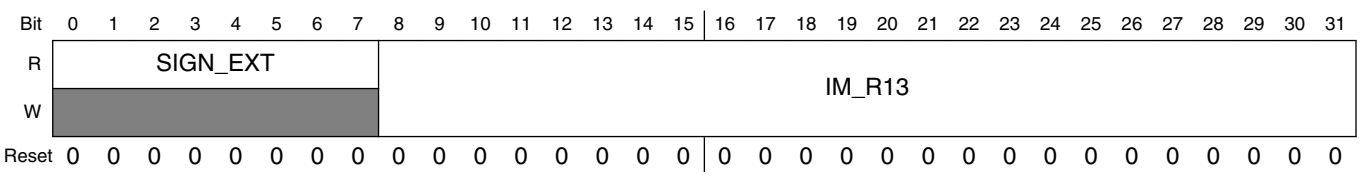


SPT_WR_R13_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R13	Real part of Work Register R13

45.8.122 Work Register R13 Imaginary (SPT_WR_R13_IM)

Address: 0h base + 2BCh offset = 2BCh

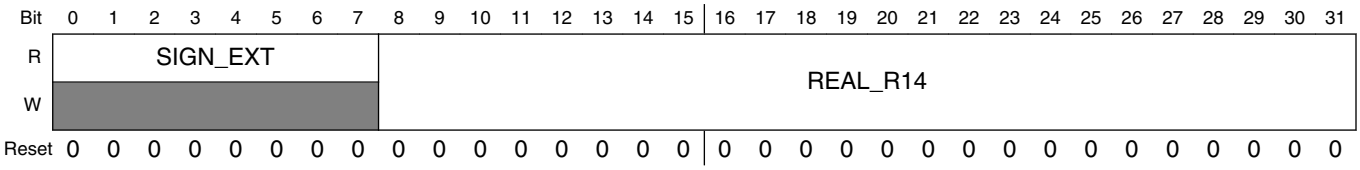


SPT_WR_R13_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R13	Imaginary part of Work Register R13

45.8.123 Work Register R14 Real (SPT_WR_R14_RE)

Address: 0h base + 2C0h offset = 2C0h

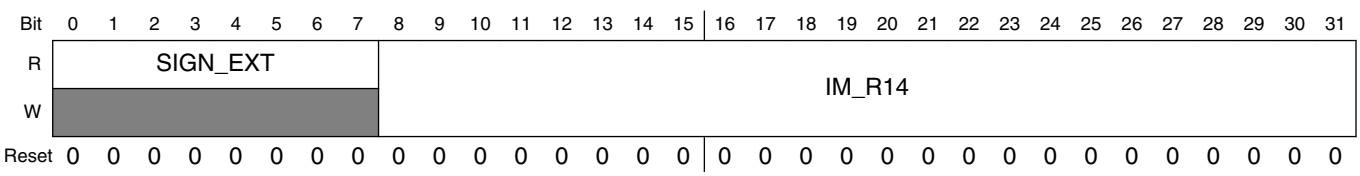


SPT_WR_R14_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R14	Real part of Work Register R14

45.8.124 Work Register R14 Imaginary (SPT_WR_R14_IM)

Address: 0h base + 2C4h offset = 2C4h

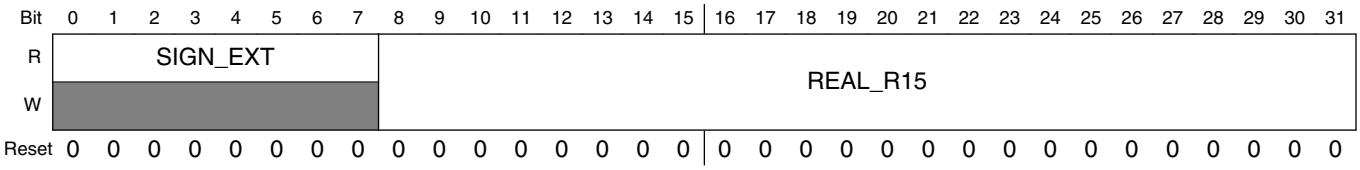


SPT_WR_R14_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R14	Imaginary part of Work Register R14

45.8.125 Work Register R15 Real (SPT_WR_R15_RE)

Address: 0h base + 2C8h offset = 2C8h

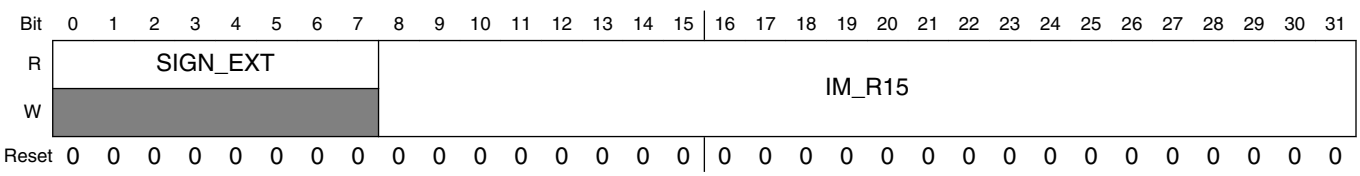


SPT_WR_R15_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R15	Real part of Work Register R15

45.8.126 Work Register R15 Imaginary (SPT_WR_R15_IM)

Address: 0h base + 2CCh offset = 2CCh

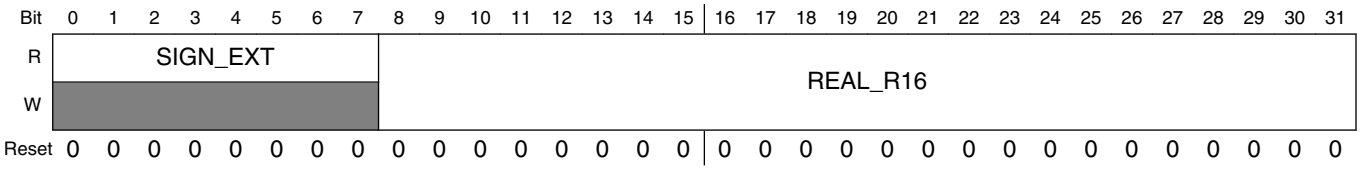


SPT_WR_R15_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R15	Imaginary part of Work Register R15

45.8.127 Work Register R16 Real (SPT_WR_R16_RE)

Address: 0h base + 2D0h offset = 2D0h

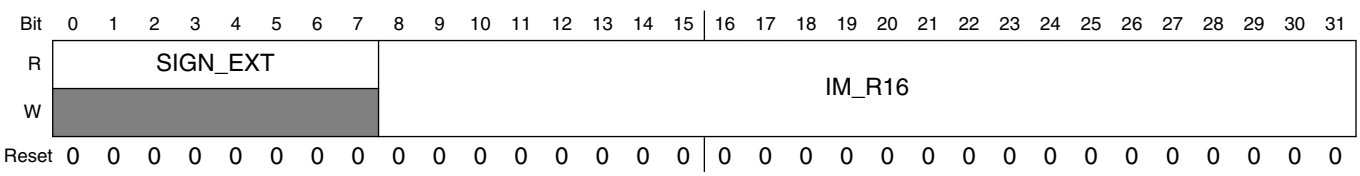


SPT_WR_R16_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R16	Real part of Work Register R16

45.8.128 Work Register R16 Imaginary (SPT_WR_R16_IM)

Address: 0h base + 2D4h offset = 2D4h

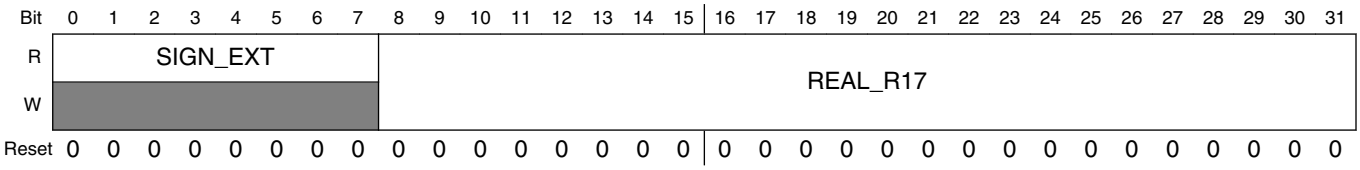


SPT_WR_R16_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R16	Imaginary part of Work Register R16

45.8.129 Work Register R17 Real (SPT_WR_R17_RE)

Address: 0h base + 2D8h offset = 2D8h

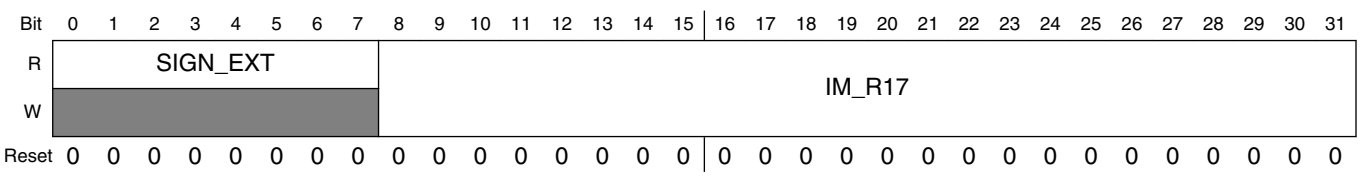


SPT_WR_R17_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R17	Real part of Work Register R17

45.8.130 Work Register R17 Imaginary (SPT_WR_R17_IM)

Address: 0h base + 2DCh offset = 2DCh

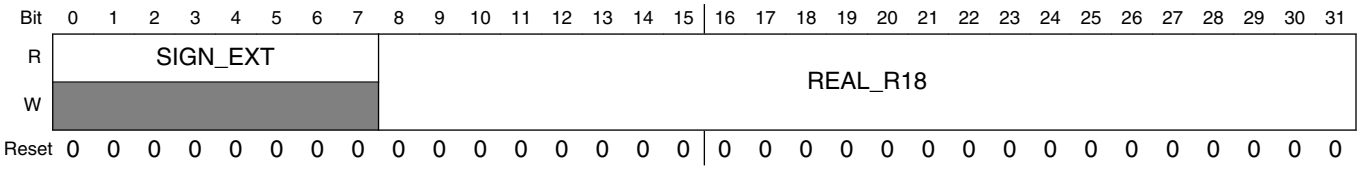


SPT_WR_R17_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R17	Imaginary part of Work Register R17

45.8.131 Work Register R18 Real (SPT_WR_R18_RE)

Address: 0h base + 2E0h offset = 2E0h

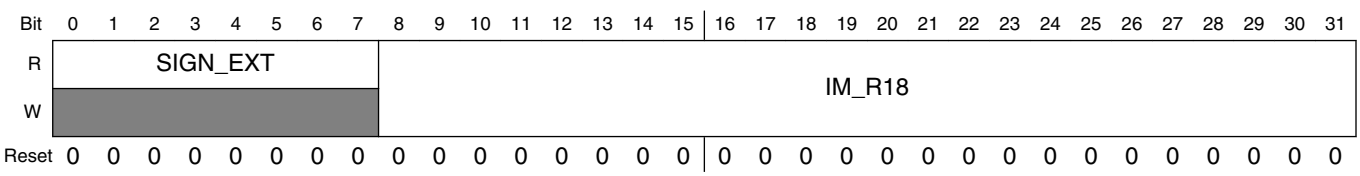


SPT_WR_R18_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R18	Real part of Work Register R18

45.8.132 Work Register R18 Imaginary (SPT_WR_R18_IM)

Address: 0h base + 2E4h offset = 2E4h

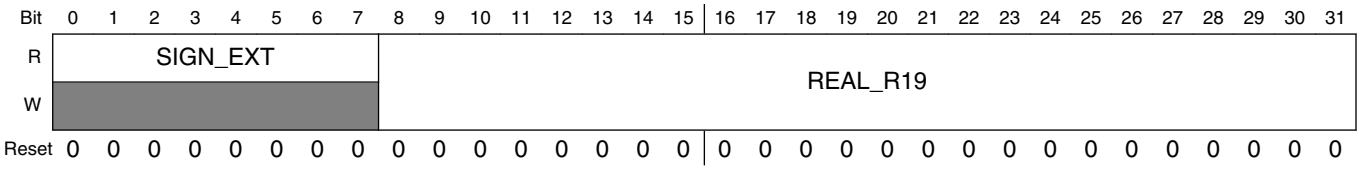


SPT_WR_R18_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R18	Imaginary part of Work Register R18

45.8.133 Work Register R19 Real (SPT_WR_R19_RE)

Address: 0h base + 2E8h offset = 2E8h

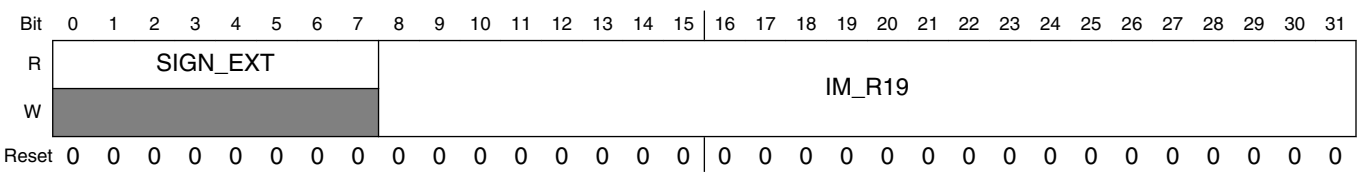


SPT_WR_R19_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R19	Real part of Work Register R19

45.8.134 Work Register R19 Imaginary (SPT_WR_R19_IM)

Address: 0h base + 2ECh offset = 2ECh

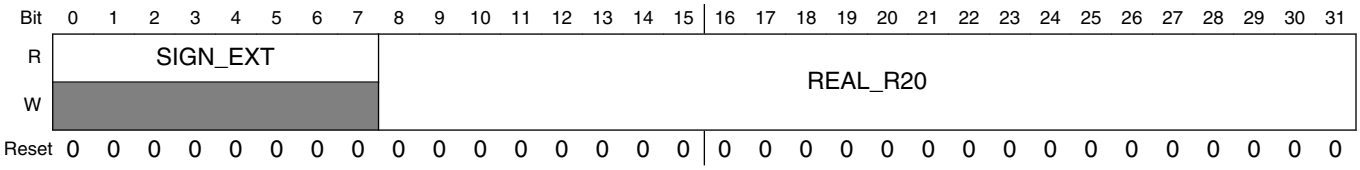


SPT_WR_R19_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R19	Imaginary part of Work Register R19

45.8.135 Work Register R20 Real (SPT_WR_R20_RE)

Address: 0h base + 2F0h offset = 2F0h

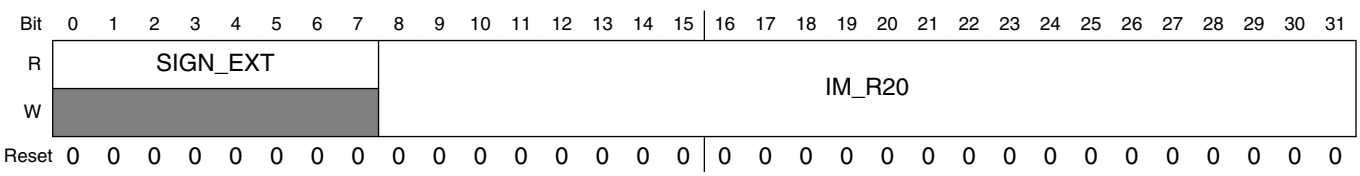


SPT_WR_R20_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R20	Real part of Work Register R20

45.8.136 Work Register R20 Imaginary (SPT_WR_R20_IM)

Address: 0h base + 2F4h offset = 2F4h

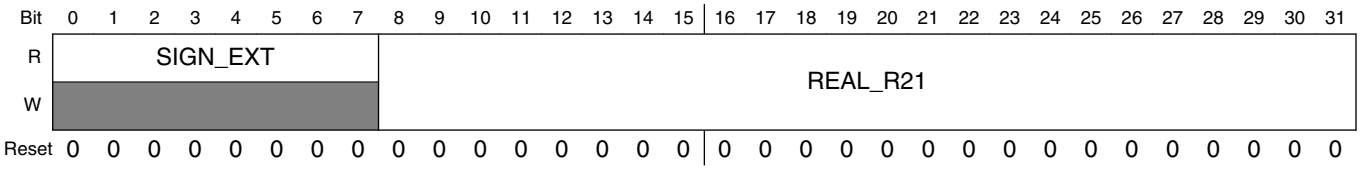


SPT_WR_R20_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R20	Imaginary part of Work Register R20

45.8.137 Work Register R21 Real (SPT_WR_R21_RE)

Address: 0h base + 2F8h offset = 2F8h

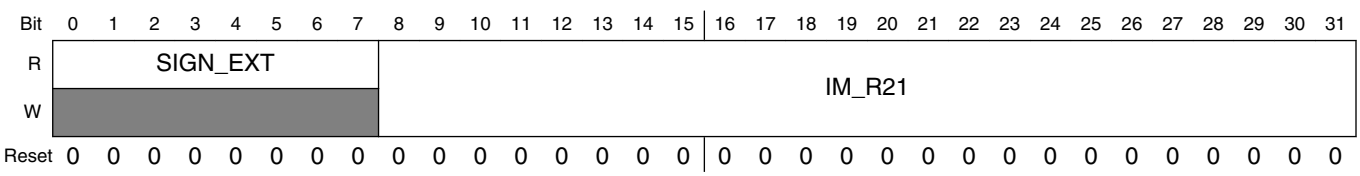


SPT_WR_R21_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R21	Real part of Work Register R21

45.8.138 Work Register R21 Imaginary (SPT_WR_R21_IM)

Address: 0h base + 2FCh offset = 2FCh

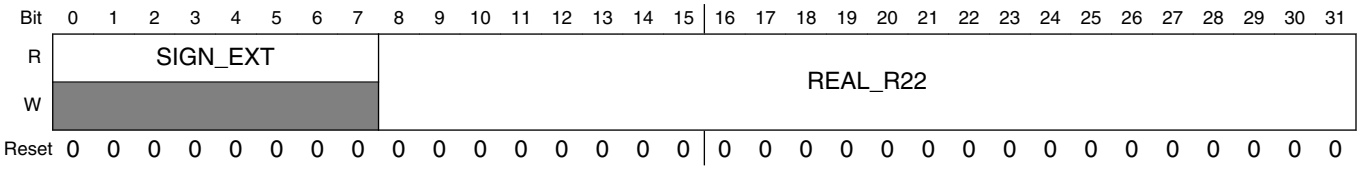


SPT_WR_R21_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R21	Imaginary part of Work Register R21

45.8.139 Work Register R22 Real (SPT_WR_R22_RE)

Address: 0h base + 300h offset = 300h

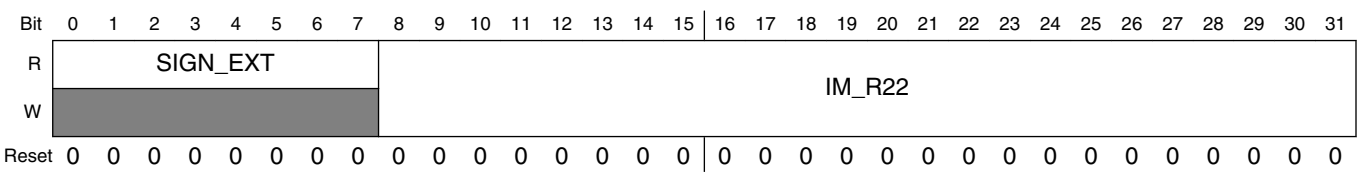


SPT_WR_R22_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R22	Real part of Work Register R22

45.8.140 Work Register R22 Imaginary (SPT_WR_R22_IM)

Address: 0h base + 304h offset = 304h

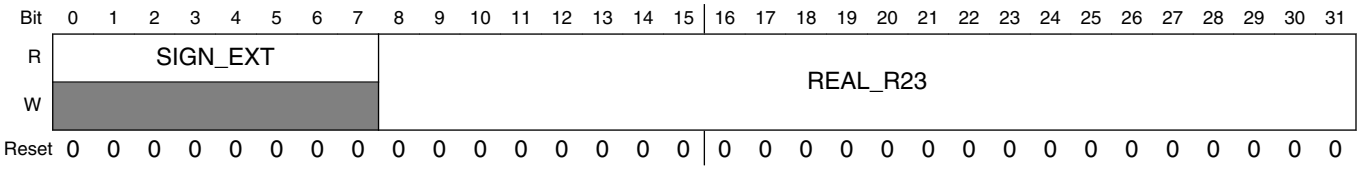


SPT_WR_R22_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R22	Imaginary part of Work Register R22

45.8.141 Work Register R23 Real (SPT_WR_R23_RE)

Address: 0h base + 308h offset = 308h

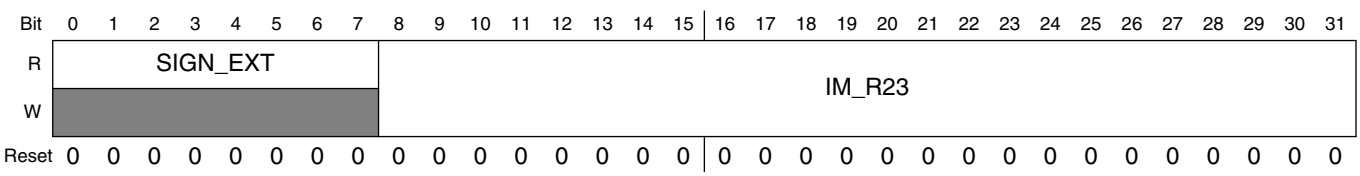


SPT_WR_R23_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R23	Real part of Work Register R23

45.8.142 Work Register R23 Imaginary (SPT_WR_R23_IM)

Address: 0h base + 30Ch offset = 30Ch

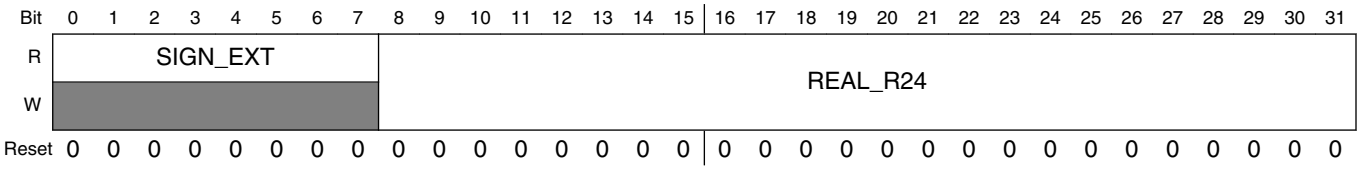


SPT_WR_R23_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R23	Imaginary part of Work Register R23

45.8.143 Work Register R24 Real (SPT_WR_R24_RE)

Address: 0h base + 310h offset = 310h

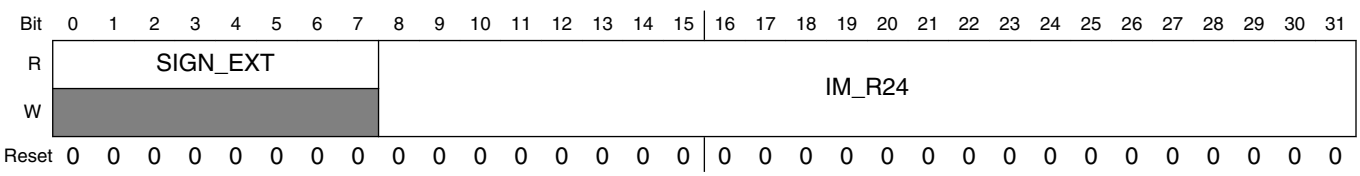


SPT_WR_R24_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R24	Real part of Work Register R24

45.8.144 Work Register R24 Imaginary (SPT_WR_R24_IM)

Address: 0h base + 314h offset = 314h

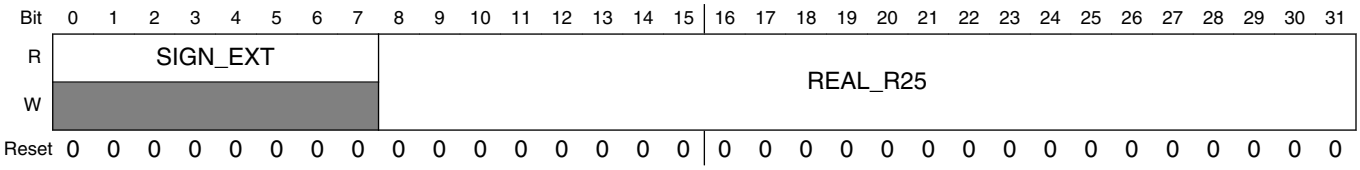


SPT_WR_R24_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R24	Imaginary part of Work Register R24

45.8.145 Work Register R25 Real (SPT_WR_R25_RE)

Address: 0h base + 318h offset = 318h

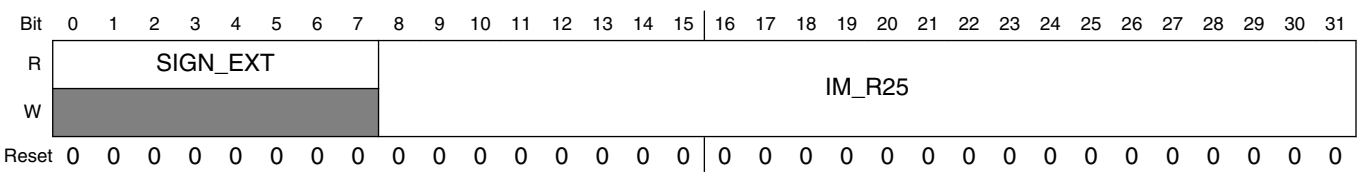


SPT_WR_R25_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R25	Real part of Work Register R25

45.8.146 Work Register R25 Imaginary (SPT_WR_R25_IM)

Address: 0h base + 31Ch offset = 31Ch

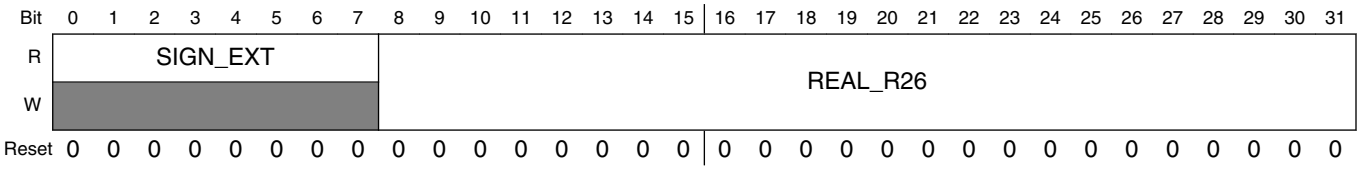


SPT_WR_R25_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R25	Imaginary part of Work Register R25

45.8.147 Work Register R26 Real (SPT_WR_R26_RE)

Address: 0h base + 320h offset = 320h

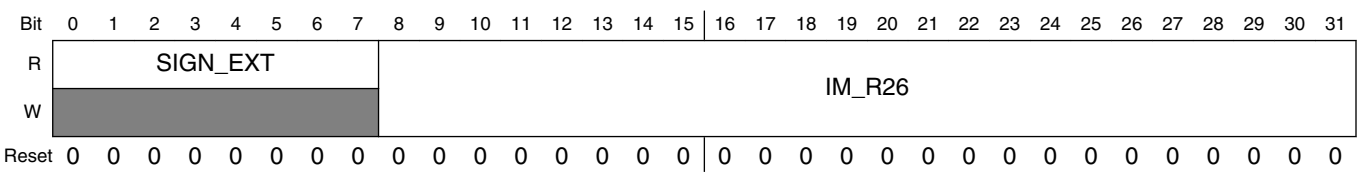


SPT_WR_R26_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R26	Real part of Work Register R26

45.8.148 Work Register R26 Imaginary (SPT_WR_R26_IM)

Address: 0h base + 324h offset = 324h

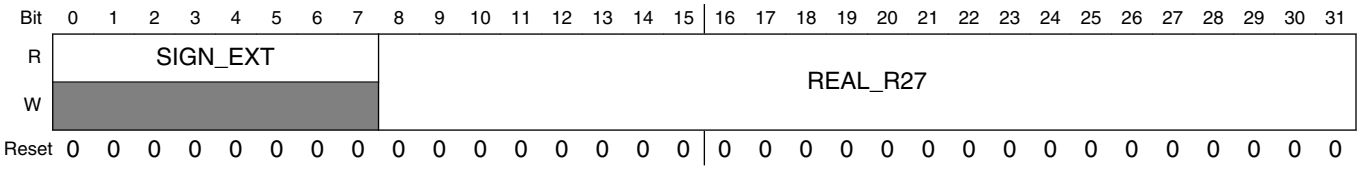


SPT_WR_R26_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R26	Imaginary part of Work Register R26

45.8.149 Work Register R27 Real (SPT_WR_R27_RE)

Address: 0h base + 328h offset = 328h

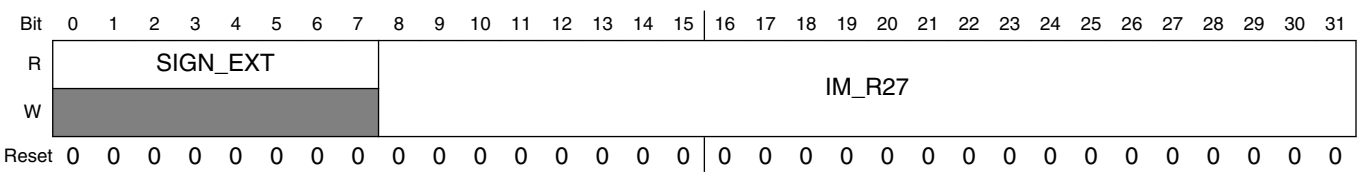


SPT_WR_R27_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R27	Real part of Work Register R27

45.8.150 Work Register R27 Imaginary (SPT_WR_R27_IM)

Address: 0h base + 32Ch offset = 32Ch

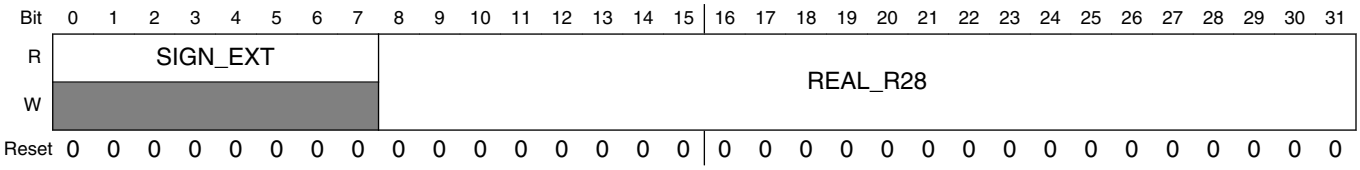


SPT_WR_R27_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R27	Imaginary part of Work Register R27

45.8.151 Work Register R28 Real (SPT_WR_R28_RE)

Address: 0h base + 330h offset = 330h

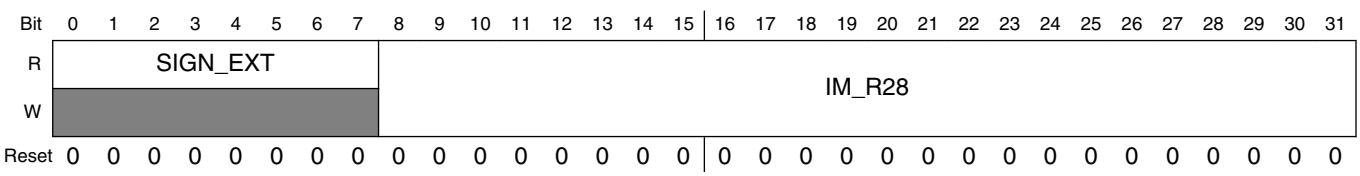


SPT_WR_R28_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R28	Real part of Work Register R28

45.8.152 Work Register R28 Imaginary (SPT_WR_R28_IM)

Address: 0h base + 334h offset = 334h

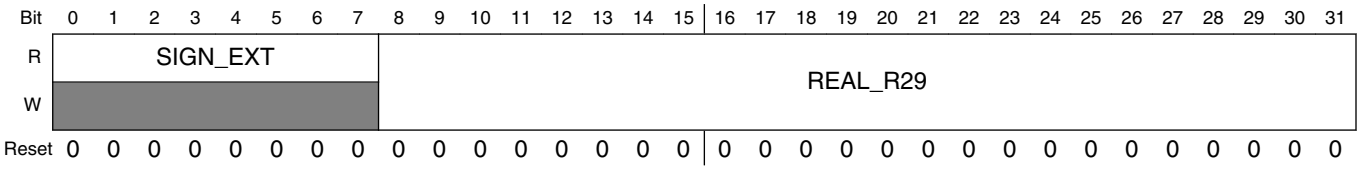


SPT_WR_R28_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R28	Imaginary part of Work Register R28

45.8.153 Work Register R29 Real (SPT_WR_R29_RE)

Address: 0h base + 338h offset = 338h

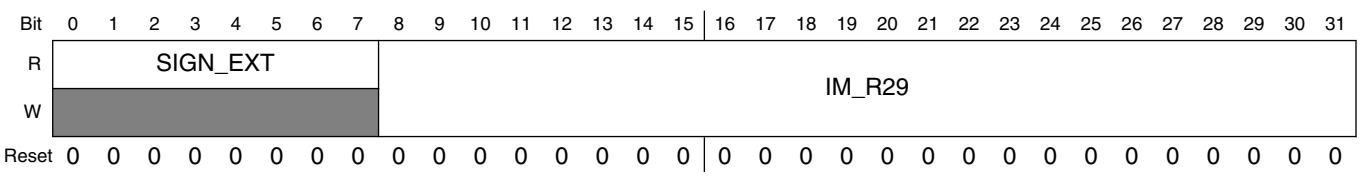


SPT_WR_R29_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R29	Real part of Work Register R29

45.8.154 Work Register R29 Imaginary (SPT_WR_R29_IM)

Address: 0h base + 33Ch offset = 33Ch

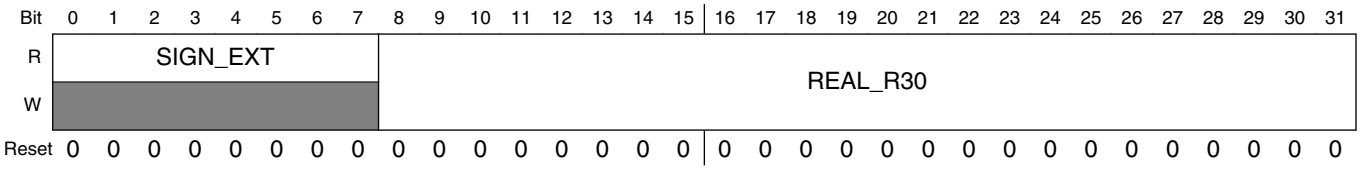


SPT_WR_R29_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R29	Imaginary part of Work Register R29

45.8.155 Work Register R30 Real (SPT_WR_R30_RE)

Address: 0h base + 340h offset = 340h

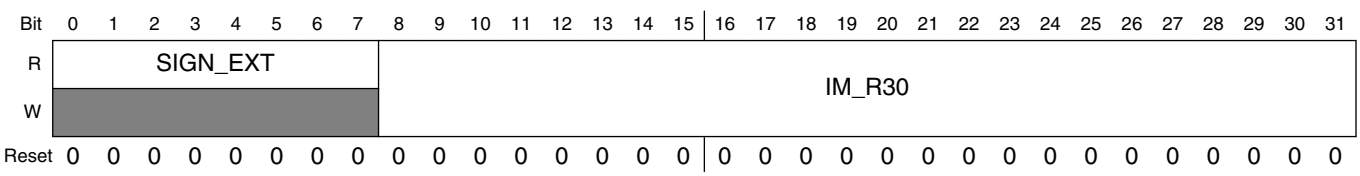


SPT_WR_R30_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R30	Real part of Work Register R30

45.8.156 Work Register R30 Imaginary (SPT_WR_R30_IM)

Address: 0h base + 344h offset = 344h

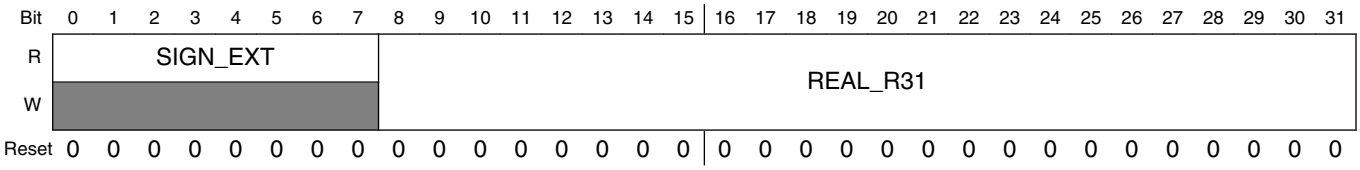


SPT_WR_R30_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R30	Imaginary part of Work Register R30

45.8.157 Work Register R31 Real (SPT_WR_R31_RE)

Address: 0h base + 348h offset = 348h

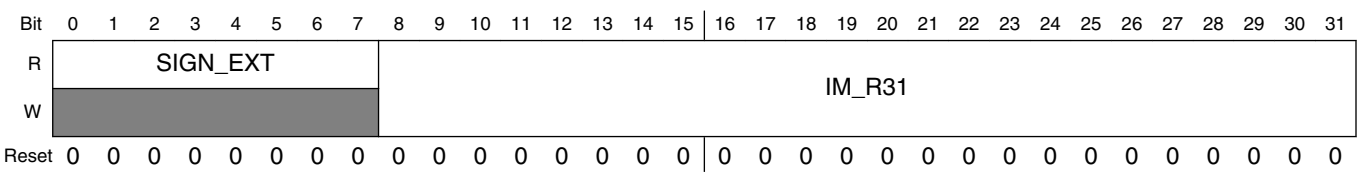


SPT_WR_R31_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R31	Real part of Work Register R31

45.8.158 Work Register R31 Imaginary (SPT_WR_R31_IM)

Address: 0h base + 34Ch offset = 34Ch

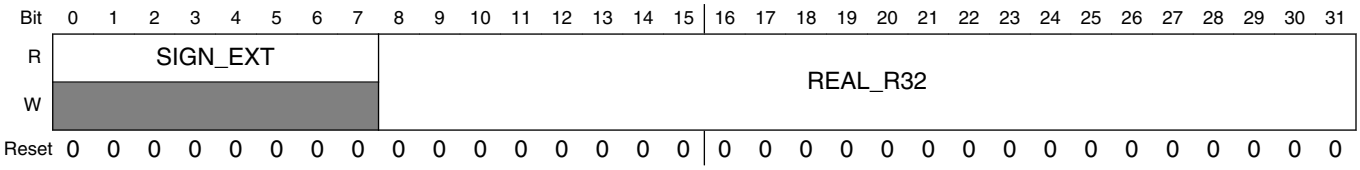


SPT_WR_R31_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R31	Imaginary part of Work Register R31

45.8.159 Work Register R32 Real (SPT_WR_R32_RE)

Address: 0h base + 350h offset = 350h

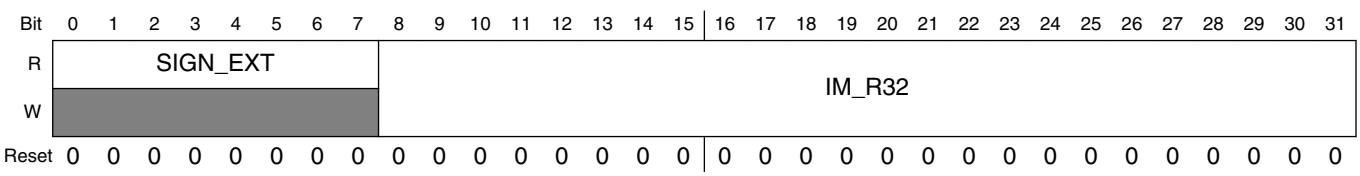


SPT_WR_R32_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R32	Real part of Work Register R32

45.8.160 Work Register R32 Imaginary (SPT_WR_R32_IM)

Address: 0h base + 354h offset = 354h

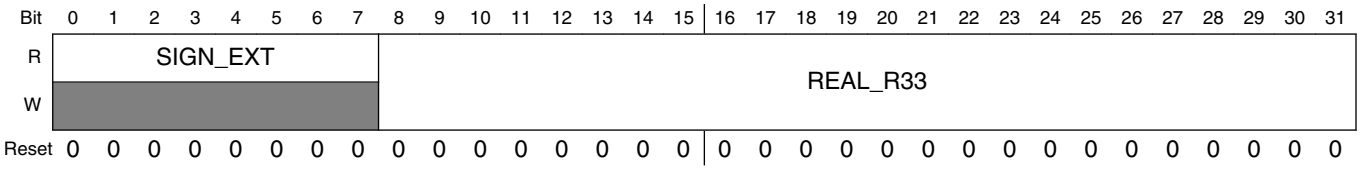


SPT_WR_R32_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R32	Imaginary part of Work Register R32

45.8.161 Work Register R33 Real (SPT_WR_R33_RE)

Address: 0h base + 358h offset = 358h

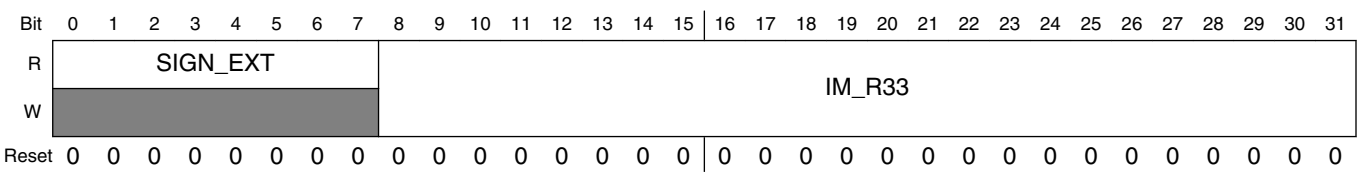


SPT_WR_R33_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R33	Real part of Work Register R33

45.8.162 Work Register R33 Imaginary (SPT_WR_R33_IM)

Address: 0h base + 35Ch offset = 35Ch

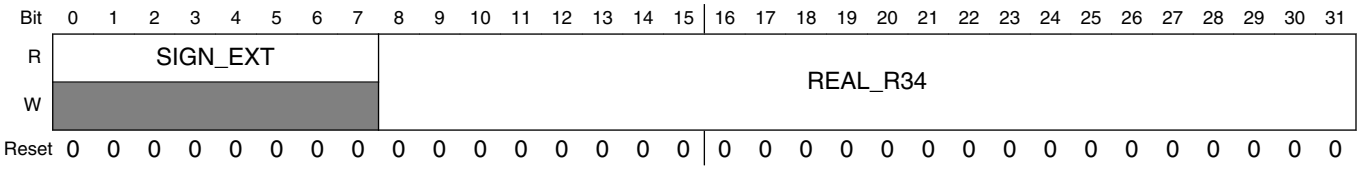


SPT_WR_R33_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R33	Imaginary part of Work Register R33

45.8.163 Work Register R34 Real (SPT_WR_R34_RE)

Address: 0h base + 360h offset = 360h

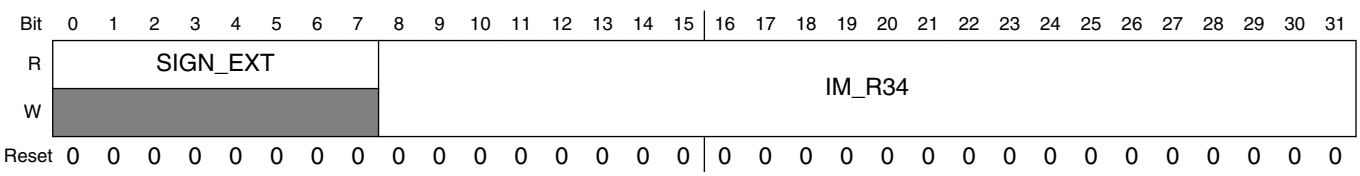


SPT_WR_R34_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R34	Real part of Work Register R34

45.8.164 Work Register R34 Imaginary (SPT_WR_R34_IM)

Address: 0h base + 364h offset = 364h

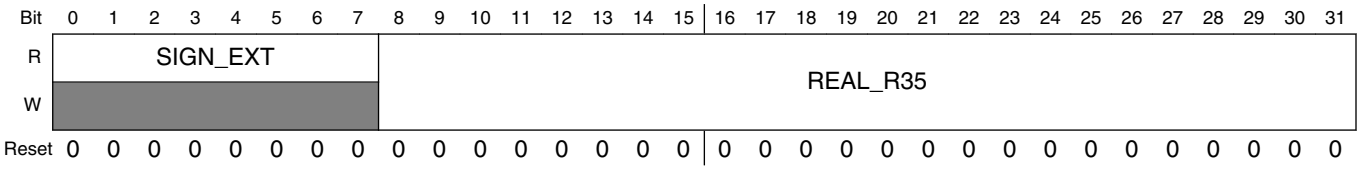


SPT_WR_R34_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R34	Imaginary part of Work Register R34

45.8.165 Work Register R35 Real (SPT_WR_R35_RE)

Address: 0h base + 368h offset = 368h

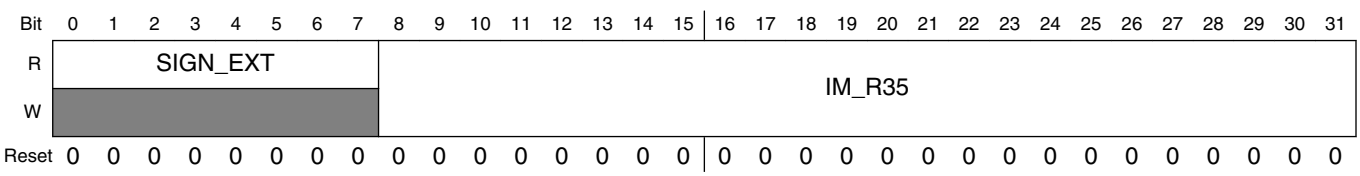


SPT_WR_R35_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R35	Real part of Work Register R35

45.8.166 Work Register R35 Imaginary (SPT_WR_R35_IM)

Address: 0h base + 36Ch offset = 36Ch

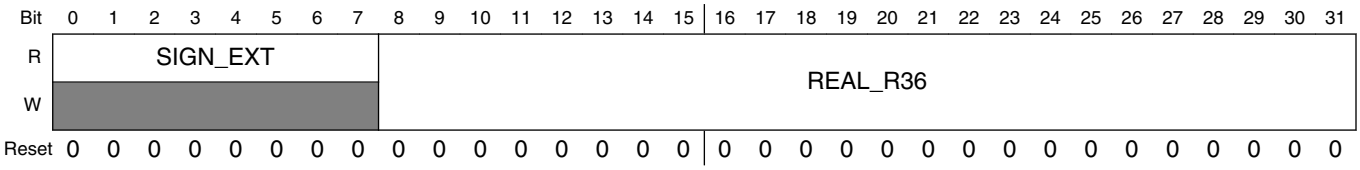


SPT_WR_R35_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R35	Imaginary part of Work Register R35

45.8.167 Work Register R36 Real (SPT_WR_R36_RE)

Address: 0h base + 370h offset = 370h

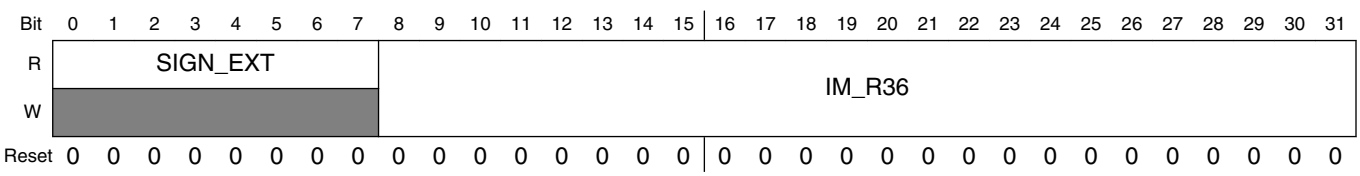


SPT_WR_R36_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R36	Real part of Work Register R36

45.8.168 Work Register R36 Imaginary (SPT_WR_R36_IM)

Address: 0h base + 374h offset = 374h

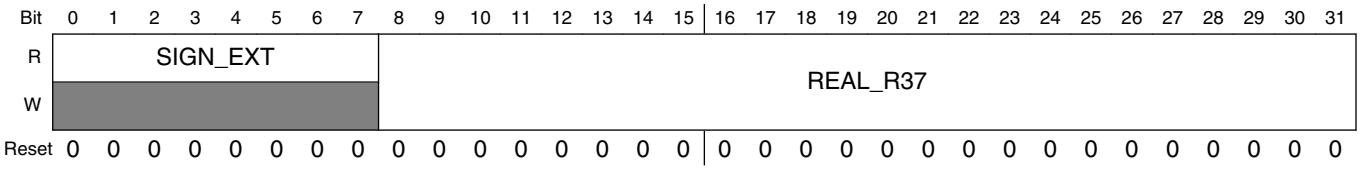


SPT_WR_R36_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R36	Imaginary part of Work Register R36

45.8.169 Work Register R37 Real (SPT_WR_R37_RE)

Address: 0h base + 378h offset = 378h

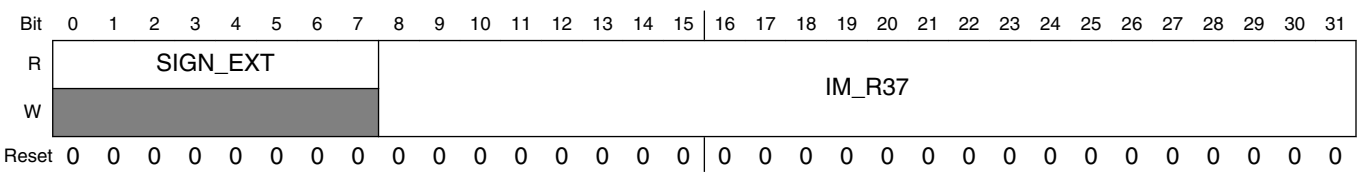


SPT_WR_R37_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R37	Real part of Work Register R37

45.8.170 Work Register R37 Imaginary (SPT_WR_R37_IM)

Address: 0h base + 37Ch offset = 37Ch

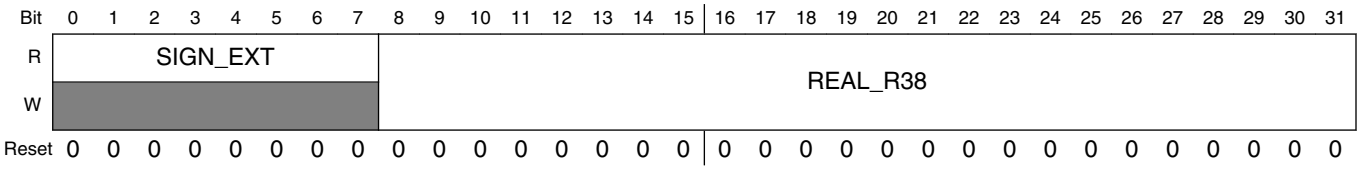


SPT_WR_R37_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R37	Imaginary part of Work Register R37

45.8.171 Work Register R38 Real (SPT_WR_R38_RE)

Address: 0h base + 380h offset = 380h

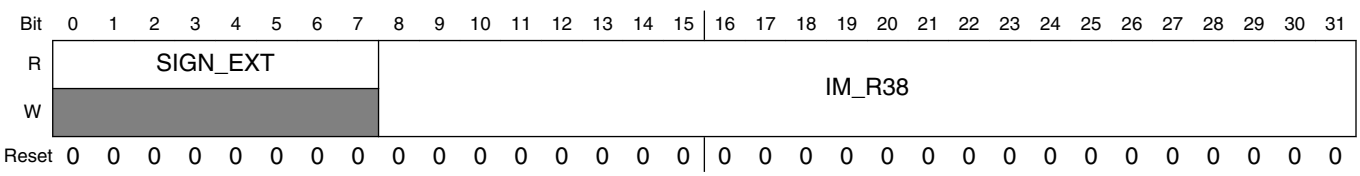


SPT_WR_R38_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R38	Real part of Work Register R38

45.8.172 Work Register R38 Imaginary (SPT_WR_R38_IM)

Address: 0h base + 384h offset = 384h

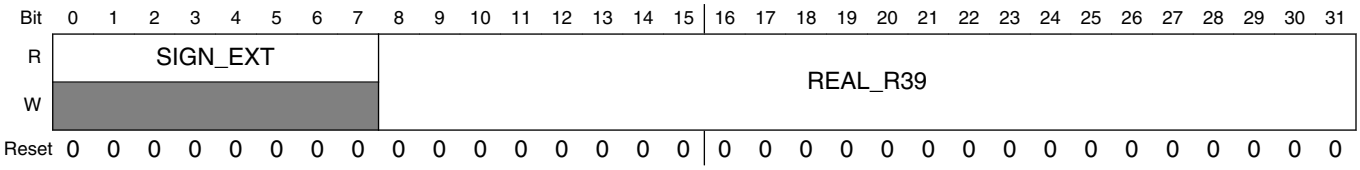


SPT_WR_R38_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R38	Imaginary part of Work Register R38

45.8.173 Work Register R39 Real (SPT_WR_R39_RE)

Address: 0h base + 388h offset = 388h

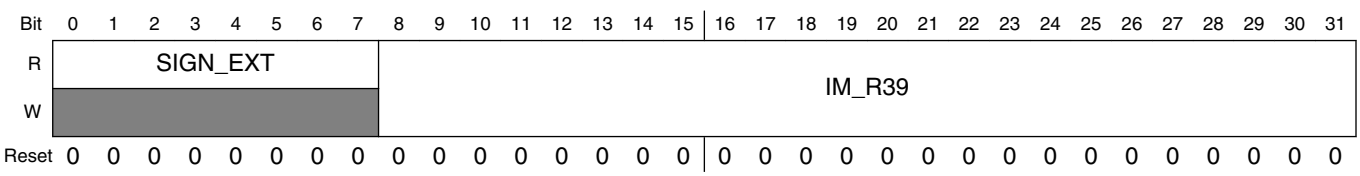


SPT_WR_R39_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R39	Real part of Work Register R39

45.8.174 Work Register R39 Imaginary (SPT_WR_R39_IM)

Address: 0h base + 38Ch offset = 38Ch

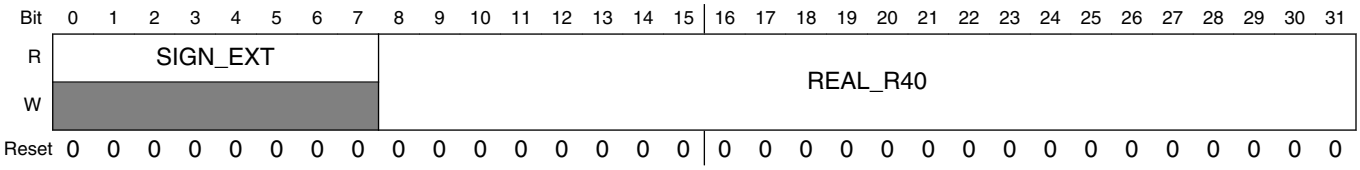


SPT_WR_R39_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R39	Imaginary part of Work Register R39

45.8.175 Work Register R40 Real (SPT_WR_R40_RE)

Address: 0h base + 390h offset = 390h

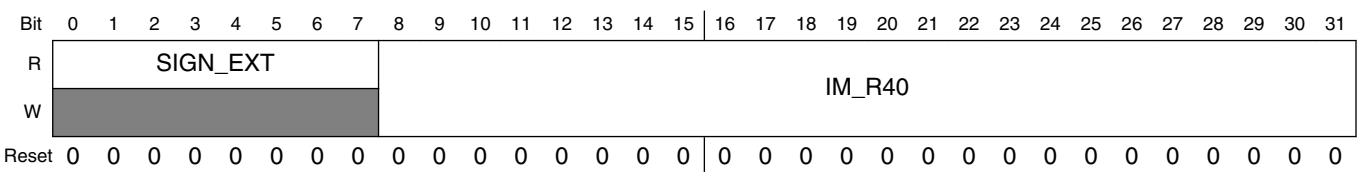


SPT_WR_R40_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R40	Real part of Work Register R40

45.8.176 Work Register R40 Imaginary (SPT_WR_R40_IM)

Address: 0h base + 394h offset = 394h

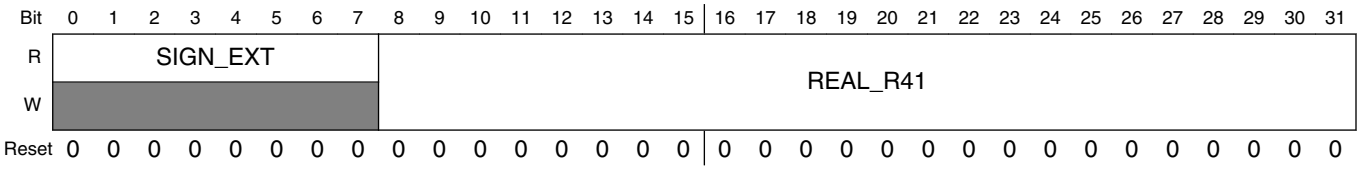


SPT_WR_R40_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R40	Imaginary part of Work Register R40

45.8.177 Work Register R41 Real (SPT_WR_R41_RE)

Address: 0h base + 398h offset = 398h

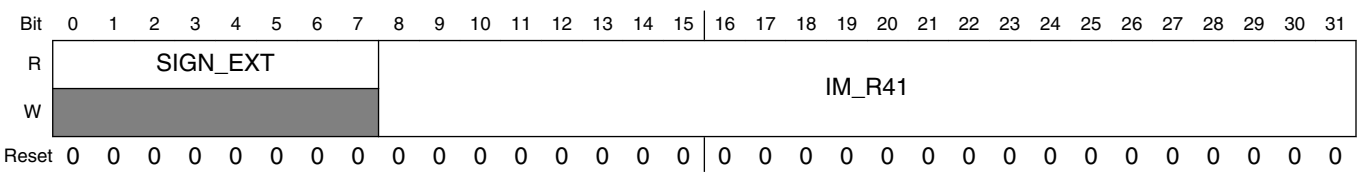


SPT_WR_R41_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R41	Real part of Work Register R41

45.8.178 Work Register R41 Imaginary (SPT_WR_R41_IM)

Address: 0h base + 39Ch offset = 39Ch

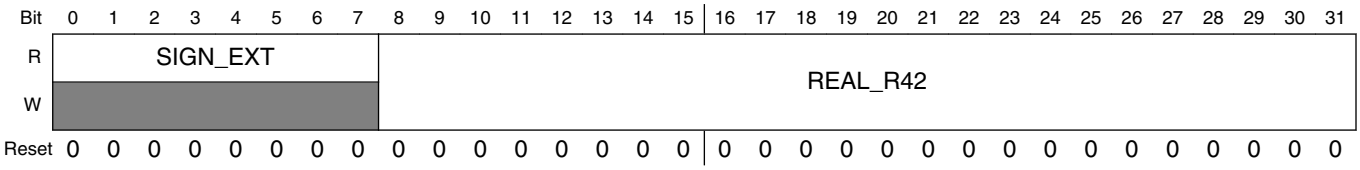


SPT_WR_R41_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R41	Imaginary part of Work Register R41

45.8.179 Work Register R42 Real (SPT_WR_R42_RE)

Address: 0h base + 3A0h offset = 3A0h

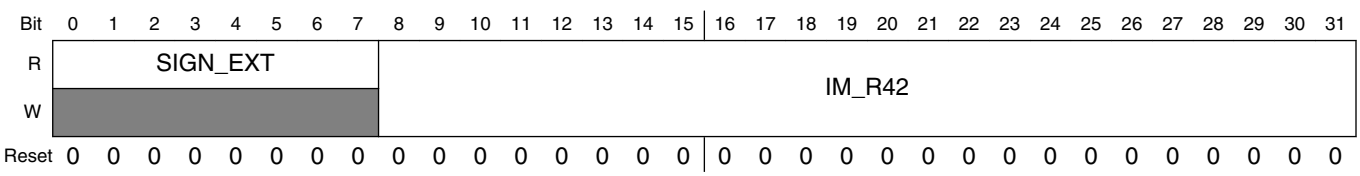


SPT_WR_R42_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R42	Real part of Work Register R42

45.8.180 Work Register R42 Imaginary (SPT_WR_R42_IM)

Address: 0h base + 3A4h offset = 3A4h

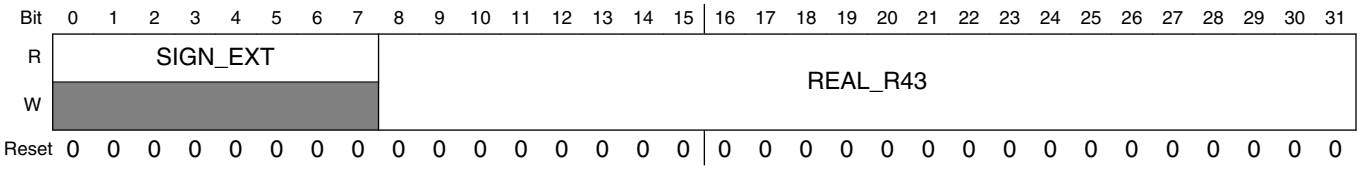


SPT_WR_R42_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R42	Imaginary part of Work Register R42

45.8.181 Work Register R43 Real (SPT_WR_R43_RE)

Address: 0h base + 3A8h offset = 3A8h

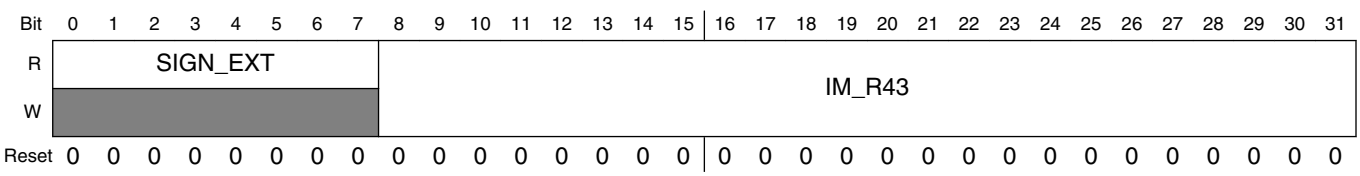


SPT_WR_R43_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R43	Real part of Work Register R43

45.8.182 Work Register R43 Imaginary (SPT_WR_R43_IM)

Address: 0h base + 3ACh offset = 3ACh

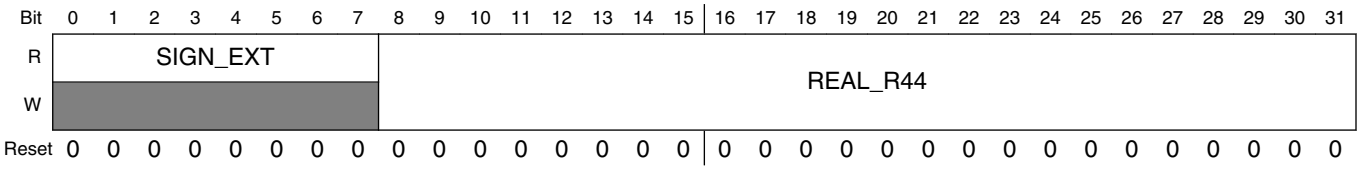


SPT_WR_R43_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R43	Imaginary part of Work Register R43

45.8.183 Work Register R44 Real (SPT_WR_R44_RE)

Address: 0h base + 3B0h offset = 3B0h

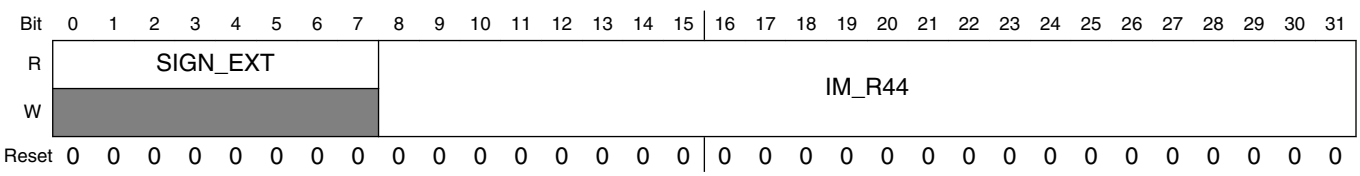


SPT_WR_R44_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R44	Real part of Work Register R44

45.8.184 Work Register R44 Imaginary (SPT_WR_R44_IM)

Address: 0h base + 3B4h offset = 3B4h

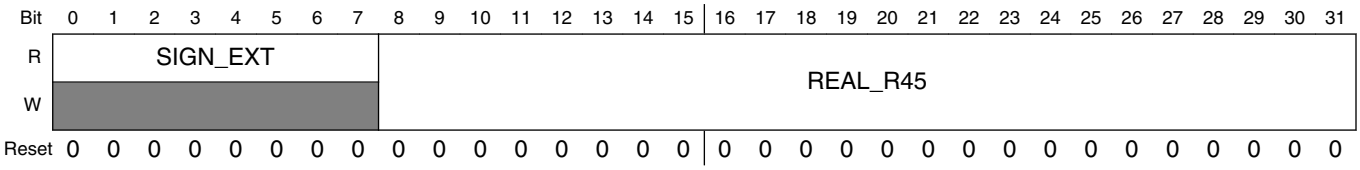


SPT_WR_R44_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R44	Imaginary part of Work Register R44

45.8.185 Work Register R45 Real (SPT_WR_R45_RE)

Address: 0h base + 3B8h offset = 3B8h

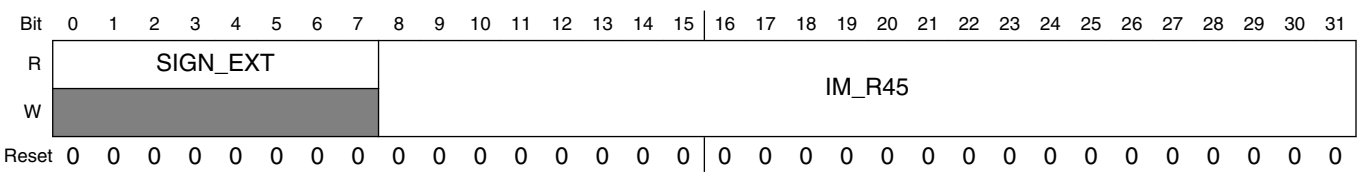


SPT_WR_R45_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R45	Real part of Work Register R45

45.8.186 Work Register R45 Imaginary (SPT_WR_R45_IM)

Address: 0h base + 3BCh offset = 3BCh

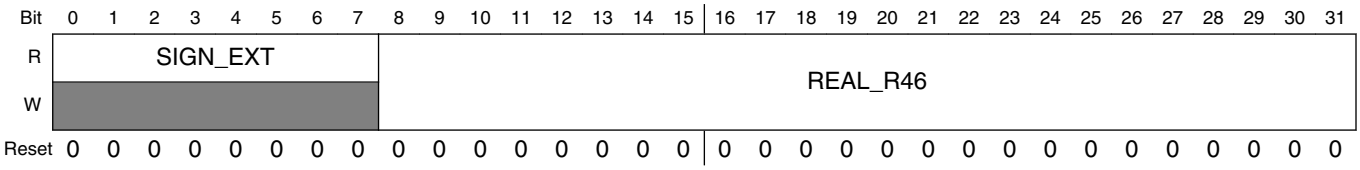


SPT_WR_R45_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R45	Imaginary part of Work Register R45

45.8.187 Work Register R46 Real (SPT_WR_R46_RE)

Address: 0h base + 3C0h offset = 3C0h

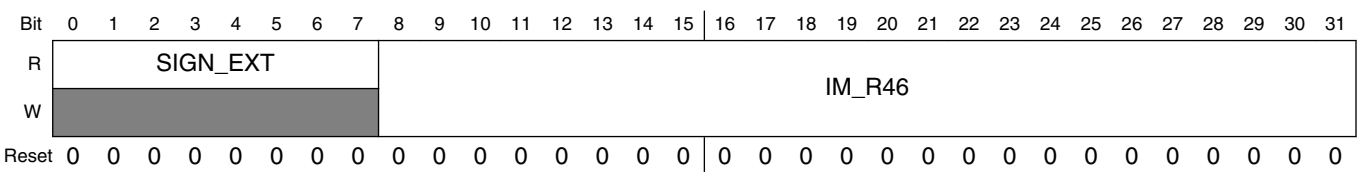


SPT_WR_R46_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R46	Real part of Work Register R46

45.8.188 Work Register R46 Imaginary (SPT_WR_R46_IM)

Address: 0h base + 3C4h offset = 3C4h

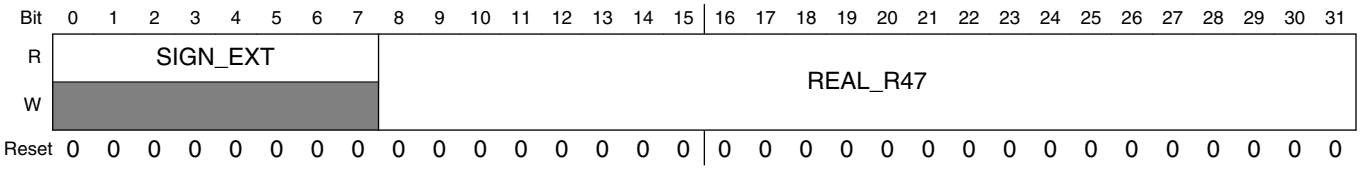


SPT_WR_R46_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R46	Imaginary part of Work Register R46

45.8.189 Work Register R47 Real (SPT_WR_R47_RE)

Address: 0h base + 3C8h offset = 3C8h

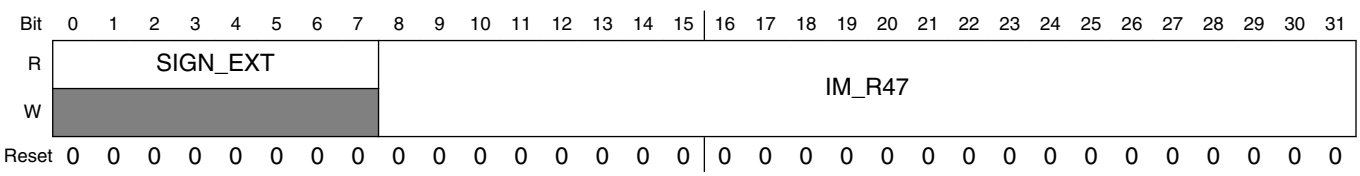


SPT_WR_R47_RE field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 REAL_R47	Real part of Work Register R47

45.8.190 Work Register R47 Imaginary (SPT_WR_R47_IM)

Address: 0h base + 3CCh offset = 3CCh



SPT_WR_R47_IM field descriptions

Field	Description
0–7 SIGN_EXT	Sign Extension This field is the Sign Extension of MSB of the work register data. Can't be written from IPS but 23rd bit which was written(from IPS or internally) will be read on these bits
8–31 IM_R47	Imaginary part of Work Register R47

45.9 Functional Description

45.9.1 Common instruction fields

The following sections define some commonly used instruction set fields. These definitions are common across all instructions using these bitfields.

45.9.1.1 Opcode

[OPCODE] - This 6-bit bitfield identifies the hardware accelerator the instruction is meant for. This bitfield occupies the same location in every instruction format. Table 45-5 lists the opcodes assigned to every hardware accelerator.

45.9.1.2 Source and Destination address

SRC_ADD/DEST_ADD - Source address [SRC_ADD] field in the instruction defines the location of the internal SPT memory resources where the input operands are to be read from. The SRC_ADD can point to Operand RAM, twiddle RAM or the work registers.

Destination address [DEST_ADD] field in the instruction defines the location of the internal SPT memory resources where the output operands are to be written to. The DEST_ADD field can point to Operand RAM, twiddle RAM or the work registers.

Refer to SPT internal memory map for details of addressing these internal memory resources.

45.9.1.3 Indirect Memory Addressing

Indirect Memory Addressing[IMA] bit provides the option of using indirect addressing for source and destination addresses. When enabled, bits 88 down to 83 of the instruction word (for instructions other than PDMA) point to a WORK REGISTER which in turn contains the source and destination addresses. Both the source and destination addresses are contained in a single WORK REGISTER - bits 39 to 24 for source address and bits 15 to 0 for destination address.

When the IMA bitfield is set, only the SRC_ADD bitfield is referred to, to get the work register address. The DEST_ADD bitfield is ignored.

In case of PDMA, Indirect Memory Addressing bit provides the option of using indirect addressing for System RAM and SPT/Operand RAM addresses. When enabled, the instruction fields[56:51] point to a WORK REGISTER which in turn contains the System RAM and SPT/Operand RAM addresses. Both the System RAM and SPT/Operand RAM addresses are contained in a single WORK REGISTER - LSBs for SPT/Operand address([23:0]) and MSBs([47:25]) for System RAM address offset.

SYS_MEM_ADR = SYS_MEM_BASE[command] + SYS_MEM_OFFS[WREG.IMAG]

45.9.1.4 Source and destination address increment

[SRC_ADD_INC]/[DEST_ADD_INC] - An option of incrementing the source and destination address is provided in most instructions. When the source address increment value is set to a value other than 0, the address for every next fetch of 8 operands is incremented by that value. Similarly, when the destination address increment value is set to a value, the address of every next write to the memory is incremented by that value.

Figure 45-4 shows how the address is incremented for subsequent fetches when the SRC_ADD_INC bitfield of the instruction is set to a value. With source or destination address increment as 0, address will not increase for subsequent fetch.

Note: The user must ensure that the source address, destination address, source address increment and destination address increment in a command word are such that the input operands are never overwritten by the output of the module.

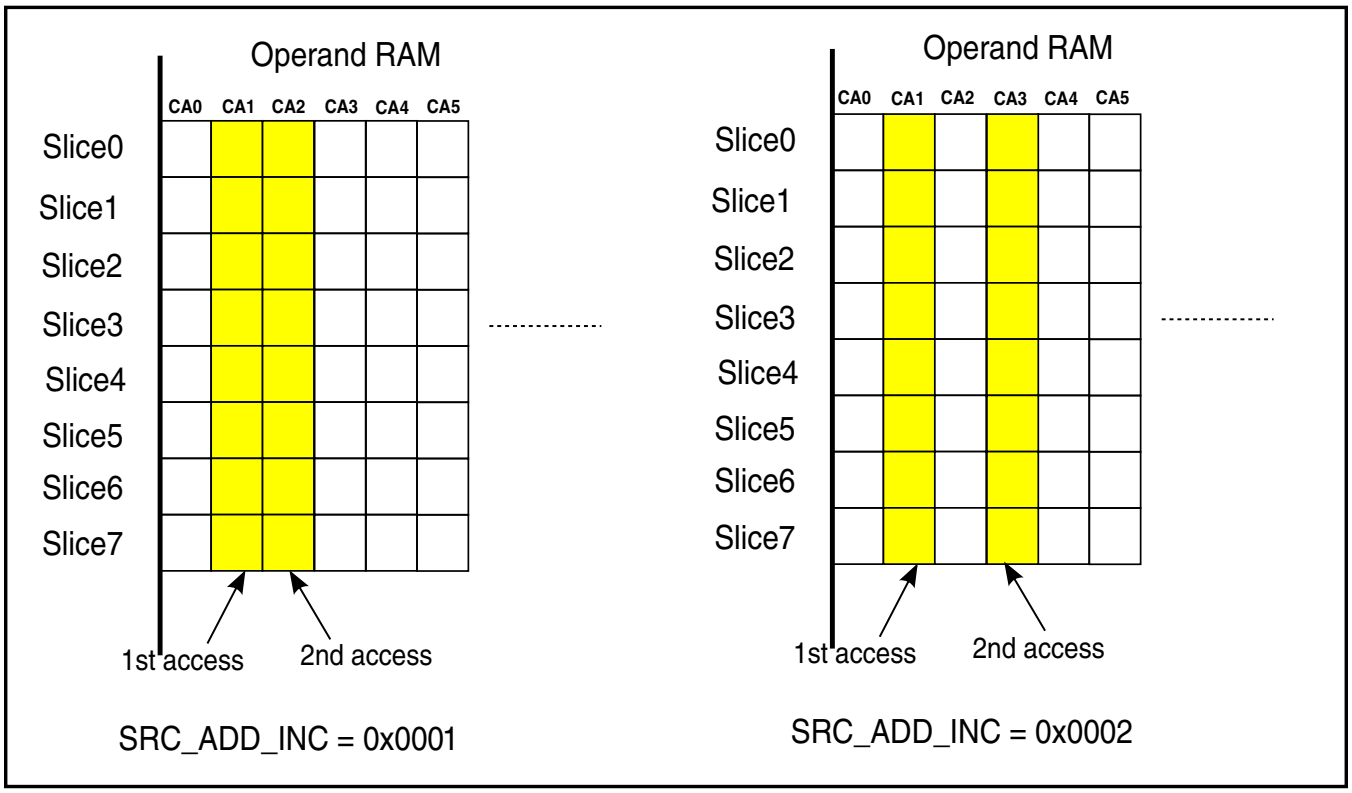


Figure 45-4. Address increment in operand RAM

45.9.1.5 Vector size

[VEC_SZ] - Vector size is defined as the number of operands on which an operation is to be performed. The size of each operand can either be one internal memory location (48bits/32bits) or half a location (24bits/16bits) in case of packed operands.

If the vector size is given as zero, then it is assumed to be 8192 operands. The definition of Vector Size is slightly different for PDMA. Refer PDMA instruction for more details.

45.9.1.6 Input Datatype/Preprocessing

The instruction bitfield IN_DATTYP is used to define the type of input data and instruction bitfield PREPROC is used to define the type of pre-processing required. The following table along with PREPROC describes the different pre-processing requirements with different types of input formats

Table 45-4. Input Datatype

Input Data	PreProcessing	Number of bits
Real	Absolute value = $\|x_k\|$	24
Complex	Sum of absolute of real and imaginary part and right shifted by 1 (| Re(x_k) | + | Im(x_k) |) >> 1	24
	Magnitude of complex operand. Refer Vector Magnitude for more details	
Log	No preprocessing	14

45.9.2 Command Sequencer

45.9.2.1 Introduction

The command sequencer reads and interprets a single instruction in the command queue. It triggers the operation specific scheduler depending on the command. A completed instruction is reported to the command queue for updating the instruction pointer. If program sequence is stalled by certain condition, the update of instruction pointer is suppressed and further program execution is suspended until this condition is cleared.

45.9.2.2 Description

The command sequencer starts operation by fetching instructions from the specified location in the system memory. The incoming instructions are stored in a command queue from where they are executed. The command queue has a size of 16 memory locations of 128-bit width. Data comes in from the CSDMA in 32 chunks of 64 bits each. It receives data from the DMA at the AHB clock frequency and gives out data to the command sequencer circuitry at the SPT clock frequency. The command sequencer does not have to wait for the command queue to be filled, it can begin execution even while the queue is being filled. An instruction start signal is given when an instruction is fired and a done signal is received when the command execution is over. Note that any illegal access to SRAM by SPT sequencer will generate PRAM crossbar fault in FCCU.

The sequencer supports early pre-fetch of instructions. If this feature is enabled, then, if the last 4 instructions in the command queue (i.e. instruction 13 to 16) are not NEXT and JUMP instructions then the sequencer requests the DMA to fetch new data at the start of the 13th instruction, else when the last instruction in the queue is issued the sequencer

also requests the DMA to refill its queue. If early pre-fetch feature is disabled then the default behavior is that when the last instruction in the queue is issued the sequencer also requests the DMA to refill its queue

Another situation where the sequencer requests a refill of the queue is when a NEXT or JUMP instruction is issued to an address outside the command queue.

It should be noted that the command sequencer queue does not have ECC protection. It also does not have parity or any other detection.

45.9.2.3 Processing states

The command sequencer finite state machine (FSM) operates in one of the following processing states:

RST: This is the state when the reset signal of the SPT is asserted.

START: When the reset is de-asserted the command sequencer enters the START state in the next clock cycle. It stays in this state until SPT_GBL_CTRL[PG_ST_CTRL] is asserted and no residual instruction fetch and no residual asynchronous PDMA instruction is in progress.

SETUP: When SPT_GBL_CTRL[PG_ST_CTRL] is asserted in the START state the sequencer moves to the SETUP state. Configuration error flags are reset to zero only in the SETUP state. Thereafter on receiving an acknowledge signal the command sequencer moves to the DEBUG state if the SPT_CS_MODE_CTRL[CS_SYS_DEBUG] is set and 'system debug' signal is asserted or if SPT_CS_MODE_CTRL[CS_IMM_DEBUG] is set, else it moves to the default RUN state.

DEBUG: This is the debug state of the SPT. There are four debugging modes in this state: halt mode, step once mode, step to next breakpoint mode and instruction jamming mode. In the halt mode the sequencer does not execute any instruction and remains halted. In the step once mode the command sequencer can step one instruction at a time; in the step to next breakpoint mode it keeps executing instructions till it reaches the next enabled breakpoint. The instruction jamming mode allows instruction execution directly through software without involving the command queue.

RUN: This is the run mode of the SPT and it is the default state of the sequencer. In this state the program in the command queue is executed till the STOP command is reached.

WAIT: The sequencer goes to the WAIT state when the WAIT command is executed, and then waits for the specified event to occur before it exits this state.

STOP: This state is reached when the STOP command is executed or when the SPT_CS_MODE_CTRL[STOP] is asserted. A 'softreset' signal is given out in this state which can be used by other modules to reset their circuitry. The sequencer remains in this state for one clock cycle and moves to the START state.

ASYNCSTOP: This state is reached when the SPT_CS_MODE_CTRL[ASYNCSTOP] signal is asserted or if an error is detected. The 'softreset' signal is also asserted in the ASYNCSTOP state. The sequencer remains in this state for one clock cycle and moves to the START state.

The command sequencer can make a state transition only on the completion of an instruction and never while an instruction is being executed, the only exception being the transition to the ASYNCSTOP state, which is in the next clock cycle. It should be noted that the SPT_CS_MODE_CTRL[STOP] or SPT_CS_MODE_CTRL[ASYNCSTOP] request has precedence over all else.

The present processing state can be assessed by SW by reading either the SPT_CS_STATUS0 configuration register or the SPT_CS_STATUS3 configuration register

Figure 45-5 shows the command sequencer FSM.

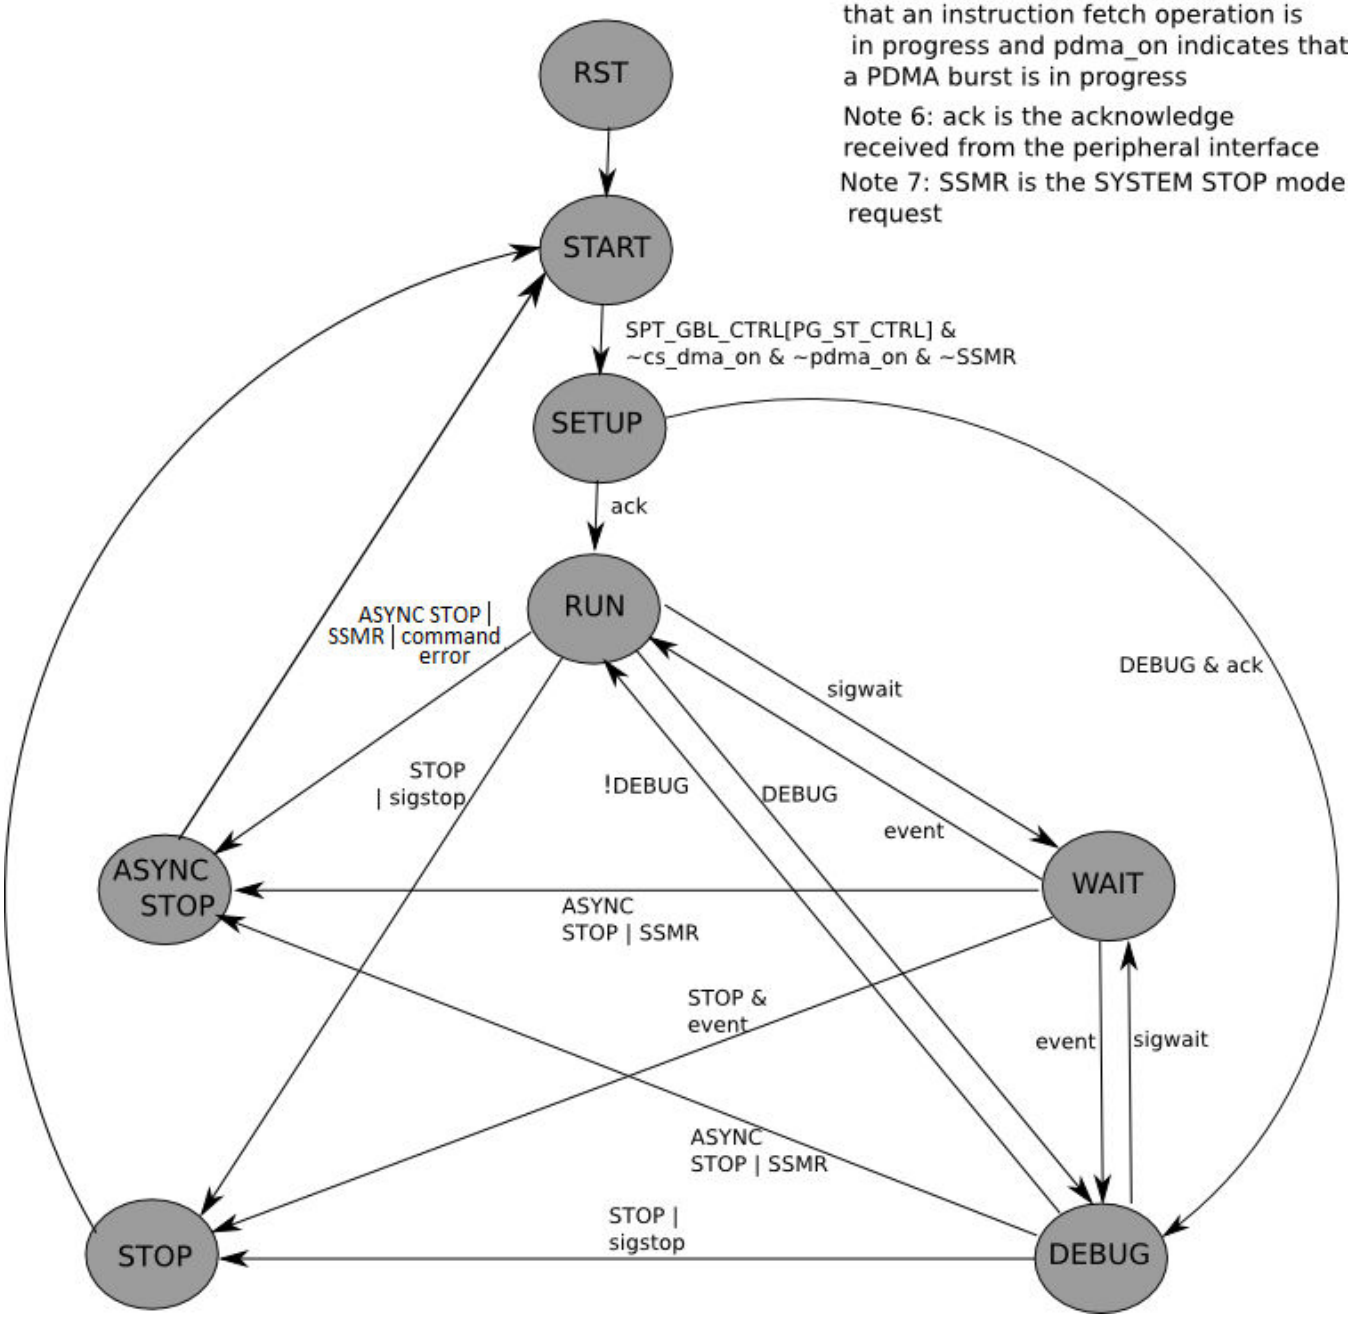

Figure 45-5. Command Sequencer FSM

45.9.2.4 Command Description

The command sequencer supports a variety of commands which are divided into two categories, operation commands and control commands.

Operation commands perform data processing operations on a given vector of data.

Control commands help to facilitate the program flow by defining loops, or checkpoints, or by performing basic data operations.

Table 45-5 provides a list of the SPT commands.

Table 45-5. List of SPT commands

Command	Opcode	Description	Details
Operation Commands			
WIN	100001	Performs a window round	Refer to FFT Instructions Format, Table 45-38, Table 45-36
RDX4	100010	Performs a Radix4 round	Refer to FFT Instructions Format, Table 45-40
RDX2	100011	Performs a Radix2 round	Refer to FFT Instructions Format, Table 45-42
HIST	100100	Performs a histogram operation	Refer to HIST instruction format
COPY	100101	Performs a copy operation	Refer to Copy Instruction Format
VMT	100110	Performs selected vector math	Refer to VMT Instruction Format
MAXS	100111	Performs maxima search operation	Refer to MAXS Instruction Format
PDMA	101000	Performs a DMA operation	Refer to PDMA instruction
FIR	101001	Performs a Finite Impulse Response (FIR) filter operation	Refer to FIR Filterand Table 45-44
SCP	101010	Scalar Product	Refer to Scalar Product
IRDX4	101011	Inverse Radix4	Refer to Inverse FFT
IRDX2	101100	Inverse Radix2	Refer to Inverse FFT
Control Commands			
SET	000001	Load target with value	Refer to SET Instruction Format
GET	000010	Copy value to work register	Refer to GET Instruction Format
ADD	000011	Add value to target	Refer to ADD Instruction Format
STOP	000100	Terminate sequence	Refer to STOP Instruction Format
LOOP	000101	Enters a loop, next commands are repeated	Refer to LOOP and NEXT Instruction Format , Table 45-13
NEXT	000110	Iterate loop	Refer to LOOP and NEXT Instruction Format , Table 45-15
SYNC	000111	Synchronize flow	Refer to SYNC Instruction Format
WAIT	001000	Suspends operation until event	Refer to WAIT Instruction Format
EVT	001001	Generates an event	Refer to EVT Instruction Format

Table continues on the next page...

Table 45-5. List of SPT commands (continued)

Command	Opcode	Description	Details
WATCHDOG	001010	Controls the watchdog timer	Refer to WATCHDOG Instruction Format
SUB	001011	Sub value from target	Refer to SUB Instruction Format
CMP	001100	Compare two values	Refer to CMP Instruction Format
JUMP	001101	Jump to forward or backward location	Refer to JUMP Instruction Format
SEL	001110	Select source to move to destination	Refer to SEL Instruction Format

The following sections provide a description of the control commands and their instruction formats.

45.9.2.4.1 SET Instruction Format

SET can be used to modify single entries in twiddle RAM, operand or work registers without involvement of the CPU. Only immediate values or work register values can be loaded. In case of the twiddle RAM being the destination the lower 16 bits from the real and imaginary part of the source operand are filled into the twiddle RAM.

If the IMA bit is set then the source address (if source is not immediate data) and destination address are taken from a work register. The SET command takes 2 cycles to execute if immediate data is the source and 3 cycles if a work register is the source. The SET command gives an error signal if the source is not immediate data or a work register, or if the source or destination is a work register with an index greater than 47. The SET command word format is shown in Table 45-6

Table 45-6. SET Instruction Format

Table 45-7. SET Instruction bit description

Bits	Bit Field	Description
[121]	SRC	This 1-bit field specifies whether the source of the data to be loaded is the immediate value or a work register.
		0 – immediate data
		1 – work register
[109]	IMA	Decides whether addressing is immediate (from the instruction itself) or indirect.
		0 - Immediate addressing
		1-Indirect addressing; the address comes from a work register for both, the source and the destination. This work register index is the 6 lower bits of the SRC_ADD field.
[95:80]	SRC_ADD	This 16-bit field gives the source of the data. It is used to give the source work register when the SRC field is set.
[79:64]	DEST_ADD	This 16-bit field gives the destination address. It can be the address of the operand RAM, twiddle RAM or work register.
[47:0]	IMM_DAT	This 48-bit field gives the immediate value to be loaded.

45.9.2.4.2 GET Instruction Format

GET command can be used to copy single entries from twiddle RAM or operand RAM to work registers for access by CPU. When the source is the twiddle RAM the 32-bit data from the twiddle RAM gets stored in the lower 16 bits of the real and imaginary parts of the work register, and the upper 8 bits are sign extended. The GET command takes 3 clock cycles for execution.

If the IMA bit is set then the source address and the destination address are taken from a work register.

The GET instruction gives an error signal if the source is any other than operand RAM or twiddle RAM, or if the destination is not a work register, or if the destination is a work register with an index greater than 47. The GET instruction command word format is shown in Table 45-8

Table 45-8. GET Instruction Format

Table 45-9. GET Instruction bit description

Bits	Bit Field	Description
[109]	IMA	Decides whether addressing is immediate (from the instruction itself) or indirect.
		0 - Immediate addressing
		1-Indirect addressing; the address comes from a work register for both, the source and the destination. This work register index is the 6 lower bits of the SRC_ADD field.
[95:80]	SRC_ADD	This is the address of the operand RAM or twiddle RAM.
[79:64]	DEST_ADD	This is the work register address.

Figure 45-6 shows the options for SET, GET and COPY commands

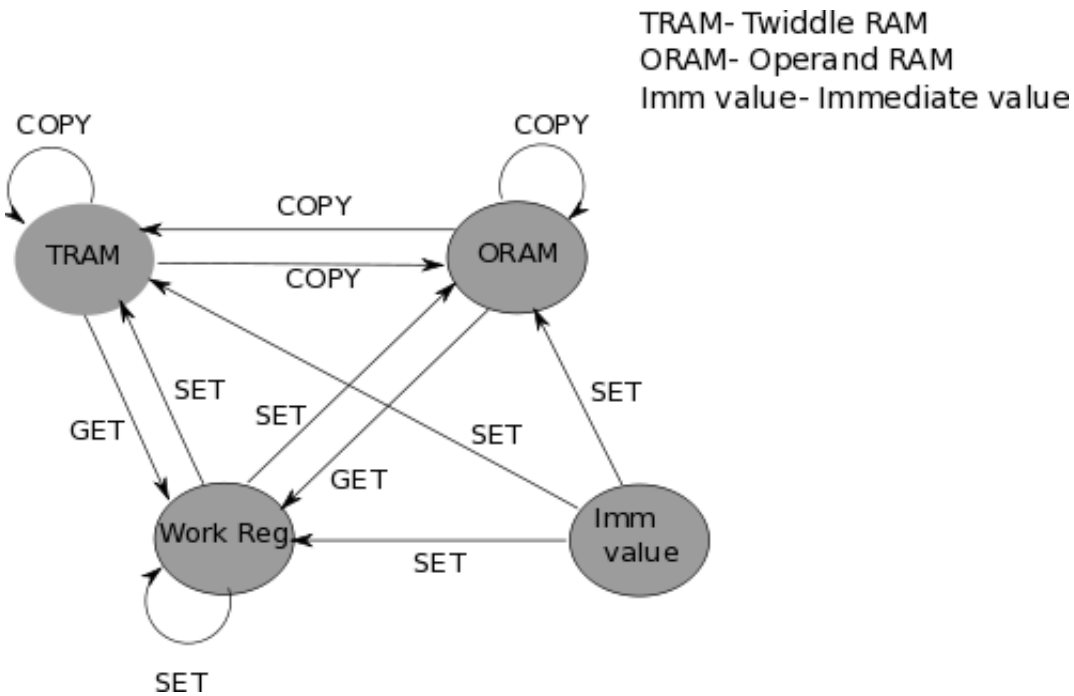

Figure 45-6. Options for SET, GET and COPY commands

45.9.2.4.3 ADD Instruction Format

ADD can be used to modify single entries in twiddle RAM, operand RAM or work registers without involvement of the CPU. Only immediate values or work register values can be added. In this operation the single entry from the operand RAM, twiddle RAM or a work register is read and the second value obtained from the immediate data or another work register is added to it and the sum(of the real as well as imaginary part) is stored back to an address in the twiddle RAM, operand RAM or a work register.

Therefore the ADD command can be summarized as

SRC1 + SRC2 -> DEST or

SRC1 + IMM_DAT -> DEST

where SRC1 and DEST can be twiddle RAM, operand RAM or a work register,

SRC2 can be a work register,

IMM_DAT is the immediate value field in the command word

The sum can be optionally shifted left by 1-bit. Also, a modulo 2^N (N = 0 to 24) operation is performed on the optionally shifted sum before it is written back to the memory.

When a 32-bit twiddle RAM entry is the source to be modified then only the lower 16 bits from the real and imaginary parts of the source are used and when the twiddle RAM is the destination only the lower 16 bits of the sums of real and imaginary parts are written back. The ADD command word format is shown in Table 45-10

The ADD instruction takes 5 cycles to complete.

An error condition is indicated if the SRC2 address is any other than of a work register.

Also error conditions are raised if for SRC1, SRC2 or DEST the address is of a work register with index greater than 47 (This takes into consideration only the 6 bits used to specify the work register index).

[95:80]	SRC1_ADD	This field gives the SRC1 address. It can be the address of the operand RAM, twiddle RAM or work register.
[79:64]	DEST_ADD	This field gives the destination address. It can be the address of the operand RAM, twiddle RAM or work register.
[63:48]	SRC2_ADD	If the SRC field is HIGH, then this field gives the address of the work register containing SRC2 operand.
[47:0]	IMM_DAT	This 48-bit field gives the immediate value to be added.

45.9.2.4.4 STOP Instruction Format

This is the final command of a sequence of instructions. On arrival of the STOP command the sequencer goes into STOP state, and no more instructions can be executed. If an asynchronous PDMA instruction is in progress when STOP command is fired then the sequencer waits for it to complete before entering the STOP state To restart the

instruction sequence, SPT_GBL_CTRL[PG_ST_CTRL] is set, the sequencer goes to the SETUP state, then to the RUN state (or the DEBUG state) and the command execution goes to the first instruction specified by SPT_CS_PG_ST_ADDR. The command word format for STOP instruction is shown in Table 45-12

Table 45-12. STOP Instruction Format

127	126	125	124	123	122	121	120	119	118	117	116	115	114	113	112

45.9.2.4.5 LOOP and NEXT Instruction Format

The LOOP command starts a loop and gives the number of iterations. There can be four levels of nested loops. If a fifth LOOP instruction is started then an error condition is indicated; an error condition also occurs if a LOOP command of zero iterations is fired. The NEXT command is used to mark the end of the loop; if a NEXT command is decoded and there is no loop in progress then also an error is raised. A new fetch is performed by the command sequencer only when the last instruction in the command queue is reached (or the 13th instruction in case of early pre-fetch) or during a NEXT instruction pointing to a location outside the span of the command queue. If the loop is contained within the command queue, then no new fetching of data into the queue is executed. LOOP and NEXT finish execution in 1 clock cycle. The command word format for LOOP instruction is shown in Table 45-13

45.9.2.4.6 SYNC Instruction Format

The SYNC command synchronizes the processing flow of the SPT. If independent operations were started asynchronous, e.g. a VMT and an asynchronous PDMA operation, the SYNC command enables the definition of a point in the instruction sequence where all previous scheduled commands must be finished, before the next instruction in the sequence is executed. The command word format for the SYNC instruction is shown in Table 45-16

Table 45-16. SYNC Instruction Format

127	126	125	124	123	122	121	120	119	118	117	116	115	114	113	112

45.9.2.4.7 WAIT Instruction Format

The WAIT command executes in one clock cycle and causes the sequencer to go to the WAIT state where it waits for the specified event. When the event occurs the sequencer comes back to the previous state (which could be RUN or DEBUG) and moves on to execute the subsequent commands.

Between two WAIT commands there should be a gap of >2 peripheral clock cycles. So, suppose SPT clock frequency=200 MHz and peripheral clock frequency=66.6 MHz, the ratio of SPT clock frequency to peripheral clock frequency=3. Thus the gap should be >3x2 SPT clock cycles.

There are 17 signals on which WAIT can occur. They are eight SW-generated events, six signals coming from CTE (or in case of MIPICSI2 these can be the hsync and vsync signals), chirp acquisition done, frame acquisition done and pdma transfer done. The SW-

generated events can be produced by writing to the SPT_CS_SW_EVTREG configuration register. The WAIT on these events can only be positive-edge or positive-level triggered. The WAIT on the CTE or MIPICSI2 signals can be both positive or negative, edge or level triggered.

In case of 'chirp acquisition done', 'frame acquisition done' and 'pdma transfer done' signals the WAIT can be positive edge triggered or positive level triggered. For a positive edge triggered WAIT command, the WAIT ends by directly corresponding to the awaited signal coming from the PDMA module(for pdma transfer done) or Acquisition module (for chirp acquisition done or frame acquisition done). However, if the WAIT is on a level triggered signal then the situation is a bit different.

To handle the positive level triggering case the chirp acquisition done, frame acquisition done and pdma transfer done signals they are also internally registered inside the WAIT module, and if WAIT for the event on any of these lines is on positive level triggering then it is this registered version of the event which is used to end the WAIT. But it should be noted that the internal registers are cleared when event on WAIT occurs either for positive level or even posedge event. These internal registers are also resettable through peripheral interface by writing a '1' to the SPT_EVENT_RST_CTRL configuration register. It is intended that the registered version of the event is used when there is probability of the event arriving before wait on that event starts, thereby ensuring that the event does not get missed.

Figure 45-7 shows the handling of pdma transfer done, frame acquisition done and chirp acquisition done.

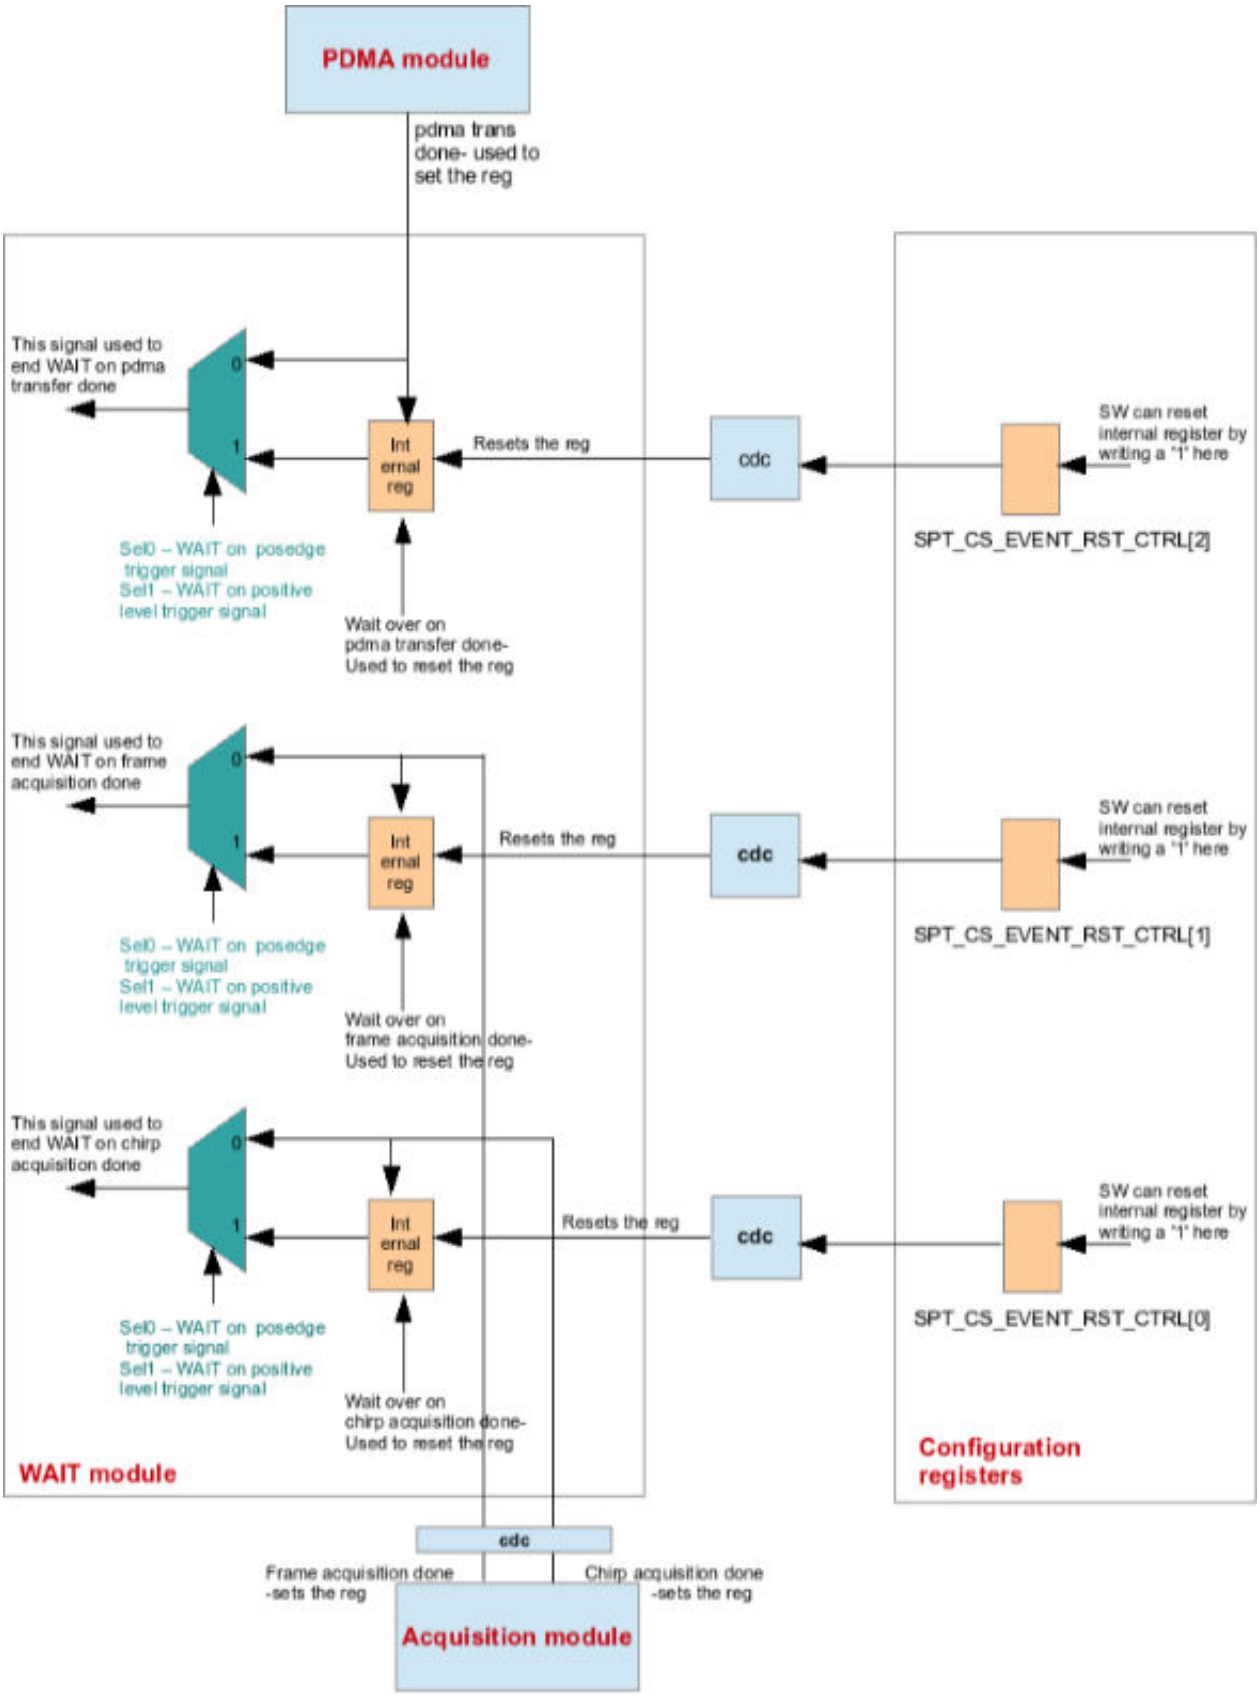

Figure 45-7. Handling of pdma transfer done, frame acquisition done and chirp acquisition done

The WAIT command word format is shown in Table 45-17

		11 – Negative edge triggered
[116:112]	EV	This field specifies the awaited event
		00000-00111- Waits for SW- generated event. There are eight lines on which SW can generate events. 00000- Event awaited on LSB line 00111- Event awaited on MSB line The WAIT on these SW events can only be positive edge triggered or positive level triggered.
		01000- Event awaited on cte_evt[0]
		01001- Event awaited on cte_evt[1]
		01010- Event awaited on cte_evt[2]
		01011- Event awaited on cte_evt[3]

Table continues on the next page...

Table 45-18. WAIT Instruction bit description: (continued)

		01100- Event awaited on cte_rcs or csi_hsync
		01101- Event awaited on cte_rfs or csi_vsync
		01110- Event awaited on 'chirp acquisition done' signal. The WAIT on this event can be only positive edge triggered or positive level triggered.
		01111- Event awaited on 'frame acquisition done' signal.The WAIT on this event can be only positive edge triggered or positive level triggered.
		10000 to 11111- Event awaited on 'pdma transfer done' signal.The WAIT on this event can be only positive edge triggered or positive level triggered.

NOTE

The signals cte_evt[x] are used to signal an event from the CTE to the SPT WAIT module. These signals are also called spt_evt[x].

45.9.2.4.8 EVT Instruction Format

This commands throws up the specified event. It executes in one clock cycle. There are eight lines on which events can be thrown up. An event is issued when a '1' is written on its line and is reset when a '0' is written on it. It should be noted an event fired in the SPT domain crosses to a configuration register on the peripheral interface which is a slower domain. This enforces the constraint that there should be a gap of 12 SPT clock cycles between two events fired on the same line.

When an event is set or reset, the value is also written on the SPT_CS_EVTREG1 and SPT_CS_EVTREG2 configuration registers (these are identical configuration registers meant for two different CPU cores). So SW can read these registers to find out which of eight lines has thrown up an event. SW can also reset these registers by writing a '1' on them

The EVT command word format is shown in Table 45-19

Table 45-19. EVT Instruction Format

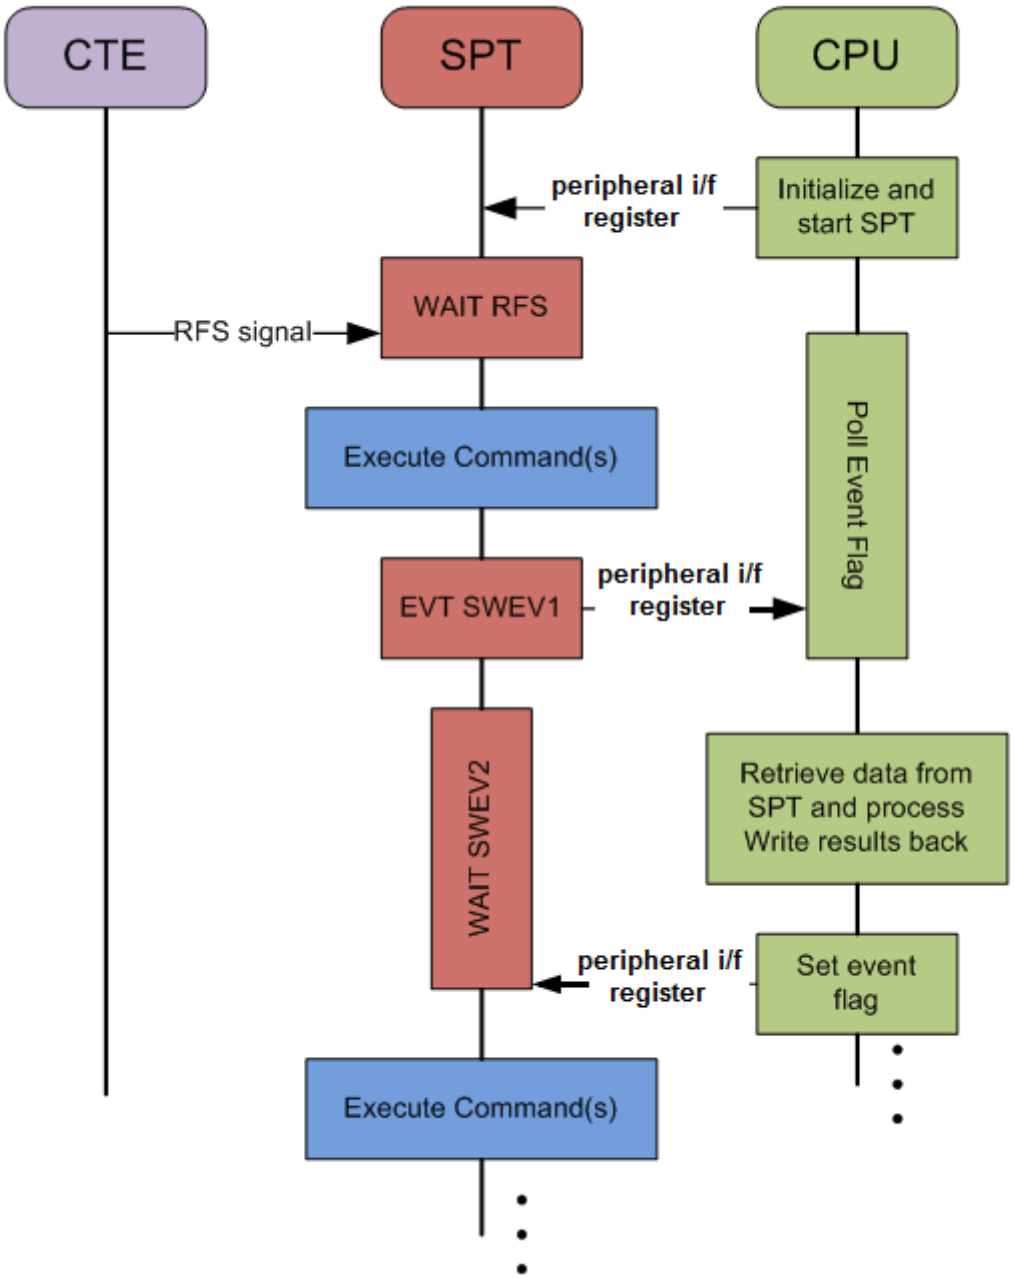

Figure 45-8. CPU-SPT synchronization using WAIT and EVT commands.

45.9.2.4.9 WATCHDOG Instruction Format

The watchdog requires 24 bits. It can be loaded and started to count down, or it can be halted (stopped) or it can be reset with the WATCHDOG command. This is the count mode, and in this mode when the counter counts down to zero an interrupt can be generated and a bit in the SPT_CS_STATUS0 configuration register is set.

The watchdog counter value is reflected in the configuration map in the SPT_CS_WD_COUNT register, to be read by SW. Due to this clock domain crossing from the SPT domain to the slower configuration map domain it is required that the programmed initial value for the watchdog timer be 32 or greater.

Additionally, the watchdog can work in the event mode where it can be loaded with a value and used as a flag. In this case a CTE event (or in case of MIPICSI2 the vsync and hsync events) is specified and when the event arrives the watchdog is reset to zero. SW can enquire about the awaited event by reading the SPT_CS_STATUS2 configuration register.

NOTE

When the watchdog circuit is waiting for an event, it is not recommended to fire another 'event mode' watchdog command until the wait for the first event is over.

The WATCHDOG instruction executes in 1 clock cycle. It should be noted that the watchdog timer is immediately reset upon getting the 'soft reset' signal from the command sequencer. The command word format for WATCHDOG instruction is shown in Table 45-21

[121:120]	EV_TR	This 2-bit field gives the type of event triggering.
		00 - Level 0 triggered
		01 - Level 1 triggered
		10 - Positive edge triggered
		11 - Negative edge triggered
[117:116]	OP	Decides the watchdog operation and mode
		00- Watchdog counter is loaded with the initialization value, and the counter starts counting down. This is the count mode
		01- Stops the counter in the count mode
		10- Resets the counter in the count mode
		11- The watchdog counter is enabled to be used as a flag. The counter resets when the specified event occurs. This is the event mode
[114:112]	EV	This field specifies the event which resets the timer
		000- cte_evt[0]
		001- cte_evt[1]
		010- cte_evt[2]
		011- cte_evt[3]
		100- cte_rcs or csi_hsync
		101 to 111- cte_rfs or csi_vsync
[23:0]	CNT_IN_VAL	This 24-bit field gives the value to which the counter is initialized.

45.9.2.4.10 SUB Instruction Format

SUB can be used to modify single entries in twiddle RAM, operand RAM or work registers without involvement of the CPU. Only immediate values or work register values can be subtracted. In this operation the single entry from the operand RAM, twiddle RAM or a work register is read and the second value obtained from the immediate data or another work register is subtracted from it and the difference (of the real as well as imaginary part) is stored back to an address in the twiddle RAM, operand RAM or a work register.

Therefore the SUB command can be summarized as

SRC1 - SRC2 -> DEST or

SRC1 - IMM_DAT -> DEST

where SRC1 and DEST can be twiddle RAM, operand RAM or a work register,

SRC2 can be a work register,

IMM_DAT is the immediate value field in the command word

The difference can be optionally shifted left by 1-bit. Also, a modulo 2^N (N = 0 to 24) operation is performed on the optionally shifted difference before it is written back to the memory.

When a 32-bit twiddle RAM entry is the source to be modified then only the lower 16 bits from the real and imaginary parts of the source are used and when the twiddle RAM is the destination only the lower 16 bits of the differences of real and imaginary parts are written back. The SUB command word format is shown in Table 45-23

The SUB instruction takes 5 cycles to complete.

An error condition is indicated if the SRC2 address is any other than of a work register.

Also error conditions are raised if for SRC1, SRC2 or DEST the address is of a work register with index greater than 47 (This takes into consideration only the 6 bits used to specify the work register index).

Table 45-23. SUB Instruction Format

		10111 - modulo 2^23
		11000 to 11111 - modulo 2^24
[95:80]	SRC1_ADD	This field gives the SRC1 address. It can be the address of the operand RAM, twiddle RAM or work register.
[79:64]	DEST_ADD	This field gives the destination address. It can be the address of the operand RAM, twiddle RAM or work register.
[63:48]	SRC2_ADD	If the SRC field is HIGH, then this field gives the address of the work register containing SRC2 operand.

Table continues on the next page...

Table 45-24. SUB Instruction bit description (continued)

[47:0]	IMM_DAT	This 48-bit field gives the immediate value to be subtracted.

45.9.2.4.11 CMP Instruction Format

CMP can be used to enhance the decision making ability of SPT without involvement of the CPU. In this operation the first value is the single entry read from the operand RAM, twiddle RAM or a work register and the second value is obtained from the immediate data or another work register. This second value is subtracted from it and the result is stored back to the destination address in the twiddle RAM, operand RAM or a work register.

This result consists of status bits which indicate whether the first value is i) greater than, ii) greater than or equal to, iii) less than, iv) less than or equal to, v) or equal to the second value. This result is stored for real as well as imaginary part. It is intended that the CMP instruction will be used together with the SEL or JUMP instruction, where the result produced by CMP will be utilized by SEL or JUMP instruction.

Therefore the CMP command can be summarized as

SRC1 - SRC2 -> DEST or

SRC1 - IMM_DAT -> DEST

where SRC1 and DEST can be twiddle RAM, operand RAM or a work register,

SRC2 can be a work register,

IMM_DAT is the immediate value field in the command word

It should be noted that both the comparisons are considered to be a signed comparison.

The resulting status flags are stored in the destination in the following format:

Table 45-25. Format of result stored in the destination

Bit position in destination	Description of corresponding status bit
0	Real part of SRC1 == Real part of SRC2
1	Real part of SRC1 <= Real part of SRC2
2	Real part of SRC1 < Real part of SRC2
3	Real part of SRC1 >= Real part of SRC2
4	Real part of SRC1 > Real part of SRC2
5	Imaginary part of SRC1 == Imaginary part of SRC2
6	Imaginary part of SRC1 <= Imaginary part of SRC2

Table continues on the next page...

Table 45-25. Format of result stored in the destination (continued)

7	Imaginary part of SRC1 < Imaginary part of SRC2
8	Imaginary part of SRC1 >= Imaginary part of SRC2
9	Imaginary part of SRC1 > Imaginary part of SRC2
Others	0

When a 32-bit twiddle RAM entry is the source then only the lower 16 bits from the real and imaginary parts of the source are used for comparison. The CMP command word format is shown in Table 45-26

The CMP instruction takes 5 cycles to complete.

An error condition is indicated if the SRC2 address is any other than of a work register and the SRC field is HIGH.

Also error conditions are raised if for SRC1, SRC2 or DEST the address is of a work register with index greater than 47 (This takes into consideration only the 6 bits used to specify the work register index).

Table 45-27. CMP Instruction bit description (continued)

		0 – immediate data
		1 – work register
[95:80]	SRC1_ADD	This field gives the SRC1 address. It can be the address of the operand RAM, twiddle RAM or work register.
[79:64]	DEST_ADD	This field gives the destination address. It can be the address of the operand RAM, twiddle RAM or work register.
[63:48]	SRC2_ADD	If the SRC field is HIGH, then this field gives the address of the work register containing SRC2 operand.
[47:0]	IMM_DAT	This 48-bit field gives the immediate value to be added.

45.9.2.4.12 JUMP Instruction Format

The JUMP command can be used for branching or to form looping structures in the code. Unconditional (forced) as well as conditional jump operations are supported. In a conditional JUMP the specified bit of the specified WR is read and if the bit is SET then a jump operation is performed to the jump address, else the program moves to the next command.

It is the responsibility of the user to ensure that the instruction format is correct. It is also the responsibility of the user to ensure that the destination provided for the JUMP command does not violate the program structure e.g. infinite loops, or JUMP to a location outside the program, or JUMP into or outside of a loop.

This instruction is intended to be used in conjunction with the CMP command. The result of the CMP command can be stored in a WR, and the JUMP instruction reads this value stored in the specified WR .

The status flags from the previous CMP instruction are checked by JUMP command according to the following format:

Table 45-28. Format of status flags checked by JUMP instruction

Bit position in WR	Description of corresponding status bit
0	Real part of previous CMP instruction shows that result of the instruction is 'equal to'.
1	Real part of previous CMP instruction shows that result of the instruction is 'less than or equal to'.
2	Real part of previous CMP instruction shows that result of the instruction is 'less than'.
3	Real part of previous CMP instruction shows that result of the instruction is 'greater than or equal to'.

Table continues on the next page...

Table 45-30. JUMP Instruction bit description

Bits	Bit Field	Description
[121]	COND_TYPE	Decides whether the jump operation is a conditional or unconditional jump
		0 – Unconditional jump

Table continues on the next page...

Table 45-30. JUMP Instruction bit description (continued)

		1 – Conditional jump
[120:117]	COND_SEL	This bit specifies the WR bit to be read
		0- Bit 0 is to be read
		1- Bit 1 is to be read
		2- Bit 2 is to be read
		3- Bit 3 is to be read
		4- Bit 4 is to be read
		5- Bit 5 is to be read
		6- Bit 6 is to be read
		7- Bit 7 is to be read
		8- Bit 8 is to be read
		9 to 15- Bit 9 is to be read
[88:83]	SEL_WR	This field selects the WR number to be read. The value of this field can be from 0 to 47.
[63:32]	JUMP_ADDR	This is the jump offset location. It is a 32-bit relative memory location, relative to the memory location at which the JUMP command is stored. This offset is stored in a 2's complement format.

45.9.2.4.13 SEL Instruction Format

The SEL command can read one of the three specified source addresses and store it in the destination. Which of the three sources is to be read is dependent on the result of the previous CMP instruction, and hence this instruction is intended to be used in conjunction with the CMP command. The result of the CMP command can be stored in a WR, and the SEL instruction reads this value stored in the specified WR (either the real part or the imaginary part). If the result stored in the WR specifies that the previous result was 'greater than' then SRC3 is read, if the previous result was 'equal to' then SRC2 is read, else SRC1 is read and then written to the destination address.

Therefore the SEL command can be summarized as

if comparison result == 'greater than' then SRC3 -> DEST

else if comparison result == 'equal to' SRC2 -> DEST

else SRC1 -> DEST

where SRC1, SRC2, SRC3 and DEST can be twiddle RAM, operand RAM or a work register,

The status flags from the previous CMP instruction are checked by SEL command according to the following format:

Table 45-31. Format of status flags checked by SEL instruction

Bit position in WR	Description of corresponding status bit
0	Real part of previous CMP instruction shows that result of the CMP instruction is 'equal to'. Hence SRC2 is transferred to destination.
2	Real part of previous CMP instruction shows that result of the instruction is 'less than'. Hence SRC1 is transferred to destination.
4	Real part of previous CMP instruction shows that result of the instruction is 'greater than'. Hence SRC3 is transferred to destination.
5	Imaginary part of previous CMP instruction shows that result of the instruction is 'equal to'. Hence SRC2 is transferred to destination.
7	Imaginary part of previous CMP instruction shows that result of the instruction is 'less than'. Hence SRC1 is transferred to destination.
9	Imaginary part of previous CMP instruction shows that result of the instruction is 'greater than'. Hence SRC3 is transferred to destination.
Others	Not used by SEL command

When a 32-bit twiddle RAM entry is the selected source to be transferred to destination then only the lower 16 bits from the real and imaginary parts of the source are used and when the twiddle RAM is the destination only the lower 16 bits of the differences of real and imaginary parts are written back. The SEL command word format is shown in Table 45-32

The SEL instruction takes 5 cycles to complete.

An error conditions are raised if for SRC1, SRC2, SRC3 or DEST the address is of a work register with index greater than 47 (This takes into consideration only the 6 bits used to specify the work register index).

An error is also specified if the SEL_WR field which selects the WR to be read is greater than 47.

Table 45-33. SEL Instruction bit description

Bits	Bit Field	Description
[121]	RE_IM_B	Decides whether the real or imaginary part is selected for deciding the source to be transferred to destination
		0 – Imaginary part is to be used for selection
		1 – Real part is to be used for selection
[88:83]	SEL_WR	This field gives the index of the WR to be read
[79:64]	DEST_ADD	This field gives the destination address. It can be the address of the operand RAM, twiddle RAM or work register. In case the destination is a WR then bits 72 down to 67 specify the index of WR.
[63:48]	SRC2_ADD	This field gives the SRC2 address. It can be the address of the operand RAM, twiddle RAM or work register. In case SRC2 is a WR then bits 56 down to 51 specify the index of WR.
[47:32]	SRC3_ADD	This field gives the SRC3 address. It can be the address of the operand RAM, twiddle RAM or work register. In case SRC3 is a WR then bits 40 down to 35 specify the index of WR.
[31:16]	SRC1_ADD	This field gives the SRC1 address. It can be the address of the operand RAM, twiddle RAM or work register. In case SRC1 is a WR then bits 24 down to 19 specify the index of WR.

45.9.2.5 Command Sequencer and PDMA instruction

The command sequencer executes the commands in a sequential manner i.e. only after the present command is executed is the subsequent command fired. The exception here is the PDMA command. There are two types of PDMA commands, synchronous PDMA command and asynchronous PDMA command. A synchronous PDMA command, like any other instruction, is strictly sequential. However the asynchronous PDMA instruction may be executed concurrently along with any other instruction.

Case 1: An instruction (other than PDMA) is being executed and the subsequent instruction is an asynchronous PDMA instruction. In this situation the instruction will finish execution before the PDMA instruction is started.

Case 2: An asynchronous PDMA instruction is being executed and the subsequent instruction is any instruction other than PDMA. Here, the command sequencer does not wait for the PDMA instruction to complete and fires the following instruction.

Case 3: An asynchronous PDMA instruction followed by another PDMA instruction. In this case the first asynchronous PDMA instruction will finish execution before the second PDMA instruction is executed.

45.9.2.6 Error Handling

Errors are divided into two categories, command errors and non-command errors. The command errors are those which are caused by wrong command word options or even wrong order of instructions (like a NEXT instruction being decoded before a loop has begun). All the other error conditions (like parity error, etc.), exceptions or overflows are grouped under non-command errors.

Whenever a command error occurs the command sequencer goes to the ASYNCSTOP state and an error bit is set in the configuration map. From there it goes to the START state. To restart the execution of the program the CPU then has to assert the SPT_GBL_CTRL[PG_ST_CTRL]. On such a restart the sequencer goes to the SETUP state and the error bit is reset. Whenever a non-command error occurs, the sequencer does not go to the ASYNCSTOP state but just sets a bit in the configuration map and the command sequencer moves on.

Another important register is the interrupt enable register. When a bit of this register is set, it means that the error bit corresponding to it causes an interrupt; if the interrupt enable register bit is reset then there is no interrupt to the CPU. In such a condition the CPU would have to poll the error bits periodically to catch an error.

In case of a command error SPT_CS_ERR_INST_ADDR is filled with the address of the instruction causing the error and the corresponding error configuration bit is raised. All error bits are reset in the SETUP state. All error bits are resettable by SW.

The CPU can stop the program (in the RUN or DEBUG state) flow by setting SPT_CS_MODE_CTRL[STOP]. Here the sequencer goes to the STOP state after the current instruction has finished executing. The CPU can also cause an asynchronous STOP by setting the SPT_CS_MODE_CTRL[ASYNCSTOP] and the sequencer goes to the ASYNCSTOP state; this is an asynchronous soft reset and so does not wait for the current instruction to complete.

The command errors correspond to the following configuration register bits:

- SPT_CS_STATUS1[ILL_OPCODE]
- SPT_CS_STATUS1[ILL_LOOP]
- SPT_CS_STATUS1[ILL_0CNTLOOP]
- SPT_CS_STATUS1[ILL_NEXT]
- SPT_CS_STATUS1[ILL_SET]
- SPT_CS_STATUS1[ILL_GET]
- SPT_CS_STATUS1[ILL_ADD]
- SPT_CS_STATUS1[JAM_ILL_OPCODE]
- SPT_CS_STATUS1[JAM_ILL_SYNC]
- SPT_CS_STATUS1[JAM_ILL_LOOP]
- SPT_CS_STATUS1[JAM_ILL_NEXT]
- SPT_CS_STATUS1[JAM_ILL_JUMP]
- SPT_DMA_ERR_STATUS[ILLEGAL_COMMAND_ERR] (this error will also show up as SPT_CS_STATUS1[ILL_OPCODE])
- SPT_DMA_ERR_STATUS[DMA_COMMAND_ERR]
- SPT_HW_ACC_ERR_STATUS[VMT_TWI_DVS_ERR]
- SPT_HW_ACC_ERR_STATUS[VMT_SS_CB_ERR]
- SPT_HW_ACC_ERR_STATUS[VMT_CON_RL_ERR]
- SPT_HW_ACC_ERR_STATUS[HIST_INVALID_WR_ACCESS_ERR]
- SPT_HW_ACC_ERR_STATUS[HIST_VECLEN_NOT_MULTOF8_ERR]
- SPT_HW_ACC_ERR_STATUS[HIST_SRC_NOT_OR_ERR]
- SPT_HW_ACC_ERR_STATUS[HIST_SRCADDR_NOT_MULTOF8_ERR]
- SPT_HW_ACC_ERR_STATUS[HIST_DESTADDR_NOT_MULTOF8_ERR]
- SPT_HW_ACC_ERR_STATUS[COPY_IP_CMD_ERR]
- SPT_HW_ACC_ERR_STATUS[MAXS_IP_CMD_ERR]
- SPT_HW_ACC_ERR_STATUS[FFT_ILL_SHFTVAL]
- SPT_HW_ACC_ERR_STATUS[FFT_WIN_RND_ERR]
- SPT_HW_ACC_ERR_STATUS[FFT_RDX4_RND_ERR]
- SPT_HW_ACC_ERR_STATUS[FFT_QE_VL_OVS_ERR]
- SPT_HW_ACC_ERR_STATUS[FFT_TW_OVS_ERR]

- SPT_HW_ACC_ERR_STATUS[FFT_MULT_COEFF_ERR]
- SPT_HW_ACC_ERR_STATUS[FFT_MULT_COEFF2_ERR]
- SPT_HW_ACC_ERR_STATUS[FFT_OPR_ADDR_ERR]
- SPT_HW_ACC_ERR_STATUS[FFT_RDX2_RND_ERR]

The non-command errors (and exceptions and overflows) correspond to the following register bits:

- SPT_MEM_ERR_STATUS[WR_LCK_VIOL]
- SPT_MEM_ERR_STATUS[TR_PAR_ERR]
- SPT_MEM_ERR_STATUS[WR_OR_3_ACC_CONTN]
- SPT_MEM_ERR_STATUS[WR_OR_2_ACC_CONTN]
- SPT_MEM_ERR_STATUS[OR_DMA_PAR_ERR]
- SPT_MEM_ERR_STATUS[OR_MOD_PAR_ERR]
- SPT_DMA_ERR_STATUS[SDMA_WR_ERR]
- SPT_DMA_ERR_STATUS[SDMA_RD_ERR]
- SPT_DMA_ERR_STATUS[PDMA_AHB_ERR]
- SPT_DMA_ERR_STATUS[SDMA_AHB_ERR]
- SPT_DMA_ERR_STATUS[CS_AHB_ERR]
- SPT_DMA_ERR_STATUS[SDMA_RD_ERR_BYP]
- SPT_DMA_ERR_STATUS[SDMA_WR_ERR_BYP]
- SPT_DMA_ERR_STATUS[LINE_LEN_EXCD_ERR]
- SPT_DMA_ERR_STATUS[LINE_LEN_EXCD_BYP_ERR]
- SPT_DMA_ERR_STATUS[INCMPLT_SMPL_RCVD]
- SPT_HW_ACC_ERR_STATUS[VMT_SHIFT_OVF_ERR]
- All bits of SPT_HIST_OVF_STATUS0
- All bits of SPT_HIST_OVF_STATUS1

NOTE

During reading of OPRAM/TRAM, the reads happen on all slices unconditionally. Therefore even if the data of a particular memory location is not used but the memory location has a parity error then the parity error will be flagged. In case of FFT commands like RDX4 and RDX2 due to design optimization eight locations before the start of the twiddle address will also be read if quadrature extension is enabled. If there is a valid parity error on any of these eight locations then the parity error will be flagged. Thus, for RDX4 and RDX2 commands it is recommended that the entire TRAM is initialized, and in general both OPRAM and TRAM are initialized before being used.

NOTE

In case of multiple parity errors occurring during memory read, the address of the first memory location encountering parity error is sent out to MEMU.

NOTE

When SPT_GBL_CTRL[SPT_EN] is LOW all the status registers must be ignored and before SPT_GBL_CTRL[SPT_EN] is deasserted all the interrupts must be disabled

45.9.2.7 Debug Strategy

45.9.2.7.1 Entering the debug state and various debugging modes

The sequencer can go to the DEBUG state directly from the SETUP state or from the RUN state. The sequencer enters the DEBUG state by the following ways:

1. The sequencer is in the RUN state and SPT_CS_MODE_CTRL[CS_IMM_DEBUG] is set. Then the sequencer moves to the DEBUG state upon completion of current command.
2. The sequencer is in the RUN state and the SPT_CS_MODE_CTRL[CS_BKPT_DEBUG] field is set in the configuration map. Then the command sequencer can move from the RUN state to the DEBUG state when it hits any of the four breakpoints. These breakpoints can be enabled or disabled through the configuration map. There is also the option to automatically disable a breakpoint after a break occurs at that particular breakpoint.
3. The sequencer is in the RUN state and the SPT_CS_MODE_CTRL[CS_SYS_DEBUG] field is set in the configuration map. The sequencer moves from the RUN state to the DEBUG state in synchronization with the CPU. When the CPU hits a breakpoint it raises the ‘system debug’ signal and the sequencer enters the debug state.
4. The sequencer can go directly from the SETUP state to the DEBUG state if the SPT_CS_MODE_CTRL[CS_SYS_DEBUG] is set and 'system debug' signal is asserted or if SPT_CS_MODE_CTRL[CS_IMM_DEBUG] is set.

When both SPT_CS_MODE_CTRL[CS_BKPT_DEBUG] and SPT_CS_MODE_CTRL[CS_SYS_DEBUG] fields are set then whether the command sequencer enters the DEBUG state due to its own breakpoints or due to the system debug signal depends on which occurs first. If SPT_CS_MODE_CTRL[CS_IMM_DEBUG] field is set then this has priority and the sequencer enters debug state when the present command is done.

When in the DEBUG state the sequencer supports the following four sub-modes as determined by SPT_CS_MODE_CTRL[DEBUG_MD].

SPT_CS_MODE_CTRL[DEBUG_MD] = 00b: The sequencer remains halted.

SPT_CS_MODE_CTRL[DEBUG_MD] = 01b: Step once mode (sequencer steps ahead by one instruction)

SPT_CS_MODE_CTRL[DEBUG_MD] = 10b: Step to the next breakpoint mode.
SPT_CS_MODE_CTRL[DEBUG_MD] = 11b: Instruction jamming mode

The sequencer exits the DEBUG state if SPT_CS_MODE_CTRL[CS_IMM_DEBUG] is reset and SPT_CS_MODE_CTRL[CS_BKPT_DEBUG] is reset and if either SPT_CS_MODE_CTRL[CS_SYS_DEBUG] field is reset or system debug signal is low.

It should be noted that the breakpoints locations should not be set on the first program location (which corresponds to the value stored in register SPT_CS_PG_ST_ADDR).

45.9.2.7.2 Instruction Jamming mode

The instruction jamming feature is provided in the command sequencer to directly fill instructions through SW. This feature can be used during debugging to arbitrarily insert commands in a program flow. For example, a PDMA command could be inserted at a certain location in the program flow to DMA out data from the operand RAM or twiddle RAM for analysis.

Instruction jamming can be used only in the DEBUG state. To use this feature SW can set SPT_CS_MODE_CTRL[DEBUG_MD] == 11b. It should then also put the required succeeding instruction in SPT_CS_JAM_INST0, SPT_CS_JAM_INST1, SPT_CS_JAM_INST2 and SPT_CS_JAM_INST3 registers (these 4 32-bit registers contain the 128-bit jamming instruction), and reset SPT_CS_STATUS0[JAM_OVR] by writing a ‘1’ to it . The sequencer then executes the inserted instruction and halts and SPT_CS_STATUS0[JAM_OVR] gets set. If SPT_CS_INTEN0[JAM_OVR_INTEN] is also set then an interrupt is issued when SPT_CS_STATUS0[JAM_OVR] gets set.

Note that the SYNC, LOOP, NEXT and JUMP instructions should not be used in jamming mode; these will cause a flag to be set indicating that an inadmissible instruction was fired and command sequencer goes to ASYNCSTOP state. Similarly use of invalid opcodes will cause a flag to be set and sequencer goes to ASYNCSTOP state. It is also not advisable to run the WAIT instruction in the jam mode since it will alter the state of the command sequencer fsm. WAIT instruction is intended only to be used for diagnostic purposes i.e. to verify that the command sequencer fsm correctly goes to the WAIT state on execution of WAIT command and to check the working of WAIT module.

Note that asynchronous operation is not supported in the instruction jamming mode. An asynchronous PDMA instruction will be treated as a synchronous PDMA instruction. If a command error occurs then the command sequencer goes to the ASYNCSTOP state.

45.9.2.7.3 Stepping mode

In the stepping modes the sequencer can execute instructions one-by-one under SW control or continuously execute instructions till it reaches pre-defined breakpoints. SW can set four breakpoints at specific locations (corresponding to the absolute system memory address) in the program flow. When the command sequencer is in the DEBUG state and SPT_CS_MODE_CTRL[DEBUG_MD] == 01b and SPT_CS_STATUS0[STEP_ONCE_OVR] is reset (by writing a '1' to it) the sequencer executes one instruction and then halts and SPT_CS_STATUS0[STEP_ONCE_OVR] is set. If SPT_CS_INTEN0[STEP_ONCE_INTEN] is also set then an interrupt is issued when CS_STATUS0[STEP_ONCE_OVR] gets set.

Similarly if SPT_CS_MODE_CTRL[DEBUG_MD] == 10b and SPT_CS_STATUS0[STEP_JUMP_OVR] is reset (by writing a '1' to it) then the sequencer keeps executing instructions till it reaches the next enabled breakpoint and halts, and if there is no ongoing asynchronous PDMA instruction the SPT_CS_STATUS0[STEP_JUMP_OVR] field is set. If SPT_CS_INTEN0[STEP_JUMP_INTEN] is also set then an interrupt is issued when CS_STATUS0[STEP_JUMP_OVR] gets set.

It should be noted that in the 'step to next breakpoint' mode the sequencer compares the address of the present instruction being executed with the addresses of the four breakpoints and if any of them matches (and the corresponding breakpoint is enabled) the program execution breaks at the end of the instruction.

45.9.3 SPT Acquisition

45.9.3.1 Introduction

The data acquisition block receives maximum 14-bit samples from the ADCs or MIPICSI2, cuts out the samples in the acquisition window and performs on-the fly mathematical operations with these samples. The 16-bit results are forwarded to the SDMA (Sample DMA). Acquisition starts when it is enabled and triggered by the CTE (Cross Timing Engine) for ADC samples.

The following figure shows the block diagram of the Acquisition Block. ACQ_OPS stands for Acquisition operations module.

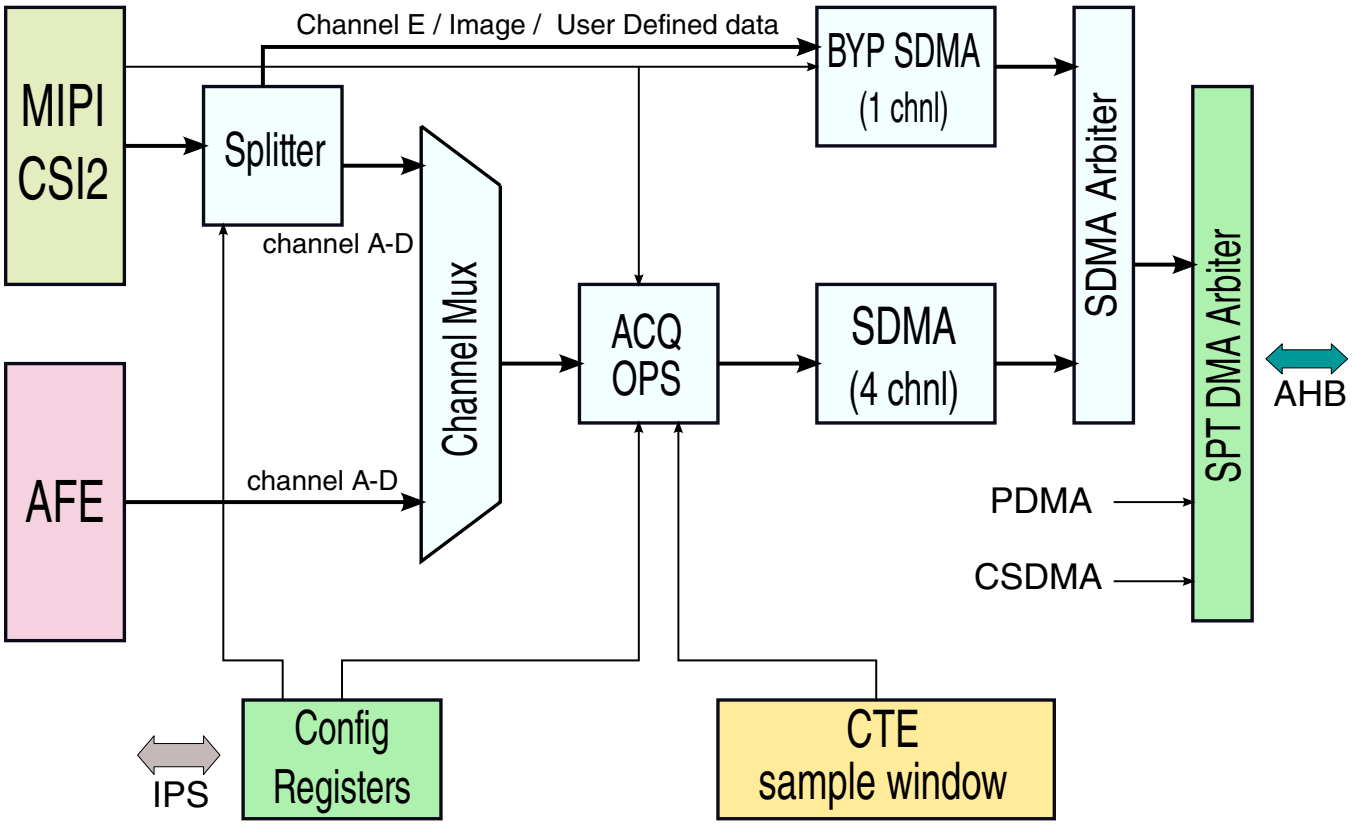

Figure 45-9. Acquisition Block

The ADC module provides 14-bit data which will be qualified by a data valid pulse. The data valid pulses for the enabled ADC channels can appear either concurrently or sequentially. For concurrent sampling mode, the data valid pulses for all ADC channels appear simultaneously while in sequential sampling mode, they appear in a staggered fashion with the order of staggering maintained for all 8 channels.

45.9.3.2 MIPICSI2 Interface

The register field ACQ_GBL_CTRL_0[CSI_ADC_SEL] is used to decide the source of the data to be acquired from. Acquisition receives frame start, chirp start and acquisition window from MIPICSI2, similar to the signals received from CTE in case of ADC as source. CTE phase inverse signal should be tied to 0. Along with the 24 bit input data, it also gives the data valid and data type signal to acquisition block. The data type can be changed within a frame but it should remain the same throughout a chirp. When combining Embedded/User defined data type with RGB/YUV data type, SPT_ACQ_GBL_CTRL_0[INF_SMPLS] bit needs to be set. For the 4 channel mode,

20MSPS is the maximum data rate supported in each channel for RAW8/10/12. RAW14 does not support 20MSPS. SPT receives data for all the channels from MIPICSI2 and then discards the data corresponding to the disabled channels.

The splitter decodes the incoming data based on the register ACQ_CSI_CTRL. If the data type is RAW 8/10/12/14, it is assigned channel numbers and stored in the 4chnl SDMA after arithmetic operations are performed on it. If the fifth channel is configured, the data is sign extended and then MSB aligned and stored in Bypass SDMA. If the data type is RGB/YUV/Embedded/User defined, it is directly stored in the 1 channel Bypass SDMA. RGB and YUV-10bit data write in two 16-bit locations of Bypass SDMA each valid cycle, Embedded and User defined data write in one 16-bit location every two valid cycle, while the rest of the formats one 16 bit location is written every valid cycle. Hence, if the valid cycles are in odd numbers (infinite samples in chirp) for embedded and user defined data, the last sample will be missed.

The possible sequences as programmed for the RAW data formats to be given to acquisition are shown in figures below for both with and without fifth channel. The (*) marked data are repetitive samples which are not stored in the SDMA. The data rate given for each sequence is the maximum possible data rate.

Figure 45-10. Input data sequence with ChannelE

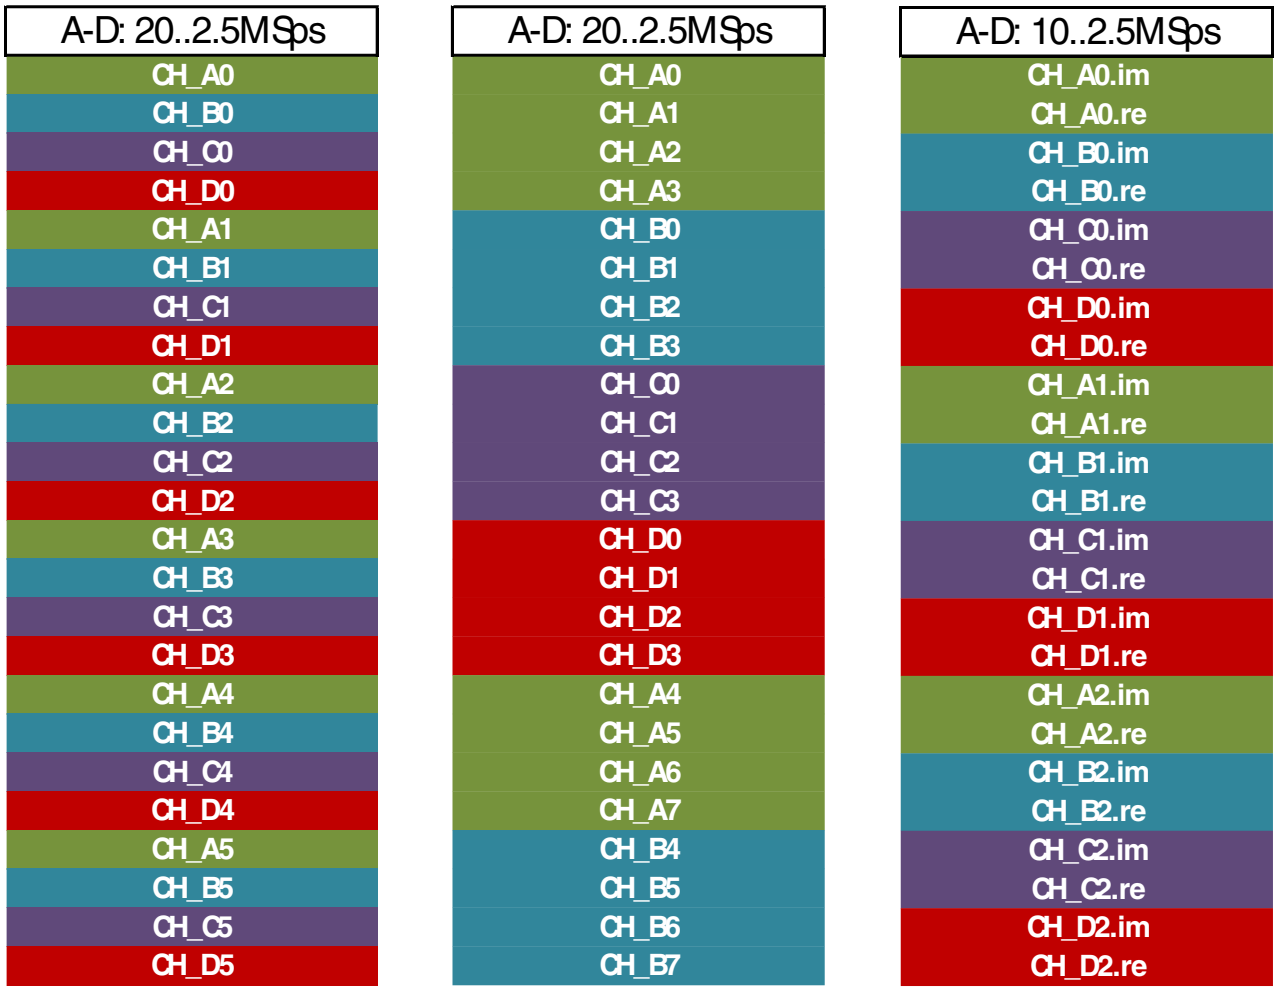

Figure 45-11. Input data sequence without ChannelE

45.9.3.3 Channel Select and Re-order

The channels selector switches between MIPICSI2 and the integrated ADCs. Each channel can be enabled or disabled for further processing by a mask, which is programmed with the configuration registers. Refer to the ACQ_GBL_CTRL_0[CH_x_SEL] fields for more information. When a channel is disabled its samples are invalid.

In order to simplify PCB routing it is possible to swap the channel numbers of ADCs, e.g. ADC_B channel becomes ADC_A and so on. Only a swap of two neighboring channels and a channel reverse swap is supported. Swapping does not apply for samples from MIPICSI2. If programmed wrongly, the channel will be treated as invalid. The figure and table below provide information on the swapping operation for both cases of 4ADC channels and 8ADC channels.

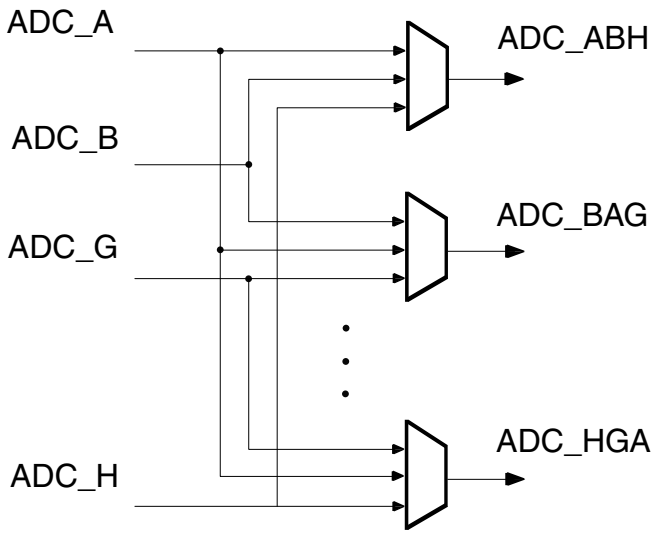

Figure 45-12. ADC Channel Multiplexer

Input channel H	X						X	X

Figure 45-13. ADC Channel Swap

45.9.3.4 Acquisition Window

The acquisition window is defined by the window start signal of the CTE and a programmable length in sampling clock pulses in a chirp (default value is 256). Acquisition starts with the rising edge of this window. It stops when either sample counter is exceeded or with the falling edge of the window signal provided by the CTE; whichever is earlier. When MIPICSI2 interface is enabled, acquisition receives frame start, chirp start, acquisition window signals from MIPICSI2 instead of CTE.Multiple Acquisition windows within a single chirp is not supported.

If window signal from CTE/MIPICSI2 deasserts before programmed number of samples have been acquired, it is possible (in case of sequential sampling) that some channels have provided data, while others were yet to provide data. In such cases, acquisition block appends junk data to complete data acquisition from all channels and proceeds to transfer this data to SRAM via SDMA. An exception will be generated in such cases.

During Initialization, acquisition block must be enabled (by setting SPT_GBL_CTRL[ACQ_EN]), before arrival of RFS (radar frame start) from CTE. This should be followed by assertion of window signal from CTE, thus initiating acquisition of radar samples.

NOTE

User must ensure that the minimum time between de-assertion of acquisition window at chirp boundary and subsequent chirp/ frame start (programmable via CTE) must be at least 1us for proper operation of acquisition block. Similarly, the time between deassertion of chirp and subsequent assertion of its acquisition window must be greater than the sum of 5 AFE/ MIPICSI2 interface clock cycles and 5 AHB interface clock cycles.

NOTE

When acquisition window does not appear after a chirp (i.e the chirp is followed by another chirp with any acquisition window) or there are valid samples without acquisition window, such a chirp is known to be an empty chirp. An empty chirp results in the following:

- Chirp Counter does not increment for an empty chirp
- In 2D Mode, SDMA Buffer address does not increment by line length after an empty chirp
- An empty chirp is not counted in the Buffer Length count which is used to reset the SDMA Base Address.

NOTE

Please ensure that the width of RFS/RCS pulses going towards Acquisition are greater than or equal to 2 MIPICSI2 clock periods for MIPICSI2 interface and 2 AHB clock periods for AFE interface.

NOTE

If infinite number of samples are programmed for an interleaved format read with AFE interface or Embedded/User defined data type in MIPICSI2 interface, then acquisition

window should go low when even number of samples have been acquired to avoid data loss.

45.9.3.5 Acquisition Operations

The mathematical operations performed on the incoming 14-bit signed data sample are: min, max, toggle check, sum, offset compensation and phase inverse compensation. The results of min, max, toggle check and sum are stored in registers. Offset and phase inverse compensation change the values of the samples. Before offset and phase inverse compensation, the incoming samples are left shifted by 1 bit and sign extended to 16 bits. The values for offset compensation are programmed by configuration registers (ACQ_CTRL0/1/2/3). The following figure provides implementation details.

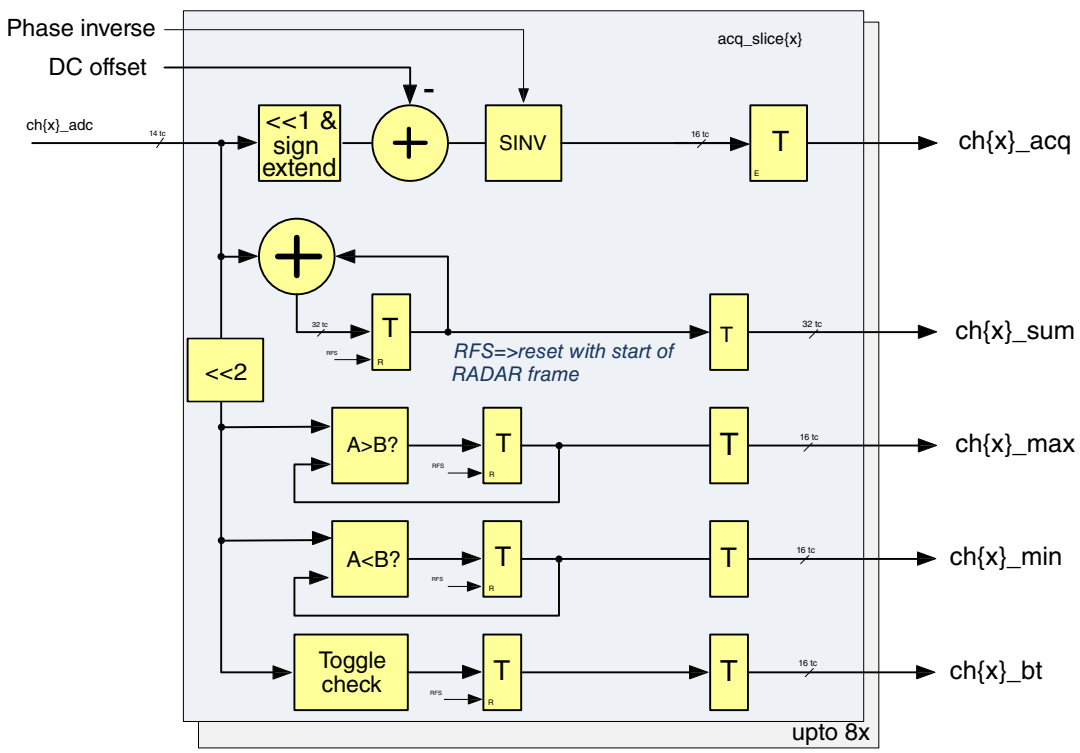

Figure 45-14. Acquisition Operations

Min, max, toggle check and sum operations are calculated on all valid samples during the acquisition window only. These operations are performed over the entire RADAR frame. With the start of the RADAR frame, indicated by RFS, the accumulating registers are cleared. Phase inverse value and the offset are constant for single acquisition window. The offset can be different for each channel but the phase inverse value is common to all channels.

45.9.3.5.1 Min, Max and Sum Calculation

The 'Min' operation (refer ch{x}_min in the above figure) looks for the global minimum value within the acquisition windows over the entire frame. Similarly 'Max' operation (refer ch{x}_max in the above figure) looks for the global maximum value. The 'Sum' operation (refer ch{x}_sum in the above figure) accumulates the samples during acquisition window to calculate sum of all samples over the entire frame. The results of these operations are signed. The result from the 'Sum' operation can be used by the CPU for average calculation.

The results of these operations are stored in the acquisition status registers ranging from ACQ_STATUS_x0 to ACQ_STATUS_x1, where 'x' represents corresponding ADC channel. The results for "Min" and "Max" operations are MSB aligned and stored in a 16 bit field. The unused LSB's are padded with zero's. These statistics are valid to be sampled only after end of frame event.

45.9.3.5.2 Toggle Check

The toggle check is a reliability feature and shall check that each bit can change. For this purpose, each single bit is observed during acquisition window, and if toggled at least once (i.e. one rising and one falling edge), then the corresponding bit position is set to ‘1’. The result of this operation is MSB aligned and stored in a 16 bit field in the acquisition status register ACQ_STATUS_x2, where 'x' represents corresponding ADC channel. The unused LSB bits DO NOT TOGGLE and are padded with zeros. These statistics are valid to be sampled only after end of frame event.

45.9.3.5.3 Offset and Phase Inverse Compensation

Phase Inverse compensation is a specific operation to compensate a pi phase shift by sign inversion. The phase inverse signal is provided by CTE. If this signal is logic '0', no phase inversion is performed, while logic '1' leads to phase inversion operation. If the incoming samples are from MIPICSI2, this signal should be logic '0'.

Offset compensation logic corrects the ADC offset values, depending on the result of the mean value of the previous cycles. These offset values are programmed using configuration registers (ACQ_CTRL0/1/2/3). This offset value is subtracted from the left-shifted sample value as shown in figure "Acquisition Operations" above.

45.9.3.6 Sample DMA

The SDMA is responsible for merging ADC samples in to memory words and to arrange the data into packets.

There are two sample DMAs in acquisition:

- 4 channel SDMA
- 1 channel Bypass SDMA

4 channel SDMA stores the shifted data from the incoming channels, while the Bypass SDMA stores image data and the fifth channel calibration data. Only when the fifth channel is on, both the SDMAs have to be configured appropriately. If its the ADC or the RAW data MIPICSI2 interface only the 4 channel SDMA should be configured and if image data is being received only the Bypass SDMA should be configured. Both the SDMAs are connected to a SDMA arbiter, which processes the requests in round robin fashion and gives it to the SPT arbiter.

45.9.3.6.1 ADC Data Transfer

Four 16-bit ADC samples are used to build a 64-bit word for bus transfer to system RAM memory. The number of samples being transferred for each chirp is always equal to the configured number of samples in acquisition window multiplied by the number of enabled ADC channels.

Figure 45-15. ADC Data Transfer

45.9.3.6.2 Sample Interleaving

The samples of the ADC channels are interleaved channel-wise and collected in DMA buffer. The number of active channels and their order can be configured using ACQ_GBL_CTRL_0 register. Multiple data organization methods are available. This can be configured using SDMA_CTRL1[DATA_ORG_CFG] field.

Denoting the ADC channels with A,B,C,… and the sample count with A_x then following configurations are supported:

- Interleaved : $A_0B_0C_0D_0$, $A_1B_1C_1D_1$, ..., $A_{n-1}B_{n-1}C_{n-1}D_{n-1}$
- Tile 4 : $A_0A_1A_2A_3$, $B_0B_1B_2B_3$, ..., $D_{n-4}D_{n-3}D_{n-2}D_{n-1}$
- Tile 8 : $A_0A_1A_2A_3$, $A_4A_5A_6A_7$, $B_0B_1B_2B_3$, ..., $D_{n-4}D_{n-3}D_{n-2}D_{n-1}$

The interleaved mode can be used for SPT operations only when the number of channels enabled are greater than 4. For the case where the number of channels enabled is less than 5, they can only be used when SPE (Signal Processing Engine in CPU) needs to work on

the data, and not SPT. This is because interleaved mode with less than 5 channels leads to 4 ADC samples being packed together back to back. This particular form of data organization is not usable by Hardware Accelerator blocks within SPT.

The tile transfer determines the intermediate buffer size to bridge DMA latencies. To support Tile-8 mode, it has 8 channels x 8 words x 16 bits x 2 (double buffering) = 256 bytes.

Figure 45-20. Image data storage

45.9.3.6.3 SDMA Data Transfer

The data is transferred to system memory (system RAM/TCM, preferably a separate bank which is not being used by any other Master like for ex: Flexray). The transfer to main memory is performed by the SDMA module, depending on its configuration. The DMA operation is scheduled once and runs autonomously when enough samples are available in buffer.

The data transfer is triggered, when one of the two buffers of either of the SDMAs has been filled. The burst size is dependent on the SDMA data organization selected and the number of channels enabled. Refer DMA Arbitration for details on various burst sizes available. The final burst after the acquisition window may be residual burst, with less data. The ADC sample buffer is flushed with the last burst of a chirp. Whenever a burst is done, data from the other SDMA is transferred in case atleast one buffer of each SDMA is full. The bypass SDMA always transfers the 64x16bits buffer at once, so if the number of samples programmed are not a multiple of 64 (multiple of 128 in case of Embedded/ User Defined), some junk data will be appended in the last burst. Similarly, when 4 or less channels are enabled for MIPICSI2 all modes or ADC interleaved mode, if the number of samples is not a multiple of 16, some junk data will be transfered in the end.

45.9.3.6.4 SDMA Addressing Modes

The SDMA supports linear write (1D) and orthogonal (2D) write operations. This can be configured using SDMA_CTRL1[TRF_MOD] bit.

With linear write mode, the data is transferred consecutively to the target memory, i.e. each ADC data packet follows the other. The target address is auto-incremented with the next transfer by the number of previous transferred data words. The target address is reset to the start address with an active edge of the frame start signal.

With orthogonal write mode, the data is transferred to the target memory while the configured line length is not exceeded, otherwise the data is dropped. The address is auto-incremented like in linear write mode until the next active edge of chirp start signal (RCS). At this moment, the next target address is calculated as sum of previous start address and the line length. Line length can be configured using SDMA_CTRL1[LINE_LEN] field. The target address is also reset to the original start address with an active edge of the frame start signal (RFS). Any unused memory is not filled.

The Buffer Length field programmed by SDMA_CTRL1[SDMA_BUF_LEN] provides the number of chirps for which samples are stored in System RAM back to back; after which target address is reset to start address from next successive chirp onwards. This happens regardless of linear/orthogonal mode. However, a frame start signal always causes target address to reset to start address. Refer to SDMA_CTRL1[SDMA_BUF_LEN] for more details.

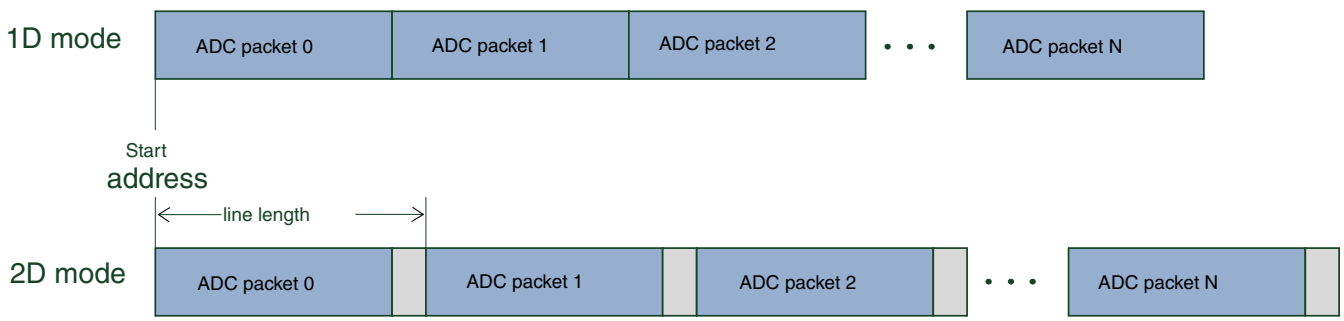

Figure 45-21. SDMA Modes

45.9.4 Operand RAM

45.9.4.1 Introduction

The operand RAM stores the operands for operations like FFT, Histogram, Programmable DMA (PDMA). The operand RAM is divided into 4 banks. Each bank consists of 8 slices. Each slice has a width of 48 bits (+4 parity bits). Each bank can either have a read access or a write access every clock cycle.

The operand RAM configuration is :

8 slices of (48 bits +4 parity bits) x 512 depth per bank. There are 4 such banks.

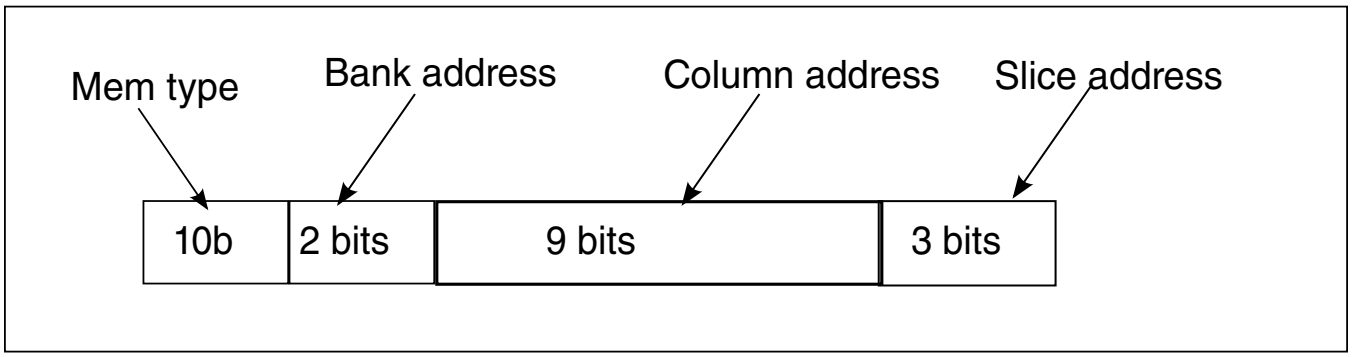

Figure 45-22. Operand RAM addressing bits

45.9.4.2 Operand RAM : Error Detection

Two parity bits are provided for every 24 bits. Parity bit 0 contains the XORed value of all the even bits and parity bit 1 contains the XORed values of all the odd bits. The arrangement of data and parity bits are shown in the figure below.

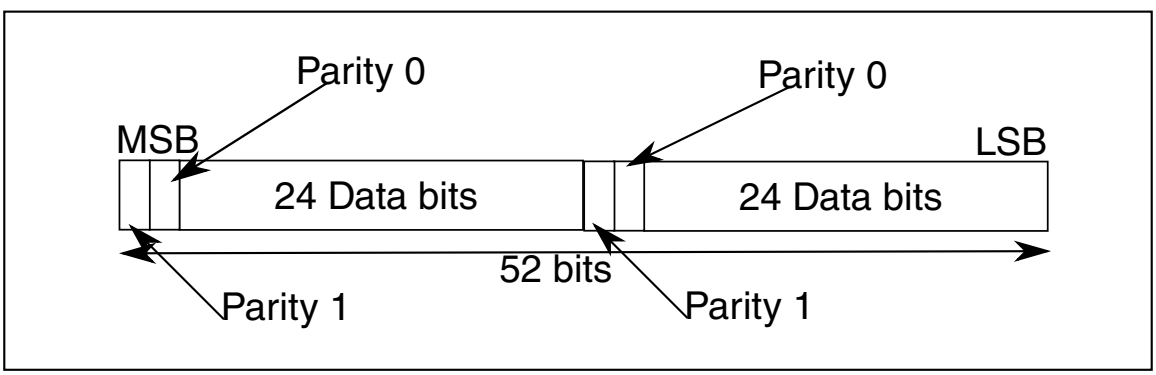

Figure 45-23. Data and parity

45.9.4.3 Operand RAM accesses

The operand RAM is accessed by all the hardware accelerators: COPY, MAXS,HIST, FFT, VMT, GET, SET and ADD instructions. All the hardware accelerators are allowed to have one read and one write transaction on the operand RAM provided they are not on the same bank. The PDMA is allowed to have one read or write transaction to the operand RAM. For every address accessed, the operand RAM controller provides the data for 8 consecutive locations. Slice unaligned accesses are not allowed. For every address coming to the SPT RAM controller, data is read from/written to all the 8 slices in a bank. Word enables are provided to selectively write data to any 24 bit word.

Every bank can have either a read or a write transaction at one time. Simultaneous reads and writes to one bank are not allowed. In case a hardware accelerator requests for reads and writes in the same bank, writes will be given a priority and "wait" will be asserted for the read transaction. In case there is a contention on any one bank between the hardware accelerators and the PDMA, the PDMA is given a priority and "wait " is asserted for the hardware accelerators.

Figure 45-24 shows the locations accessed with an aligned slice address.

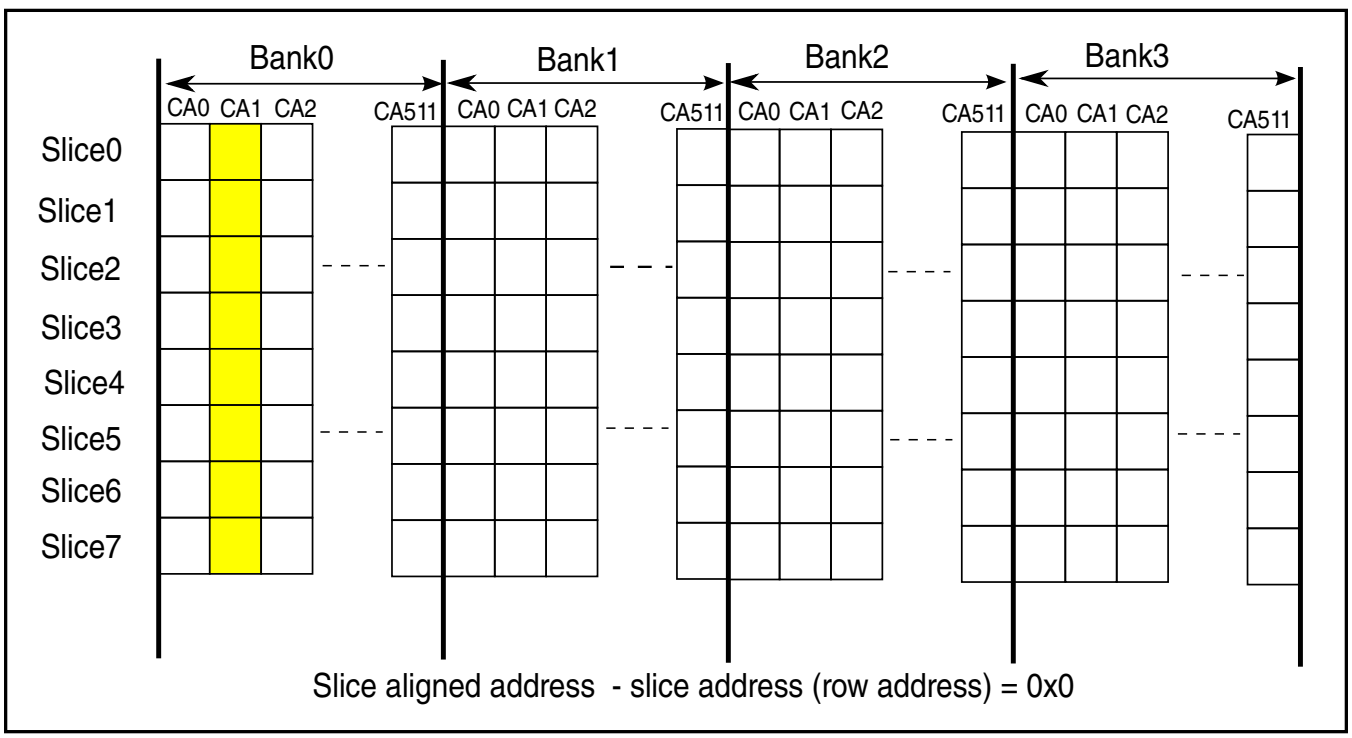

Figure 45-24. Slice aligned access

45.9.5 Twiddle RAM

45.9.5.1 Introduction

The twiddle RAM holds constants like coefficients, which are used during some operations. It is also organized in slices of 8 to enable parallel access to 8 coefficients simultaneously and can be initialized with DMA operations. Operations can use the twiddle RAM as source and destination, but concurrent read and write is not supported. All hardware accelerators and DMA can access the twiddle RAM. However, at one time only one interface can be active.

The configuration of the twiddle RAM is :

8 slices of 36 bits X 512 depth. Each location has 32 bits of data and 4 bits of parity.

It is possible to read 8 different locations, one in each slice. Therefore, 8 address buses are required from each of the modules. The addressing bits for the twiddle RAM is shown in Figure 45-25.

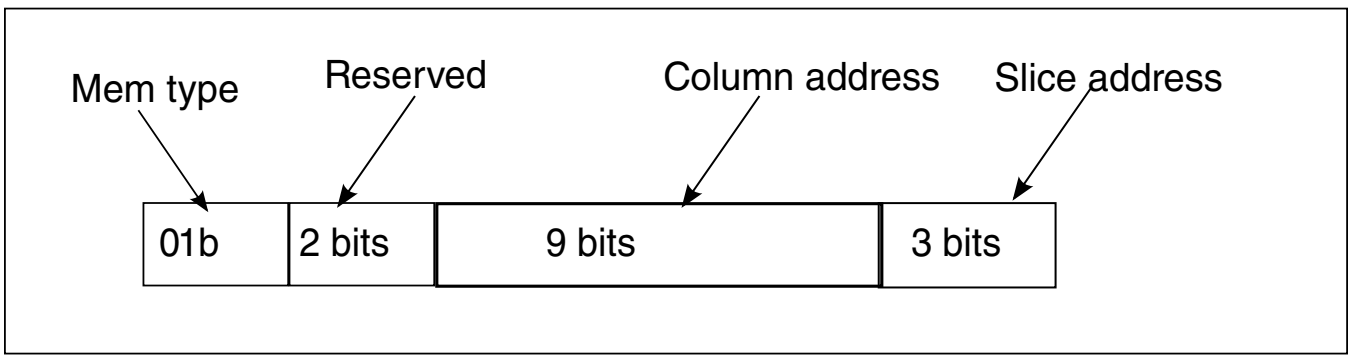

Figure 45-25. Twiddle RAM address bitwidths

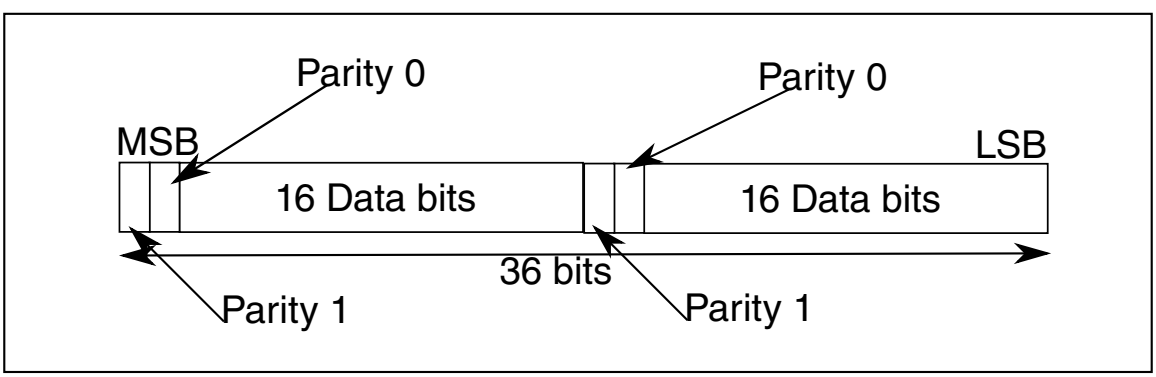
Since there is only one bank in twiddle RAM, the two bank bits of address are don't care.

45.9.5.2 Twiddle RAM : Error Detection

Two parity bits are provided for every 16 data bits.Parity bit 0 contains the XORed value of all the even bits and parity bit 1 contains the XORed values of all the odd bits. The arrangement of data and parity bits are shown in the Figure 45-26.

Figure 45-26. Data and parity



45.9.5.3 Twiddle RAM Organization and Twiddle Generation

Twiddles are organized as 8 slices by N/8 entries as shown below:

Col. addr.	CA0	CA1	CA2	CA3	CA4	...	CA_N/8-1
slice0	tw1	tw2	tw3	tw4	tw5	...	twN/8
slice1	tw1	tw2	tw3	tw4	tw5	...	twN/8
slice2	tw1	tw2	tw3	tw4	tw5	...	twN/8
slice3	tw1	tw2	tw3	tw4	tw5	...	twN/8
slice4	tw1	tw2	tw3	tw4	tw5	...	twN/8
slice5	tw1	tw2	tw3	tw4	tw5	...	twN/8
slice6	tw1	tw2	tw3	tw4	tw5	...	twN/8
slice7	tw1	tw2	tw3	tw4	tw5	...	twN/8

For example, for FFTs of size 512, there are 8 entries for each twiddle factor and a total of N/8 or 64 unique twiddle factors.

Twiddle factors are generated by using the formula Equation 13 on page 1982

$$W_N^k = e^{-j2\pi k/N}$$

Equation 13. Formula for generation of Twiddle Factor

Here N is the FFT size.

To generate twiddle factors, the following pseudo code can be used:

```
<codeblock>
for  n = 1 to FFT_Length / 8
    Real = int_scale * cos(-2 * pi * n / FFT_Length);
    Imaginary = int_scale * sin(-2 * pi * n / FFT_Length);
The Real and Imaginary parts of these equations can then be rounded to 16 bit integer values
and then placed into a 32 bit entry
</codeblock>
```

The user need only define twiddles for one quadrant (- Imaginary, + Real) and the SPT logic determines other needed twiddles by real / imaginary swaps and sign inversions. The SPT defines this real / imaginary swap and sign inversion process as quadrature extension.

As an example, consider the following twiddle factors for FFT length 32. First, a text style listing the 8 copies for 32 / 8 = 4 total unique twiddles is shown below:

```
#Twiddle RAM values for FFT length 32
0x4000: 32137 +i -6393
0x4001: 32137 +i -6393
0x4002: 32137 +i -6393
0x4003: 32137 +i -6393
0x4004: 32137 +i -6393
0x4005: 32137 +i -6393
0x4006: 32137 +i -6393
0x4007: 32137 +i -6393

```

45.9.6 Work register

45.9.6.1 Introduction

Certain SPT operations need single values for calculation (such as coefficients) or generate single output results (such as sum). Such values can be saved in result/operand registers.

A total of 48 such registers are available which can be directly accessed by the CPU via the peripheral interface. All Work Registers (R0 to R47) are 32-bit accessible only. The work register can also be used with specific commands to extract or initialize specific Operand RAM or Twiddle RAM cells.

The addressing bits for Work registers is shown in the figure below.

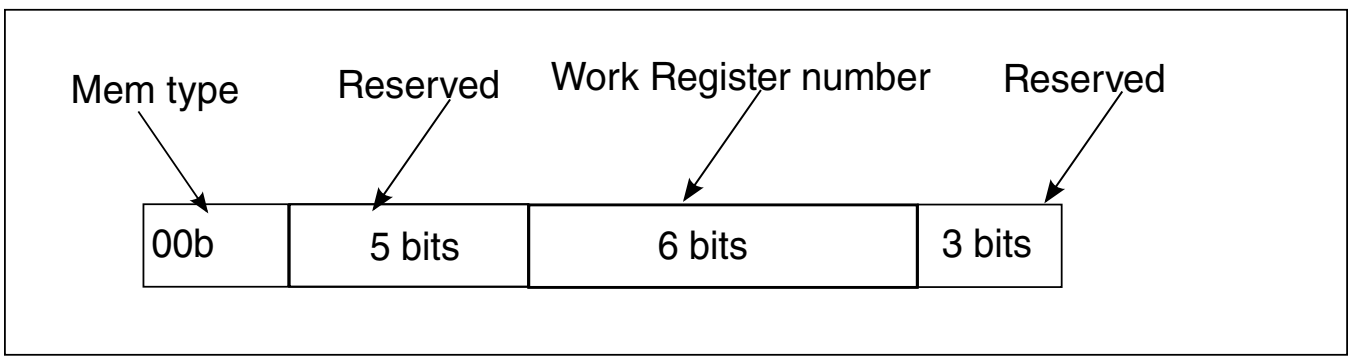

Figure 45-27. Work Register addressing bits

45.9.6.2 Work Register accesses

Each work register is a 48 bit register which is accessible to the SPT internal modules as well as the CPU and external parties. The CPU and external modules can access the work registers via the peripheral interface.

The following points define the behavior of the accesses to work registers.

1. Every work register contains a 48 bit data (24 bit real and 24 bit imaginary)
   a. Peripheral side view of each register are two consecutive registers with 24 bit value in each (rest 8 bit are reserved)
2. Writes have two modes
   a. Writes locked mode - Writes are locked for either CPU or SPT
   b. Writes unlocked mode - Both CPU and SPT can write into the register. Coherency has to be tackled by the software. In case of contention while writing

data in unlocked mode, SPT writes will be given a priority and the CPU write will be lost.

3. Two control bits are provided for each work register to define whether a work register is locked and for which party (SPT/CPU). WR_CTRL_x_REGs provide these control bits.
4. Reads are free from both the interfaces (SPT/CPU)
   a. Reads by the CPU via the peripheral interface assume that the data is stable (CPU is responsible to read the data when it is stable). CPU can use handshaking mechanisms to ensure that stable data is read.
5. Writes by the CPU via the peripheral interface will be written to the work registers after a delay - required for clock domain crossing. There wont be any wait assertion for the first write but wait will only be asserted if next read or write happens within 3 IPG + 2 SPT clock cycles
6. In case CPU writes to a work register locked for SPT, a transfer error is generated.
7. In case SPT writes to a work register locked for CPU, MEM_ERROR_REG[SPT_LCK_VIOL] bit is set and an interrupt can be generated if enabled.

It is recommended to use the writes locked mode of the work registers to ensure that there is no contention.

NOTE

The assumption here is that the peripheral clock frequency is slower than the frequency at which the SPT works.

NOTE

When SPT is disabled using SPT_GBL_CTRL[SPT_EN] and then enabled again, the values of the Work Registers are indeterminate. To ensure that the Work Registers are reset the user must write 0x0 to SPT_WR_R0_RE before enabling SPT. Other than for the purpose of resetting the work registers they should only be written when SPT_EN=1.

NOTE

When the SPT executes a STOP command at the end of a command sequence, the work register values are not deterministic until they are re-initialized. The CPU should not rely on access to the work registers between a STOP command and the launching of a new command sequence, instead the WAIT and EVT commands should be used to manage the timing of accesses when both SPT and CPU must interact with work registers during command sequence execution.

45.9.7 FFT core

45.9.7.1 Introduction

The FFT module implements two Radix4 kernels. Both Radix4 operations can only be used in the same context, e.g. to perform the Fast Fourier Transform (FFT), Inverse FFT, Scalar Product (SCP), Finite Impulse Response Filtering (FIR) or Windowing (WIN) operations. The kernel operation is auto-repeated for the operand length defined by the instruction. A complete FFT is built from several Radix4 or Radix2 rounds, each of which need a command.

The FFT module shall perform 2^N real and complex FFTs with N ranging from 3 to 12.

45.9.7.2 Features

- Automated operation for single rounds
- FFT and Inverse FFT basic operations
  - Radix4 butterfly and twiddle multiplication
  - Radix2 butterfly and twiddle multiplication
- Windowing for Pre and Post multiplication with coefficients
  - Constant, full vector and partial vector
- Twiddle handling
  - Offset/modulo address calculation for twiddles
  - Reduced twiddle storage
  - Sub-sampling of twiddles possible
- Scaling
  - Fixed result scaling
  - Input scaling with selectable gain
- Advanced calculation
  - FIR filter and Scalar Product operation
  - Real number FFT support
  - Combination of many small FFTs with single operation
- Reordering of input operands

45.9.7.3 Input Data

The input operand vector consists of real or complex values, stored in the operand RAM. For FFT operation the vector length N must be a power of two, greater than or equal to 8, and for Windowing operation, Scalar Product or FIR filtering the vector length should be a multiple of 8. Twiddles and multiplication coefficient vectors are fetched from twiddle RAM. A single multiplication coefficient can also be loaded from work registers or can be given as part of the command (immediate data).

45.9.7.4 Output Data

The results are stored in operand RAM.

45.9.7.5 Kernel Operations

A single Radix4 kernel may perform the following operations:

- Radix2 with two operands, performed two times in a single step using a single butterfly. Thus the two butterflies process eight input operands in each clock cycle. This operation is performed using the RDX2 or IRDX2 command.
- Radix4 with four operands, performed by a single butterfly. Thus the two butterflies in the kernel can process eight input operands each clock cycle. This operation is performed using the RDX4 or IRDX4 command.
- Windowing with four operands, by a single butterfly. This is essentially a complex multiplication operation. Thus the two butterflies can perform eight complex multiplications (or windowing operations) each clock cycle. This operation is performed using the WIN command. Window operations may precede or follow Radix rounds.
- Multiply/Accumulate with four operands, using a single butterfly. Thus the two butterflies can perform eight complex multiplications and the products are added together. This is similar to the operation of an FIR filter with eight taps.
- Multiply-add operation using a single or two butterflies. This operation is used to calculate the scalar product.

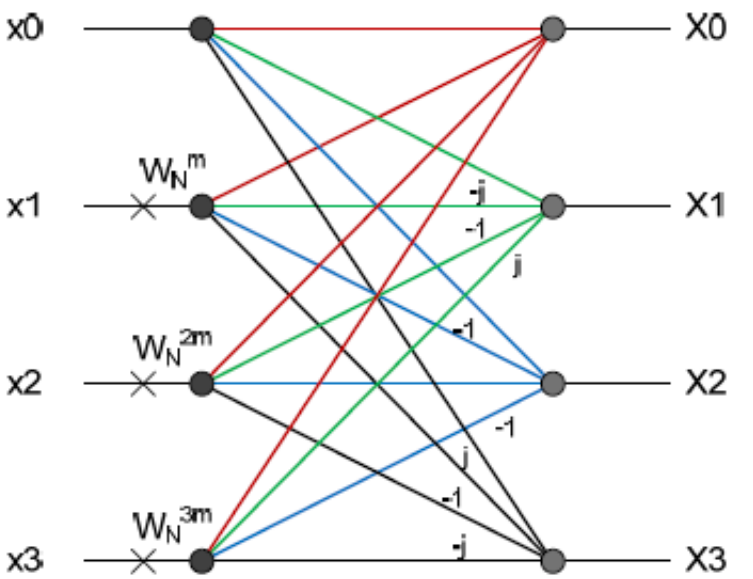
The source operands and the results are stored in the operand RAM, and the twiddles are read from twiddle RAM. The round counter in the Radix2 or Radix4 instruction determines the addressing scheme for source operands and the results as well as the read twiddles. Results are stored in way making concatenation of rounds easy. For this purpose, the Radix operation reads from and writes to same addresses, preferably at different banks to ensure full performance. If read and write were done on the same bank, then the performance would be affected; it would be slower by a factor of two.

The twiddle coefficients for RDX4, RDX2, IRDX4 and IRDX2 commands are stored in twiddle RAM.

The coefficients for windowing and multiply/accumulate and multiply-add operations are also stored in twiddle RAM. Additionally, windowing operation can use constant coefficients from the command word itself (immediate data) or a work register.

45.9.7.6 Principle of Operation

A special symbol is used for the Radix4 operation which is shown in the following picture. The operation consists of complex multiplications and a butterfly addition.



$$\begin{pmatrix} X0 \\ X1 \\ X2 \\ X3 \end{pmatrix} = \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & -j & -1 & j \\ 1 & -1 & 1 & -1 \\ 1 & j & -1 & -j \end{bmatrix} \begin{pmatrix} 1x0 \\ W_N^m x1 \\ W_N^{2m} x2 \\ W_N^{3m} x3 \end{pmatrix}$$

Figure 45-28. Radix4 Butterfly

The complete FFT is split into steps and rounds of Radix operations. A single command performs one round of selected operation, consisting of multiple Radix operations per round. A $N=4^k$ FFT (k=2,3,4,5,6) is completed after 4^{k-1} Radix operations per round and k rounds. Since each step executes two Radix operations, only $4^{k-1}/2$ steps are required to finish one round.

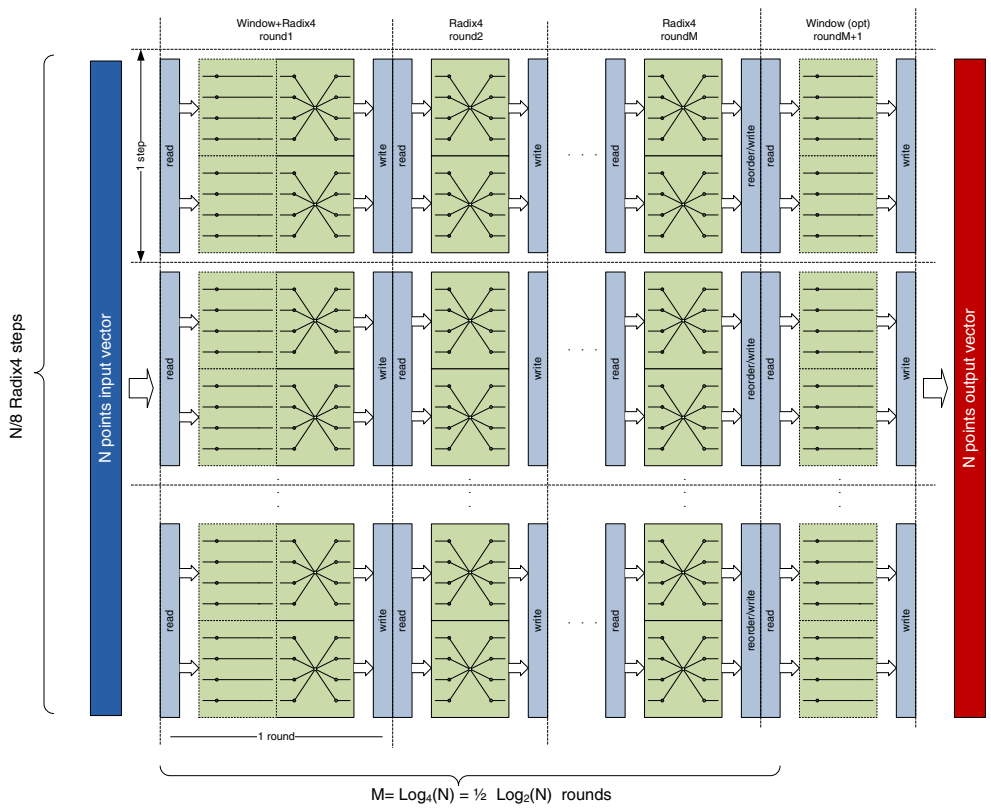


Figure 45-29. Principle of Operation

The initial round can be combined with window operation, and this extra window operation will not take additional cycles. There is a WIN bit in the FFT instruction which can be used in the first stage as all FFT twiddles are 1. Another window round can be appended after the final Radix round, which requires additional steps.

Table 45-34. FFT stages

FFT Size	Steps	Radix4 Rounds	Radix2 Rounds(last round)	Radix kernel invocations
8	1	1	1	2
16	2	2	0	4
32	4	2	1	12
64	8	3	0	24
128	16	3	1	64
256	32	4	0	128
512	64	4	1	320

Table continues on the next page...

Table 45-34. FFT stages (continued)

FFT Size	Steps	Radix4 Rounds	Radix2 Rounds(last round)	Radix kernel invocations
1024	128	5	0	640
2048	256	5	1	1536
4096	512	6	0	3072

45.9.7.7 Window Multiplication

The window operation uses the same Radix4 kernel, but bypasses the butterfly after complex multiplications. The window operation can be done separately using a WIN command or as a part of RDX4 command. When window operation is done as a part of RDX4 command it is allowed only in the first round. To enable a complete complex vector multiplication, the first twiddle factor can be chosen different from 1.

There are three types of vector multiplications:

- with a single constant
- with a full vector, of the same size as the operand vector
- with a partial vector of a smaller size, and repeated elements

The constant for multiplication can be located in twiddle RAM or work register or immediate value (as part of the command). For a full vector or partial vector multiplication the coefficients are stored in the twiddle RAM. The partial vector multiplication uses an address offset and a modulo to get each element of the multiplier vector. The full vector multiplication multiplies each element from the operand vector with an element of multiplier vector. The address of the elements of the multiplier vector is incrementing.

Table 45-35 shows the different memory address calculation modes for window multiplication.

Table 45-35. Memory address calculation modes for window muliplication

Mode	Action
0	multiply with a single 32-bit complex immediate value
1	multiply with a single 32-bit complex constant from coefficient address (twiddle RAM address or work register index).
2	increment and modulus applied after every Radix4 step. coeff_addr = coeff_base_addr+ ((step*MCA_INC) % MCA_MOD) * 8 + m where step denotes the step number. This step number = 0 in the first clock cycle, 1 in the second clock cycle, etc.

Table continues on the next page...

Table 45-35. Memory address calculation modes for window muliplication (continued)

	MCA_INC = the address increment value MCA_MOD = modulo value m = 0 to 7, is the index of the address generated in a single step (out of the 8 addresses)
3	Reserved

For a full vector multiplication the window multiplication mode should be =2 and MCA_MOD = 0.

When window operation is done as a part of RDX4 command the window coefficients need to be stored in a continuous, reordered manner. This pattern is described for various vector lengths in the figures shown below. In this particular case the window multiplication mode should be = 2, MCA_INC = 1 and MCA_MOD = 0. However an exception is the combined FFT16 operation where if the same window is needed to be used for all the different sets of operands, the MCA_MOD field should be set to 1. Similarly for combined FFT32 operation where also the same window is needed to be used for all the different sets of operands, and so the MCA_MOD field should be set to 2. CA stands for Column address in the figures below.

Figure 45-32. Window Coefficients in Twiddle RAM for 128, 256, 512, 1024, 2048 and 4096 point FFT

For the WIN command of the RDX4 or IRDX4 where the windowing option is enabled in round=0, it is possible to specify the type of window coefficients as complex, real only or imaginary only. In case of real only window it is assumed that the coefficients are all real and stored only in the real part of the TRAM memory locations. In case of imaginary only window it is assumed that the coefficients are all real and stored only in the imaginary part of the TRAM memory locations.

45.9.7.8 FIR Filter

The command word for FIR filter must give the twiddle RAM address where the tap coefficients are stored. These taps are stored in all the slices of the twiddle RAM at that particular address. If the number of taps is less than eight then the remaining taps are assumed to be zero. The tap stored at slice0 of the twiddle RAM is the tap which gets the undelayed input from the operand RAM.

For the FIR command it is possible to specify the type of tap coefficients as complex, real only or imaginary only. In case of real only taps it is assumed that the coefficients are all real and stored only in the real part of the TRAM memory locations. In case of imaginary only taps it is assumed that the coefficients are all real and stored only in the imaginary part of the TRAM memory locations.

It is intended that the tap coefficients or operands be filled such that they give unity gain for filter output. This gain is defined with respect to a 4-tap filter. Thus if an 8-tap filter is being used then the tap coefficients can be half the magnitude. If a 2-tap filter is used then to achieve unity gain the tap coefficients can be similar to the 4-tap case but the operands are doubled by enforcing a left-shift by 1 position through the command word.

There are two types of intializations:

- Zero run-in initialization where the unoccupied locations contain zeroes.
- Constant run-in initialization where the unoccupied locations contain the value of the first input operand.

45.9.7.9 FFT Special Usage

45.9.7.9.1 Inverse FFT

The FFT kernel also supports the inverse radix4 and inverse radix2 operations through the IRDX4 and IRDX2 commands.

The FFT kernel calculates the inverse radix according to the following equation:

$$f(n) = \sum_{k=0}^{N-1} F(k)\, e^{+j2\pi nk/N}$$

Figure 45-33. Inverse radix equation

The inverse radix commands are similar to the RDX4 and RDX2 commands, however RDX2 command supports the REAL_FFT bit, but there is no such corresponding bit in IRDX2.

45.9.7.9.2 Combined FFT8, FFT16 and FFT32

With a low round and step count, the pipeline stages limit the reachable performance. Fewer pipeline stages would result in an increase in hardware and power. This drawback appears especially with a high count of FFT8, FFT16 and FFT32 operations.

To overcome this issue, FFT8, FFT16 or FFT32 operations can be aggregated. The operations are combined in a way that the first round is executed together for a number of different sets of input data, as defined by the vector length. The vector length must be a value dividable by 8,16 or 32, as the case may be. After the complete vector has been processed in the first round, the second round and third round(for FFT32) are executed. The result of this operation gives N times the individual FFTs, where N which is the vector length divided by 8,16 or 32, also denotes the number of aggregated sets of input data. The speed-up results from the fact that pipelining contributes only once to the operation time within a round.

Note: Even when the combined FFT8, FFT16 or FFT32 option is in use, only 8, 16 or 32 twiddles respectively need to be stored in all the twiddle RAM slices regardless of the vector size.

45.9.7.9.3 2^odd FFT

FFTs with a size that is an odd power of two (e.g. 8, 32, 128, 512, 2048) cannot be built from Radix4 operations solely. They are constructed from Radix4 rounds and a final Radix2 round. For instance, 512 point FFT can be constructed by 4 RDX4 instructions(0-3 rounds) and last round(4) as RDX2 instruction.

45.9.7.9.4 Real Number FFT

A lot of typical FFT operations in RADAR processing are just with real input data. The FFT algorithm is defined in a generic way and does not need to be aware of input data with all zero imaginary components, however a real only FFT can be about twice as fast than its complex counterpart. There are two basic options to implement a real number only N-point FFT:

- by extending the real number with a zero imaginary part and performing the N point FFT
- by mixing two N point real data to N point complex data and performing N point complex FFT. Then split the 2 outputs by using Radix2 command with REAL_FFT field set.

The first option has trivial implementation, however it suffers performance bottlenecks. The second option generates a complex vector by setting the real part to vector1 and the imaginary part to vector2. Afterwards, an complex N point FFT is performed, which delivers a merged result for the FFTs of both input vectors. A final decomposition round is required to separate the results for both input vectors. Depending on the vector size, the second option is nearly twice as efficient as the first option, only the decomposition round represents a small penalty.

The first option is the default option, when real data are used. The complex part is set to zero during DMA transfer or by an explicit copy instruction. The second option requires an additional copy instruction to construct the input vector and an additional round with Radix2 butterflies(REAL_FFT set).

45.9.7.9.5 Adaptive scaling

The adaptive scaling feature is optional for rdx2 and rdx4 and also irdx4 and irdx2 commands, and is not applicable to FIR and WIN and SCP commands.

For rdx2 and rdx4 and also irdx4 and irdx2 operations, as output data is being written to the OPRAM, an MSB occupation counter checks the number of unoccupied MSB bits in the entire output data chunk. This counter value gives an idea of the attenuation of the output and therefore also of the amount of magnification possible.

In the next round the input data before being given to the butterflies is shifted left by the amount previously calculated by the MSB occupation counter. This helps to increase the resolution of the FFT operation.

During adaptive scaling, in round=0 only, the normal pre-shift value specified by the command word is given to the barrel shifter before the butterflies. In round>0 the value calculated by the MSB occupation counter is given to the barrel shifter, the pre-shift value is ignored.

The value of MSB occupation counter is not allowed to exceed 4 in any cycle. Thus the total shift cannot exceed 24 left shifts.

At the end of every command the accumulated value of shifts that have already occurred is stored in the work register specified in the command word. Also, each work register can store 8 such accumulated values at different offsets. This offset value is also supplied in the command word. The next round shift value remains stored only in the MSB occupation counter. This makes it necessary that the different rounds of the FFT operation be performed continuously one after the other.

The command word also decides whether the MSB occupation counter counts unoccupied bits from bit 23 downwards or from bit 15 downwards.

It should be noted that in case of indirect memory access, the work register chosen to read source and destination addresses should not be the same as the register to which the accumulated shift values are stored at the end of each command

Figure 45-34 shows the FFT operation with adaptive scaling enabled.

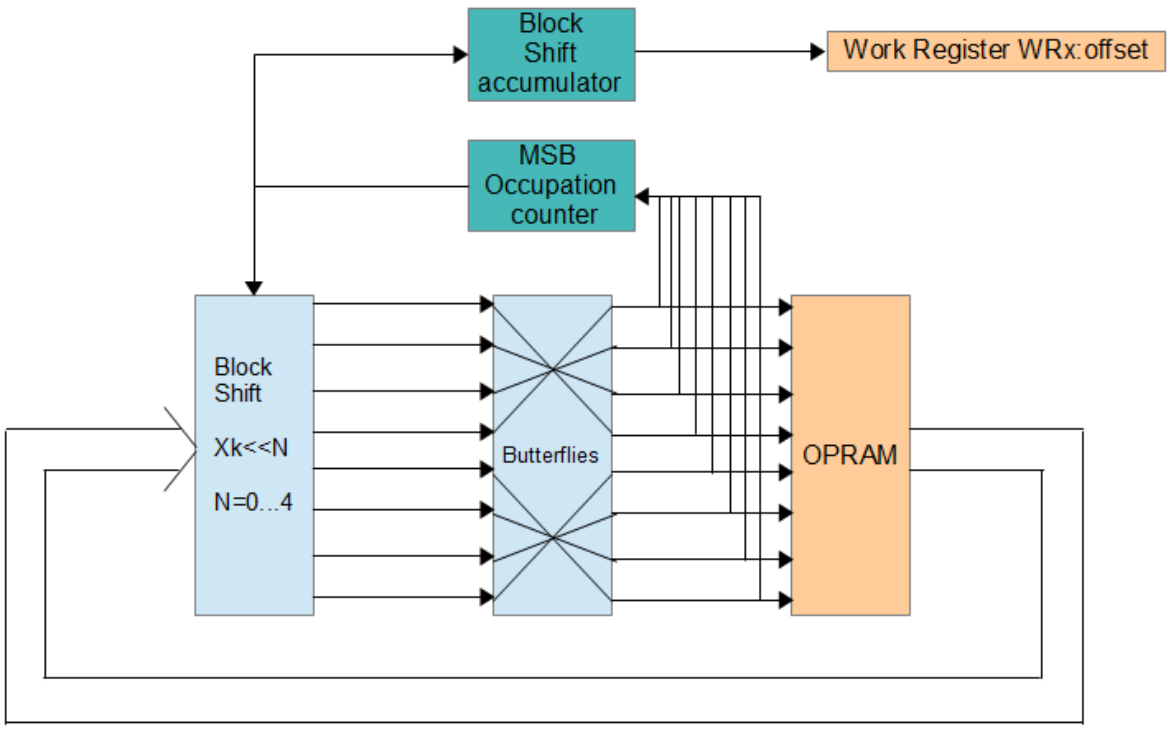

Figure 45-34. FFT operation with adaptive scaling enabled

45.9.7.9.6 Scalar Product

Scalar Product operation can be performed using the Radix 4 or Radix 2 kernels by executing the SCP command. Scalar product is basically a multiply-add operation. SCP allows scalar product operations with 2, 4 or 8 coefficients. The command requires eight operands each cycle, so the vector length should be a multiple of eight. When 2-coefficient scalar product is calculated then four output values are given out each cycle and stored at consecutive locations. When 4-coefficient scalar product is calculated then two output values are given out each cycle and stored at consecutive locations. When 8-coefficient scalar product is calculated then one output values is given out each cycle and stored at consecutive locations.

The 8-coefficient operation is possible by a slight modification in the Radix4 butterfly structure. The complex multipliers multiply the coefficients with the inputs operands and the eight products from the two butterflies are then added together.

The command word for SCP must give the twiddle RAM address where the coefficients are stored. In case of 4-coefficient case the coefficients come from slice0 to slice3 of TRAM for both the products. In case of 2-coefficient case the coefficients come from slice0 and slice1 of TRAM for all the four products.

For the SCP command it is possible to specify the type of TRAM coefficients as complex, real only or imaginary only. In case of real only coefficients it is assumed that the coefficients are all real and stored only in the real part of the TRAM memory locations. In case of imaginary only coefficients it is assumed that the coefficients are all real and stored only in the imaginary part of the TRAM memory locations.

It is intended that the coefficients or operands be filled such that they give unity gain for filter output. This gain is defined with respect to a 4-coefficient scalar product. Thus if an 8-coefficient operation is being done then the coefficients can be half the magnitude. If a 2-coefficient operation is done then to achieve unity gain the coefficients can be similar to the 4-coefficient case but the operands are doubled by enforcing a left-shift by 1 position through the command word.

Figure 45-35 shows the kernel operation for 8-coefficient, 4-coefficient and 2-coefficient operations.

Table 45-41. RDX4 Instruction bit description

Bits	Bit Field	Description
[121]	IN_DATTYP	Input data type
		0 - Real
		1 - Complex
[120:119]	WIN_TYPE	Indicates the type of window coefficients
		00 - Windowing is not enabled
		01 - complex window coefficients
		10 - window is real and stored in the imaginary part of every TRAM memory location
		11 - window is real and stored in the real part of every TRAM memory location
[118:116]	FFT_RND	FFT Round
		000-Round 0 (Reversed Input Stage)
		001-Round 1 (Highest for FFT16 & 32)
		010-Round 2 (Highest for FFT64 & 128)
		011-Round 3 (Highest for FFT256 & FFT512)
		100-Round 4 (Highest for FFT1024 & FFT 2046)
		101-Round 5 (Highest for FFT4096)
		110 and 111-Reserved
[114]	ADPTV	0 - Adaptive scaling not enabled
		1 - Adaptive scaling enabled
[113]	ADPTV_SHFT	1 - MSB occupation counter counts unoccupied bits from bit 23 downwards
		0 - MSB occupation counter counts unoccupied bits from bit 15 downwards
[112]	QUAD_EXT	Quadrature Extension
		0 – No quadrature extension
		1 – Quadrature extension used
[111:110]	REPEAT	Decides whether combined fft operation is enabled or not
		00 - No combined fft operation
		01 - Combined FFT8, for vector length/8 x FFTs
		10 - Combined FFT16, for vector length/16 x FFTs
		11 - Combined FFT32, for vector length/32 x FFTs
[109]	IMA	Indirect memory addressing

Table continues on the next page...

Table 45-41. RDX4 Instruction bit description (continued)

Bits	Bit Field	Description
		0 - Immediate memory addressing
		1 - Indirect memory addressing for source and destination addresses
[108:96]	VEC_SZ	Vector size/length
[95:80]	SRC_ADD	Source address
[79:64]	DEST_ADD	Destination address
[63:48]	MULT_COEF_ADD	Twiddle or Multiplier Coefficient address
[47:40]	SRC_ADD_INC	Source address increment
[39:32]	DEST_ADD_INC	Destination address increment
[31:28]	MCA_MOD	Multiply Coefficient Address modulo value, modulus is 2^n this entry (only valid with window)
		0000 - no modulo calculation
		0001- modulo 2
		0010- modulo 4
		0011- modulo 8
		0100- modulo 16
		0101- modulo 32
		0110- modulo 64
		0111- modulo 128
		1000- modulo 256
		1001 to 1111- modulo 512
[27:25]	ADPTV_OFFSET when SHFTVAL_SRC = 0 & FFT_RND > 0	This offset value gives the location in a Work Register where the accumulated Block Shift value is written at the end of every fft round
		000 - Value written in bits 5:0 of Work Register
		001 - Value written in bits 11:6 of Work Register
		010 - Value written in bits 17:12 of Work Register
		011 - Value written in bits 23:18 of Work Register
		100 - Value written in bits 29:24 of Work Register
		101 - Value written in bits 35:30 of Work Register
		110 - Value written in bits 41:36 of Work Register
		111 - Value written in bits 47:42 of Work Register
	ADPTV_OFFSET when SHFTVAL_SRC = 1 & FFT_RND = 0	This field gives the offset in a Work Register from where shift value for pre-scaling is obtained
		000 - Value comes from bits 5:0 of WR
		001 - Value comes from bits 11:6 of WR
		010 - Value comes from bits 17:12 of WR
		011 - Value comes from bits 23:18 of WR
		100 - Value comes from bits 29:24 of WR
		101 - Value comes from bits 35:30 of WR
		110 - Value comes from bits 41:36 of WR

Table continues on the next page...

Table 45-41. RDX4 Instruction bit description (continued)

Bits	Bit Field	Description
		111 - Value comes from bits 47:42 of WR
[24:16]	MCA_INC	Multiply Coefficient Address Increment, Address offset from coefficient to coefficient
[15:10]	ADPTV_WRNUM when SHFTVAL_SRC = 0 & FFT_RND > 0	Gives the Work Register index where the accumulated Block Shift value is written at the end of every fft round
	ADPTV_WRNUM when SHFTVAL_SRC = 1 & FFT_RND = 0	Gives the index of Work Register from where the pre-scaling left shift value is obtained
[9:8]	MULT_MOD	Mult Mode
		00 - Mode 0 - multiply with a single 32-bit complex immediate value
		01- Mode 1 - multiply with a single 32-bit complex constant from coefficient address (twiddle RAM address or work register index).
		10- Mode 2 - increment and modulus applied after every Radix4 step. coeff_addr = coeff_base_addr + ((step*MCA_INC) % MCA_MOD) * 8 + m where step denotes the step number. This step number = 0 in the first clock cycle, 1 in the second clock cycle, etc. MCA_INC = the address increment value MCA_MOD = modulo value m = 0 to 7, is the index of the address generated in a single step (out of the 8 addresses)
		11- Reserved
[7]	SHFTVAL_SRC	Gives the source from where the pre-scaling left shift value is obtained. In case WIN_TYPE > 0 this field should be SET only if MULT_MOD != 0, else there is an error indication.
		0 - Value comes from the command word
		1 - Value comes from Work Register
[6:4]	SHFT_VAL	Pre-scaling left shift value
		000 – no shift
		001 – shift left 1 bit
		010 - shift left 2 bits
		011 - shift left 3 bits
		100 - shift left 4 bits
		101 to 111 - shift left 8 bits
[2:0]	TW_OVS	Twiddle Oversampling - to use stored Wn with n > k*vector length
		0000 – no oversampling
		0001 – oversampling factor of 2
		0010 – oversampling factor of 4
		0011 – oversampling factor of 8
		0100 – oversampling factor of 16
		0101 - oversampling factor of 32

Table continues on the next page...

Table 45-41. RDX4 Instruction bit description (continued)

Bits	Bit Field	Description
		0110 – oversampling factor of 64
		0111 – oversampling factor of 128
		1000 – oversampling factor of 256
		1001 to 1111 - oversampling factor of 512

Radix2 Instruction

The table below shows the instruction bit encoding used for Radix2(RDX2) Command. The details of each bit field is defined in the sections below.

Table 45-42. RDX2 Instruction

127	126	125	124	123	122	121	120	119	118	117	116	115	114	113	112

Table 45-45. FIR Instruction bit description

Bits	Bit Field	Description
[121]	IN_DAT_TYP	Input data type
		0- Real data
		1 - Complex data
[120:119]	WIN_TYPE	Indicates the type of window coefficients
		00 - complex window coefficients
		01 - complex window coefficients
		10 - window is real and stored in the imaginary part of every TRAM memory location
		11 - window is real and stored in the real part of every TRAM memory location
[116]	INIT	Decides which type of initialization process is to be performed during FIR operation
		0 - Zero run-in initialization performed
		1 - Constant run-in initialization performed
[115:112]	NO_OF_TAPS	Gives the number of taps in the FIR filter
		0000 - 2 tap filter
		0001 - 2 tap filter

Table continues on the next page...

Table 45-45. FIR Instruction bit description (continued)

Bits	Bit Field	Description
		0010 - 2 tap filter
		0011 - 3 tap filter
		0100 - 4 tap filter
		0101 - 5 tap filter
		0110 - 6 tap filter
		0111 - 7 tap filter
		1000 to 1111 - 8 tap filter
[109]	IMA	Indirect memory addressing
		0 - Immediate memory addressing
		1 - Indirect memory addressing for source and destination addresses
[108:98]	VEC_SZ	Vector size/length, should be a multiple of 8
[95:80]	SRC_ADD	Source address
[79:64]	DEST_ADD	Destination address
[63:48]	TAP_COEFF_ADD	Gives the twiddle RAM address where the tap coefficients for the FIR filter are stored
[47:40]	SRC_ADD_INC	Source address increment
[39:32]	DEST_ADD_INC	Destination address increment
[27:25]	SHFTVAL_OFST	This field gives the offset in a Work Register from where shift value for pre-scaling is obtained
		000 - Value comes from bits 5:0 of WR
		001 - Value comes from bits 11:6 of WR
		010 - Value comes from bits 17:12 of WR
		011 - Value comes from bits 23:18 of WR
		100 - Value comes from bits 29:24 of WR
		101 - Value comes from bits 35:30 of WR
		110 - Value comes from bits 41:36 of WR
		111 - Value comes from bits 47:42 of WR
[15:10]	SHFTVAL_WR_NO	Gives the index of Work Register from where the pre-scaling left shift value is obtained
[7]	SHFTVAL_SRC	Gives the source from where the pre-scaling left shift value is obtained
		0 - Value comes from the command word

Table continues on the next page...

Table 45-45. FIR Instruction bit description (continued)

Bits	Bit Field	Description
		1 - Value comes from Work Register
[6:4]	SHFT_VAL	Pre-scaling before multiplication
		000 - No shift
		001 - Left shift by 1 bit
		010 - Left shift by 2 bits
		011 - Left shift by 3 bits
		100 - Left shift by 4 bits
		101 to 111 - Left shift by 8 bits

45.9.7.11

Inverse Radix4 Instruction

The table below shows the instruction bit encoding used for Inverse Radix4(IRDX4) Command. The details of each bit field are defined in the sections below. For MULT_MODE=0, refer to fields will be as described in WIN Instruction (MULT_MODE =00)

Table 45-46. IRDX4 Instruction (MULT_MODE !=00)

		101 - Value written in bits 35:30 of Work Register
		110 - Value written in bits 41:36 of Work Register
		111 - Value written in bits 47:42 of Work Register
	ADPTV_OFFSET when SHFTVAL_SRC = 1 & FFT_RND = 0	This field gives the offset in a Work Register from where shift value for pre-scaling is obtained
		000 - Value comes from bits 5:0 of WR
		001 - Value comes from bits 11:6 of WR
		010 - Value comes from bits 17:12 of WR
		011 - Value comes from bits 23:18 of WR
		100 - Value comes from bits 29:24 of WR
		101 - Value comes from bits 35:30 of WR
		110 - Value comes from bits 41:36 of WR
		111 - Value comes from bits 47:42 of WR
[24:16]	MCA_INC	Multiply Coefficient Address Increment, Address offset from coefficient to coefficient
[15:10]	ADPTV_WRNUM when SHFTVAL_SRC = 0 & FFT_RND > 0	Gives the Work Register index where the accumulated Block Shift value is written at the end of every fft round

Table continues on the next page...

Table 45-47. IRDX4 Instruction bit description (continued)

Bits	Bit Field	Description
	ADPTV_WRNUM when SHFTVAL_SRC = 1 & FFT_RND = 0	Gives the index of Work Register from where the pre-scaling left shift value is obtained
[9:8]	MULT_MOD	Mult Mode
		00 - Mode 0 - multiply with a single 32-bit complex immediate value
		01- Mode 1 - multiply with a single 32-bit complex constant from coefficient address (twiddle RAM address or work register index).
		10- Mode 2 - increment and modulus applied after every Radix4 step. coeff_addr = coeff_base_addr + ((step*MCA_INC) % MCA_MOD) * 8 + m where step denotes the step number. This step number = 0 in the first clock cycle, 1 in the second clock cycle, etc. MCA_INC = the address increment value MCA_MOD = modulo value m = 0 to 7, is the index of the address generated in a single step (out of the 8 addresses)
		11- Reserved
[7]	SHFTVAL_SRC	Gives the source from where the pre-scaling left shift value is obtained. In case WIN_TYPE > 0 this field should be SET only if MULT_MOD = 0, else there is an error indication.
		0 - Value comes from the command word
		1 - Value comes from Work Register
[6:4]	SHFT_VAL	Pre-scaling left shift value
		000 – no shift
		001 – shift left 1 bit
		010 - shift left 2 bits
		011 - shift left 3 bits
		100 - shift left 4 bits
		101 to 111 - shift left 8 bits
[2:0]	TW_OVS	Twiddle Oversampling - to use stored Wn with n > k*vector length
		0000 – no oversampling
		0001 – oversampling factor of 2
		0010 – oversampling factor of 4
		0011 – oversampling factor of 8
		0100 – oversampling factor of 16
		0101 - oversampling factor of 32
		0110 – oversampling factor of 64
		0111 – oversampling factor of 128
		1000 – oversampling factor of 256
		1001 to 1111 - oversampling factor of 512

		111- Value comes from bits 47:42 of WR
[15:10]	SHFTVAL_WR_NO	If SHFTVAL_SRC is set, then the this field indicates the index of Work Register that gives the shift value
[7]	SHFTVAL_SRC	Gives the source from which value of shift for pre-scaling is obtained
		1- Shift value comes from Work Register
		0- Shift value comes from command word
[6:4]	SHFT_VAL	Pre-scaling before multiplication
		000 - No shift
		001 - Left shift by 1 bit
		010 - Left shift by 2 bits
		011 - Left shift by 3 bits
		100 - Left shift by 4 bits
		101 to 111 - Left shift by 8 bits

45.9.8 COPY

45.9.8.1 Introduction

The copy operation primarily moves N values from one address location to another one. The operation works with 8 operands simultaneously. Many different flavours of the COPY operation are supported. These are described in the following sections.

45.9.8.2 Principle of Operation

The basic copy operation simply copies N vector elements from source address to the destination address. In case of packed operands with REAL or LOG2 data type the number of clock cycles taken by the copy operation is half as compared to a case of unpacked or COMPLEX operands. Many variations and options are available with the COPY hardware accelerator.

It is also possible to copy data from Operand RAM to Twiddle RAM and vice-versa. When copying data from Operand RAM to Twiddle RAM, 16 LSB bits of both real and imaginary operands get copied. Rest of the bits are ignored. This is shown in the figure below.

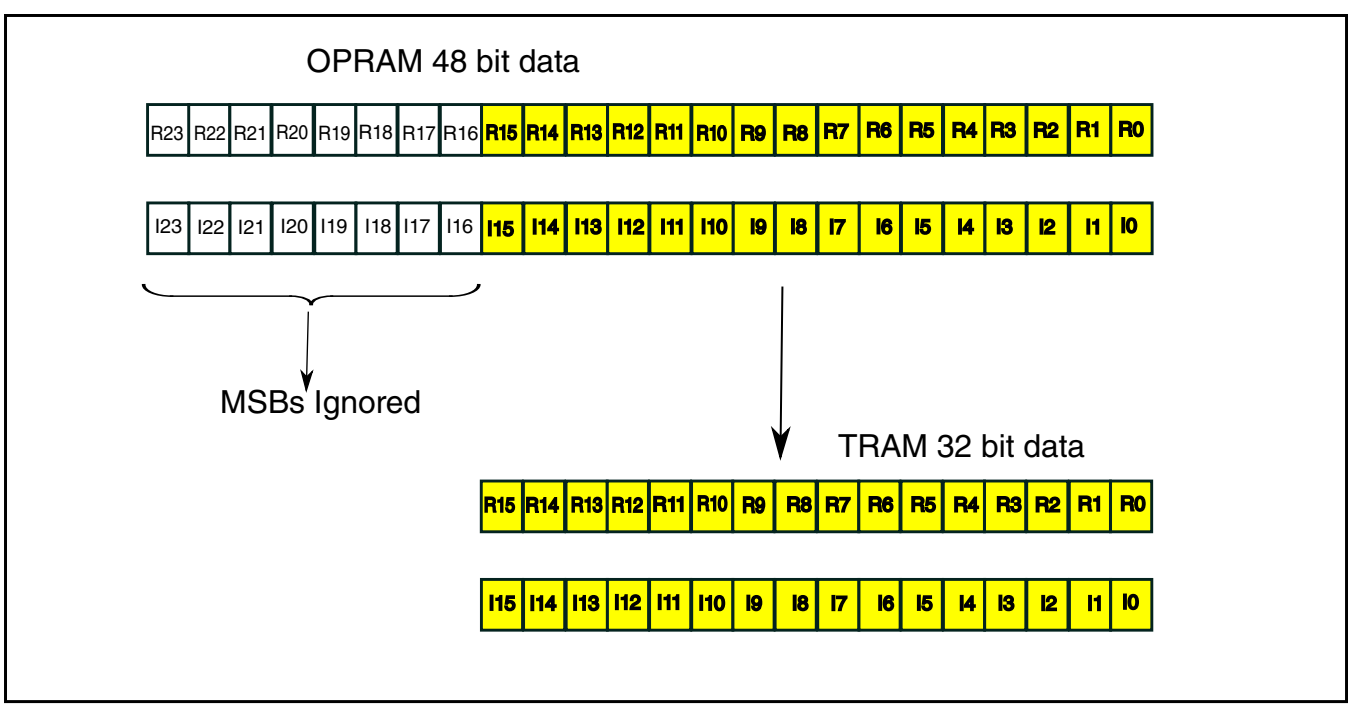

Figure 45-37. OPRAM to TRAM copy

When data is copied from Twiddle RAM to Operand RAM the MSB bit of both real and imaginary operands get extended to fill up the MSB locations. This is shown in the figure below.

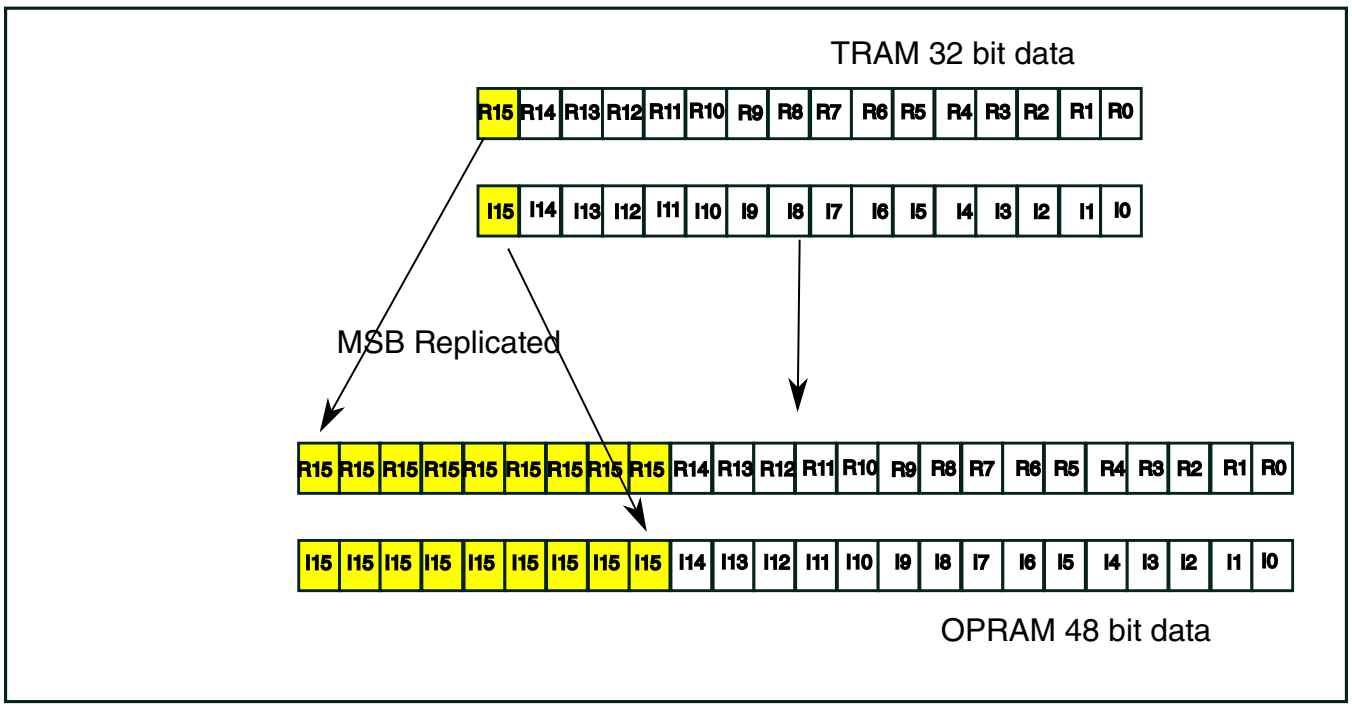

Figure 45-38. TRAM to OPRAM copy

Source and Destination addresses must be a multiple of 8 for all copy types other than Copy Shift operation. In Copy Shift operation the destination address cannot be a multiple of 8.

The different types of copy operations are described in the section below.

45.9.8.2.1 Simple Copy

Simple copy - A simple copy operation copies N elements, where N = VEC_SZ, from the address pointed to by the SRC_ADD to the address pointed to by the DEST_ADD. The source and destination addresses may be incremented for every next read as per the SRC_ADD_INC and DEST_ADD_INC values.

45.9.8.2.2 Threshold Copy

Greater than or equal to threshold copy - A greater than or equal to threshold copy operation copies elements from the SRC_ADD greater than the threshold value, to the DEST_ADD. All other elements are set to 0. The threshold value is stored in the address pointed to by the THLD_ADD. Only one threshold value is used for the entire vector length. Figure 45-39 shows an example of greater than threshold copy.

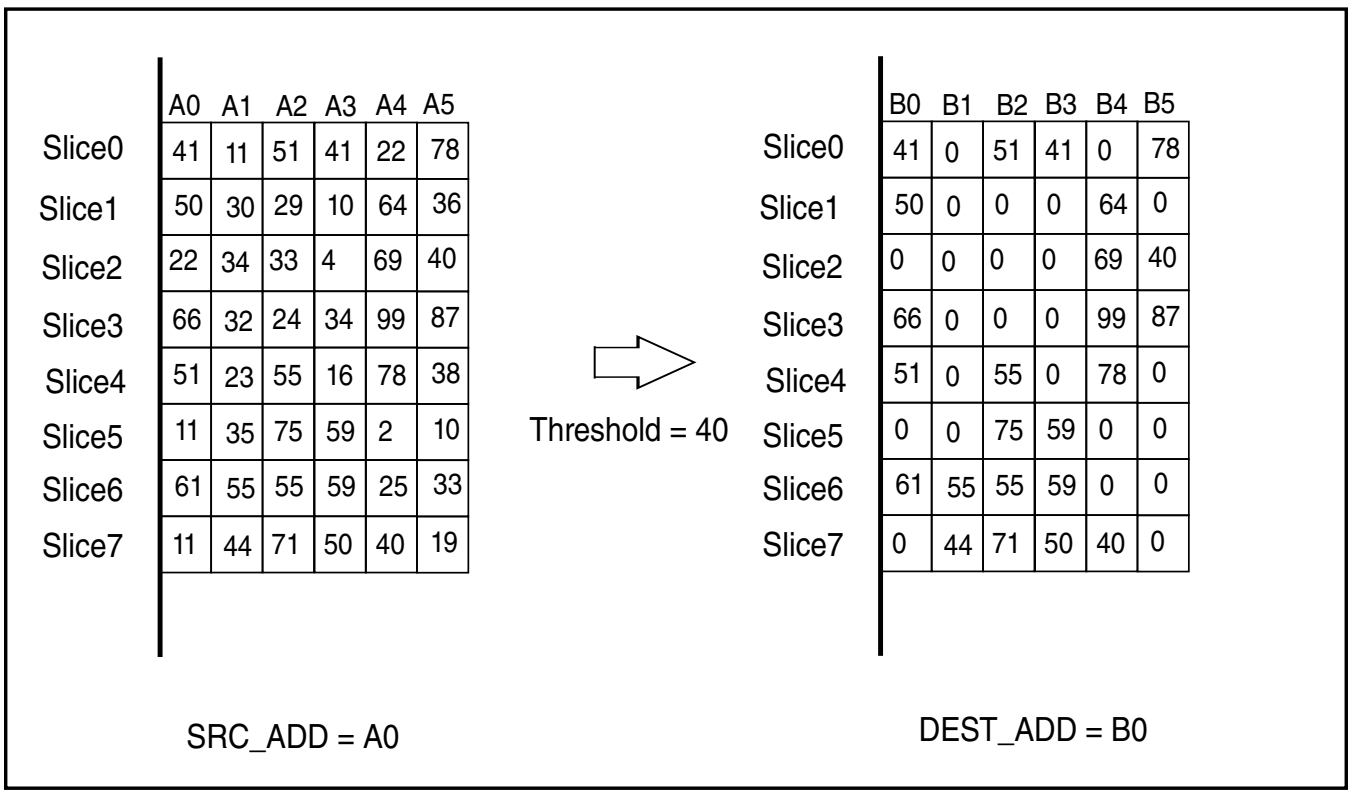

Figure 45-39. Greater than or equal to threshold copy

Less than threshold copy - A less than threshold copy operation copies elements from the SRC_ADD less than the threshold value, to the DEST_ADD. All other elements are set to 0. The threshold value is stored in the address pointed to by the THLD_ADD.

A count of all the elements reset to 0 is kept in WR_R0_RE[REAL_R0]. The RST_ACC bitfield of the instruction when set, resets the accumulated value in this register.

The threshold values are preprocessed values. No preprocessing is done on the threshold values. Only the real part of the THLD_ADD is used as the threshold value. It is advisable to keep the threshold values in one of the work registers. Keeping the threshold values in OPRAM or TRAM leads to lower performance.

45.9.8.2.3 Transpose Copy

Transpose copy - Transposition is a special copy operation that converts a column vector to a row vector and vice versa. Since in that case only 8 input operands are available concurrently, an intermediate buffer is required to perform this operation with sufficient performance. A transpose operation is only done on a matrix of 8x8. An option of block transpose is also provided in which multiple blocks of 8x8 are transposed. The transpose copy is only available with a vector of total length in multiples of 64. Number of 8x8 blocks to be transposed is given by VEC_SZ/64. Figure 45-40 shows as example of transpose copy operation.

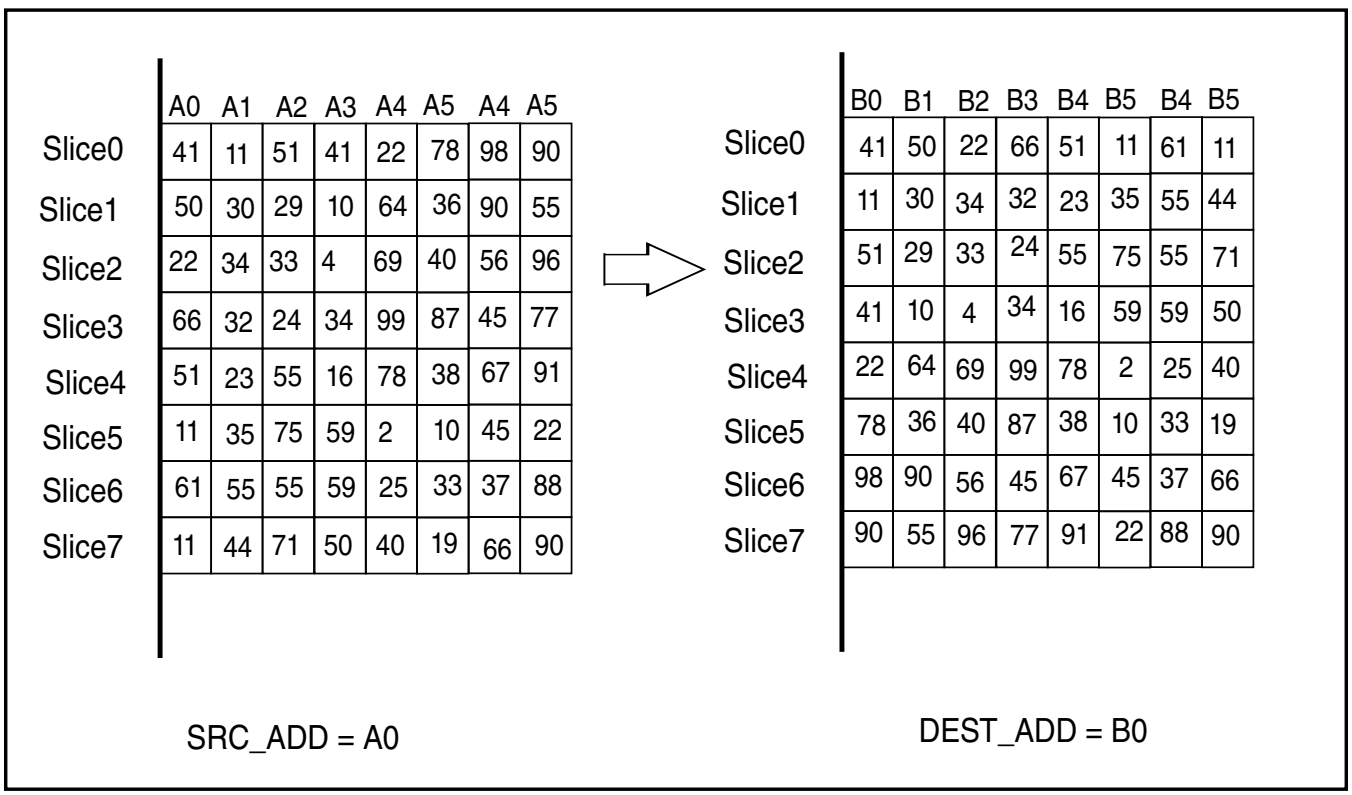

Figure 45-40. Transpose copy

45.9.8.2.4 Copy Real Pack

The copy real pack operation copies the real components from the input operands at the source address and packs them together at the destination address. The operands at the destination address after this operation are all real components in packed format. Figure 45-41 shows an example of copy real pack operation.

For copy real pack operation the VEC_SZ should be a multiple of 16.

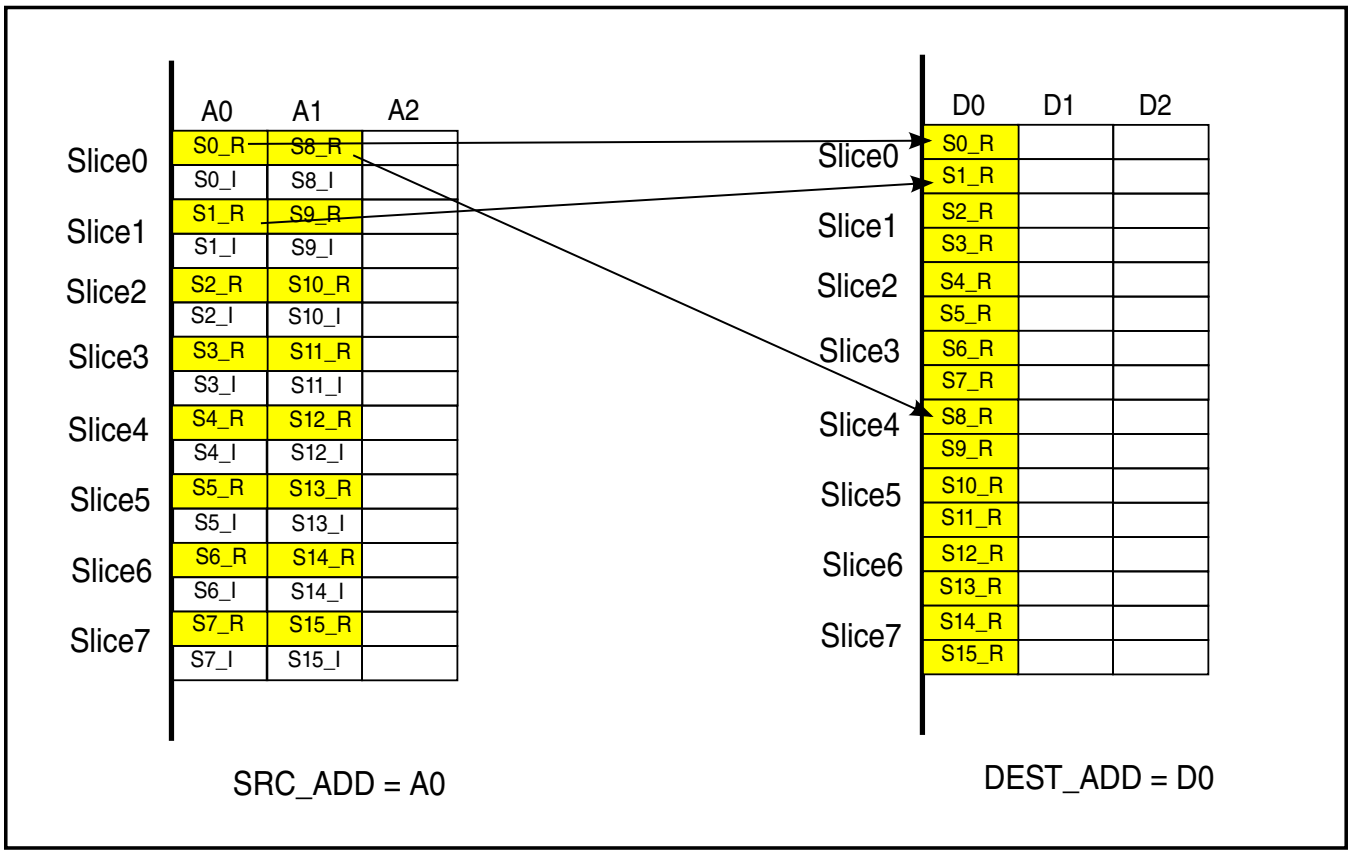

Figure 45-41. Copy real pack

45.9.8.2.5 Copy Imaginary Pack

The copy imaginary pack operation is similar to copy real pack operation except that instead of real components, imaginary components get copied to the destination address. The operands at the destination address after this operation are all imaginary components in packed format. Figure 45-42 shows an example of copy imaginary pack operation.

For copy imaginary pack, VEC_SZ should be a multiple of 16.

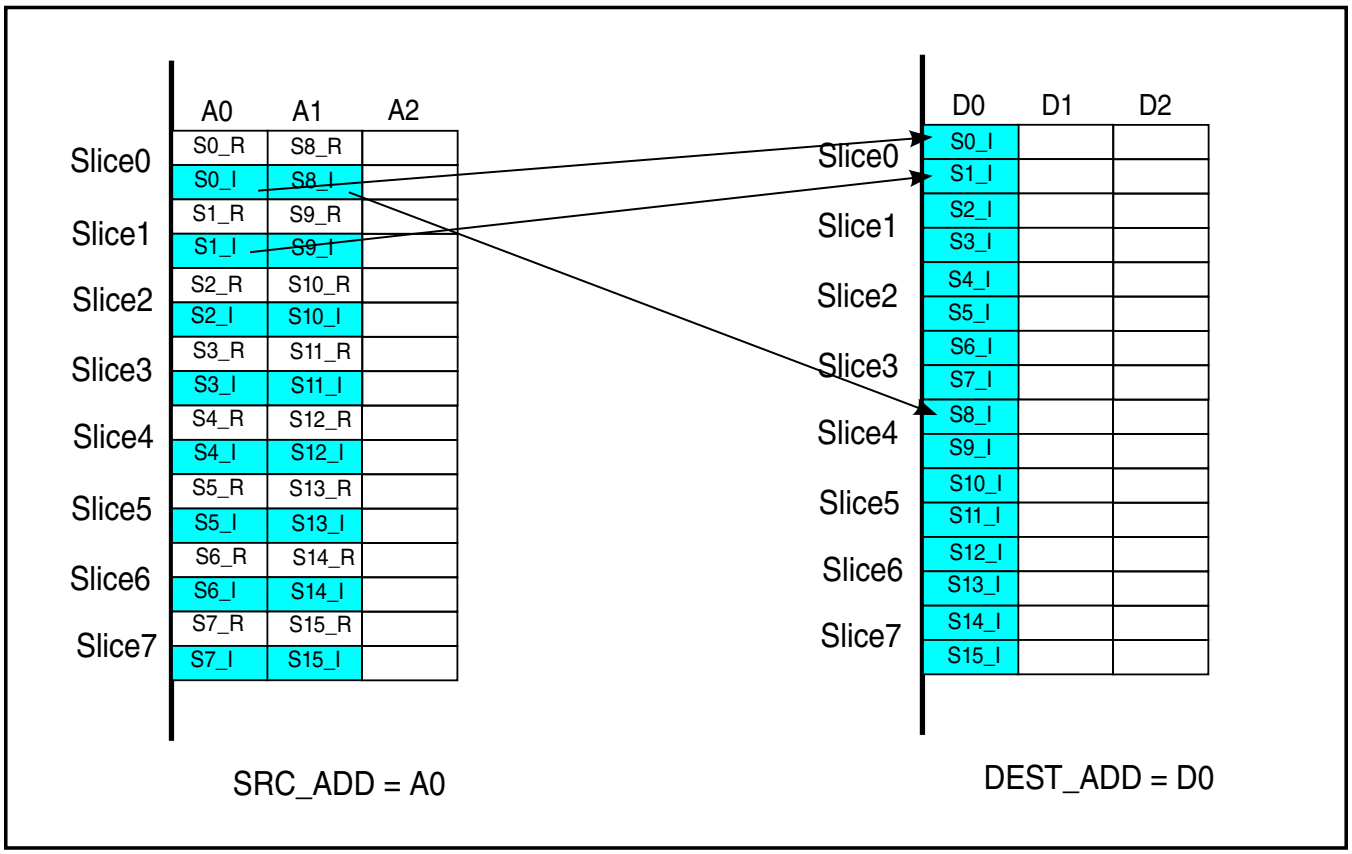

Figure 45-42. Copy imaginary pack

45.9.8.2.6 Copy Unpack

The copy unpack operation is an inverse of the copy pack operations. In the copy unpack operation the real and imaginary components at the source address are unpacked to the real components of the destination address. The imaginary components at the destination address may be kept as is or may be reset. This is decided by the RST_N_KEEP bit of the instruction set.

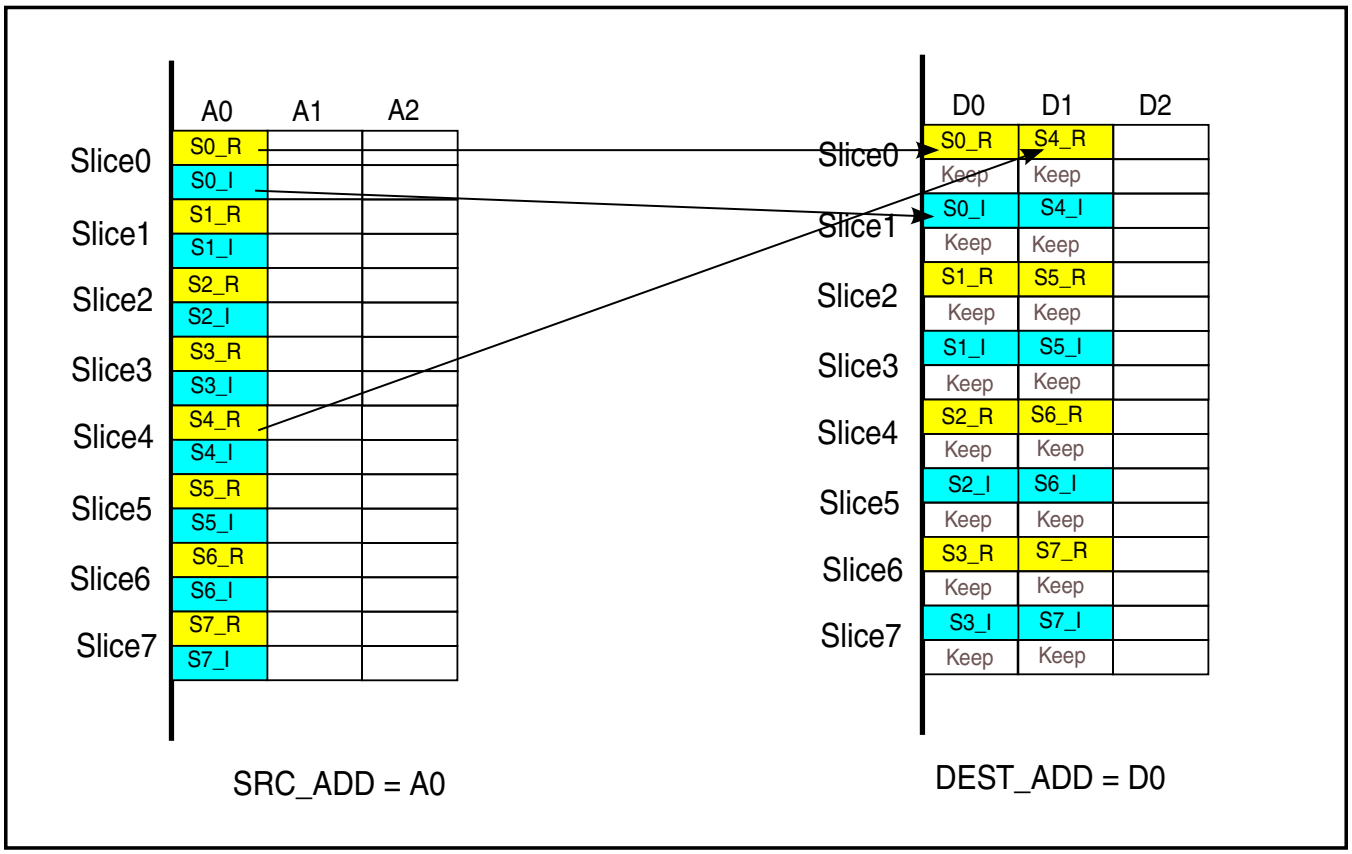

Figure 45-43. Copy unpack

45.9.8.2.7 Partial Copy Real

Partial copy real - The partial copy real operation copies only real operands from the source address to the destination address. The imaginary components at the destination may be kept as is or may be reset. This is decided by the RST_N_KEEP bit of the instruction set.

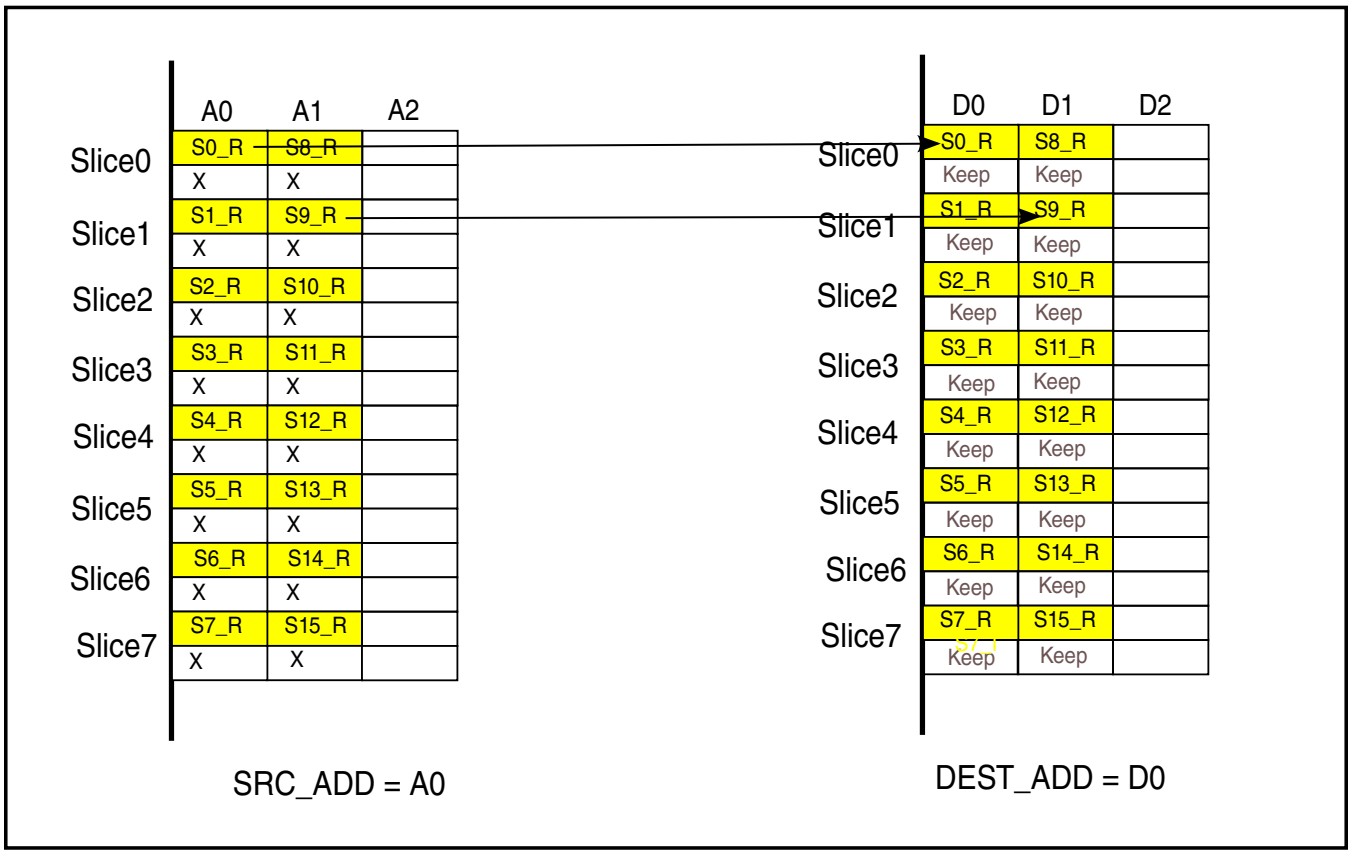

Figure 45-44. Partial copy real

45.9.8.2.8 Partial Copy Imaginary

The partial copy imaginary operation copies only imaginary operands from the source address to the destination address. The real components at the destination may be kept as is or may be reset. This is decided by the RST_N_KEEP bit of the instruction set.

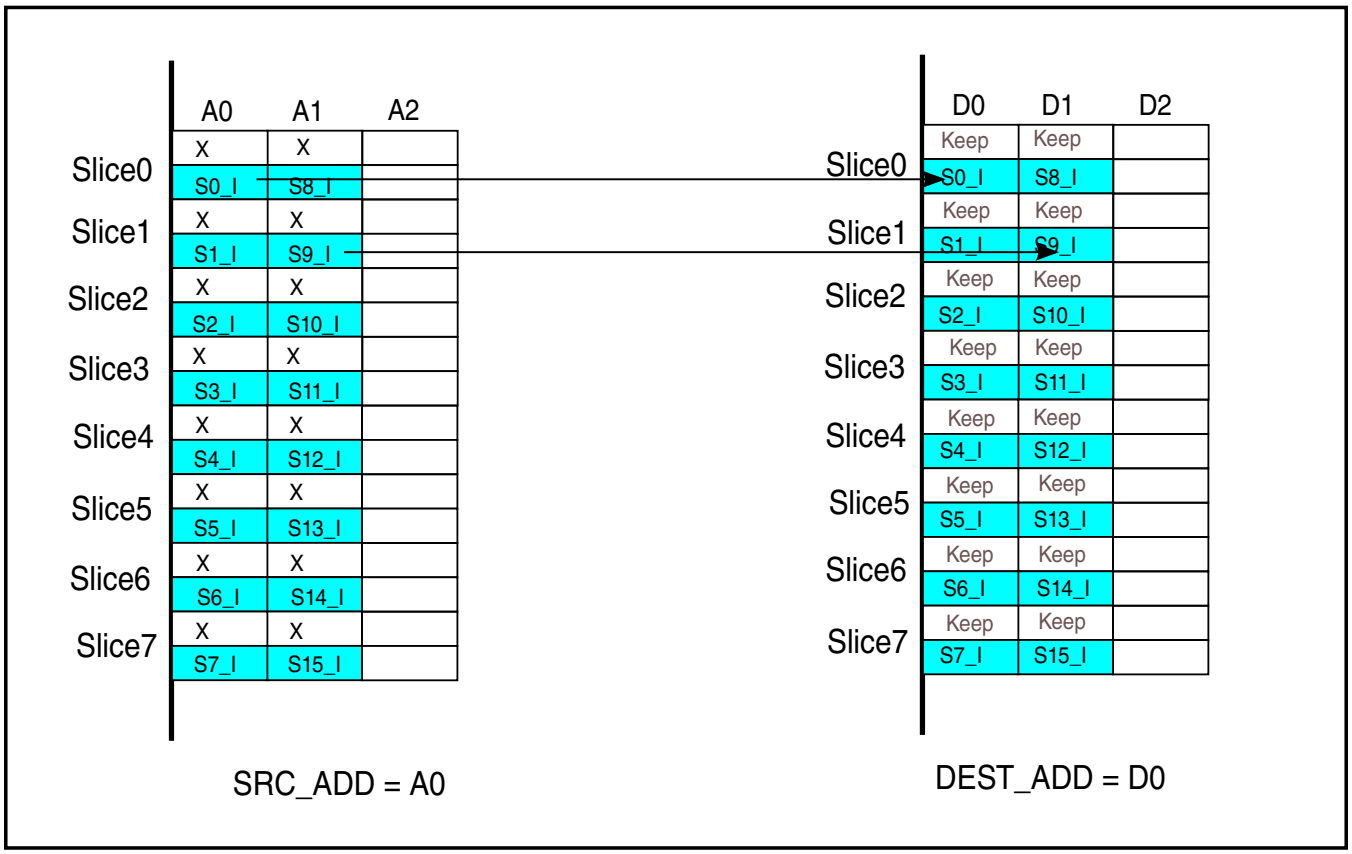

Figure 45-45. Partial copy imaginary

45.9.8.2.9 Partial Copy Real to Imaginary

The partial copy real to imaginary operation copies the real components at the source address to the imaginary components at the destination address. The real components at the destination may be kept as is or may be reset. This is decided by the RST_N_KEEP bit of the instruction set.

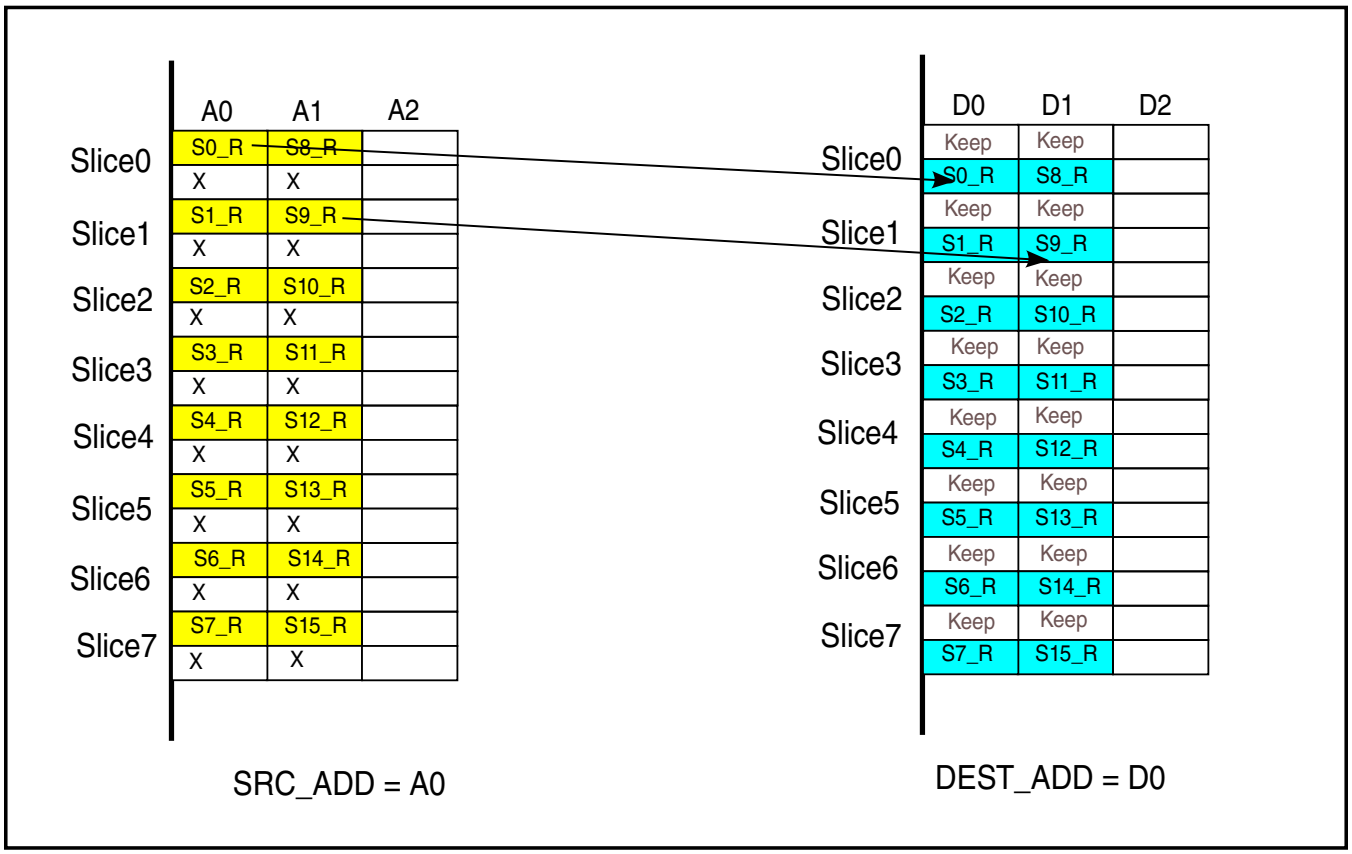

Figure 45-46. Partial copy real to imaginary

45.9.8.2.10 Partial Copy Imaginary to Real

The partial copy imaginary to real operation copies the imaginary components at the source address to the real components at the destination address. The imaginary components at the destination may be kept as is or may be reset. This is decided by the RST_N_KEEP bit of the instruction set.

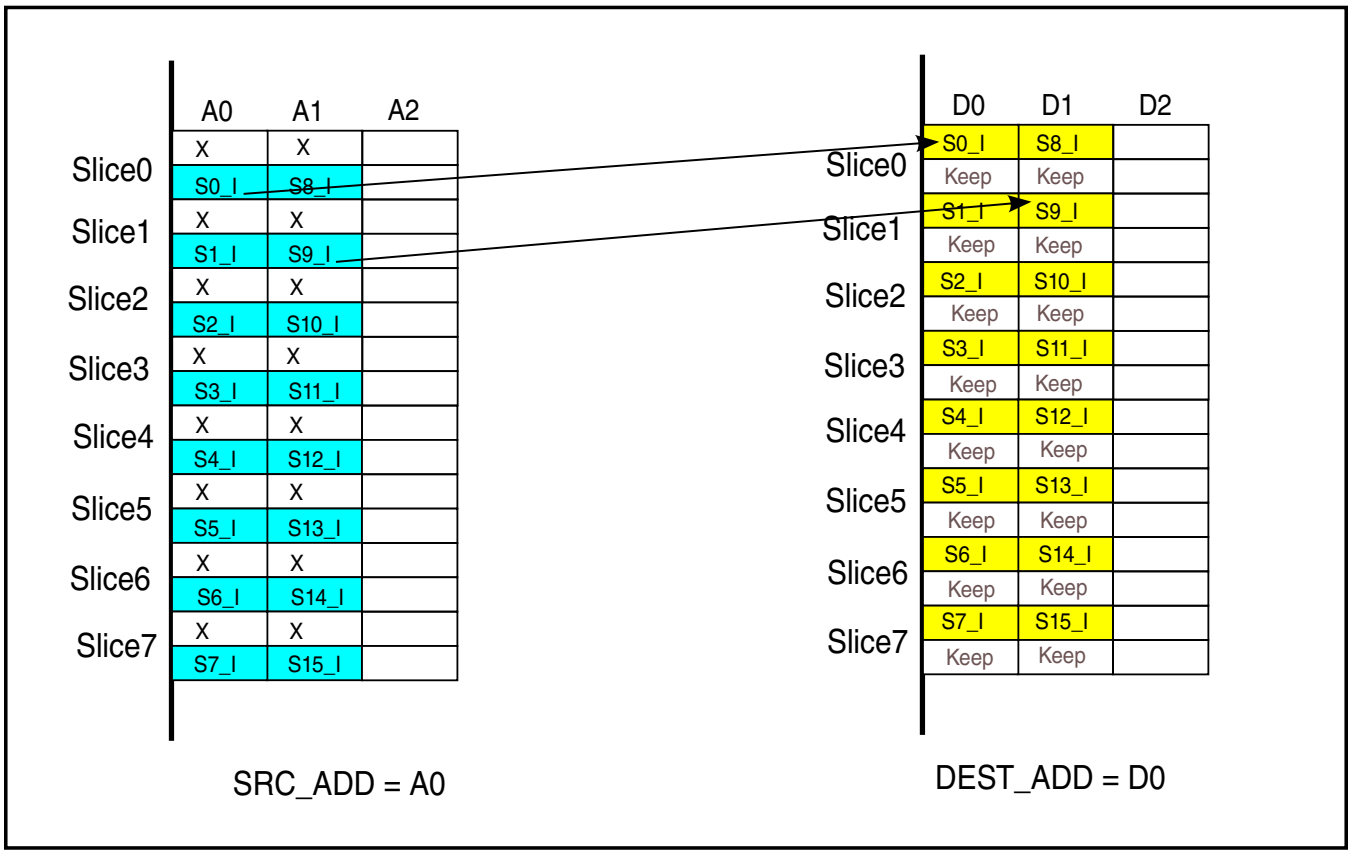

Figure 45-47. Partial copy imaginary to real

45.9.8.2.11 Clear

A clear operation simply overwrites certain elements at the DEST_ADD to 0. The SRC_ADD bitfield in this case is ignored by the controller. Which elements should be overwritten is determined by the MASK bitfield. The MASK bitfield is a 16 bit value where each bit stands for a real or imaginary component. A '1' in any location implies that the particular component is to be cleared. A '0' implies that the particular element is to be kept as is.

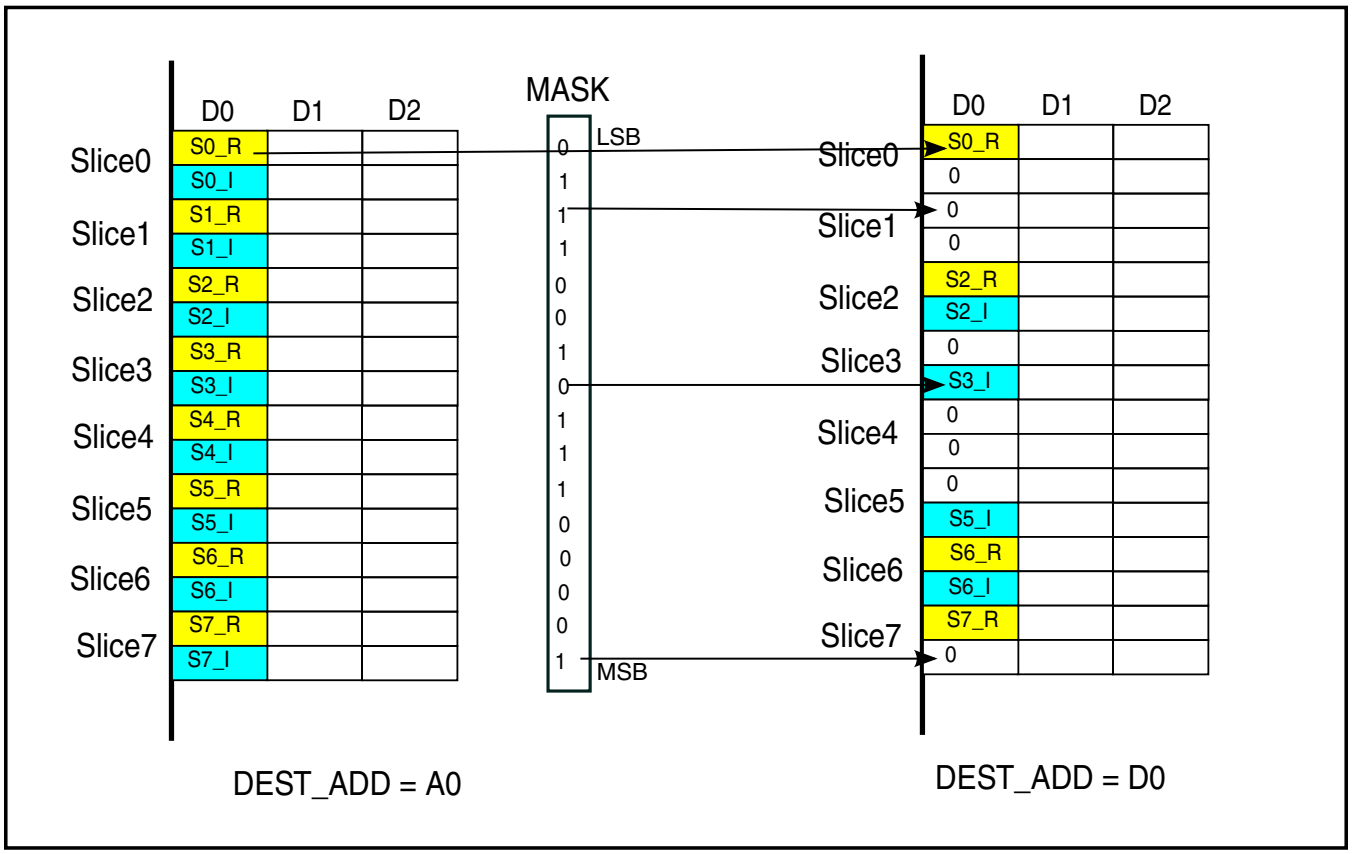

Figure 45-48. Copy clear with mask

45.9.8.2.12 Copy Shift

The copy shift operation copies the input operands at address SRC_ADD and copies them to destination address DEST_ADD just like simple copy operation. However, shift copy allows unaligned destination addresses. Therefore, the last three address bits of DEST_ADD defines the amount of shift. Figure 45-49 shows an example of copy shift operation. It is illegal for a copy shift operation to have an 8 aligned destination address (last three address bits 0). When such a configuration is selected, SPT_HW_ACC_ERR[COPY_IP_CMD_ERR] is set.

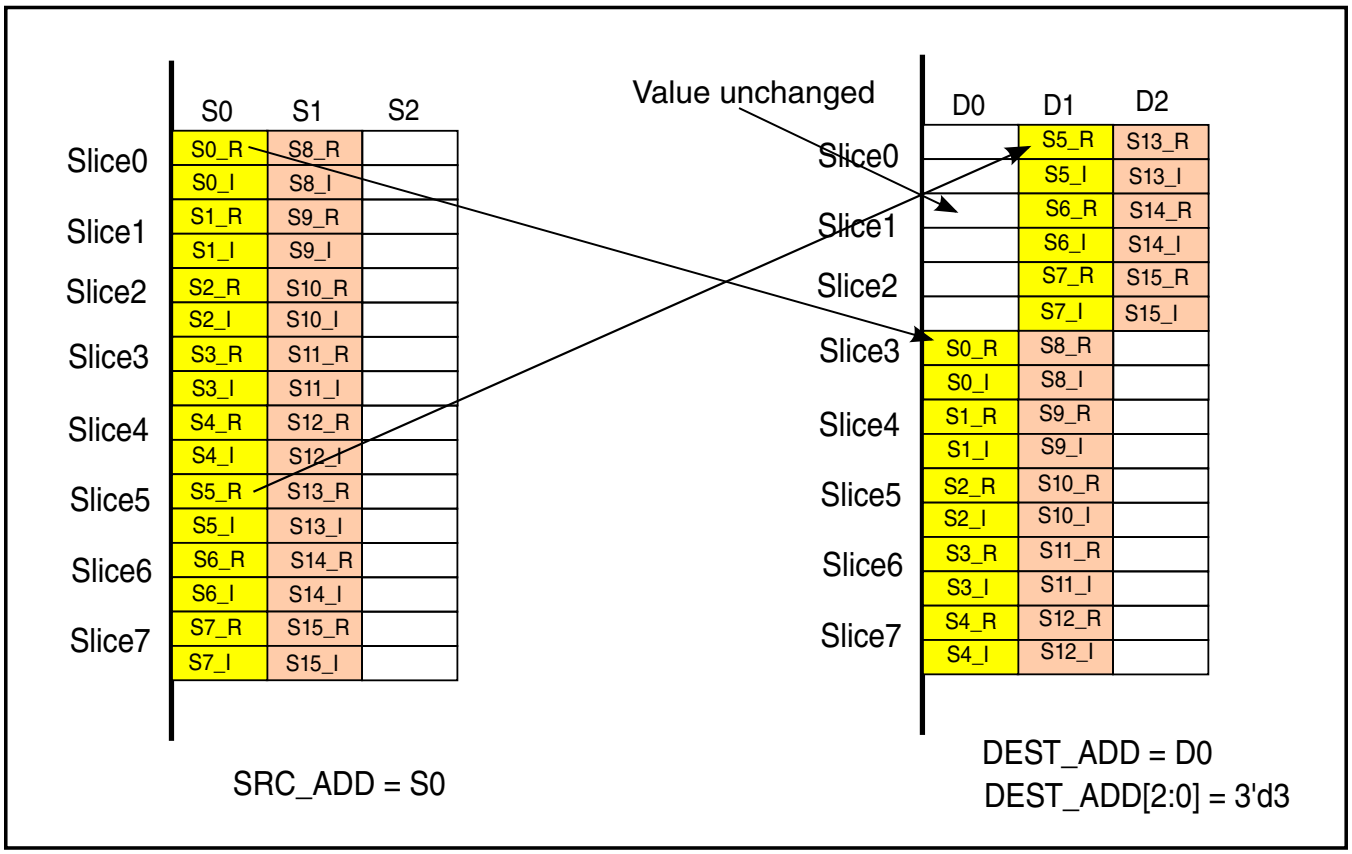

Figure 45-49. Copy Shift

45.9.8.2.13 8x4 Transpose Copy

8x4 Transpose copy - Transposition is a special copy operation that converts a column vector to a row vector and vice versa. Since in that case only 8 input operands are available concurrently, an intermediate buffer is required to perform this operation with sufficient performance. This unaligned transpose operation is done on a matrix of 8x4 (forward) or 4x8 (backward). For forward transpose, one column of 8 is converted into two rows of 4, and vice versa for backward transpose. An option of block transpose is also provided in which multiple blocks of 8x8 are transposed. The transpose copy is only available with a vector of total length in multiples of 64. Number of 8x8 blocks to be transposed is given by VEC_SZ/64. Figure 45-50 shows as example of both forward and backward transpose copy operation.

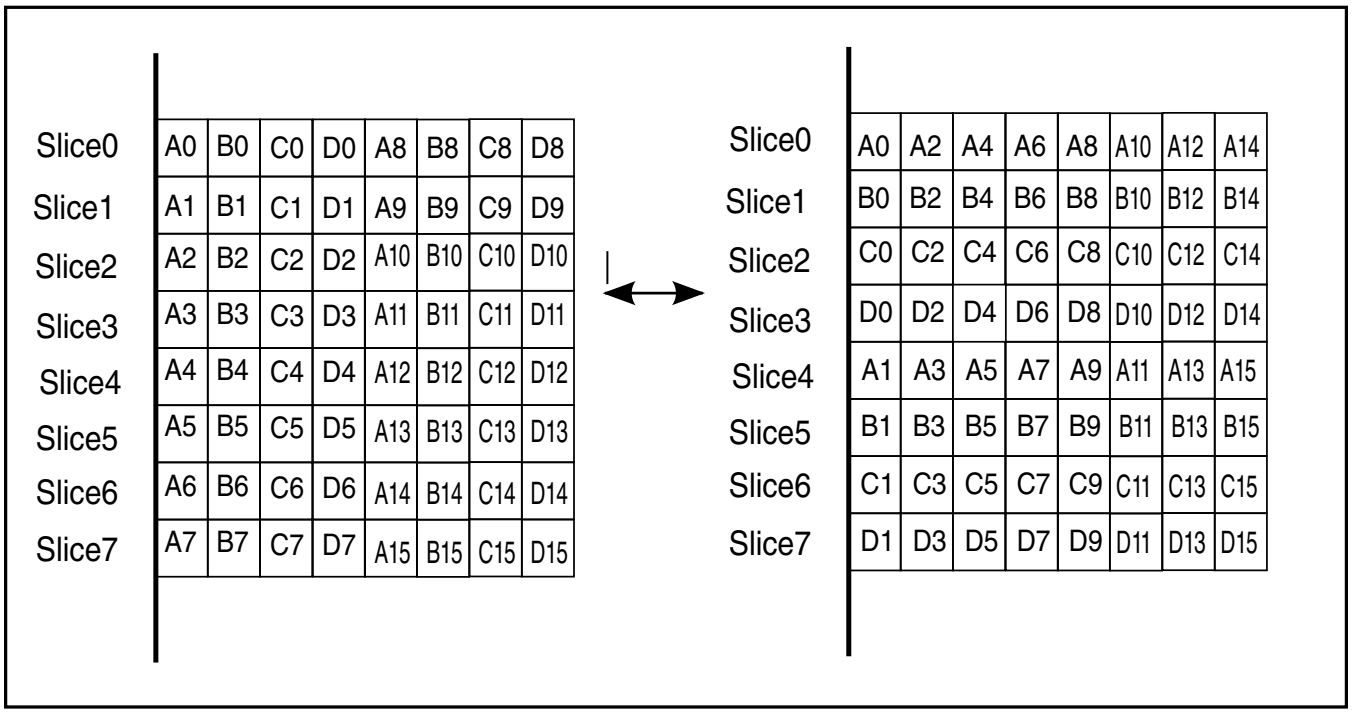

Figure 45-50. 8x4 Transpose copy

45.9.8.3 Copy Instruction Format

The table below shows the instruction bit encoding used for COPY. The details of each bit field and their operation is defined in the sections below.

Table 45-52. COPY Instruction

[31:16]	MASK	Clear mask for clear operation
[15:0]	THLD_ADD	Threshold address

45.9.8.3.1 Block source and destination address increment

Section Transpose Copy describes the copy transpose operation. Copy transpose can work on multiple blocks of 8x8. An option is provided to increment the subsequent block addresses by the increment value. When the block source address increment value is set to a non-zero value, the address for the next 8x8 block fetch of operands is incremented by that value+1. Similarly, when the block destination address increment value is set to a non-zero value, the address of next block write to the memory is incremented by that value+1. By default when the block address increment value is set to 0, the address is incremented by 1 slice location. When the increment is a non-zero value, the address is incremented by (1+increment value) slice locations.

The block source and destination address increment fields are only valid when copy transpose operation is selected. For all other operations these fields are ignored.

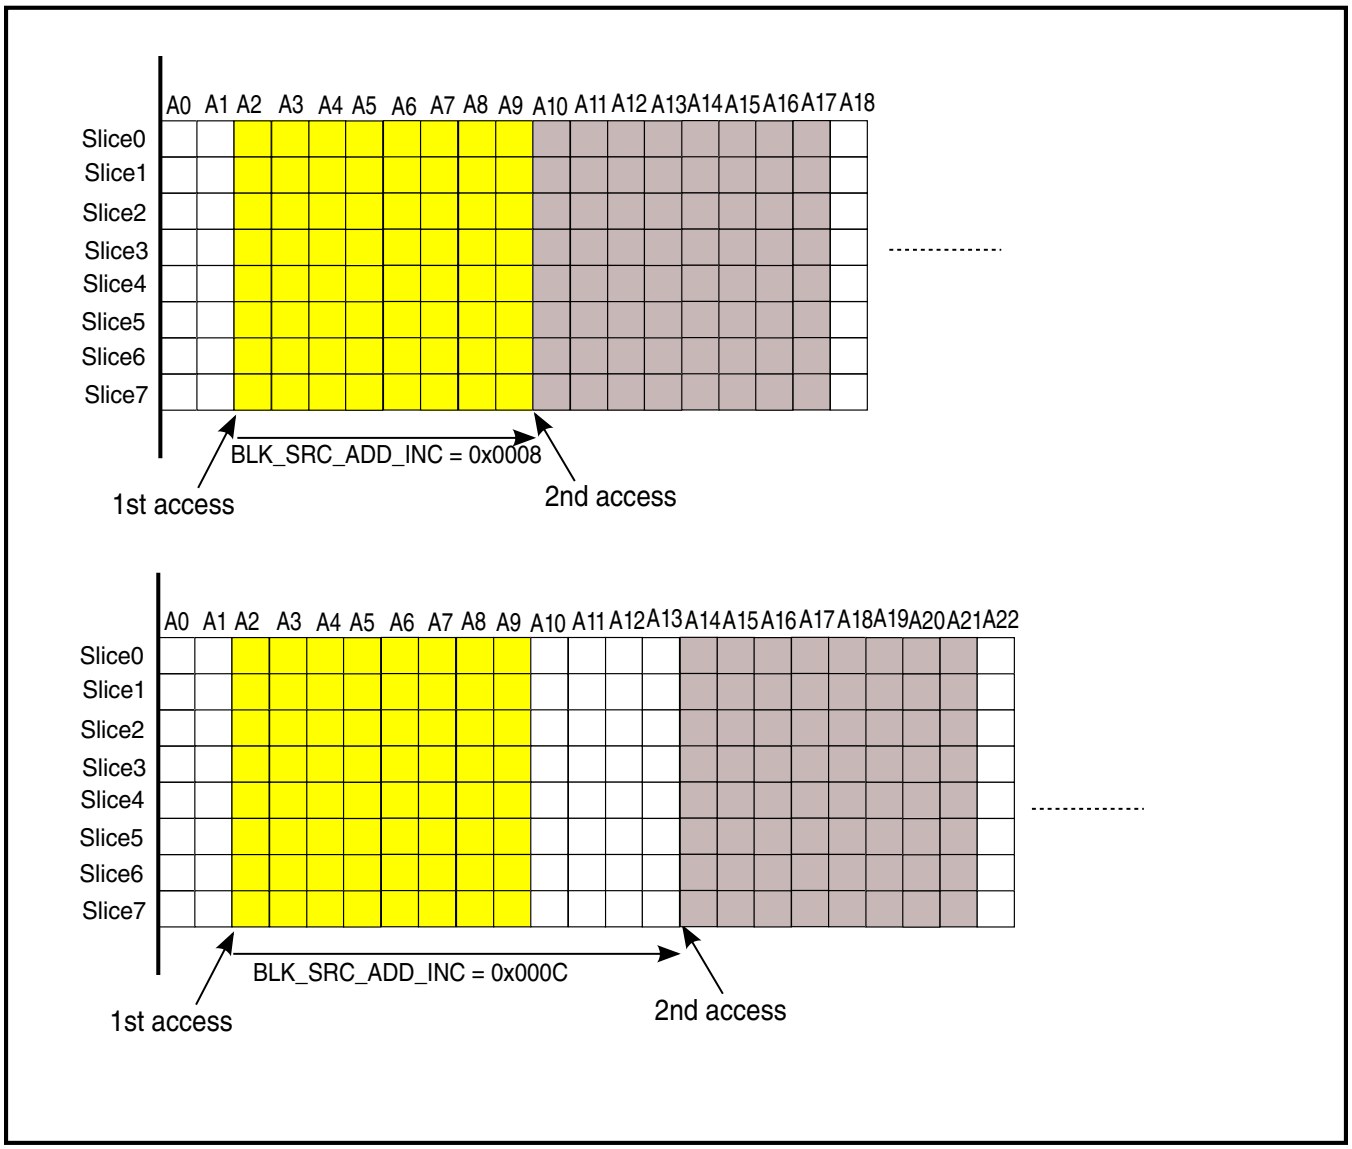

Figure 45-51. Block source address increment example

45.9.9 Programmable DMA

45.9.9.1 Introduction

The PDMA module is used to transfer the data from SPT internal memories (Twiddle RAM and Operand RAM) to system RAM and vice-versa. The PDMA transfer does not support data transfer to/from work register. The module is used to transfer the results of any mathematical operations on the data into the main system RAM via the System bus crossbar.

Transfer is initiated by the command from the sequencer. All the DMA control information comes from sequencer (i.e. input from command). The details of the command is provided in this chapter. The different fields in the command specify information such as the amount of data to be transferred, source and destination address of transfer.

PDMA module is capable of implementing various address schemes both for input and output. This gives software the flexibility to move data from source to destination seamlessly.

Apart from this, the module is capable of performing aggregation or compression/ decompression operation on-the-fly. This helps in reducing the data flow toward arbiter. The various compression schemes supported allow PDMA to compress the incoming data by various compression ratios thereby reducing the data traffic on the crossbar.

The PDMA is connected to the arbiter along with SDMA and command sequencer. The priority of access is highest for SDMA followed by PDMA and then the command sequencer.

All the register of the SPT blocks are implemented at common register interface. The status registers allow the PDMA to inform the software about any error condition encountered or the current number of words being transferred to the destination

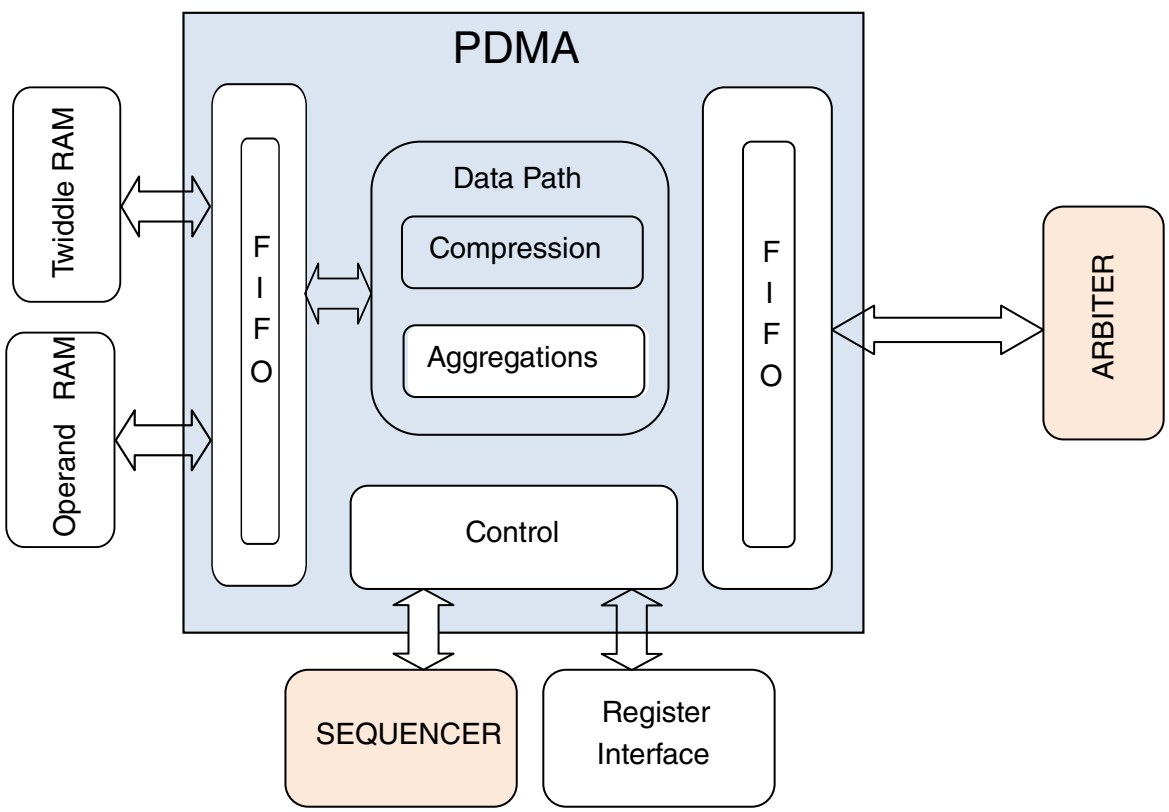

Figure 45-52. PDMA block diagram

45.9.9.2 Features

PDMA module has following features:

- PDMA data transfer is initiated by the sequencer and it provides the current status to the sequencer
  - One data transfer instruction is active at a time
- PDMA transfer is controllable from the sequencer input. It transfers the data between:
  - System RAM/Flash/TCM to Operand Ram or Twiddle Ram (SPT internal RAMs) and vice versa

  Note: PDMA cannot transfer the data between the twiddle ram and operand RAM
- Capable of handling 8 complex data in single cycle
- Data transfer size is controllable from the sequencer input
  - Maximum transfer Size from the twiddle ram is 4K
  - Maximum transfer size from the operand ram is 16K
  - Error if size exceeds the prescribed limit or size is 0
  - Transfer size is in terms of
    - Number of 64-bit words when transferring from System RAM to SPT/ Operand RAM's.
    - Number of 48-bit words when transferring from SPT/Operand RAM to System RAM.
    - Number of 32-bit words when transferring from Twiddle RAM to System RAM.
- Source and destination address is controllable from the sequencer input
- Addressing schemes
  - Skip ‘N’ address after ‘M’ address
  - M,N (for both source / destination) are input from the sequencer. These are in multiples of 8.

  Note: If the maximum address is exceeded, the address pointer rolls over.
- Separate control from the command for sign extension and 0 padding from the control
- Performs special packing and unpacking scheme on the fly.
  - 16-bit complex packing
  - 24-bit complex packing
  - 24-bit real packing
  - 16-bit real packing
  - 48-bit binary packing
  - 16-bit Mix Mode : Mode that combines two columns with 16-bit complex operands

    - CP6 compression
    - CP4 compression
    - CP8 compression
    - CP16 compression
    - CP4FMTA compression
    - CP4FMTB compression
    - CP8FMTB compression
    - CP16FMTB compression
- Separate control for sign extension or zero padding for all the packing/unpacking schemes
- Rounding of mantissa (during compression) is done by adding a random number (implemented using LFSR) or fixed value 'h80
- Compression algorithm
    - LFSR used for rounding off in format conversion
    - CP4, CP6, CP8, CP16, CP4FMTA, CP4FMTB, CP8FMTB, CP16FMTB compression and de-compression (except for CP16)
- Supports aggregation
    - Absolute
    - Index Value
    - Index cross sum

  Note: If aggregation is enabled then Packing/ Unpacking scheme doesn't have any effect on the data
- Keeps count of number of bytes transferred
    - Resets on every new transfer initiated
    - Updates signal provided at the end of transfer for register to store
- Generates errors
    - DMA command error : These are generated if the following conditions are encountered in the PDMA instruction
        - System and SPT/Operand memory start address is not in multiple of 8
        - Vector length is not a multiple of 8 for any SPTRAM-SRAM transfer
        - Vector length is not a multiple of 16 for 16 bit Mix Mode SPTRAM-SRAM transfer
        - Vector length is not a multiple of 4 for 16 bit complex pack SRAM-SPTRAM transfer
        - Vector length is not a multiple of 4 for 16 bit complex swap pack SRAM-SPTRAM transfer
        - Vector length is not a multiple of 8 for 24 bit complex pack SRAM-SPTRAM transfer
        - Vector length is not a multiple of 4 for 24 bit Real pack SRAM-SPTRAM transfer

- Vector length is not a multiple of 2 for 16 bit Real pack SRAM-SPTRAM transfer
- Vector length is not a multiple of 8 for 16 bit Mix Mode pack SRAM-SPTRAM transfer
- Vector length is not a multiple of 8 for 48 bit binary pack SRAM-SPTRAM transfer
- Vector length is not a multiple of 2 for CP4D pack SRAM-SPTRAM transfer
- Vector length is not a multiple of 16 for CP16 pack SPTRAM-SRAM transfer
- Any memory continuous address is set as zero
- OPRAM Continuous Address should be in multiple of 2 for 16 bit Mix Mode
- vector length is set as zero
- Transfer initiated to or from work registers
- Aggregation Mode does not support decompression
- Incorrect data packing mode specified
- Higher vector length programmed than permissible.
- Vector length is not a multiple of 2 for CP4DFMTB pack SRAM-SPTRAM transfer
- Vector length is not a multiple of 2 for CP8FMTB pack SRAM-SPTRAM transfer
- Vector length is not a multiple of 4 for CP16FMTB pack SRAM-SPTRAM transfer
- Vector length is not a multiple of 16 for CP16FMTB pack SPTRAM-SRAM transfer
- SRAM continuous address is not power of 2 in case of CP4FMTB, CP4DFMTB, CP8FMTB, CP16FMTB

- iIlegal command error : It is generated if proprietary algorithms are used by the non-authorized users.

45.9.9.3 Data Packing/Unpacking

The PDMA supports various methods to pack/unpack data being transfered between SPT RAM/Twiddle RAM and System RAM. While transferring the data between memories the data can be adjusted to 64 bits controlled by Sign Extension bit in the PDMA instruction (SE).

SE means sign extension of the value to the right. Sign extension appends '0' bits to the left if the right value MSB is '0' and '1' if the right value MSB is '1'.The data that needs to be transfered can be in any of the formats. The various methods supported are as follows:

- 16-bit packing: This packs four 16-bit complex data in SPT RAM into one 64-bit data in System RAM
- 24-bit complex packing: This packs 24-bit real and 24-bit imaginary part stored in the SPT RAM is stored in 64-bit data in System RAM. Each data is sign extended with MSB bit replicated for the remaining 8 bits
- 24-bit real packing: This packs two 24-bit data into one 64-bit data in System RAM. The bits are sign extended to make these 32-bit each
- 16-bit real packing: This packs four 16-bit data into one 64-bit data
- 48-bit binary packing: Each 48-bit data in SPT RAM is converted to 64-bit in System RAM by appending zero's in the MSB.
- 16-bit Mix Mode: This mode combines two columns with 16 bit complex operands to 8x 64 bits and vice versa
- Compression Modes (CP4/CP6/CP8/CP16/CP4FMTA/CP4FMTB/CP8FMTB/ CP16FMTB) are special types of data packing schemes which reduce the amount of data that is written in System RAM.
- CP6 compression packing: This takes in 6 complex data (each having 24-bit real and 24-bit imaginary) into 64-bit output at the System RAM side.
- CP4 Compression packing: This takes in 4 complex data (each having 24-bit real and 24-bit imaginary) into 64-bit output at System RAM side.
- CP8 Compression packing: This takes in 8 complex data (each having 24-bit real and 24-bit imaginary) into 64-bit output at System RAM side.
- CP16 compression packing: This takes in 16 complex data (each having 24-bit real and 24-bit imaginary) into 4 x 64 bit output at System RAM side.
- CP4FMTA Compression packing: This takes in 4 complex data (each having 24-bit real and 24-bit imaginary), compresses it into 32-bit value. Two 32-bit values are packed and stored as 64 bit output at System Ram side.
- CP4FMTB Compression packing: This takes in 4 complex data (each having 24-bit real and 24-bit imaginary), compresses it into 64-bit mantissa and 4 bit exponent and stores mantissa and exponent at System Ram side seperately starting from different offset.
- CP8FMTB Compression packing: This takes in 8 complex data (each having 24-bit real and 24-bit imaginary), compresses it into two 64-bit mantissas and 4 bit exponent and stores mantissa and exponent at System Ram side seperately starting from different offset.
- CP16FMTB Compression packing: This takes in 16 complex data (each having 24-bit real and 24-bit imaginary), compresses it into four 64-bit mantissas and 4 bit exponent and stores mantissa and exponent at System Ram side seperately starting from different offset.

NOTE

Assumption is that input is 24-bit real at LSB and 24-bit imaginary component at MSB. Compression would be done while transferring the data to System RAM and de-compression would be done while transferring the data to SPT/Twiddle RAM.

CP16 does not have decompression.

Figure 45-58. Data Format 4

45.9.9.4 Linear Feedback Shift Register

Linear Feedback is a shift register whose input bit is a linear XOR function of its previous state. In our case the LFSR polynomial is:

$x^{64}+x^{61}+x^{34}+x^{9}+1$

LFSR is used only during the compression modes by the PDMA.

LFSR is controlled by the registers interface. The initial value to be loaded in LFSR can be set by software. This value gets loaded to the LFSR when the control bit (PDMA_LFSR_LOAD_EN) is set from the software. This bit automatically gets cleared by the design. PDMA should be in inactive state while programming this bit.

45.9.9.5 Compression

The PDMA includes a function for on-the fly data decompression and compression. It is a special case for packing/unpacking. The compression function is lossy and can only be applied to complex data. Depending on the compression mode, the module takes up to 4/6/8 complex operands and packs them into a single bit word thereby resulting in data compression.

Table 45-54. Compression type comparison

Compression Type	Input Data(48-bit complex)	Output Data(64-bit)	Compression Ratio
CP4	4	1	3
CP6	6	1	4.5
CP8	8	1	6
CP16	16	4	3
CP4FMTA	4	0.5	6
CP4FMTB	4x16	16+1	2.82
CP8FMTB	8x16	2x16+1	2.91
CP16FMTB	16x16	4x16+1	2.95

PDMA module supports the following compression modes:

1. **CP6 compression**

   The CP6 compression involves compressing 6 complex numbers(A-F) and storing them as a single 64-bit number. The compression assumes the 7th and 8th complex number is zero and ignores this for compression procedure as mentioned below.

   A0 B0 C0 D0 E0 F0 0 0

A1 B1 C1 D1 E1 F1 0 0

.....

.....

A7 B7 C7 D7 E7 F7 0 0 …

2. **CP4 compression**

   The CP4 compression involves compressing 4 complex numbers and storing them as a single 64-bit number.

   There are two different flavors for CP4. In this case the software shall store the numbers as follows

   A0 B0 C0 D0 0 0 0 0

   A1 B1 C1 D1 0 0 0 0

   .....

   .....

   A7 B7 C7 D7 0 0 0 0

   All other steps remain as in CP6 compression.

3. **CP4D compression**

   This is similar to the CP4 mode described above. The only variation is in terms of the way PDMA will compress data chunks.

   A0 B0 C0 D0 A1 B1 C1 D1

   A2 B2 C2 D2 A3 B3 C3 D3

   A4 B4 C4 D4 A5 B5 C5 D5

4. **CP8 compression**

   CP8 compression takes 8 input complex operands and compresses them to one 64-bit words.

5. **CP16 compression**

   CP16 is different from other compression modes. It packs 16 complex operands into 4 64-bit words. It does not use random numbers(LFSR) and does not store common exponents.

6. **CP4FMTA compression**

The CP4FMTA compression involves compressing 4 complex numbers and storing them as a single 32-bit number. Next 4 complex numbers compress to store complete 64 bit number.

In this case the software shall store the numbers as follows

A0 B0 C0 D0 0 0 0 0

A1 B1 C1 D1 0 0 0 0

.....

.....

A7 B7 C7 D7 0 0 0 0

All other steps remain as in CP6 compression.

7. **CP4DFMTA compression**

   This is similar to the CP4FMTA mode described above. The only variation is in terms of the way PDMA will compress data chunks.

   A0 B0 C0 D0 A1 B1 C1 D1

   A2 B2 C2 D2 A3 B3 C3 D3

   A4 B4 C4 D4 A5 B5 C5 D5

8. **CP4FMTB compression**

   The CP4FMTB compression involves compressing 4 complex numbers and storing them as a single 64-bit mantissa and 4 bit exponent.

   There are two different flavours for CP4FMTB. In this case the software shall store the numbers as follows

   A0 B0 C0 D0 0 0 0 0

   A1 B1 C1 D1 0 0 0 0

   .....

   .....

   A7 B7 C7 D7 0 0 0 0

   All other steps remain as in CP6 compression.

9. **CP4DFMTB compression**

This is similar to the CP4FMTB mode described above. The only variation is in terms of the way PDMA will compress data chunks.

A0 B0 C0 D0 A1 B1 C1 D1

A2 B2 C2 D2 A3 B3 C3 D3

A4 B4 C4 D4 A5 B5 C5 D5

10. **CP8FMTB compression**

    The CP8FMTB compression involves compressing 8 complex numbers and storing them as two 64-bit mantissas and 4 bit exponent.

11. **CP16FMTB compression**

    The CP16FMTB compression involves compressing 16 complex numbers and storing them as four 64-bit mantissas and 4 bit exponent.

12. **Decompression**

    This runs in the reverse direction with all missing bits being filled with sign extended bit or zero padding depending on the instruction. This procedure generates 8 complex output values per clock cycle for CP6/CP8 and 4 complex output for CP4/CP4D. CP16 decompression is not valid. For CP4FMTB, CP4DFMTB, CP8FMTB, CP16FMTB, mantissa and exponent values are read from different SRAM location starting from SYSRAM_MEM_START_ADDR and SPT_PDMA_FMTB_EXP_ADDR_STATUS respectively.

NOTE

For CP4FMTB, CP4DFMTB, CP8FMTB and CP16FMTB, first exponent is stored or read from address given by SPT_PDMA_FMTB_EXP_ADDR_STATUS. After this same skip and continuous address scheme will be used for both mantissas and exponent. Exponent base address is calculated as:

- For TRANS_TYPE = 1 :

```
if (DATA_PACKING == CP4FMTB_COMPRESSION)
  VECTOR_LEN_2 = VECTOR_LEC>>3
else
  VECTOR_LEN_2 = VECTOR_LEN>>2
```

- For TRANS_TYPE = 0:

```
  VECTOR_LEN_2 = VECTOR_LEN
```

-
```
JUMP_ADDR = VECTOR_LEN_2/SYSRAM_CONTINOUS_ADDR
REMAINDER_ADDR = VECTOR_LEN_2-JUMP_ADDR*
```

```
SYSRAM_CONTINOUS_ADDR
```

- ```
  if(REMAINDER_ADDR == 0)
    MULTIPLE_FACTOR = JUMP_ADDR
  else
    MULTIPLE_FACTOR = JUMP_ADDR + 1
  ```

- ```

Table 45-56. PDMA instruction fields description

Bit	Bit Field	Description
127:122	OPCODE	Opcode for PDMA command (101000b)
121	TAG_N_BITFLD	1b: Operation needs to be performed on tagged data.Bit Number 24 used to determine if data is tagged. Used in aggregation mode.
		0b:Operation needs to be performed on non zero data(data is packed in terms of bit fields)
120	SE/COMP_RND	Sign Extension/Compression Rnd bit.This bit is multiplexed.

Table continues on the next page...

Table 45-56. PDMA instruction fields description (continued)

Bit	Bit Field	Description
		In non compression mode : Sign Extension bit. This indicates whether input data should be sign extended or zero padded during packing/unpacking • 0b - Zero padding • 1b - Sign Extension
		In compression mode : Compression Rand bit. This indicates whether LFSR random value should be added or fixed value should be added for compression. • 0b - LFSR random value selected • 1b - Fixed value 'h80 selected
119	IMA	0b : No indirect address
		1b : source and destination address are indirect i.e a work register contains the address of the PDMA source and destination
118:114	DATA_PACKING	Defines the data packing type
		00000b -16-bit complex pack
		00001b - 24-bit complex pack
		00010b - 24-bit real pack
		00011b - 16-bit real pack
		00100b - 48-bit binary pack
		00101b - 16-bit complex swap pack
		00110b - 16-bit mode for clubbing 2 channels data
		00111b - CP4 compression
		01000b - CP6 compression
		01001b - CP8 compression
		01010b - CP16 compression
		01011b - CP4D compression
		01101b - Absolute aggregation
		01110b - Index value aggregation
		01111b - Index Cross Sum aggregation
		10000b - CP4FMTA compression
		10001b- CP4DFMTA compression
		10010b- CP4FMTB compression
		10011b- CP4DFMTB compression
		10100b- CP8FMTB compression
		10101b-CP16FMTB compression
113	TRANS_TYPE	Direction of transfer from PDMA
		0b: System RAM to Operand/Twiddle RAM
		1b : Operand/Twiddle RAM to System RAM
112	SYNC	1b : Synchronous Data transfer. Current PDMA Transfer needs to finish before next instruction is initiated.
		0b : Asynchronous Data Transfer. Current transfer does not need to finish for the next instruction to be initiated.

Table continues on the next page...

Table 45-56. PDMA instruction fields description (continued)

Bit	Bit Field	Description
111:96	VECTOR_LEN	Number of Address locations to be read from source side. Source could be SRAM or OPRAM/Twiddle RAM. Vector length should be programmed in such a way so that it results in multiple of 8 number of locations access on OPRAM/Twiddle RAM. For CP4FMTB, CP4DFMTB, CP8FMTB, CP16FMTB, for SRAM to SPTRAM transfer, this field corresponds to the number of 64 bit mantissa words to be read.
95:65	SYSRAM_MEM_START_ADDR	System RAM Address that determines the start location for the transfer. It should be in multiple of 8.
63:48	OPRAM_MEM_START_ADDR	Operand/Twiddle RAM Address that determines the start location for the transfer. This should be in multiples of 8.
47:36	OPRAM_SKIP_ADDR	Number of words (48*8-bit each) that should be skipped after operand/twiddle RAM continuous address are read or written
35:24	OPRAM_CONTINUOUS_ADDR	Number of words (48*8-bit each) that should be read or written before the jump for operand/twiddle RAM. DMA would start with continuous address
23:12	SYSRAM_SKIP_ADDR	Number of words (64-bit each) that should be skipped after System RAM continuous address are read or written
11:0	SYSRAM_CONTINUOUS_ADDR	Number of words (64-bit each) that should be read or written before the jump. DMA would start with continuous address. For CP4FMTB, CP4DFMTB, CP8FMTB, CP16FMTB, this field values should be programmed in power of 2

45.9.9.6.1 Source and destination continuous/skip Address

The PDMA module supports transfer of data between Operand/Twiddle RAM and System RAM. The source and destination can be controlled by the instruction fields. Both source and destination have an option of specifying continuous and skip address.

These fields control the location and amount of data that will be transfered between the memories. These fields are used in conjunction with the System RAM/Operand RAM Start Address and System RAM/Operand RAM Skip Address.

Continuous address controls the number of data (48 *8 bit in case of operand/twiddle RAM and 64 bits in case of System RAM) that will be read/written before the jump which is specified by skip address.

- If continuous address = 0, the SPT module throws a DMA command error.
- If continuous address = 1 for operand RAM/twiddle RAM it means after START address/SKIP address we need to read/write 8 locations before another skip.
- If continuous address = 1 for System RAM it means after START address/SKIP address we need to read/write 1 location (64 bits) before another skip.
- If skip address = 0 it means continuous transfer.
- If skip address = 1 for operand RAM/twiddle RAM it means after every continuous address we need to skip 8 locations

- If skip address = n for operand RAM/twiddle RAM it means after every continuous address we need to skip n*8 locations.
- If skip address = 1 for System RAM it means after every continuous address we need to skip 1 System RAM location(64 bits each).
- If skip = n for System RAM it means after every continuous address we need to skip n System RAM locations(64 bits each).

The user will have to program both of them to transfer chunk of data from one memory to the other. Assuming base address = 0x8000

For Operand/SPT RAM

- Continuous address = 1, Skip address = 0.
- Final Address : 8000,8001,8002,8003,8004,8005,8006,8007,8008, 8009,800A,800B, 800C,800D,800E,800F
- Continuous address = 1, Skip address = 1.
- Final Address = 8000,8001,8002,8003,8004,8005,8006,8007,8010, 8011,8012,8013,8014,8015,8016,8017
- Continuous address = 2, Skip address = 1.
- Final Address = 8000,8001,8002,8003,8004,8005,8006,8007,8008, 8009,800A, 800B,800C,800D,800E,800F,8018, ,8019,801A,801B,801C,801D,801E,801F
- Continuous address = 2, Skip address = 2.
- Final Address = 8000,8001,8002,8003,8004,8005,8006,8007,8008, 8009,800A, 800B,800C,800D,800E,800F,8020, ,8021,8022,8023,8024,8025,8026,8027

For System RAM

- Continuous address = 1, Skip address = 0: Final Address = 8000,8008,8010,8018.
- Continuous address = 1, Skip address = 1: Final Address = 8000,8010,8020,8030
- Continuous address = 2, Skip address = 1: Final Address = 8000,8008,8018,8020
- Continuous address = 2, Skip address = 2: Final Address = 8000,8008,8020,8028

So if a user specifies Operand/Twiddle RAM Memory start address as 0x100, Continuous address as 2 and skip address as 4, the PDMA will start transfering data starting from 0x100 to 0x110 with 16 words(48 bit each) transfered and then will skip the next 32 words and so on.The next continuous address will start from 0x130 to 0x140.

Similarly if a user specifies System RAM Memory start address as 0x100, Continuous address as 2 and skip address as 4, the PDMA will start transfering data starting from 0x100 to 0x110 with 16 bytes transfered and then will skip the next 32 bytes and so on. The next continuous address will start from 0x130 to 0x140.

.

45.9.9.6.2 Data Aggregation

Some operations deliver sparse vector/matrix results and only certain values are interesting for the following processing. For this purpose, it is possible not to transfer the complete vector to System RAM, but only a selected part, which depends on the values itself. The values must meet some criteria, either they must be a max or greater 0

Data Aggregation is only supported for transfer from SPT/Operand RAM to System RAM. This is not supported for transfers from System RAM to SPT/Operand RAM.

The following modes are supported for data aggregation:

- Absolute, only values which are Max or greater 0 are transferred
- Indexed value, for any value which is a Max or greater 0 its offset to the source address (element 0) and the value itself is transferred, all other values are skipped
- Indexed cross sum, for any value which is a Max or greater 0 its offset to the source address (element 0) and the sum of all bits in the value is transferred, all other values are skipped

The aggregation mode works with only 16 bit values.To explain aggregation with an example, let us consider the following data that needs to be transferred to system RAM:

0: i10939 + 12876

1: i63846 + 0

2: i0 + 56617

3: i43918 + 28847

4: i0 + 54068

5: i23263 + 0

6 :i57885 + 0

7: i0 + 0

When transferring using aggregation mode for value only, following is the format:

0:12876,10939,63486,56617

1:28847,43918,54068,23262

2:57885,....,.....,....

All values greater than zero are transferred.

When transferring using aggregation mode value and index, following gets transferred:

0: 0,12876,1,10939

1: 3,63846,4,56617

2: 6,28847,7,43918

3: 8,54068,11,23263

4: 13,57885,.....

In the above example all values real and imaginary which are > 0 are transferred along with index with base index starting from element 0 (Real part of first number)

Similarly when transferring data using aggregation mode indexed cross sum, following gets transferred:

0: 0, 6,1, 9

1: 3, 10, 4, 9

2: 6, 9, 7, 9

3: 8, 8, 11, 11

Here along with the index from base value, sum of all the bits is transferred for the numbers which are greater than zero. So for number 10939 (10101010111011) we transfer 9 as the bit sum.

45.9.10 DMA Arbiter

45.9.10.1 DMA Arbitration

The SPT module has just one AHB master interface with 3 different sources of data i.e SDMA, PDMA & Command sequencer queue DMA. Each of these modules provides the DMA arbitration logic with the interface details in terms of the number of data that needs to be transferred, address of the transfer and whether the module intends to read or write data from/to System RAM. It should be noted that SDMA has two sub-sources, the main SDMA and the bypass SDMA, and these are arbitrated inside the Acquisition module.

PDMA and command data transfers can be both stalled, however the amount of data of PDMA transfers is significantly higher than for commands. It is important to note that since ADCs provide continuous stream of data, the transfers from the acquisition/SDMA cannot be delayed.

The default priority scheme assumes the following order:

- Acquisition main SDMA or bypass SDMA write (top priority)

- RAM transfer PDMA
- Command DMA read (lowest priority)

All DMA transfers generate bursts of data. Arbitration between different sources can only take place at the borders of bursts. The Bursts will never be broken. PDMA gives control on the number of data that needs to be transferred via the instruction format. However this control is not available for SDMA & CSDMA. Tables below show the various burst sizes that are being used for main SDMA, since for transfers from main SDMA these are controlled by the different modes supported in main SDMA. For bypass SDMA always a single burst of INCR16 is initiated.

Table 45-57. Burst Size in main SDMA for various acquisition Modes/Channels enabled when source is ADC or Complex mode from MIPICSI2

MODES	Interleaved	Tile 4	Tile 8
NUM_CHNL = 1	16 (INCR16)	2(2XINCR)	2(2XINCR)
NUM_CHNL = 2	16 (INCR16)	4 (INCR4)	4 (INCR4)
NUM_CHNL = 3	16 (INCR16)	6(INCR4+2XINCR)	6(INCR4+2XINCR)
NUM_CHNL = 4	16 (INCR16)	8(INCR8)	8(INCR8)
NUM_CHNL = 5	16 (INCR16)	10(INCR8+2XINCR)	10(INCR8+2XINCR)
NUM_CHNL = 6	16 (INCR16)	12(INCR8+INCR4)	12(INCR8+INCR4)
NUM_CHNL = 7	16 (INCR16)	14(INCR8+INCR4+2XINCR)	14(INCR8+INCR4+2XINCR)
NUM_CHNL = 8	16 (INCR16)	16(INCR16)	16(INCR16)

Table 45-58. Burst Size in main SDMA for various acquisition Modes/Channels enabled when source is MIPICSI2

MODES	Interleaved	Tile 4	Tile 8
NUM_CHNL = 1	16 (INCR16)	4(INCR4)	4(INCR4)
NUM_CHNL = 2	16 (INCR16)	8(INCR8)	8(INCR8)
NUM_CHNL = 3	16 (INCR16)	12(INCR8+INCR4)	12(INCR8+INCR4)
NUM_CHNL = 4	16 (INCR16)	16(INCR16)	16(INCR16)

The PDMA however behaves differently than the SDMA. The burst size is not fixed. Instead based on the number of data that needs to be transfered, the DMA arbiter initiates the transaction on the AHB bus. PDMA has an output FIFO which continues to fill till there is 16 data in the FIFO. This is the default setting in case the amount of data to be transferred is large. The arbiter then initiates an INCR16 on the AHB bus to transfer the data. In case the amount of data is less, then the PDMA pre-calculates the number of data that needs to be transferred and accordingly adjusts the burst size.It is however possible to control the burst that PDMA initiates based on setting in the control registers. The software can ensure SPT only initiates INCR4/INCR8 or INCR16 only.

It is also possible to control the size of each burst that is initiated on the AHB bus by Command Sequencer by programming field SPT_CS_MODE_CTRL[CSDMA_BRST_SZ].

Table 45-59. AHB Master ID for SDMA, PDMA and Command Sequencer

Source	AHB Master ID
Main SDMA	14
Bypass SDMA	10
PDMA	6
Command Sequencer	13

Back to back transactions on the PDMA will have no idle cycles. However when there is a switch between PDMA/SDMA/Command sequencer, one cycle will be lost in arbitrating and initiating a new burst.

In order to provide the Command sequencer access within a long PDMA burst so that it does not keep waiting until PDMA finishes, the SPT supports a 16 bit register SPT_PDMA_CONTROL[PDMA_COUNT_CS_PRIORITY] which needs to be programmed. This specifies the number of clock cycles after which the command sequencer will get access. The PDMA will finish the existing burst and handover the access to the command sequencer.

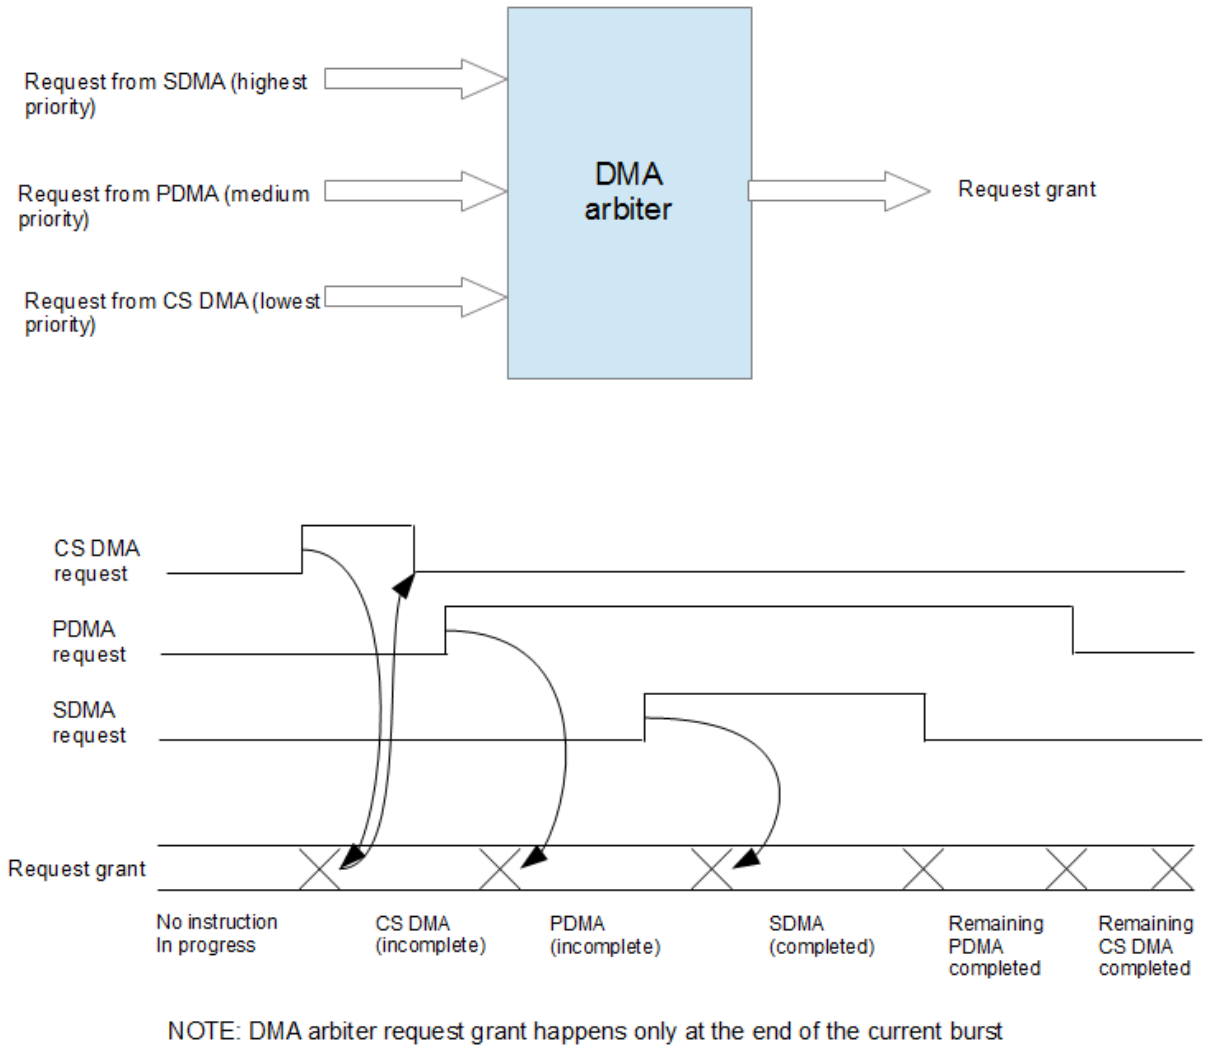

Figure 45-59. DMA arbiter

45.9.11 VMT

45.9.11.1 Introduction

Vector Math is a collection of basic operations on vector data. The operations are performed on 8 operands in parallel for the given length of vector. Some operations can be concatenated within a single processing step.

45.9.11.2 Principle of operation

The vector math unit is implemented as fully pipelined structure with several stages performing certain mathematical operations. Flow diagram shows the 2 operations sequences and pipelining in each operation(shown as dotted lines). Each dotted line corresponds to one pipeline cycle in the design and to be accounted for throughput analysis.

In Operation Sequence 2, the very first stage performs either Abs or Mag or Conjugate operation and forwards its results to the next stage, which performs a Shift or Offset or Sum with second vector operation. The final stage takes this results and sums up the vector elements to each element. Each operation stage can also be bypassed.

In Operation Sequence 1, square of Magnitude is followed by logarithm 2.

Regardless of the source of input operands being Operand/Twiddle RAM, the input operand is sign extended to 24 bits and saturated. Saturation consists of clamping this value of input operand between 0x80_0001 and 0x7F_FFFF. The pipeline width is fixed to 24 bits from here onwards. No intermediate saturation stages exist except for Operation sequence 2, stage 2 operations; where result is saturated to 24 bits. Finally, output data is clipped to 16 bits (MSB's discarded) if destination is Twiddle RAM. This followed by a 24b/16b saturation logic based on destination RAM selected thus arriving at the result.

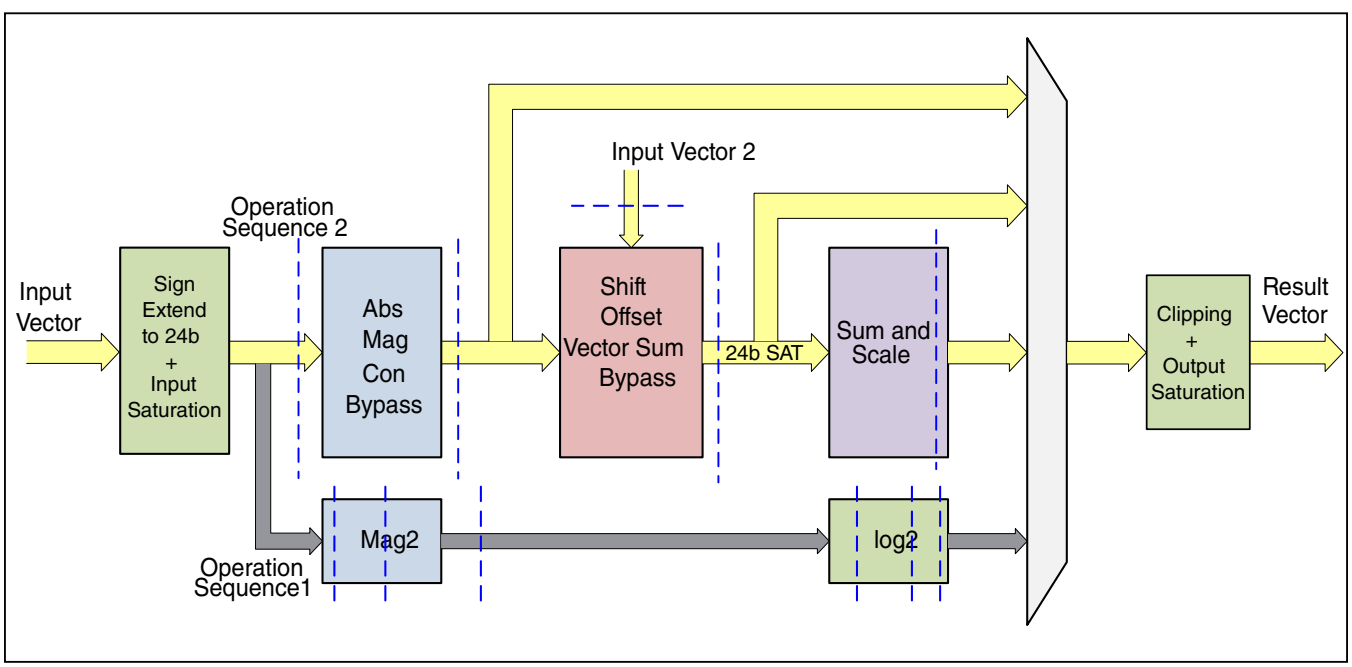

Figure 45-60. Vector Math Operation flow diagram

45.9.11.3 Vector Math Operations

The following 2 sequences of operations are supported:

45.9.11.3.1 Operation Sequence 1

The first sequence of the Valid VMT Operations as defined by field OP_SEQ1 consists of 2 stages as shown in lower branch of the VMT flow diagram

45.9.11.3.1.1 Stage 1 - Vector Mag2 operation

This operation has to be performed when Operation sequence 1 is selected. From the original 24-bit operands, approximated 12-bit operands are chosen based on the location of their leading '1' bit. The operation calculates the sum of the square magnitude value of each approximated operand.

The resulting sum has 25-bit resolution, and is given to the sub-module performing the log2 operation. The other output of the mag2 module is the exponent value corresponding to the location of the leading '1' bit.

This operation is supported for real and complex operands only. The output values are real numbers.

45.9.11.3.1.2 Stage 2 - Vector Log2 Operation

It converts the input vector to log2 numbers. The operation makes use of the binary number representation:

$$log_2(n) = log_2\left(\sum_{k=0}^{MSB} a_k 2^k\right)$$
$$= log_2\left(2^{MSB} \sum_{k=0}^{MSB} a_k 2^{k-MSB}\right)$$
$$= MSB + log_2\left(\sum_{k=0}^{MSB} a_k 2^{k-MSB}\right)$$

Figure 45-61. Formula for Log2 Calculation

The 6 leading bits (exp) are derived by counting in the log2 module's input the position of the first MSB bit that is ‘1’, where the LSB is assigned the position 0 (From this exp is subtracted the intermediate exponent value coming from the mag2 module, and a correction is done by adding 22. This gives the final exponent). The 8 LSB bits following this leading bit are used for mantissa calculation.

The log2 output occupies only 14-bit and is always a positive number. An input value of 0 results in log2 output as 0.

45.9.11.3.2 Operation Sequence 2

The second sequence of the Valid VMT Operations consists of 3 stages as shown in the VMT flow diagram.

NOTE

In this operation sequence, all 3 stages cannot be bypassed.
Atleast one math operation must be selected.

45.9.11.3.2.1 Stage 1:

45.9.11.3.2.1.1 Vector Abs

It calculates the absolute value of each operand and is selected when OP_SEQ2[5:4] = 01. It is supported for real and complex operands. The output values are real numbers.

Real operands:

$y_k = |x_k|$, $k = 0..N-1$

Complex operands :

$y_k = (|\ Re(x_k)\ | + |\ Im(x_k)\ |) >> 1,\ k = 0..N-1$

The absolute value is limited to 24 bit and has only positive numbers.

45.9.11.3.2.1.2 Vector Conjugate

It calculates the conjugate complex value of each operand. It is supported complex operands only. This is the only preprocessing operation which has complex output values.

$y_k = Re(x_k) - j\ Im(x_k)$, $k = 0..N-1$

45.9.11.3.2.1.3 Vector Magnitude

Operation calculates half of approximate root of square magnitude value of each operand. It is supported for complex operands only. The output values are real numbers.

45.9.11.3.2.2 Stage 2:

45.9.11.3.2.2.1 Vector Shift

This operation shifts the input operands by the number of positions (absolute value of b) to the left (positive b) or right (negative b). It is supported for real and complex operands. The input operands are sign extended for right shift and LSBs are lost. With left shifting ,'0' LSB bits are inserted. The value b is read from the WORK REGISTER whose address is specified by VMT instruction fields [15:0]. The bit positions [5:0] of selected WORK REGISTER location provide the value b. The valid value for this field is of 6 bits where 6th bit is sign(which decide on right or left shift) and the absolute value of this 6 bit signed field gives the actual shift value. The absolute shift value (b) is saturated to 24 for values above 24.

If a left shift operation results in overflow (sign change) for any operand, then the result is saturated to 24 bits, i.e Negative overflow causes result to saturate to 24'h80_0001, whereas positive overflow causes result to saturate to 24'h7F_FFFF. Moreover the overflow status bit HW_ACC_ERR_STATUS[VMT_SHFT_OVF_ERR] is also set on detecting overflow occurrence for any operand undergoing this operation.

Real operands:

$y_k = x_k << b,\ k = 0..N\text{-}1$

Complex operands :

$y_k = Re(x_k) << b + j\ Im(x_k) << b\ ,\ k = 0..N\text{-}1$

45.9.11.3.2.2.2 Dual Vector Sum

This operand sums each element of first vector with each element of second vector. It is supported for real and complex operands. If input type is complex, stage 1 (pre-processing) operation cannot be Vector Abs or Vector Magnitude. First Vector Source is Operand RAM and second vector is located in the Twiddle RAM. The address increment for second vector source is fixed to 1. The result is saturated to 24 bit signed values and can only be stored in Operand RAM.

$y_k = x1_k + x2_k,\ k = 0..N\text{-}1$

45.9.11.3.2.2.3 Vector Offset

It adds an offset (constant value) to each vector element Supported for real and complex operands. The value C can be provided as an immediate value or can be read from the Work Register in which case work register fields [15:0] provide $Re(C_k)$ whereas fields [39:24] provide $Im(C_k)$. The result is saturated to 24 bit signed values and can be stored in Operand/Twiddle RAM.

$y_k = (Re(x_k) + Re(C_k)) + j\ (Im(x_k) + Im(C_k))\ ,\ k = 0..N\text{-}1$

45.9.11.3.2.3 Stage 3:

45.9.11.3.2.3.1 Vector Sum and Scale

This operation is valid for real operands only. It calculates the sum of all vector elements and generates a single output value. The result can be scaled with a multiplier value S and a divider value D, which is applied last. S is a signed 16bit number. The divider value D must be a power of two; i.e. 2 raised to the power N, where N is the exponent. The values S and N are read from the Work Register where the field [15:0] provides value of S while N is given by the field [29:24] of the selected Work Register Location. N is a 6 bit value as shown in the figure below. The 48 bit signed result can be stored in operand RAM or Work Register.

$$y = \frac{S}{D}\sum_{k=0}^{N-1} x_k$$

The internal accumulator bit width is 53 bits. It is possible to start the accumulation from scratch or to continue with a previous accumulated value based on RST_ACC field in VMT instruction set. The value of exponent N must be chosen appropriately to ensure that final result can be stored within 48 bits. In the worst case, upto 5 MSB's from 53 bit result will get discarded to trim down the result to 48 bits.

45.9.11.4 Input and Output Packing

Input Packing is selected by the IN_PACK field in VMT instruction. This field is valid only when the input data type (IN_DATTYP) is real. Input operands can either be packed, unpacked real or unpacked imaginary. When input is packed, each slice of the Operand/Twiddle RAM can hold 2 operands.

Output Packing is selected using OP_PACK field in VMT instruction. When output is unpacked, the decision of whether output is unpacked real or unpacked imaginary is taken based on IN_PACK value. Programming Input to be unpacked real leads to output being unpacked real. Similarly if input is unpacked imaginary, output would be unpacked imaginary as well.

The following table provides the relationship between input data type, packing options and their effects on various other parameters.

Table 45-60. Input and Output Packing

	Possible Scenarios									
	1	2	3	4	5	6	7	8	9	10
Input Data Type	real	real	real	real	real	real	complex	complex	complex	complex
Input Packing	real (00)	real (00)	imag (01)	imag (01)	packed (10)	packed (10)	x	x	x	x
Output Packing	off	on	off	on	off	on	off	off	on	x
Vector Length	n	n	n	n	n	n	n	n	n	n
VMT result data type	real	real	real	real	real	real	real	real	real	complex
No. of accessed input addresses	n	n	n	n	n/2	n/2	n	n	n	n

45.9.11.5 VMT Operations - Source and Destination Options

When performing a Vector Math operation, it is mandatory to program the instruction fields to select any of the supported source and destination address locations. The following figure shows all valid source and destination options for various VMT math operations.

		Valid Source	Valid Destination
Sequence 1	MAG2	OPRAM, TWRAM	OPRAM, TWRAM
	LOG2		
Sequence 2, Stage 1	ABS	OPRAM, TWRAM	OPRAM, TWRAM
	MAG	OPRAM, TWRAM	OPRAM, TWRAM
	CONJ	OPRAM, TWRAM	OPRAM, TWRAM
Sequence 2, Stage 2	SHIFT	OPRAM, TWRAM	OPRAM, TWRAM
	OFFSET	OPRAM, TWRAM	OPRAM, TWRAM
	SUM	OPRAM, TWRAM *	OPRAM
Sequence 2, Stage 3	SUM & SCALE	OPRAM, TWRAM	OPRAM, WREG

*For Dual Vector Sum operation, first vector is picked from OPRAM and second vector is picked from TWRAM simultaneously.

Figure 45-62. Valid Memory Options for VMT Operations

45.9.11.6 VMT Instruction Format

The table below shows the instruction bit encoding used for VMT. The details of each bit field and their operation is defined in the sections below.

Table 45-61. VMT Instruction format

127	126	125	124	123	122	121	120	119	118	117	116	115	114	113	112

Table 45-62. VMT Instruction Fields Description

Bit	Bit Field	Description
[121]	RST_ACC	Reset Sum Scale Accumulator
		0 - Does not reset sum-scale accumulator. If current instruction executes sum-scale operation, new sum is accumulated over previous accumulated sum.
		1 - Resets sum-scale accumulator on start of instruction.
[120]	IN_DATTYP	Input Data type
		0 - Real
		1 - Complex
[119]	OP_SQ1	Operation Sequence 1
		1 - Log 2 + Mag2
		0 - Sequence 2 selected
[118:117]	OP_SQ2 - Stage1	Operation Sequence 2 - Stage1
		00 - No Preproccessing
		01 - ABS (for real and complex numbers)
		10 - Magnitude for complex values (calculate half of approximate square root of real^2 + im^2 - only valid for complex numbers)
		11 - Conjugate(Valid for complex numbers)
[116:114]	OP_SQ2 - Stage2	Operation Sequence 2 - Stage2
		000 - No Operation
		001 - Shift
		010 - Offset with Value in Work Register
		011 - Offset with Immediate value
		100 - Dual Vector sum(Only be used when Vector Source is Operand RAM and 2nd Vector Source from Twiddle RAM)
[113]	OP_SQ2 - Stage3	Operation Sequence 2 - Stage3
		0 - No Operation
		1 - Sum and Scale
[112]	OP_PACK	Output Packing - This field allows user to select types of Output Data Packing.
		0 - Output unpacked. 24 bit re/im used depending on IN_PACK selected. If IN_PACK = 01 (imaginary unpacked), then 24 bit im is used; otherwise 24 bit re is used.
		1 - Output packed (48 bit used)
[111:110]	IN_PACK	Input Packing - This field allows user to select types of Input Data Packing.
		00 - Input unpacked real (24 bit real used)

Table continues on the next page...

Table 45-62. VMT Instruction Fields Description (continued)

Bit	Bit Field	Description
		01 - Input unpacked imaginary (24 bit im used)
		10 - Input packed (48 bit used)
[109]	IMA	Indirect Memory Addressing
		0 - Immediate Memory Addressing
		1 - Indirect Memory Addressing for Source and Destination addresses
[108:96]	VEC_SZ	Vector size/length. The value of this field must be even when input packing is selected (IN_PACK = 10b).
[95:80]	SRC_ADD	Source Address (should be multiple of 8)
[79:64]	DEST_ADD	Destination Address(should be multiple of 8 except for sum and scale operation i.e. when OP_SQ2 - Stage3 = 1)
[63:48]	MULT_S_EXP_N_VAL_ADDR	Address of Working Register where multiplier (S) and exponent (N) value are stored. From of the 48 bit word stored in this location, bits [15:0] give value of multiplier (S), while bits [29:24] give value of exponent (N).
[47:40]	SRC_ADD_INC	Source address increment
[39:32]	DEST_ADD_INC	Destination address increment
[31:16]	IMDT_OFFSET_VAL_IM[31:16]	Imaginary part of immediate offset value used when OP_SQ2[116:114] = 011.
[15:0]	2ND_VEC_SRC_ADDR	As Second vector source address which is required for Dual Vector Sum selected by OP_SQ2[116:114]=100 (should be multiple of 8)
	SHIFT_VAL_ADDR(b)	As Address of Shift Value B if OP_SQ2 - Stage2 = 001
	OFFSET_VAL_ADDR	As Address of Offset Value C when OP_SQ2 - Stage2 = 010
	IMDT_OFFSET_VAL_RE[15:0]	Real part of immediate offset value if OP_SQ2 - Stage2 = 011

45.9.12 HIST

45.9.12.1 Introduction

The HIST module performs a histogram computation operation which counts the number of values falling in certain bins. 16/32/64 bins are supported. Histograms are calculated with 8 or 16 operands parallel over a vector of size N. A histogram over a vector of input data is calculated by scheduling multiple histogram kernel runs until all vector elements are processed.

45.9.12.2 Input data type

Histograms can be generated from vectors with real or complex or log2 operands. The real and complex numbers are either 16-bit or 24-bit wide. In case of log2 operands, the operation shall support also packed operands, i.e. two 14-bit lsb-aligned log2 values within 48bit. This is optional, so a command parameter is provided to decide whether log2 is packed or not. Thus, for log2 data type, 8 or 16 operands may be received with each memory read cycle (but only a single histogram will be calculated for the entire data).

Similar to the log2 data-type case, there is the option for packing 2 16-bit or 24-bit real operands in one 48-bit location. One option in the unpacked log2 or unpacked real cases is that the data input can be accepted either from the real part or the imaginary part.

The input data comes from the operand RAM only.

45.9.12.3 Result storage

The state of the histogram counters can be saved in operand RAM, twiddle RAM or work registers.

45.9.12.4 Operation modes

The Histogram operation supports several operation modes:

- Read operands, calculate histogram and save result to operand RAM, Twiddle RAM or work registers. In this option the bin counters are reset at the beginning of the command.
- Read operands, calculate histogram. In this option the bin counters are reset at the beginning of the command.
- Read operands, calculate cumulated histogram. In this option the bin counters are NOT reset at the beginning of the command.
- Save results to operand RAM, Twiddle RAM or work registers. In this option the bin counters are NOT reset at the beginning of the command.

45.9.12.5 Kernel architecture

The histogram module consists of the preprocessing operation, logarithmic coding operation, the 'compare and count' operation and the histogram bin counters. The preprocessing and the log coding operations are bypassed in case the operands are already log2 values.

45.9.12.5.1 Preprocessing

The preprocessing module enables the 'histogram processing' of different input number formats. If necessary, signed input values are converted to positive values. The following options are available:

- Abs for real input values, negative values are inverted
- Abs for complex input values, as sum of absolute of real and imaginary part
- Mag for complex values, calculates half of approximate square root of the sum of $real^2$ and im^2

The pre-processing is bypassed for log2 numbers.

For real data it is also possible to have the option of no preprocessing.

45.9.12.5.2 Log Coder

The basic algorithm is to count the bit position of the leading '1' from the MSB in each operand and append the required number of bits following the first ‘1’ MSB in order to get the index of the bin. All numbers are treated as unsigned numbers for the purpose of log coding.

The number of appended bits depends on the word length of operand and the desired number of bins. With 16-bit input data the position code has a length of 4 bits. This number can be used directly with 16 bins and 1 or 2 mantissa bits must be appended to get 32 or 64 bins respectively.

With 24-bit operands the position code has a length of 5 bits. This number can be used directly with 32 bins or 1 mantissa bit must be appended to get 64 bins.

If the input data is of log2 type then by default bin size of 64 is chosen.

Table 45-63 covers all the possible cases:

Table 45-63. Valid log coding operations

Input data type	Data size	Bin size	Appended mantissa bits
Real or complex	16-bit	16	0
Real or complex	16-bit	32	1
Real or complex	16-bit	64	2
Real or complex	24-bit	32	0
Real or complex	24-bit	64	1
Log2	Not applicable	64 (default)	Not applicable

45.9.12.5.3 Compare and Count

This module performs a comparison of the log coded number and puts equal numbers in the same bin.

The command word needs to specify a low threshold bin. All values below or equal to this threshold are counted in the specified bin. It must be ensured that the threshold value specified in the command word is not greater than the bin size, else no bins are filled.

45.9.12.5.4 Bin counter

The bin counters are incremented by the count of operands belonging to same bin. The bin counters are cleared with the start of a histogram operation. To generate cumulative histograms, the clearing can be suppressed. The limit for the number of samples for single histograms is defined by the size of the bin counter. The bin counters are protected from overflow and provide an overflow flag in the configuration map. When any counter reaches its overflow value it is saturated at that value (0xFFFF). The result of histogram operation can be saved to operand RAM, twiddle RAM or work registers with the same command or a special command.

The size of every bin counter is 16 bits.

45.9.12.5.5 Writing bin counter values to memory:

Bin counter values can be written to operand RAM, twiddle RAM and work registers. While writing to operand or twiddle RAM, 16 bins can be written in one cycle (8 values of data x2 for real and imaginary parts). While writing to work registers all the bin counter values can be written to the work register in 1 cycle; two bins can be accommodated in one work register, 1 in the real part and 1 in the imaginary part.

Data is written out to operand RAM or twiddle RAM as shown in Figure 45-63. (example for 64 bins)

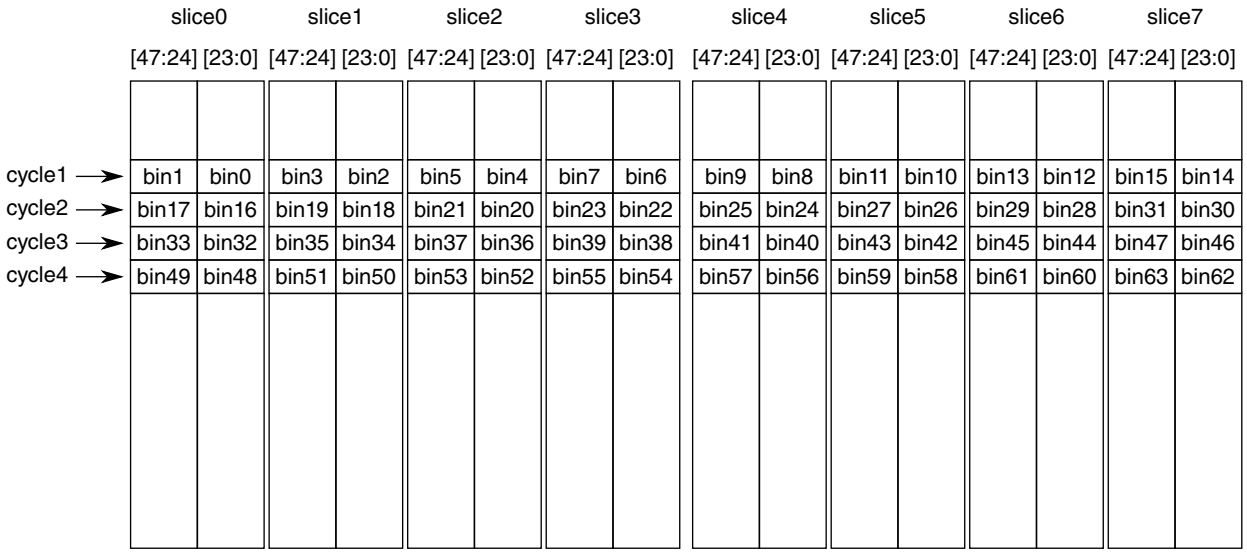

Figure 45-63. Writing bins back to memory

Data is written out to work registers as shown in Figure 45-64.

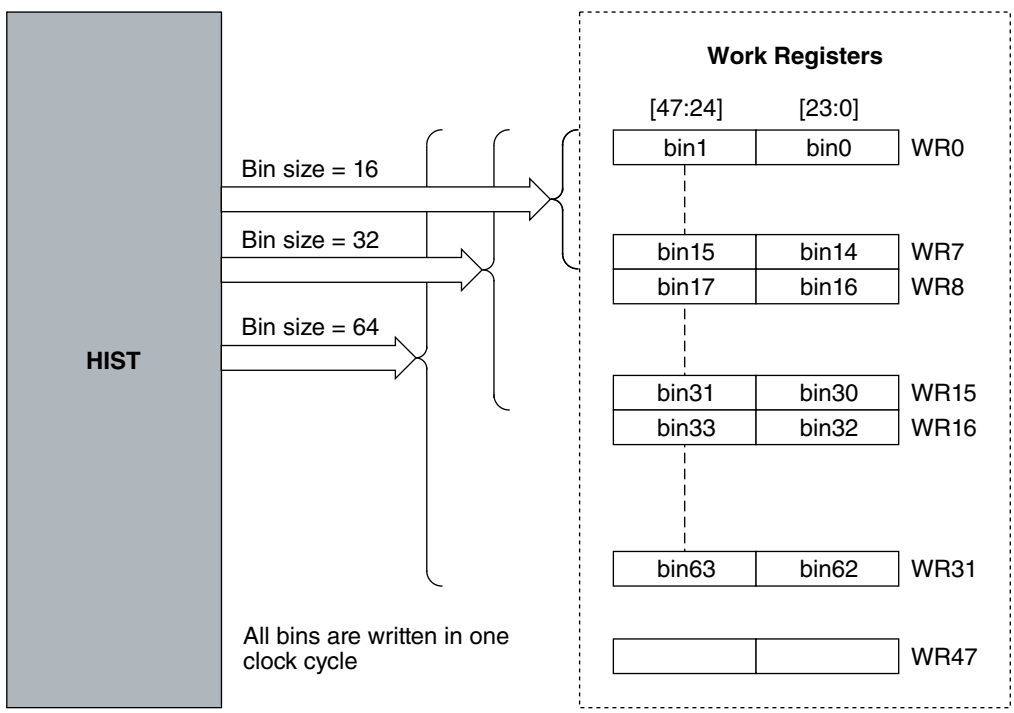

Figure 45-64. Writing bins back to work registers

45.9.12.6 HIST instruction format

The command word for the HIST instruction is shown in Table 45-64

Table 45-64. HIST Instruction Format

The various command parameters for the HIST instruction are explained in Table 45-65

Table 45-65. HIST Instruction bit description

Bits	Bit Field	Description
[121:120]	DAT_TYP	Input data type
		00 - real
		01 - complex
		1X - log2
[119:118]	PREPROC	Preprocessing (this field is checked only for real and complex input data)
		00 - for real input data type it corresponds to 'no preprocessing', for complex input data type it corresponds to abs operation
		01 - abs for real and complex input data type
		1X - for real input data type it corresponds to abs operation, for complex input data type it corresponds to mag operation

Table continues on the next page...

Table 45-65. HIST Instruction bit description (continued)

[117:116]	OP_MOD	00-read operand RAM, calculate hist and store results. In this option the bin counters are reset at the beginning of the command.
		01-read operand RAM, calculate histogram. In this option the bin counters are reset at the beginning of the command.
		10-read operand RAM, calculate cumulated histogram. In this option the bin counters are NOT reset at the beginning of the command.
		11-store results. In this option the bin counters are NOT reset at the beginning of the command.
[115:114]	BIN_SZ	00-for 16-bit input data it corresponds to 16 bins, for 24-bit input data it corresponds to 32 bins
		01-32 bins
		1X-64 bins
[111:110]	PACK_EN	2-bit field, enables packing of log2 or real input operands. For complex operands this field is ignored. The LSB decides whether the input value comes from the real component or the imaginary component
		00-Packing not enabled for log2 or real operand and data comes from real component
		01-Packing not enabled for log2 or real operand and data comes from imaginary component
		1X-Packing enabled for log2 or real operand.
[109]	IMA	Decides whether addressing is immediate (address comes from the instruction itself) or indirect.
		0-Immediate addressing
		1-Indirect addressing; the address comes from a work register for the source as well as the destination. This work register index is the bits 8:3 of the SRC_ADD field of the command word. The work register index should be from 0 to 47 else an error condition results.
[108:96]	VEC_SZ	Vector length- the vector length is the number of input data and so for the case of packed log2 or real input data it should be twice the number of storage

Table continues on the next page...

Table 45-65. HIST Instruction bit description (continued)

		locations. It is always a multiple of 8, else an error condition is raised. This field is ignored when OP_MOD = 11b
[95:80]	SRC_ADD	Source operand address. This address should be of the operand RAM only and should be a multiple of 8, else an error condition results. This field is ignored when OP_MOD = 11b
[79:64]	DEST_ADD	Destination operand address. Destination can be operand RAM, twiddle RAM or work registers. In case of work registers only the top 2-bits of the address are read and the histogram bin counters are stored in work register number 0 to work register number 31. If the address is of the operand or twiddle RAM then the address should be a multiple of 8, else it is an error condition. This field is ignored when OP_MOD = 01b or 10b
[47:40]	SRC_ADD_INC	Source address increment
[39:32]	DEST_ADD_INC	Destination address increment. This increment value is valid only when the destination is operand RAM or twiddle RAM.
[15:10]	THR	Minimum threshold bin.
[0]	DAT_SZ	Size of real and complex input data
		0 - 16-bit data
		1 - 24-bit data

45.9.13 MAX-S

45.9.13.1 Introduction

This operation searches for local or global maxima in a vector of data. A global maxima is the single value of a vector exceeding the value of each other vector element. This value can be present multiple times in a vector but it is only found once and the operation delivers a single result. A local maxima is defined as a value that is larger than both its neighbors in a vector.

The search for maxima is one of the most time-consuming operations with RADAR signal processing, therefore a highly-effective HW acceleration is necessary.

45.9.13.2 Principle of operation

The operation can find maxima in a vector of elements. To find the global maximum, the result of the current maximum operation is also compared with the result of the previous maximum operation and overwrites this result, if it is larger. To find the local maximum (peak), each value is compared with its nearest neighboring values. Optionally, the vector is padded with one more value at the beginning and the end and the search range is extended to include also the element 0 and N-1 in the search range.

A two dimentional local maxima search is implemented by multiple SPT command sequences. First, local maxima are determined in each column vector and output is tagged. After this step, the vectors are transposed and the local maxima search is repeated with each column vector again, this time with tagged inputs. The output of the second local maxima operation is in the form of bitfields. There can be an additional PDMA step which will output the aggregated list.

For local or absolute maxima calculations, comparisons are made using ">=" operator.

The MAXS module supports +ve as well as –ve input numbers. In case the incoming numbers are –ve (PREPROC = 00), and a –ve number comparison is needed, the IN_TAG and TAG_N_BITFIELD fields in the instruction need to be set to 0. Therefore, in effect, -ve number comparison can only be done when the input is not tagged and the output is not expected to be tagged.

45.9.13.2.1 Local/Absolute Maxima Definition

A global maximum is defined in the following way:

$$\text{if } (x_n >= x_k),\ gmax = x_n, \text{ where } k = 0...N-1$$

The local maximum of a vector is defined as all values x that meet following equation

$$\text{if } (x_{n-1} < x_n >= x_{n+1}),\ lmax_k = x_n, \text{ where } n = 0...N-1$$

The output of the local maxima operation can be a tagged output or a set of bitfields with a '1' on all the locations with a local maxima. The output of absolute or global maxima is the global maxima value. In case of absolute maxima, the final maxima value that is written is a pre-processed value and not the original 48 bit input.

LOC_N_ABS bitfield of the instruction defines if a local or absolute maxima is to be calculated. A '1' in this bitfield defines that a local maxima has to be calculated while a '0' on that bit implies a global maxima calculation.

45.9.13.3 MAXS Instruction Format

The table below shows the instruction bit encoding used for MAXS. The details of each bit field and their operation is defined in the sections below.

Table 45-66. MAXS Instruction

127	126	125	124	123	122	121	120	119	118	117	116	115	114	113	112

		00 - MAXS16
		01 - MAXS8
		10 - MAXS4
		11 - reserved
[15:0]	THLD_ADD	Threshold address

NOTE

Destination Increment is ignored for global max and local max bitfield output

45.9.13.3.1 Input Tagged

The input to the MAXS operation may be tagged or untagged. In case the input is in tagged format, the local maxima search only checks the tagged locations with its neighbours. If the tagged location is greater than its neighbours, it is declared a local maxima. The tagged inputs are required for the software enabled two dimentional local maxima search.

In case of global maxima, the tag bit is ignored and is removed while saving the global maxima.

The MSB (24th bit) bit is used as tag bits. Only operand of datatype log2 can be tagged. Tagging is not allowed for real or complex inputs datatypes.

45.9.13.3.2 Input Datatype

The maxs operation is possible with input data in the real, complex and log2 formats. Two bits in the instruction format are used to define the type of input to the MAXS operation.

The Table 45-68 describes the different pre-processing requirements with different types of input formats. Two bits in the instruction format are used to define the type of complex pre-processing required.

Table 45-68. Input Datatype

Input Data	PreProcessing required	Number of bits
Real	No preprocessing	24
	Abs(real) + Abs(Im)	
Complex	Abs(real) + Abs(im)	24
	Mag for complex values (calculate approx sq root of real^2 + im^2)	
Log	No Preprocessing	14

45.9.13.3.3 Input Packing

Max search can work on up to 16 operands in parallel. For this purpose, the input data need to be available in packed format, so that with 8 inputs from operand RAM, 16 24-bit operands can be processed concurrently.

In case of local maxima operation with packed input operands, if TAG_N_BITFLD bit of the instruction is set, both the 23rd and the 47th bit of the output are tagged for local maximas. Complex input datatype are always preprocessed, hence is never in packed format.

Bitfield IN_PACK of the instruction defines if the input is coming in packed format. A '10' on this bitfield implies that the input is in packed format. A '0' on the MSB signifies an unpacked format or 1 operand per 48 bits of incoming data.

45.9.13.3.4 Threshold Compare

When Threshold Compare is enabled by setting THLD_CMP bitfield of the instruction, any local maxima value is compared with the threshold value as well. And a maxima is reported only when the value is greater than the threshold. Threshold compare option is only valid for local maxima. When global maxima is selected, the THLD_CMP bitfield of the instruction is ignored. The threshold value is a second input operand for a max operation. It can be located in work registers or twiddle RAM. No preprocessing is done on the threshold value and it is used as is. In case of TAG_N_BITFIELD or IN_TAG set to 1, the threshold value should be positive, that is, the 16^{th} bit in case of read from TRAM and 24^{th} bit in case of read from OPRAM/Work registers should be 0.

It is advisable to store the threshold values in one of the work registers. Storing threshold values in OPRAM or TRAM leads to initial latency of single cycle. In addition if source of operands and threshold values are same, it leads to lower performance.

45.9.13.3.5 Output Tag/Bitfield

Local maxima output is generated based on the TAG_N_BITFLD field of the instruction. When TAG_N_BITFLD is set to zero, the local maxima outputs are generated as a string of bits with 1's in locations having a local maxima. The bits are packed in chunks of 16 and written to the LSBs of the 24-bit word in case of OPRAM and work registers. The rest of the 8 bits are set to 0. In case of twiddle RAM all 32 bits are occupied.

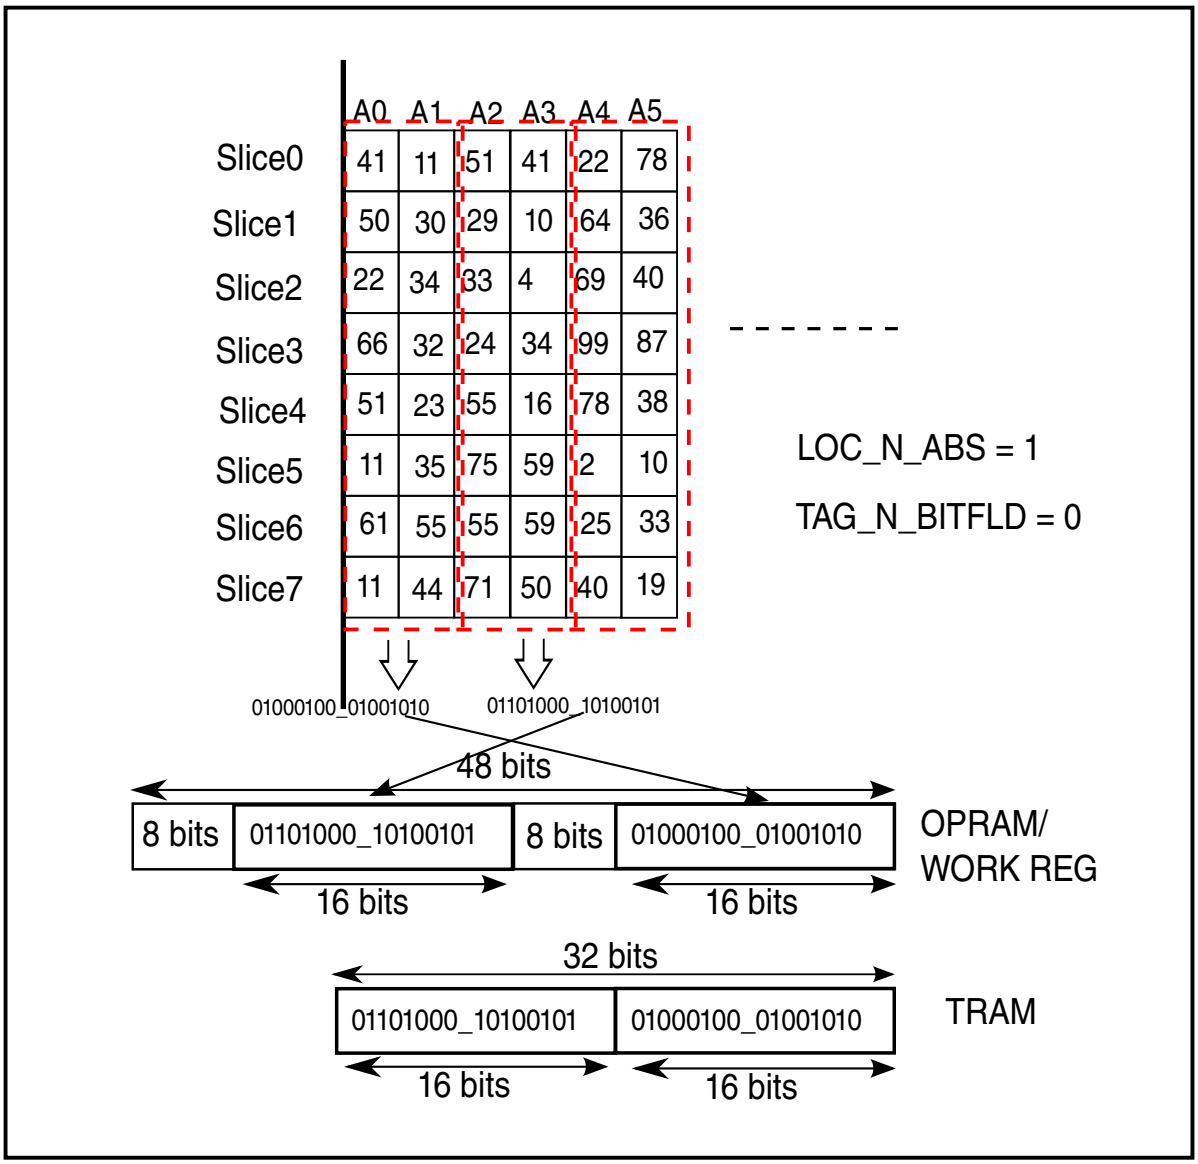

Figure 45-65. Local max bitfield packing

When TAG_N_BITFLD option is set to 1, the output vectors are simply tagged and processed inputs (not original inputs). The 24th bit is used as the tag field. The input vectors are processed, tagged and written to the DEST_ADD. The SRC_ADD remains unaltered.

In case of packed operands (IN_PACK = 10b), the bitfield for the operand occupying the Real location will go to the LSB.

The destination for tagged outputs can only be OPRAM as the 24th or 48th bit of the input word is set to 1. While the bitfields are always written in a packed manner, the tagged outputs in case of local max are packed differently. The following table shows how the outputs are packed.

Table 45-69. MAXS Output packing

loc_n_abs	in_dattype	Output Real	Output Im
Local max (output tag)	COMPLEX	Tagged output	Unchanged
	REAL/LOG (in_pack = 00b)	Tagged output	Unchanged
	REAL/LOG (in_pack = 01b)	Unchanged	Tagged output
	REAL/LOG (in_pack = 10b)	Tagged output	Tagged output

45.9.13.3.6 Cyclic extension

Cyclic extension allows the detection of local maximum at the very first or the very last vector element. After cyclic extension, the first element of the vector is also compared with the very last element of the vector and vice-versa. CYC_EXTN field in the MAXS instruction defines whether cyclic extension is to be used in the maxima calculation. Cyclic extension is only applicable with local maxima search.

45.9.13.3.7 MAXS N

MAXS N is a special operation in which multiple blocks of N operands are processed at one time. The number of operands in one operation is always equal to N, where N can be 4,8,16 given by MAXSN_SEL in the instruction. The total number of blocks is determined as VEC_SZ divided by N. The basic motivation of having this option is that the latency between the various MAXN operations are reduced. Figure 45-66 shows an example of absolute maxima MAXSN for N=16 operation executed for 16 blocks. This operation generates 16 maxima values.

All local and absolute maxima description apply for MAXSN as well, the only difference being that the operation will be carried out for multiple blocks.

As the number of generated results in case of MAXSN can be large, the destination address should be chosen carefully. WREG can only be used as destination for MAXS16. It cannot be used for MAXS8 and MAXS4 as we get multiple global maxima outputs in each cycle for these.

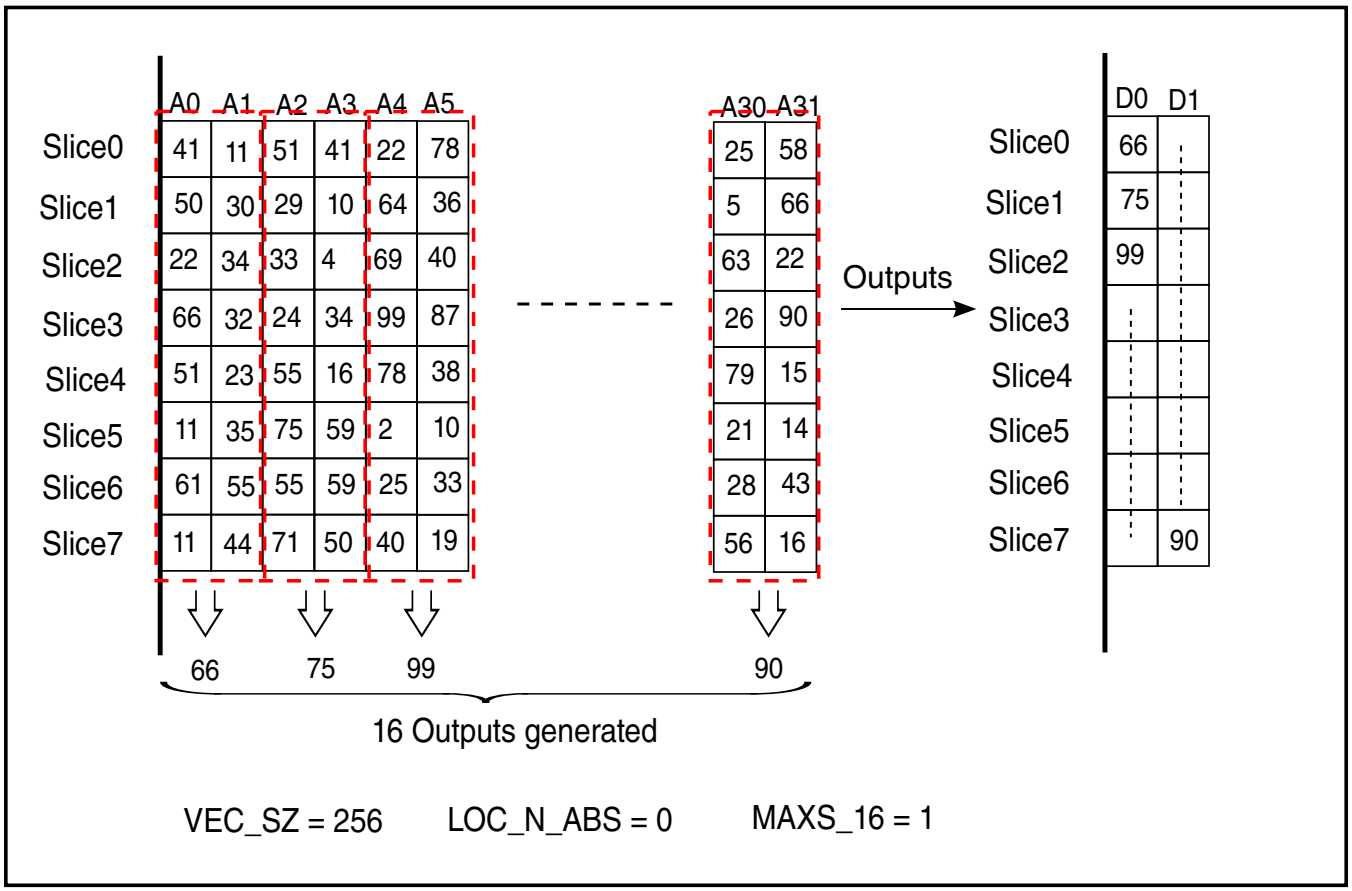

Figure 45-66. MAXS 16 for 16 blocks

When THLD_CMP is enabled (valid for local maximum only), a new threshold value is read for every new MAXSN block. For MAXS4 packed format, 4 threshold values have to be read at once, so the threshold address should be a multiple of 4. Similarly, for MAXS4 unpacked format or MAXS8 packed format, 2 threshold values have to read at once, making the address a multiple of 2. The threshold value is a preprocessed value which is read from the Real part of the vector. For MAXSN, the threshold value can only reside in TRAM and the input data can not reside in TRAM.

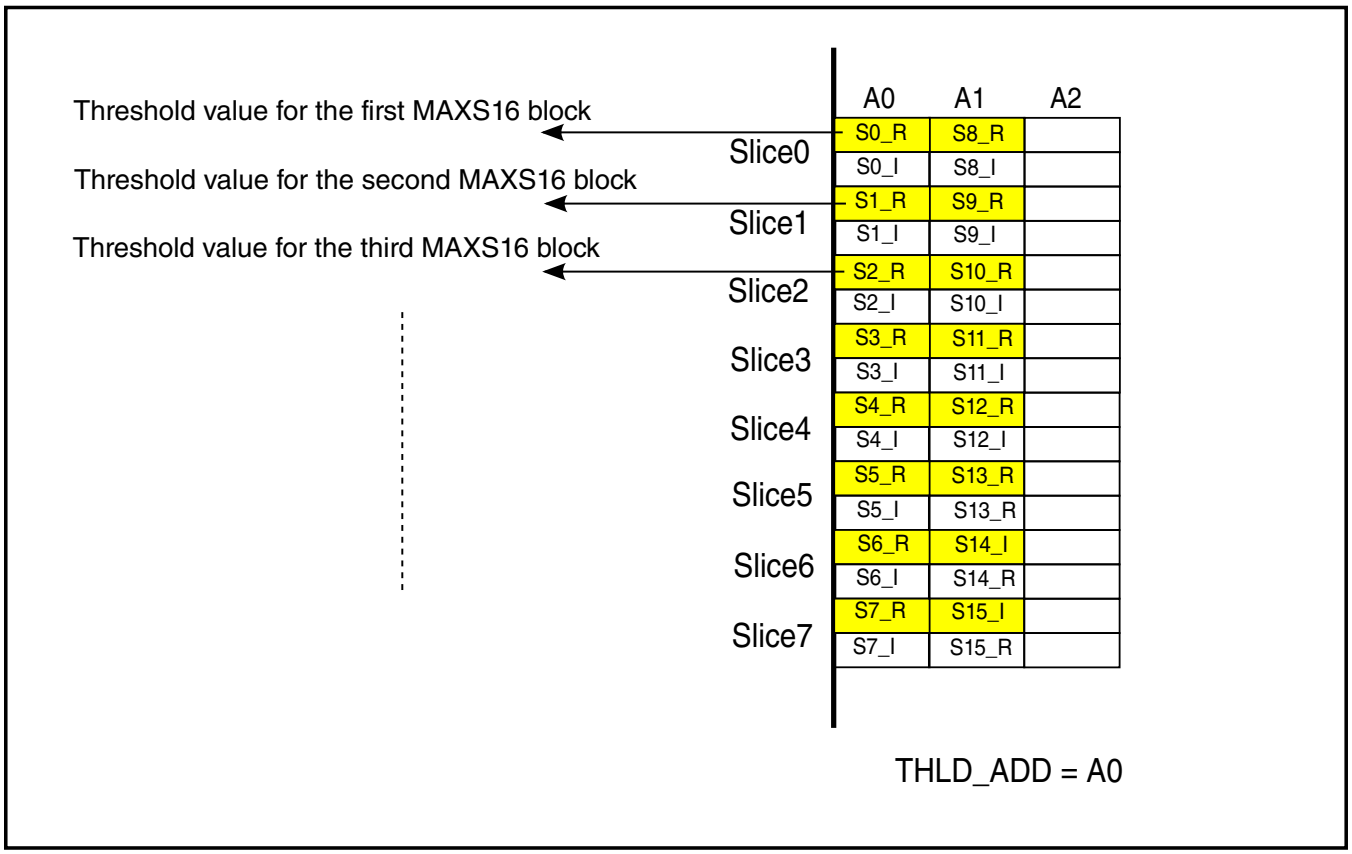

Figure 45-67. Threshold for MAXS16

45.9.13.4 Error scenarios

Maxs gives out a command error if the instruction is not programmed correctly. Table 45-70 gives the list of possible cases.

Table 45-70. Error Scenarios

ERROR	DESCRIPTION
tagged_data_log_err	local maxima with in_tag and datatype is not LOG2
tagged_data_src_add_err	in_tag data for local maxima and source address is not OPRAM
tagged_output_dest_add_err	Tagged local maxima output and destination is not OPRAM
maxsn_thld_add_err	MAXSN threshold compare for local maxima and threshold address is not TRAM
maxsn_src_add_err	MAXSN threshold compare for local maxima and source address is not OPRAM
maxsn_dest_add_err	MAXSN threshold compare for local maxima and destination address is TRAM
cmplx_data_pckd_err	data type is complex and in_pack set to 2'b10 (packed)
cmplx_no_preproc_err	data type is complex and preproc set to 0 (No preproc)

Table continues on the next page...

Table 45-70. Error Scenarios (continued)

ERROR	DESCRIPTION
dattype_rsvd	input data type = 2'b11
in_pack_rsvd	input packing = 2'b11
preproc_rsvd	preproc = 2'b11
maxsn_rsvd	maxsn_sel = 2'b11
maxs16_vec_sz_err	maxsn_sel = 2'b0 (maxs16) and vector size not a multiple of 16
vec_sz_err	vector size not a multiple of 8
packed_vec_sz_err	in_pack = 2'b10 (packed) and vector size not a mulitple of 16
src_add_wreg_err	source address is WREG
dest_add_wreg_err	local maxima and destination is WREG
maxs8_4_dest_wreg_err	maxs8 or maxs4 enabled and destination is WREG. Maxs16 supports WREG.
maxs8_4_thld_addr_err	maxs8 packed/maxs4 unpack, threshold address not multiple of 2. Maxs4 packed, threshold address not multiple of 4.

45.10 Interrupts

The SPT can schedule interrupts to the CPU. The interrupts are defined with event commands and specific flags, which are visible to the CPUs as interrupt flags. Interrupt flags can be masked out from interrupt generation. The CPU can also poll to specific interrupt flags. To offload CPU from polling, special connections are provided directly to Cores and they will become part of the Version Register in CPU. Dedicated Connections to Core1 are from the status bits of SPT_CORE1_VER_EVT and to Core2 from the status bits of SPT_CORE2_VER_EVT. The order is also same as in the status register fields. These connections are shown in Figure 45-68

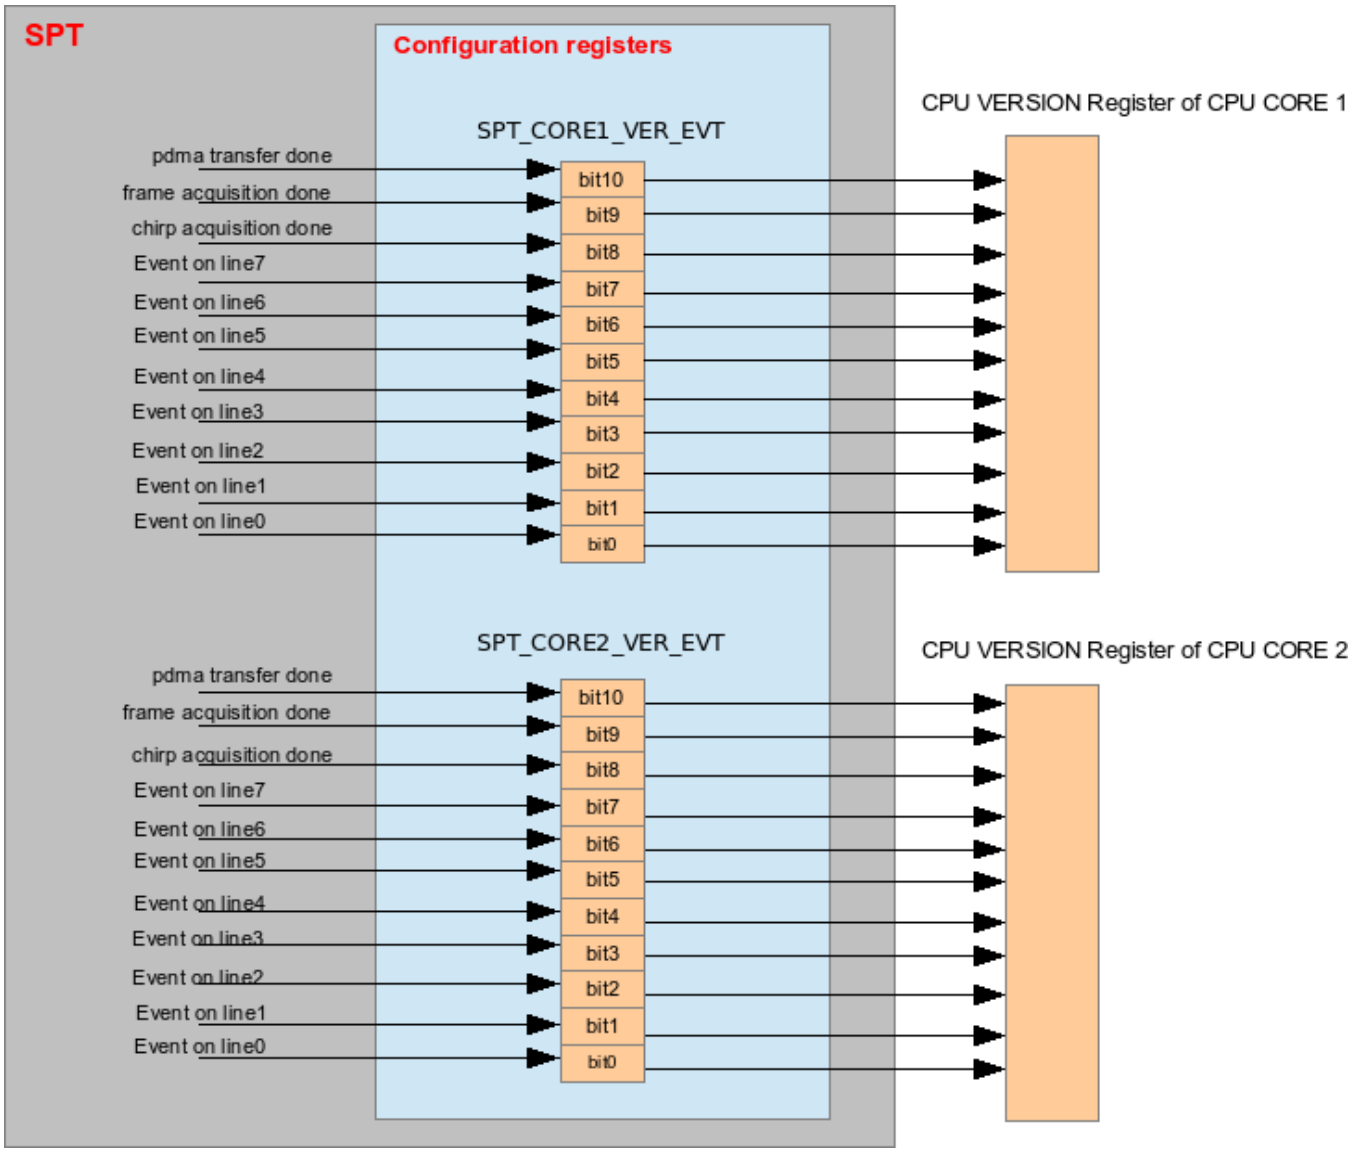

Figure 45-68. Connections between SPT and CPU VERSION Registers

Special Interrupts are connected to all the Cores and Cores can select themselves whether to watch them or ignore them. It is assumed that either a single core handles these interrupts or each core responds only a specific interrupt flag and resets it. If more than one core is using the interrupt events, then individual interrupt handler of each core will be invoked on every interrupt event, to check the state.

Following are the interrupt lines to INTC:

- SPT_IRQ_ECS - It is the general interrupt line which includes the command sequencer related status interrupts as well as the all error and overflow interrupts. SPT_IRQ_ECS consists of the following interrupt and interrupt enable register pairs:

  SPT_MEM_ERR_STATUS - SPT_MEM_ERR_INT_EN

SPT_DMA_ERR_STATUS - SPT_DMA_ERR_INT_EN

SPT_HW_ACC_ERR_STATUS - SPT_HW_ACC_ERR_IE

SPT_HIST_OVF_STATUS0 & SPT_HIST_OVF_STATUS1 - SPT_HIST_OVF_IE

SPT_CS_STATUS0 - SPT_CS_INTEN0

SPT_CS_STATUS1 - SPT_CS_INTEN1

- SPT_IRQ_DMA - This interrupt line includes the PDMA Transfer Done signal, Chirp Acquisition Done and Frame Acquisition Done signals. SPT_IRQ_DMA consists of the following interrupt and interrupt enable register pair:

  SPT_GBL_STATUS - SPT_GBL_STATUS_IE

- SPT_IRQ_EVT1 - This line includes the SPT event interrupts. This interrupt is for the CPU CORE1. SPT_IRQ_EVT1 consists of the following interrupt and interrupt enable register pair:

  SPT_CS_EVTREG1 - SPT_CS_EVT1_INTEN

- SPT_IRQ_EVT2 - This line includes the SPT event interrupts. This interrupt is for the CPU CORE2. SPT_IRQ_EVT2 consists of the following interrupt and interrupt enable register pair:

  SPT_CS_EVTREG2 - SPT_CS_EVT2_INTEN

The interrupt signals along with the WAIT and event generation capability provide hooks to the CPU to synchronize its operations with the SPT operations and with the incoming ADC/MIPICSI2 data frequency. The SPT can wait for 8 software events generated on the peripheral interface, 6 events coming from CTE (or in case of MIPICSI2 the hsync and vsync events), the PDMA transfer done signal, Chirp Acquisition Done and Frame Acquisition Done signals. It also has the capability to program the type of awaited event i.e. whether the awaited event is positive/negative edge triggered or positive/negative level triggered.

The EVT command can throw out events which can be captured by CPU on the peripheral interface.

Figure 45-69 shows the interrupt, WAIT and EVT strategy of the SPT.

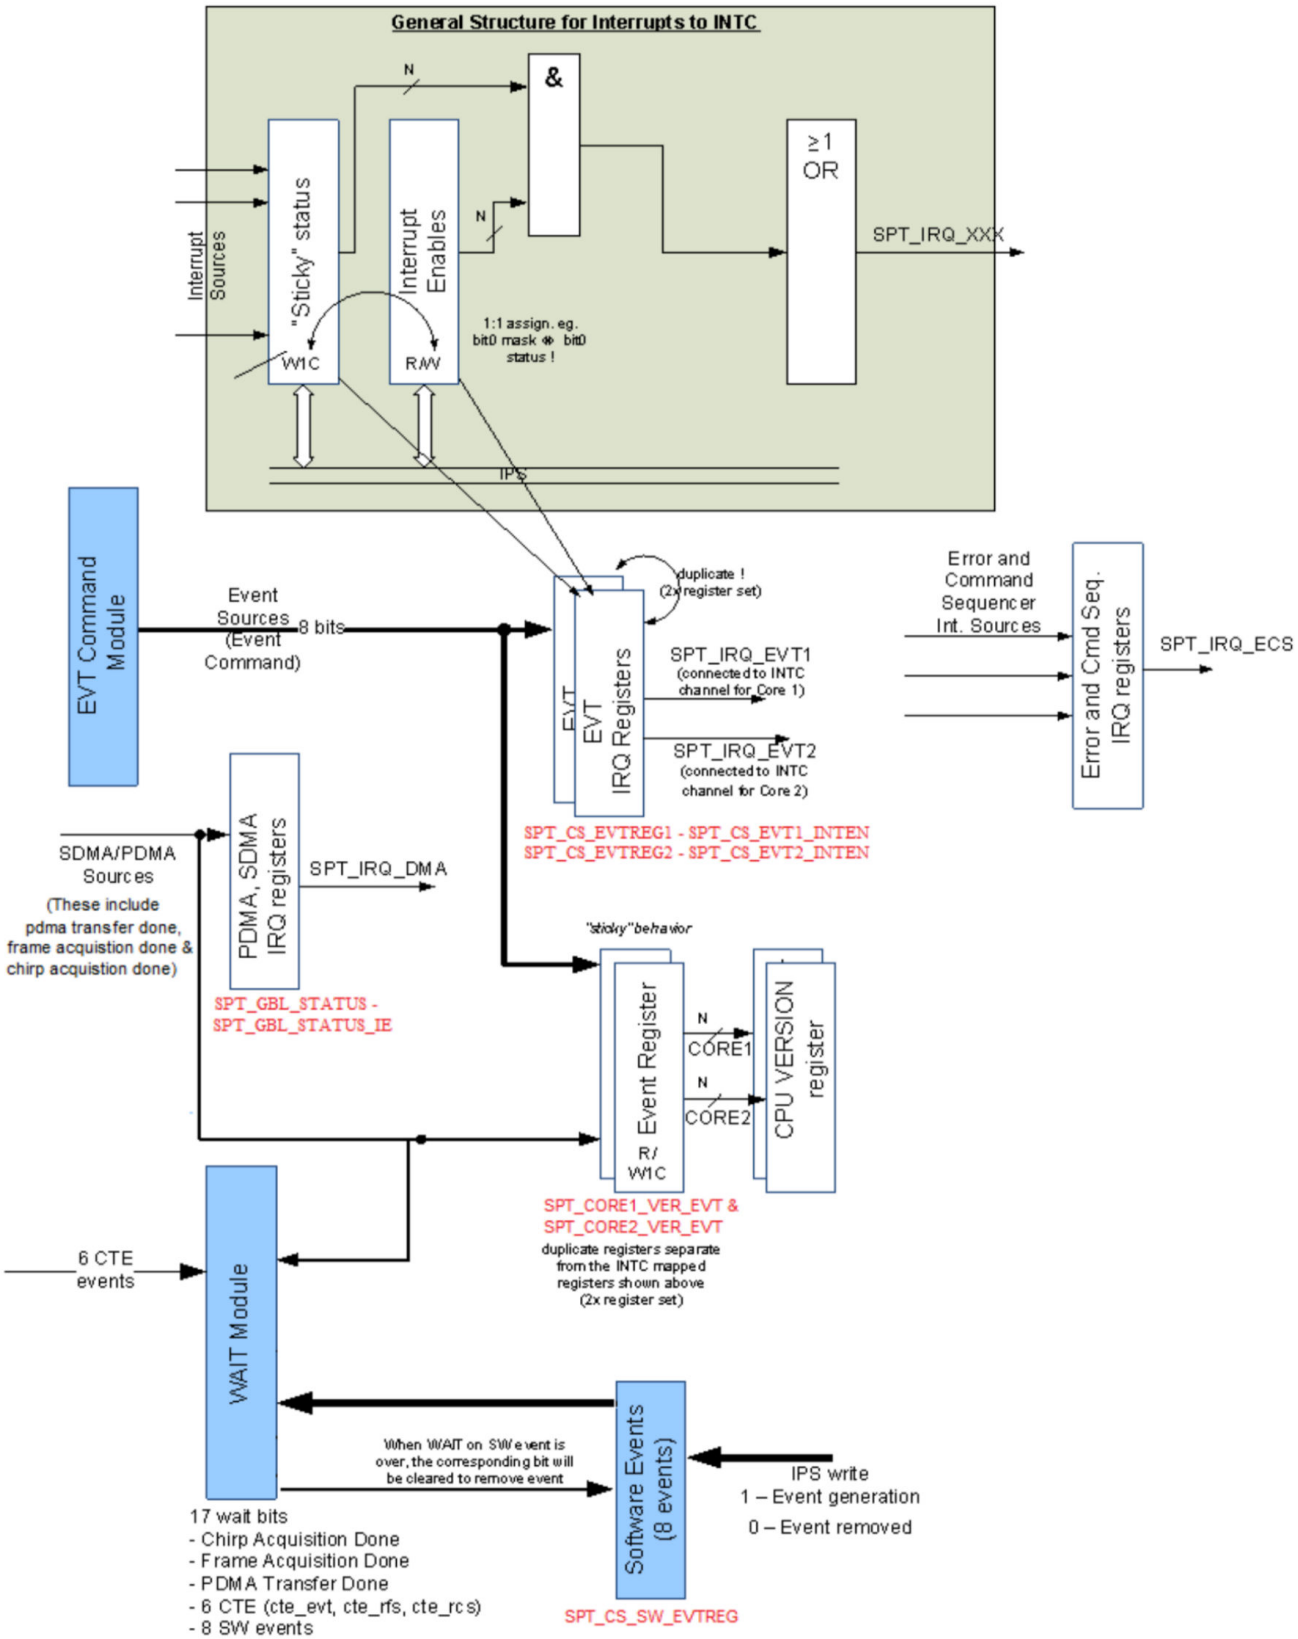

Figure 45-69. SPT interrupts, WAIT and EVT strategy

45.11 Initialization Sequence

The following steps give the sequence for SPT initialization:

1. The user must ensure that the instruction sequence is loaded into the SRAM or Flash or any Slave memory.
2. Program the Acquisition and SDMA Configuration registers. Configure the following configuration registers as per requirement: SPT_ACQ_GBL_CTRL_0, SPT_ACQ_GBL_CTRL_1, SPT_ACQ_CTRL0, SPT_ACQ_CTRL1, SPT_ACQ_CTRL2, SPT_ACQ_CTRL3, SPT_SDMA_CTRL0, SPT_SDMA_CTRL1. In case of MIPI mode, also configure SPT_ACQ_CSI_CTRL, SPT_SDMA_BYP_CTRL0, SPT_SDMA_BYP_CTRL1, SPT_ACQ_BYP_CTRL.
3. Then enable SPT_GBL_CTRL[ACQ_EN] so that Acquisition of ADC sample can start after trigger from CTE is received or input samples from MIPICSI2 can start after vsync from MIPICSI2 is received. User can choose not to enable ACQ_EN when usecase is to process data from the memory only.
4. Update the SPT_CS_MODE_CTRL register to decide the working mode for the command sequencer. The command sequencer can be initialized in the RUN state or in the DEBUG state. To initialize the sequencer in the DEBUG state the SPT_CS_MODE_CTRL[CS_IMM_DEBUG] or SPT_CS_MODE_CTRL[CS_SYS_DEBUG] field needs to be set. By programming the SPT_CS_MODE_CTRL[DEBUG_MD] the user can set the debugging mode to step once mode, step jump mode, instruction jamming mode or halt mode. User can also set upto 4 breakpoints in the debug mode by programming SPT_CS_MODE_CTRL[BKPTx_EN], SPT_CS_MODE_CTRL[BKPTx_RE] and SPT_CS_BKPT0_ADDR. SPT_CS_MODE_CTRL[PREFETCH] field can be set to enable the early pre-fetch option. Also update SPT_CS_PG_ST_ADDR which gives the location from where the Command Sequencer starts fetching data upon start-up.
5. Program SPT_CS_MODE_CTRL[CSDMA_BRST_SZ] as per requirement. This field should be held constant when the program is running.
6. Configure SPT_PDMA_LFSR_LOAD_VAL_HIGH, SPT_PDMA_LFSR_LOAD_VAL_LOW and SPT_PDMA_CTRL registers appropriately to decide the configuration for PDMA usage and priority.
7. User may also set the appropriate bits of the various interrupt enable registers.
8. Enable SPT_GBL_CTRL[SPT_EN] to enable the SPT module. Then after 10 SPT clock cycles set the SPT_GBL_CTRL[PG_ST_CTRL] field which enables Command Sequencer to fetch first 16 instructions from the address programmed in SPT_CS_PG_ST_ADDR. At this point, it is advisable for the CORE to wait for the

sequencer to go to RUN state (or DEBUG state) before writing to the peripheral interface. After this all the hardware acceleration modules will process as per instructions decoded in the sequence.

45.12 Throughput

Table 45-71 shows the number of cycles taken for implementing the various control commands:

Table 45-71. Table showing the number of cycles for control commands' implementation

Command	Mode	Total number of clock cycles
SET	Data source is immediate data	2
	Data source is Work Register	3
GET	All modes	3
ADD	All modes	5
WAIT	-	1(and then command sequencer goes to WAIT state)
EVT	-	1
WATCHDOG	-	1
LOOP	-	1
NEXT	-	1
SUB	All modes	5
CMP	All modes	5
SEL	-	5
JUMP	-	2+number of cycles to re-fill the instruction queue

Table 45-72 shows the additional pipelining cycles and also the total number of cycles taken from the implementation of the various operation commands.

Table 45-72. Table showing pipelining cycles and total number of cycles for operation commands' implementation

Command	Mode	No. of additional pipeline cycles	Total no. of cycles (throughput)
HIST (reading memory data + processing)	complex data input (abs pre-processing)	6	(Vec_len/8) + 6 + (write_cycles)
	complex data input (mag pre-processing)	7	(Vec_len/8) + 7 + (write_cycles)
	unpacked real data input	6	(Vec_len/8) + 6 + (write_cycles)

Table continues on the next page...

Table 45-72. Table showing pipelining cycles and total number of cycles for operation commands' implementation (continued)

Command	Mode	No. of additional pipeline cycles	Total no. of cycles (throughput)
	packed real data input(but the 16 received data values take 2 cycles to be processed, so there is no throughput gain)	6	(Vec_len/8) + 6 + (write_cycles)
	unpacked log2 data input	5	(Vec_len/8) + 5 + (write_cycles)
	packed log2 data input (in this case all the 16 data inputs are processed in one clock cycle, so double throughput)	5	(Vec_len/16) + 5 + (write_cycles)
HIST (write_cycles)	Destination is work register	1	-
	16 bins and destination is TRAM or OPRAM	1	
	32 bins and destination is TRAM or OPRAM	2	
	64 bins or log data input and destination is TRAM or OPRAM	4	
COPY (If preprocessing==mag then x=1, else x=0)	Transpose	x + 11	(Vec_len/8) + x + 11
	8x4 Transpose	x + 8	(vec_len/8) + x + 8
	Copy unpack	x + 4	(2*Vec_len/8) + x + 4
	Real pack or imaginary	x + 4	(Vec_len/8) + x + 4
	Partial copy real or imaginary	x + 4	(Vec_len/8) + x + 4
	Partial copy (real to imag & imag to real)	x + 4	(Vec_len/8) + x + 4
	Copy clear	x + 2	(Vec_len/8) + x + 2
	Shift	x + 5	(Vec_len/8) + x + 5
	Simple copy	x + 4	(Vec_len/8) + x + 4
	Threshold copy	x + 7	(Vec_len/8) + x + 7
MAXS (if preprocessing == MAG, then x=1 else x=0) (if IN_PACK == 2'b10, then p =16 else p =8)	maxs_en = 1 and global max	x + 7	(Vec_len/p) + 7 + x
	maxs_en = 1 with local bitfield and vector length not multiple of 16	x + 7	(Vec_len/p) + 7 + x
	maxs_en = 0 and local max with threshold	x + 9	(Vec_len/p) + 9 + x
	For all other cases	x + 8	(Vec_len/p) + 8 + x

CP8FMTB		1	
CP16FMTB		1	

NOTE

- hready wait is the number of extra cycles spent when hready is low during the entire pdma transfer
- pdma priority wait is the number of extra cycles spent when CS fetches data during a pdma transfer
- pdma access wait is the number of cycles in which access is granted to PDMA
- mult_clock = (ahb clock period/spt clock period)
- mult_clock_system= (ipg_clock_period/spt_clock_period)
- no_of_exponent = ceiling((Vec_len/effective_chunk_length)/ mantissa_per_exponent)

  mantissa_per_exponent = 16 (for CP4FMTB & CP4DFMTB)

  = 32 (for CP8FMTB)

  = 64 (for CP16FMTB)
- fmtb_mantissa_expoent_switch_delay = 4 AHB cycles per exponent (decompression mode) and 2 AHB cycles per exponent (compression mode) for CP4FMTB, CP4DFMTB, CP8FMTB, CP16FMTB

Chapter 46
Cross Triggering Engine (CTE)

46.1 Chip-specific CTE information

46.1.1 Chip-specific Cross Triggering Engine (CTE) information

CTE defines the individual timing of signals which need to be asserted in the system. It controls system's processing flow by triggering modules in the system like ADC sample capture, WGM start to enable DAC sample generation and SPT program execution for autonomous and coherent data processing. Programmable signals can be provided to eTimer for triggering other functional units.

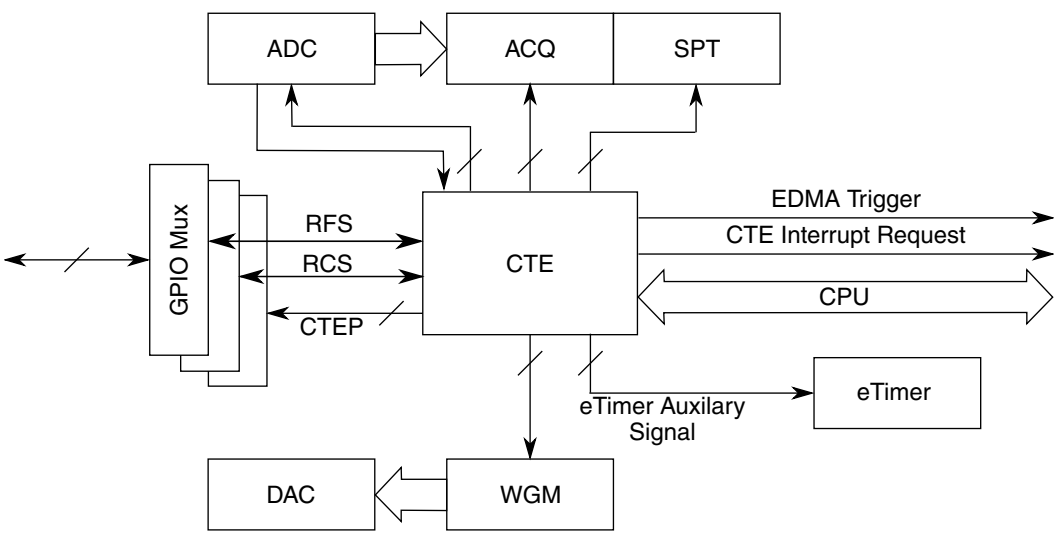

Figure 46-1. CTE Integration

The Radar processing connection between MIPI and CTE as per spec is implemented as shown below:

Input Module	Input Signal	Driving Module	Driver Signal
CTE	RCS[1]	MIPI	HSYNC

Table continues on the next page...

Input Module	Input Signal	Driving Module	Driver Signal
CTE	RFS[2]	MIPI	VSYNC

1. RCS = HSYNC
2. RFS = VSYNC

- Input to the CTE will come from a mux that will choose RCS/RFS either from HSYNC/VSYNC of MIPI or the IO-pads. This is needed because the CTE may use MIPI outputs for generating its timing information.
- Output RCS/RFS of the CTE will be muxed with MIPI's HSYNC/VSYNC and then this mux's outputs will be used by all the other IPs (AFE-filt/WGM/ENET and IO-pads). This is needed to give the timing information synchronously to all the modules.
- MCB_MISC1[IN_CTE] is used to control the input path of RCS/RFS to CTE:
  - 0 - CTE path is selected from PADS.
  - 1 - MIPI path is selected.
- MCB_MISC1[OUT_CTE] is used to control the output path of RCS/RFS from CTE:
  - 0 - CTE path is selected.
  - 1 - MIPI path is selected.

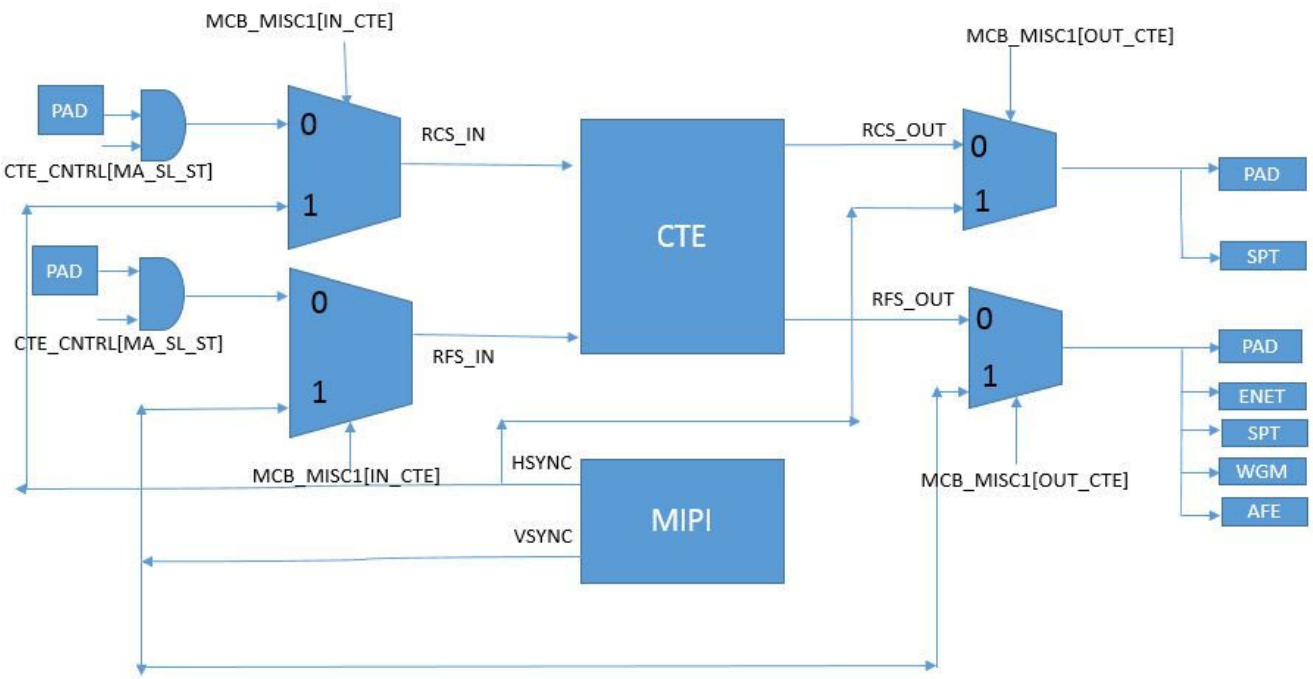

Figure 46-2. Radar processing connection

46.2 Introduction

CTE defines individual timing of signals for RADAR systems and control of the RADAR processing flow. CTE triggers ADC sample capture andDAC conversions as well asSPT program execution for autonomous and coherent data processing. Programmable signals can be provided to various modules in the system, in order to trigger other functional units and for flexible, related timing generation.

The following table lists various acronyms and their description that are used in CTE block.

Acronym	Description
SPT	Signal Processing Toolbox
WGM	Waveform Generator Module
DAC	Digital-to-Analog Converter
LUT	Look-up Table
CTE	Cross Triggering Engine
FSM	Finite State Machine
GPIO	General Purpose I/O
SW	Software
FADR	Fixed Address
CVAL	Counter Value
MISR	Multi Input Shift Register
TT	Timing table. TT0 is first timing table and TT1 is second timing table.

46.3 Block diagram

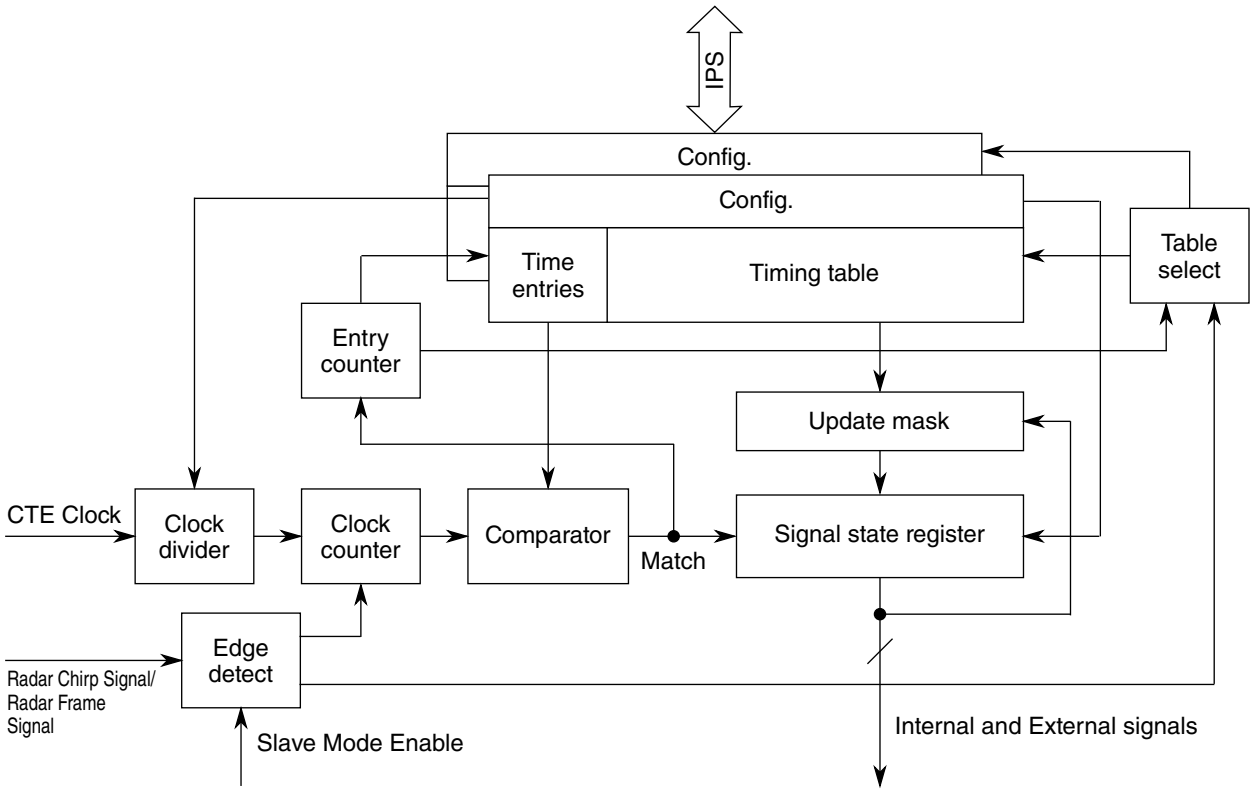

Figure 46-3. CTE block diagram

46.4 Features

CTE module has the following key features:

- Programmable timing generation for RADAR systems
- Synchronization between DAC waveform and ADC capture
- Master/slave mode
- Automatic update by eDMA
- Generation of external timing signals
- Overflow count

46.5 Modes of operation

46.5.1 Master/Slave mode

Master/slave mode operation can be selected using the Control Register master/slave select bit, CNTRL[MA_SL_ST]. By default, CNTRL[MA_SL_ST] = 0 meaning CTE operates in master mode out of reset.

46.5.1.1 Master mode

In master mode operation, the Radar Chirp Synchronization (RCS) and Radar Frame Synchronization (RFS) signals act as outputs for the control of external systems. CTE defines the values of these signals (alongside other external and internal signals) at specific time instances based on internal timing reference look-up tables. The timing tables are populated through the programming of a set of registers, see Timing table configuration section.

46.5.1.2 Slave mode

In slave mode operation, the chirp waveform generation and acquisition unit triggering depends on RCS and RFS as input signals to the CTE. RFS and RCS can be captured from I/O pads or generated by the MIPICSI2 module. Please refer to Chip-specific Cross Triggering Engine (CTE) section, for instructions on how to configure the source of these signals.

The CTE operation mode FSM starts on capture of RCS (after the synchronizer and the delay configuration block). RCS triggers the start of timing table execution, based on the CTE configuration. Capture of RFS (after the synchronizer and the delay configuration block) resets the entry address of timing table execution to ensure that the timing table execution in slave mode is started from location 0. The entry address is automatically reset to 0 after each timing table has finished execution, meaning that external RFS signal is not necessary when it can be ensured that there is enough time between each external RCS to finish timing table execution. Since each captured RCS signal triggers a timing table execution, each timing table should be programmed to represent a single chirp.

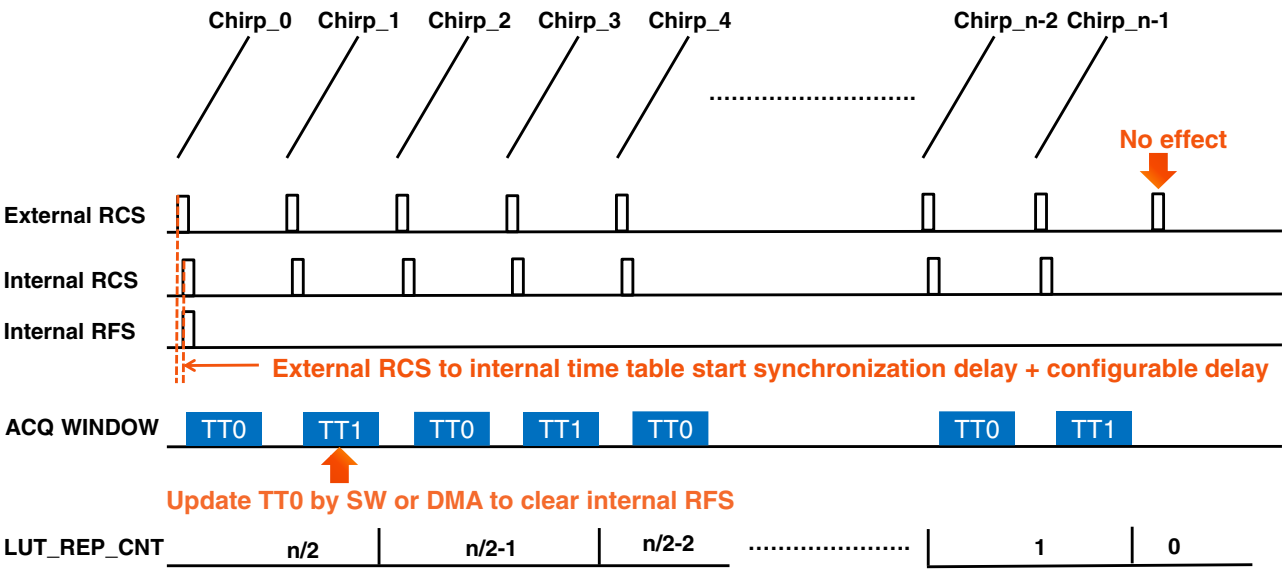

Figure 46-4. Fast chirp modulation timing – example

The internal RFS and RCS still have to be generated as in master mode, meaning the values and behavior of RCS and RFS must be programmed in the timing table registers. They have the same functionality in master and slave mode apart from the functionality that is taken care of by the external signals in slave mode as described above.

From the user perspective, RCS capturing simultaneously or after RFS is the start of the table execution and the next RCS is considered as the end. The end is also dependent upon the duration counter (CTE_LUT_DUR[TT0_DUR]/CTE_LUT_DUR1[TT1_DUR]) and this takes precedence over RCS for considering the end of execution. For example, if the next RCS comes before the TT execution ends, it is ignored. Therefore, it is the responsibility of SW to ensure that the table execution time is always less than the time difference between the two RCS signals. On the contrary, if the table execution is completed before the RCS, signal states will be driven according to the last timing entry until the duration counter expires or the next RCS is captured. Before starting a new frame after all chirps have been processed, the CTE module must be disabled then enabled to reset the FSM.

46.5.1.2.1 Capturing RCS and RFS signals

In order to capture the RCS and RFS pulses correctly, the width of these pulses must be at least twice the clock period of the CTE clock. If the pulse width is less than this, slave mode operation will not work properly. After this 2 flop synchronization, there is an edge detection block which detects the rising edge of the synchronized RCS and RFS signals.

The edge detection block is configurable and can introduce 0-15 clock cycles delay between the input and output signal using CNTRL[RFS_DLY] for RFS and CNTRL[RCS_DLY] for RCS. By adjusting these delays, CPU can control the timing relation between RCS and RFS signals.

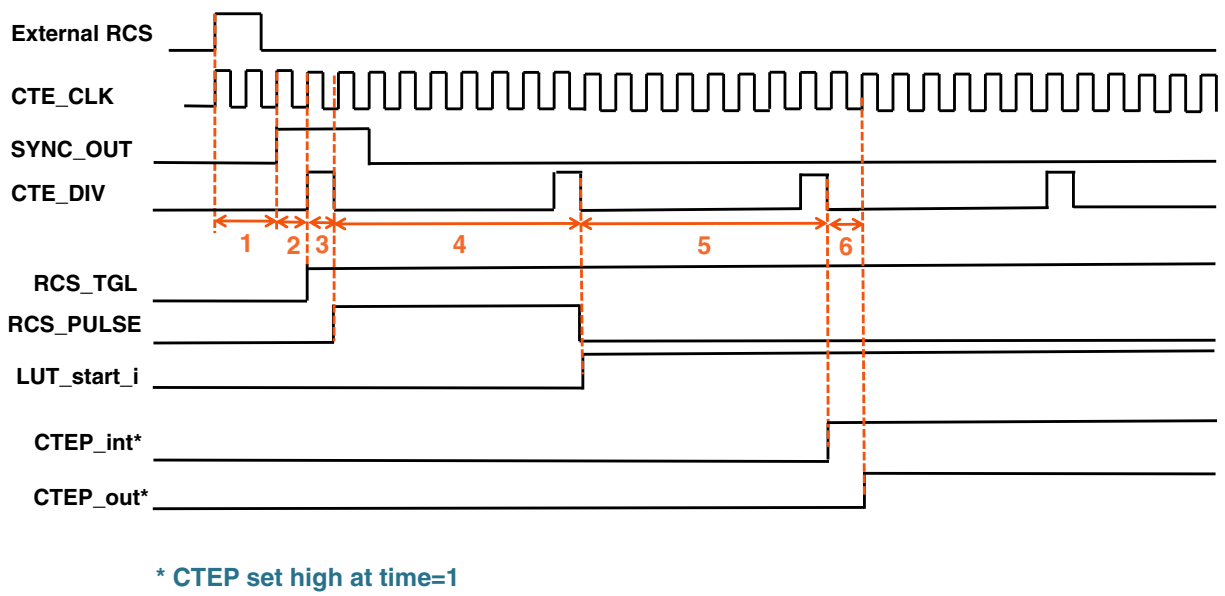

Figure 46-5. External RCS to CTE time-table start Delay_Best_Case

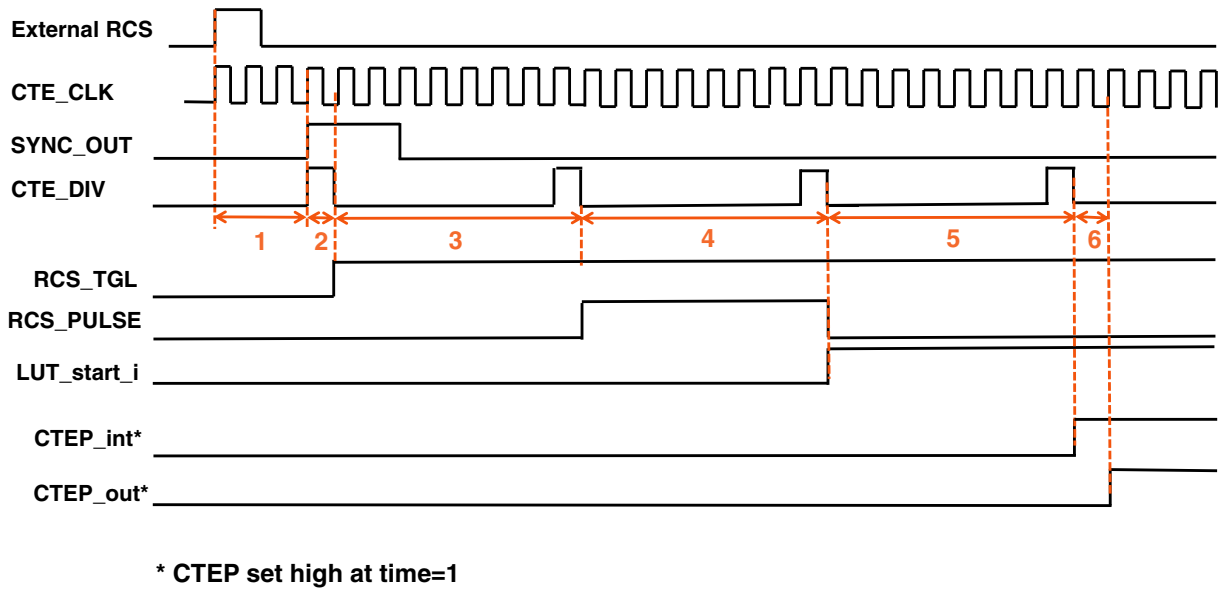

Figure 46-6. External RCS to CTE time-table Start Delay_Worst_Case

1. External RCS passes 2-flop synchronizer running on 80 MHz CTE clock (SDPLL CLK80): 2…3 x 12.5 ns = 25 ns…37.5 ns
2. RCS toggle detection is synchronized to 10/20/40/80 MHz CTE_DIV clock with 12.5% duty cycle, depending on clock selection – any edge(one CLK80 period).
3. RCS pulse is detected with CTE_DIV clock after RCS toggle is detected – negative edge only.
4. One CTE_DIV clock cycle (10/20/40/80 MHz) cycle to start time-table: 100/50/25/12.5 ns.
5. One CTE_DIV clock cycle (10/20/40/80 MHz) cycle to reach time instance 1: 100/50/25/12.5 ns.
6. One CTE clock cycle for output buffering: 12.5 ns.

NOTE

2 and 3 above can overall vary two to nine CTE clock cycles: 25 ns … 112.5 ns.

Additional delay of 0…15 CTE clock cycles (80 MHz) can be introduced via CTE_CNTRL register bit fields RCS_DLY and RFS_DLY.

46.6 Signal description

46.6.1 Signal description

The following diagram depicts all the signals of CTE module.

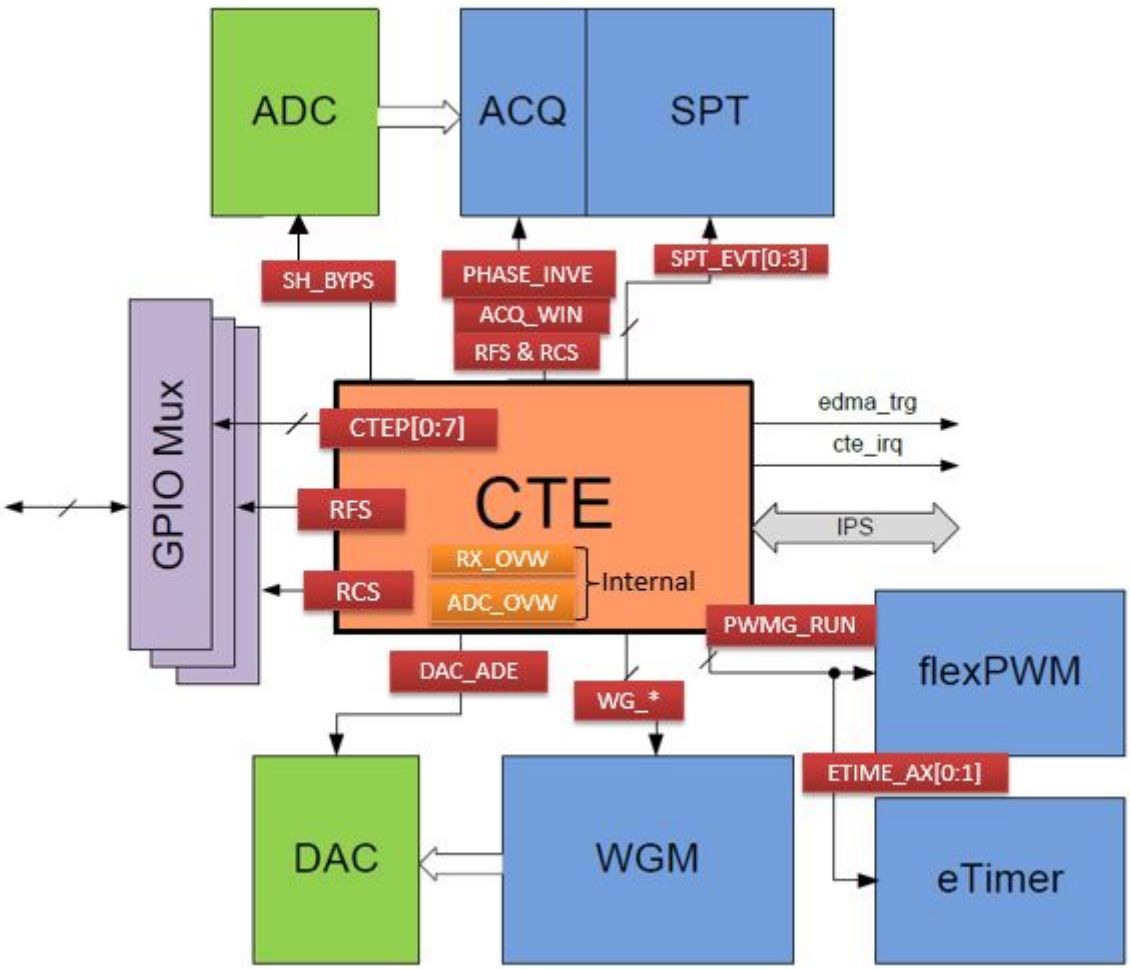

Figure 46-7. CTE signals

46.6.2 Type of external timing signals

The following table shows the list of external timing signals.

Table 46-1. External timing signals

SNo	Signal
1	CTEP[7:0][1]
2	RFS[2]
3	RCS[3]

1. These 8 bits are called CTE pulses. These pulses can be generated by the CTE block based on the timing table registers.
2. Radar frame synchronization is output in case of master mode and input in case of slave mode. This signal indicates the start of a frame. In slave mode, this signal needs to be synchronized and sampled to detect the start of a frame.
3. Radar chirp synchronization is output in case of master mode and input in case of slave mode. This signal indicates the start of a chirp within frame. In slave mode, this signal needs to be synchronized and sampled to detect the start of a chirp.

The type of external timing signal can be selected by configuring the bits corresponding to each signals in signal type0 Signal Type Register 0 (CTE_SIGTYPE0*n*) and signal type1 Signal Type Register 1 (CTE_SIGTYPE1*n*) registers.

External timing signals can be one of the following types.

46.6.2.1 Logic

Logic type is the simplest definition. Signals are asserted/de-asserted at defined timing instances in the timing table register LUT_MSB or LUT_LSB, depending on the values shown below. Signals having value as 11b are considered as don't care and do not change signal state.

- 00b: set signal to low level
- 01b: set signal to high level
- 10b: set signal to high-Z
- 11b: don't care (no change)

The signal does not reset when the last entry in the timing table is reached, but keeps its level until the next definition is reached.

46.6.2.2 Toggle

Toggle type is similar to logic type, but defines the signal state change instead of the actual level. With toggle type, the signal changes its state to the inverse with respect to the previous state when signal definition 10b was defined in LUT_MSB register for that particular signal. Value 2'b11 has no effect (don't care) and is used to skip time entries which are defined for logic signals, but shall not influence the toggle signal.

- 00b: reset signal to low level
- 01b: reset signal to high level
- 10b: toggle signal (flip level)
- 11b: don't care (no change)

A toggle signal keeps its state after the last entry in the timing table was reached until it is modified by an entry in following timing tables.

46.6.2.3 Clock

A clock signal toggles periodically with a defined period in control register1 at address 0x0004. Timing table entries define the active and inactive periods of this generated clock signal. Clock generation is started when the first entry in the timing table is 10b. If a timing entry other than 01b does not hit a corresponding subsequent generated clock edge, i.e. occurs during low or high time, the clock period is shortened or prolonged, depending on the previous state of the clock generator because entry 01b causes the rising edge of the clock if clock value is 0. If clock value is 1, entry 01b will keep it as 1.

- 00b: clock held to low
- 01b: clock active (toggling and synchronize rising edge)
- 10b: clock active (toggling)
- 11b: clock held high

See Figure 46-11 for more details.

Four independent clock counters are available for use with these clock signals. The toggle rate is defined by the divider ratio for each clock counter. The clock divider ratio is an integer number and can be defined once for each timing table as described in the control register1 CTE Control Register 1 (CTE_CNTRL1).

46.6.3 Signal configuration example

The following figure shows an example of how the signal definition can be configured for various external signals.

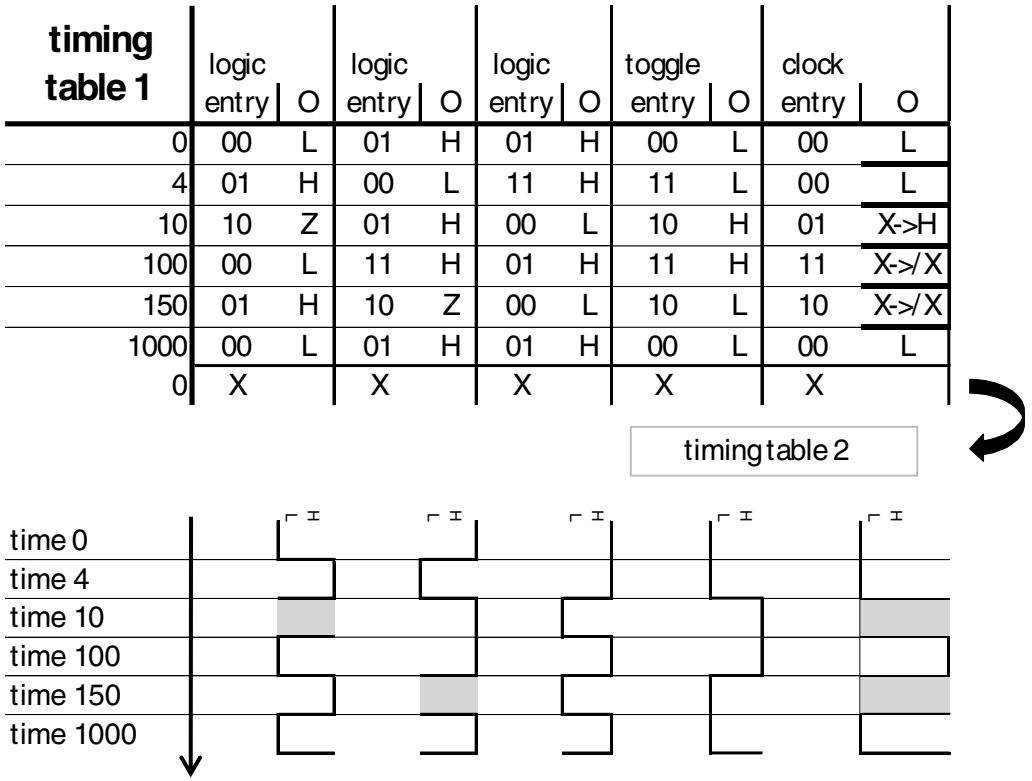

Figure 46-8. External signal configuration example

The following figure shows an example of how the signal definition can be configured for various internal signals.

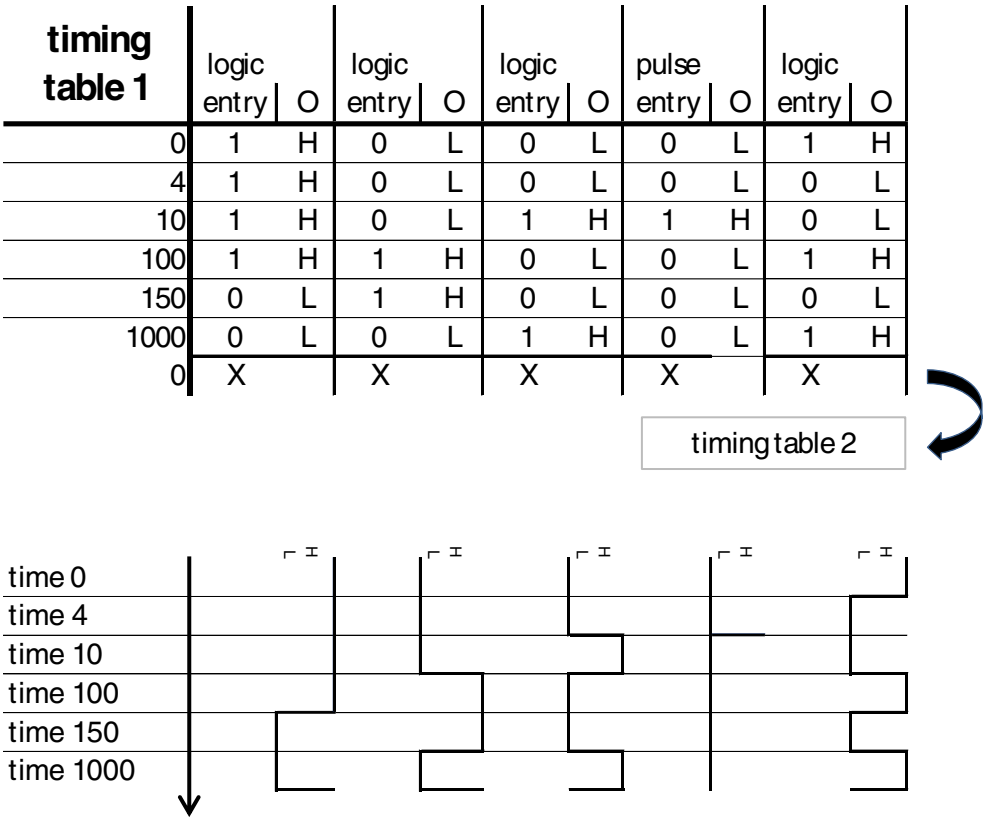

Figure 46-9. Internal signal configuration example

46.7 Memory map and register definition

The CTE is programmed by an asynchronous CPU interface. Additionally, timing tables can also be configured using the eDMA. The registers are 32 bit wide, however it shall be possible to program single bytes and words in the timing table registers without changing the other bytes of same register (masked write). It contains the interrupt mask and status, eDMA control registers and the configuration registers for the timing tables, including the timing values and assigned signal states. The register with timing values is valid for both internal and external signals. The timing values shall be 16-bit aligned.

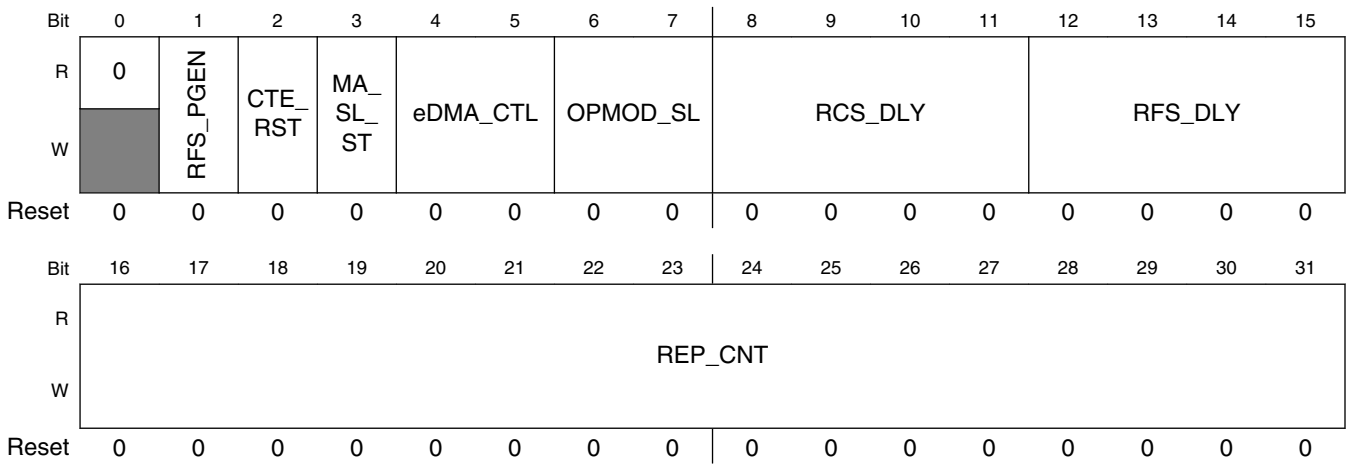
46.7.1 Control Register (CTE_CNTRL)

This is the first control register of the CTE block for controlling the data path operations and signal behaviors.

Address: 0h base + 0h offset = 0h



CTE_CNTRL field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 RFS_PGEN	Internal SW RFS Pulse Trigger. This bit is to be used in Slave mode only. This bit is used to generate a single CTE clock period wide internal RFS pulse when it is changed from 0 to 1 (Please note that this bit is not self clearing. For generating the second pulse, this bit needs to be reset and then set again by the software). This pulse is used to simulate RFS internally in order to reset the timing table execution and restart from the first entry, as if an external RFS pulse had been received.
2 CTE_RST	CTE synchronous Reset This is a synchronous reset which resets the entire CTE module on the next clock. When this bit is asserted, different CTE modules are synchronously reset on their next respective clocks. 0 CTE module reset is de-asserted. 1 CTE module reset is asserted.
3 MA_SL_ST	master/slave select This bit used to define if the CTE is working in master or slave mode. 0 CTE is in master mode (default mode). 1 CTE is in slave mode.
4–5 eDMA_CTL	eDMA trigger control These bits are used to trigger the eDMA controller for configuring the timing table registers (LUT_LSB and LUT_MSB). The trigger can be generated on reaching start of table, end of the timing table.

Table continues on the next page...

CTE_CNTRL field descriptions (continued)

Field	Description
	00 eDMA trigger generation disabled. 01 eDMA trigger will be generated at the start of timing table. 10 eDMA trigger will be generated at the end of timing table. 11 Not used. eDMA trigger generation is disabled.
6–7 OPMOD_SL	CTE FSM operation mode select. These bits are used to select the mode in which the CTE FSM operates. See the Timing Table Execution section under Functional description for details. **NOTE:** In continuous run mode or toggle mode, if the "REP_CNT" value is 0, the execution happens forever. 00 Halt Mode. In this mode timing generation is stopped. 10 Continuous run mode, Single table. In this mode the timing table is executed for the number of times programmed in the "lut_rep_cnt". 11 Continuous toggle mode, 2 tables. In this mode, the timing tables are toggled for the number of times programmed in the "lut_rep_cnt". 01 Continuous run mode, TT1. In this mode the second timing table (TT1) is executed for the number of times programmed in the "lut_rep_cnt".
8–11 RCS_DLY	Radar Chirp Synchronization Delay Control These bits are used to introduce configurable clock cycle delay in the RCS signal input when CTE is operating in slave mode. Maximum limit is 15 CTE clocks cycles. **NOTE:** In master mode, read write to these bits is supported but these bits will not have any effect on the fuctionality. 0000 No Delay. 0001 1 clock cycle delay needs to be introduced. 0010 2 clock cycle delay needs to be introduced. 0011 3 clock cycle delay needs to be introduced. 0100 4 clock cycle delay needs to be introduced. 0101 5 clock cycle delay needs to be introduced. 0110 6 clock cycle delay needs to be introduced. 0111 7 clock cycle delay needs to be introduced. 1000 8 clock cycle delay needs to be introduced. 1001 9 clock cycle delay needs to be introduced. 1010 10 clock cycle delay needs to be introduced. 1011 11 clock cycle delay needs to be introduced. 1100 12 clock cycle delay needs to be introduced. 1101 13 clock cycle delay needs to be introduced. 1110 14 clock cycle delay needs to be introduced. 1111 15 clock cycle delay needs to be introduced.
12–15 RFS_DLY	Radar Frame Synchronization Delay Control These bits define how much CTE clock delay has to be introduced in the RFS signal in slave mode. Maximum limit is 15 CTE clocks. **NOTE:** In master mode, read write to these bits is supported but these bits will not have any effect on the fuctionality. 0000 No Delay

Table continues on the next page...

CTE_CNTRL field descriptions (continued)

Field	Description
	0001 1 clock cycle delay needs to be introduced. 0010 2 clock cycle delay needs to be introduced. 0011 3 clock cycle delay needs to be introduced. 0100 4 clock cycle delay needs to be introduced. 0101 5 clock cycle delay needs to be introduced. 0110 6 clock cycle delay needs to be introduced. 0111 7 clock cycle delay needs to be introduced. 1000 8 clock cycle delay needs to be introduced. 1001 9 clock cycle delay needs to be introduced. 1010 10 clock cycle delay needs to be introduced. 1011 11 clock cycle delay needs to be introduced. 1100 12 clock cycle delay needs to be introduced. 1101 13 clock cycle delay needs to be introduced. 1110 14 clock cycle delay needs to be introduced. 1111 15 clock cycle delay needs to be introduced.
16–31 REP_CNT	Timing Table Repetition Counter This counter dictates how many times a selected timing table will be executed. If it is 0, the timing table will be executed forever.

46.7.2 CTE Control Register 1 (CTE_CNTRL1)

This is the second control register of the CTE block for controlling the data path operations and signal behaviors.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

R	0		CLKDIV_2			CLKDIV_1			0		CTECK_DV					
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CTE_CNTRL1 field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 CKSM_RST	Checksum Reset This bit when asserted will synchronously reset the checksum calculation block on the next IPG clock. This block is also reset on RFS. 0 De-asserted. Checksum calculation functions normally. 1 Checksum calculator block will be held in reset from next cycle onwards.
5 CHKSM_MD	Checksum Mode This bit defines the mode in which checksum is calculated. 0 Checksum mode means that the carry on the MSB is dropped (default). 1 MISR mode means that the carry on the MSB is fed back to the LSB of the checksum.
6 CTE_EN	CTE Enable This bit is used to enable the CTE module. **NOTE:** If it is required to re-configure CTE, this bit should be disabled and enabled at the end after all the other configuration has been done. 0 CTE is disabled. When this bit is 0, all the pending interrupts, eDMA request will be de-asserted immediately. Operational mode FSM will come to HALT and all the timing signals will be de-asserted. Internal time counter will be reset and the timing table entry counter will point to the 1st location of TT0 and all the interrupt status bits will be cleared. 1 Timing table execution is enabled. Note that when CTE enable bit is set from 0 to 1 in the middle of operation, the timing table execution will start from address 0.
7 TIMEMODE	Time mode type This bit defines if the absolute value of the time entries in the table need to be taken or if they are relative to the previous entry. The difference in these two modes is shown in Figure 46-13. 0 Relative, internal time counter will reset once it reaches the current timing entry so that the next timing instance becomes relative to the current time instance. 1 Absolute, internal time counter will not be reset hence the signal states are driven at absolute timing instances.
8–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–12 CLKDIV_4	4th Clock divider This value sets the frequency of the 4th clock dividers which will be used to generate the clock type signal. **NOTE:** This value is taken in power of 2 and the divided clock is of 50% duty cycle. 000 Forth clock divider's frequency is equal to CTE clock frequency. 001 Forth clock divider's frequency is equal to half the CTE clock frequency. 111 Forth clock divider's frequency is equal to 1/128 of CTE clock frequency.

Table continues on the next page...

CTE_CNTRL1 field descriptions (continued)

Field	Description
13–15 CLKDIV_3	3rd Clock divider This value sets the frequency of the 3rd clock dividers which will be used to generate the clock type signal. **NOTE:** This value is taken in power of 2 and the divided clock is of 50% duty cycle. 000 Third clock divider's frequency is equal to CTE clock frequency. 001 Third clock divider's frequency is equal to half the CTE clock frequency. 111 Third clock divider's frequency is equal to 1/128 of CTE clock frequency.
16–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–20 CLKDIV_2	2nd Clock divider This value sets the frequency of the 2nd clock dividers which will be used to generate the clock type signal. **NOTE:** This value is taken in power of 2 and the divided clock is of 50% duty cycle. 000 Second clock divider's frequency is equal to CTE clock frequency. 001 Second clock divider's frequency is equal to half of the CTE clock frequency. 111 Second clock divider's frequency is equal to 1/128 of CTE clock frequency.
21–23 CLKDIV_1	1st Clock divider This value sets the frequency of the 1st clock dividers which will be used to generate the clock type signal. **NOTE:** This value is taken in power of 2 and the divided clock is of 50% duty cycle. 000 First clock divider's frequency is equal to CTE clock frequency. 001 First clock divider's frequency is equal to half the CTE clock frequency. 111 First clock divider's frequency is equal to 1/128 of the CTE clock frequency.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 CTECK_DV	CTE Clock divider These 6 bits are used to define the CTE datapth clock. The value ranges from 0-63 where 0 and 1 mean the divide ratio is 1. CTE datapath runs on this clock. **NOTE:** Value 0 and 1 will result in the same clock frequency as main CTE clock and rest of the values will result in the divided clock e.g. if it is 2 then a divide by 2 clock will be resulted. Duty cycle is not equal to 50%. 000000 to 000001 Datapath is operating at CTE clock frequency. 000010 Datapath is operating at half the CTE clock frequency. 000011 Datapath is operating at 1/3 of CTE clock frequency. 111111 Datapath is operating at 1/63 of CTE clock frequency.

46.7.3 First Timing Table Register (LSB) (CTE_LUT0_LSB*n*)

These 32 registers are used to implement the first timing table which is used to configure the signal state at particular timing instances.

Address: 0h base + 8h offset + (4d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	SPT_EVT				SPT_PHIV	DAC_ADE	WG_LSEL		WG_CLD	WG_RST	WG_TGM	WG_UDM	WG_HLD	WG_RUN	RCV_OVF	ADC_OVF
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	TIME_0															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CTE_LUT0_LSB*n* field descriptions

Field	Description
0–3 SPT_EVT	SPT Event These signals are used to direct the command execution in SPT i.e. using these in a sequence helps debugging the SPT command execution sequence.
4 SPT_PHIV	SPT phase invert. This signal is sent to the SPT block to invert the phase of the signal before processing it. 0 Normal SPT processing requested. 1 SPT should invert the phase of the sample before processing.
5 DAC_ADE	DAC active data edge The intention of DAC_ADE feature is to switch the clock phase of the DAC output between radar chirps. With ADE==0, the WGM sends the first DAC word at the rising edge of the WGM clock = rising edge of dac clock and then it is stable till the next DAC clock capture edge. With ADE==1, the WGM sends the first DAC word at the rising edge of the next WGM clock = falling edge of dac clock and then it is stable till the next DAC clock capture edge.
6–7 WG_LSEL	WGM LUT select This field is sent to the WGM block to select among the 4 available LUTs in order to send data towards the DAC. 00 LUT0 is selected. 01 LUT1 is selected. 10 LUT2 is selected. 11 LUT3 is selected.

Table continues on the next page...

CTE_LUT0_LSB*n* field descriptions (continued)

Field	Description
8 WG_CLD	WGM counter load This bit when asserted loads the WGM address counter with CVAL on the next WGM clock. 0 De-asserted. 1 WGM address counter is pre-loaded with CVAL.
9 WG_RST	WGM reset This bit when asserted resets the WGM address counter to 0 on the next WGM clock. 0 Deasserted. 1 WGM address counter is reset.
10 WG_TGM	WGM toggle mode This bit when asserted forces the address counter in toggle mode. In toggle mode, counter first increments and decrements in the next WGM clock. 0 Toggle mode disabled. 1 Toggle mode enabled.
11 WG_UDM	WGM up/down mode This bit decides the mode in which the address counter operates. 0 Decrement mode (default). 1 Increment mode.
12 WG_HLD	WGM hold This signal when asserted replaces the WGM address which is used to read the LUT by FADR asynchronously. See the WGM block diagram for more details. 0 De-asserted. 1 WGM goes to the HALT mode.
13 WG_RUN	WGM run This signal is sent to the WGM module and is described below. 0 De-asserted. 1 Signal is asserted meaning that the WGM address counter is running based on wg_udm/wg_tgm signal states.
14 RCV_OVF	Receiver Overflow Mask This signal is used to enable the counter which counts the duration of the receive overflow counter at offset 0x019c. 0 Receiver overflow event is masked and counter is disabled. 1 Receiver overflow event is not masked and counter is enabled.
15 ADC_OVF	ADC overflow mask This signal is used to enable the counter which counts the duration of the ADC overflow counter at offset 0x0198.

Table continues on the next page...

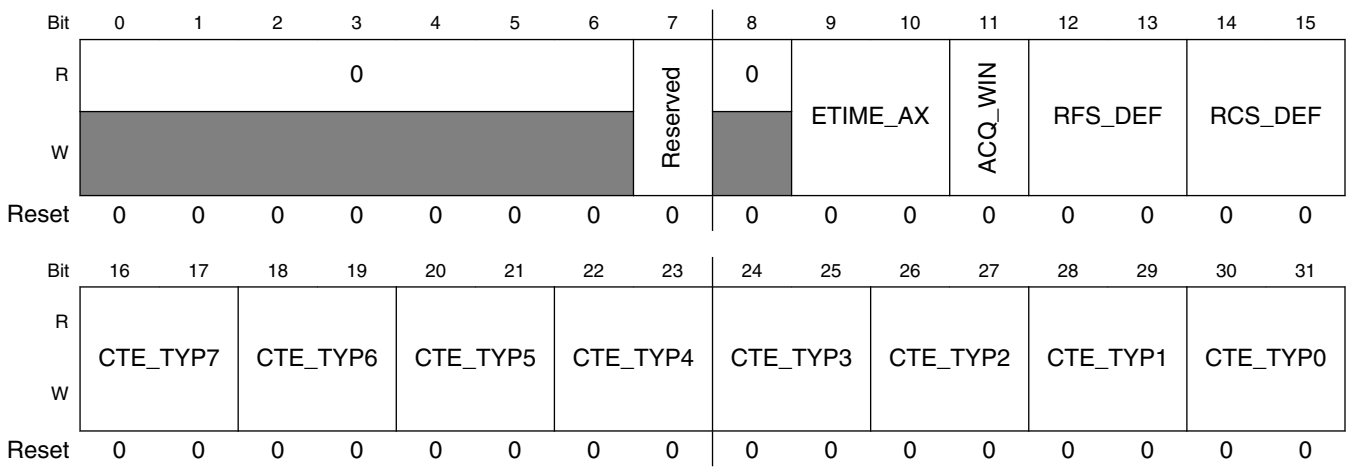
CTE_LUT0_LSB*n* field descriptions (continued)

Field	Description
	0 ADC overflow event is masked and counter is disabled. 1 ADC overflow event is not masked and counter is enabled.
16–31 TIME_0	Time instance This 16-bit field is used to enter the time instance for a particular signal definition. All the signals in the signal definition fields are associated with this particular instance of time. **NOTE:** This field should be programmed with a non-zero value if the table entry is valid and will be used to provide signal states.

46.7.4 First Timing Table Register (MSB) (CTE_LUT0_MSB*n*)

These 32 registers are used to define the signal state of the remaining signals which were not accommodated in LUT_LSB_0 register.

Address: 0h base + 88h offset + (4d × i), where i=0d to 31d



CTE_LUT0_MSB*n* field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 Reserved	This field is reserved. This field is reserved.
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–10 ETIME_AX	ETimer Auxiliary These bits are going to the ETimer in the system. 00 Both the eTimer_AUX_0 and eTimer_AUX_1 are DISABLED. 01 eTimer_AUX_0 is ENABLED and eTimer_AUX_1 is DISABLED.

Table continues on the next page...

CTE_LUT0_MSB*n* field descriptions (continued)

Field	Description
	10 eTimer_AUX_0 is DISABLED and eTimer_AUX_1 is ENABLED. 11 Both the eTimer_AUX_0 and eTimer_AUX_1 are ENABLED.
11 ACQ_WIN	CTE Acquisition Window This signal is sent to the SPT block for starting the acquisition process. 0 Acquisition process in SPT has not started. 1 Acquisition process in SPT has started.
12–13 RFS_DEF	RFS definition These bits define the signal state of the RFS signal if the CTE is operating in master mode. Signal behavior is same as that of ctep0 defined below.
14–15 RCS_DEF	RCS definition These bits define the signal state of the RCS signal if the CTE is operating in master mode. Signal behavior is same as that of ctep0 defined below.
16–17 CTE_TYP7	CTE Pulses These bits define the signal state of the 8th bit of the CTEP bus. Signal behavior is same as that of ctep0 defined in CTE_LUT0_MSB.
18–19 CTE_TYP6	CTE Pulses These bits define the signal state of the 7th bit of the CTEP bus. Signal behavior is same as that of ctep0 defined in CTE_LUT0_MSB.
20–21 CTE_TYP5	CTE Pulses These bits define the signal state of the 6th bit of the CTEP bus. Signal behavior is same as that of ctep0 defined in CTE_LUT0_MSB.
22–23 CTE_TYP4	CTE Pulses These bits define the signal state of the 5th bit of the CTEP bus. Signal behavior is same as that of ctep0 defined in CTE_LUT0_MSB.
24–25 CTE_TYP3	CTE Pulses These bits define the signal state of the 4th bit of the CTEP bus. Signal behavior is same as that of ctep0 defined in CTE_LUT0_MSB.
26–27 CTE_TYP2	CTE Pulses These bits define the signal state of the 3rd bit of the CTEP bus. Signal behavior is same as that of ctep0 defined in CTE_LUT0_MSB.
28–29 CTE_TYP1	CTE Pulses These bits define the signal state of the 2nd bit of the CTEP bus. Signal behavior is same as that of ctep0 defined in CTE_LUT0_MSB.
30–31 CTE_TYP0	CTE Pulses These bits define the signal state of the 1st bit of the CTEP bus. **NOTE:** Please note that when CTEP signals are defined as clock type, the frequency of the CTEP signal is programmable using the CTE_CLKSEL register. In this case, CTE_CLKSEL setting needs to be defined in accordance with the PAD characteristics. Please refer IO PAD characteristics in datasheet for details.

Table continues on the next page...

CTE_LUT0_MSB*n* field descriptions (continued)

Field	Description
	00 ctep0 signal will be driven with '0' irrespective of the signal type. 01 ctep0 signal will be driven with '1' in case of logic type and toggle type. In case of clock type, divided clock with a synchronous rising edge will be sent. See CNTRL1 for divided clock description. 10 ctep0 signal will be driven with 'Z' in case of signal type is logic. ctep0 will toggle its value toggle in case of signal type is toggle. Free running clock output of one of the 4 clock dividers will be sent on ctep0 if the type is defined as clock. 11 No change in the signal level in case of signal type is logic and toggle. ctep0 signal will be driven with '1' in case of signal type is clock.

46.7.5 Second Timing Table Register (LSB) (CTE_LUT1_LSB*n*)

These 32 registers are used to implement the second timing table which is used to configure the signal state at particular timing instances.

Address: 0h base + 108h offset + (4d × i), where i=0d to 31d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	SPT_EVT				SPT_PHIV	DAC_ADE	WG_LSEL		WG_CLD	WG_RST	WG_TGM	WG_UDM	WG_HLD	WG_RUN	RCV_OVF	ADC_OVF
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CTE_LUT1_LSB*n* field descriptions

Field	Description
0–3 SPT_EVT	SPT Event These signals are used to suspend the command execution in SPT i.e. using these in a sequence helps debugging the SPT command execution sequence.
4 SPT_PHIV	SPT phase invert. This signal is sent to the SPT block to invert the phase of the signal before processing it. 0 Normal SPT processing requested. 1 SPT should invert the phase of the sample before processing.
5 DAC_ADE	DAC active data edge The intention of DAC_ADE feature is to switch the clock phase of the DAC output between radar chirps.

Table continues on the next page...

CTE_LUT1_LSB*n* field descriptions (continued)

Field	Description
	With ADE==0, the WGM sends the first DAC word at the rising edge of the WGM clock = rising edge of dac clock and then it is stable till the next DAC clock capture edge. With ADE==1, the WGM sends the first DAC word at the rising edge of the next WGM clock = falling edge of dac clock and then it is stable till the next DAC clock capture edge.
6–7 WG_LSEL	WGM LUT select This field is sent to the WGM block to select among the 4 available LUTs. 00 LUT0 is selected. 01 LUT1 is selected. 10 LUT2 is selected. 11 LUT3 is selected.
8 WG_CLD	WGM counter load This bit when asserted loads the WGM address counter with CVAL. 0 De-asserted. 1 WGM address counter is pre-loaded with CVAL.
9 WG_RST	WGM reset This bit when asserted resets the WGM address counter to 0. 0 Deasserted. 1 WGM address counter is reset.
10 WG_TGM	WGM toggle mode This bit when asserted force the address counter in toggle mode. In toggle mode, counter first increments and decrements in the next cycle. 0 Toggle mode disabled. 1 Toggle mode enabled.
11 WG_UDM	WGM up/down mode This bit decides the mode in which the address counter operates. 0 Decrement mode (default). 1 Increment mode.
12 WG_HLD	WGM hold This signal is used by the WGM address counter FSM. 0 De-asserted. 1 Address FSM goes to the HALT state.
13 WG_RUN	WGM run This signal is sent to the WGM module and is described below: 0 De-asserted. 1 Signal is asserted meaning that the WGM address counter FSM starts.
14 RCV_OVF	Receiver Overflow Mask

Table continues on the next page...

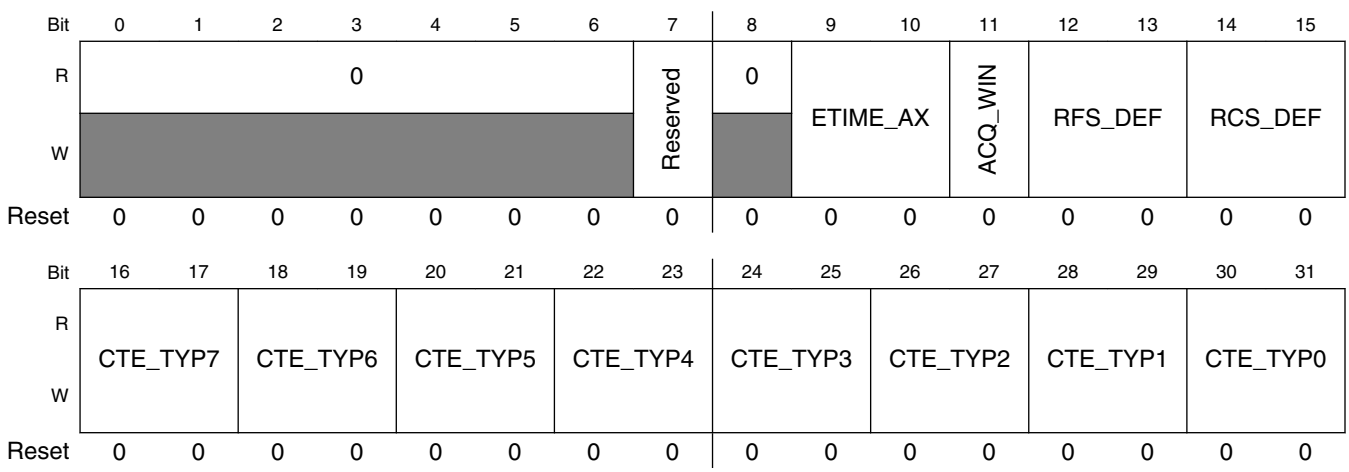
CTE_LUT1_LSB*n* field descriptions (continued)

Field	Description
	This signal is used to enable the counter which counts the duration of the receive overflow counter at offset 0x019c. 0 Receiver overflow event is not masked and counter is enabled. 1 Receiver overflow event is masked and counter is disabled.
15 ADC_OVF	ADC overflow mask This signal is used to enable the counter which counts the duration of the ADC overflow counter at offset 0x0198. 0 Receiver overflow event is masked and counter is disabled. 1 Receiver overflow event is not masked and counter is enabled.
16–31 TIME_1	Time instance This 16 bit field is used to enter the time instance for a particular signal definition. All the signals in the signal definition fields are associated with this particular instance of time. **NOTE:** This field should be programmed with a non-zero value if the table entry is valid and will be used to provide signal states.

46.7.6 Second Timing Table Register (MSB) (CTE_LUT1_MSB*n*)

This 32 register are used to define the signal behaviors of the remaining signals which were not accommodated in LUT_LSB_1

Address: 0h base + 188h offset + (4d × i), where i=0d to 31d



CTE_LUT1_MSB*n* field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

CTE_LUT1_MSB*n* field descriptions (continued)

Field	Description
7 Reserved	This field is reserved. This field is reserved.
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–10 ETIME_AX	ETimer Auxiliary These bits are going to the ETimer in the system. 00 Both the eTimer_AUX_0 and eTimer_AUX_1 are DISABLED. 01 eTimer_AUX_0 is ENABLED and eTimer_AUX_1 is DISABLED. 10 eTimer_AUX_0 is DISABLED and eTimer_AUX_1 is ENABLED. 11 Both the eTimer_AUX_0 and eTimer_AUX_1 are ENABLED.
11 ACQ_WIN	CTE Acquisition Window This signal is sent to the SPT block for starting the acquisition process. 0 Acquisition process in SPT has not started. 1 Acquisition process in SPT has started.
12–13 RFS_DEF	RFS definition These bits define the signal state of the RFS signal if the CTE is operating in master mode. Bit map description is same as ctep signal defined in LUT0_MSB.
14–15 RCS_DEF	RCS definition These bits define the signal state of the RCS signal if the CTE is operating in master mode. Bit map description is same as ctep signal defined in LUT0_MSB.
16–17 CTE_TYP7	CTE Pulses These bits define the signal state of the 8th bit of the CTEP bus. Bit map description is same as ctep signals defined in LUT0_MSB.
18–19 CTE_TYP6	CTE Pulses These bits define the signal state of the 7th bit of the CTEP bus. Bit map description is same as ctep signals defined in LUT0_MSB.
20–21 CTE_TYP5	CTE Pulses These bits define the signal state of the 6th bit of the CTEP bus. Bit map description is same as ctep signals defined in LUT0_MSB.
22–23 CTE_TYP4	CTE Pulses These bits define the signal state of the 5th bit of the CTEP bus. Bit map description is same as ctep signals defined in LUT0_MSB.
24–25 CTE_TYP3	CTE Pulses These bits define the signal state of the 4th bit of the CTEP bus. Bit map description is same as ctep signals defined in LUT0_MSB.
26–27 CTE_TYP2	CTE Pulses These bits define the signal state of the 3rd bit of the CTEP bus. Bit map description is same as ctep signals defined in LUT0_MSB.

Table continues on the next page...

CTE_LUT1_MSB*n* field descriptions (continued)

Field	Description
28–29 CTE_TYP1	CTE Pulses These bits define the signal state of the 2nd bit of the CTEP bus. Bit map description is same as ctep signals defined in LUT0_MSB.
30–31 CTE_TYP0	CTE Pulses These bits define the signal state of the 1st bit of the CTEP bus. Bit map description is same as ctep signals defined in LUT0_MSB. **NOTE:** When CTEP signals are defined as clock type, the frequency of clock is programmable using the CTE_CLKSEL register but the actual frequency is limited by the PAD characteristics. Please refer datasheet for details.

46.7.7 Signal Type Register 0 (CTE_SIGTYPE0*n*)

These two register are used to define the type of various internal and external signals corresponding to the timing tables. For example, if the signal is clock type or pulse type or logic type. SIGTYPE0_0 corresponds to TT0 and SIGTYPE0_1 corresponds to TT1.

Address: 0h base + 208h offset + (4d × i), where i=0d to 1d

46.7.9 CTE Interrupt Enable Register (CTE_INTEN)

This is the interrupt enable register for CTE interrupts. An interrupt will be generated if the enable bit is set and the corresponding event in the interrupt status register occurs.

NOTE

Please note that in case of continuous toggle mode (CNTRL[OPMOD_SL] = "11"), if user enables both start and end interrupts for both the timing tables (TT0_STEN, TT1_STEN, TT0_EDEN and TT1_EDEN), it might result into a scenario where CPU is serving interrupt very frequently. The user should judiciously enable the appropriate interrupts to avoid such scenarios.

Address: 0h base + 220h offset = 220h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

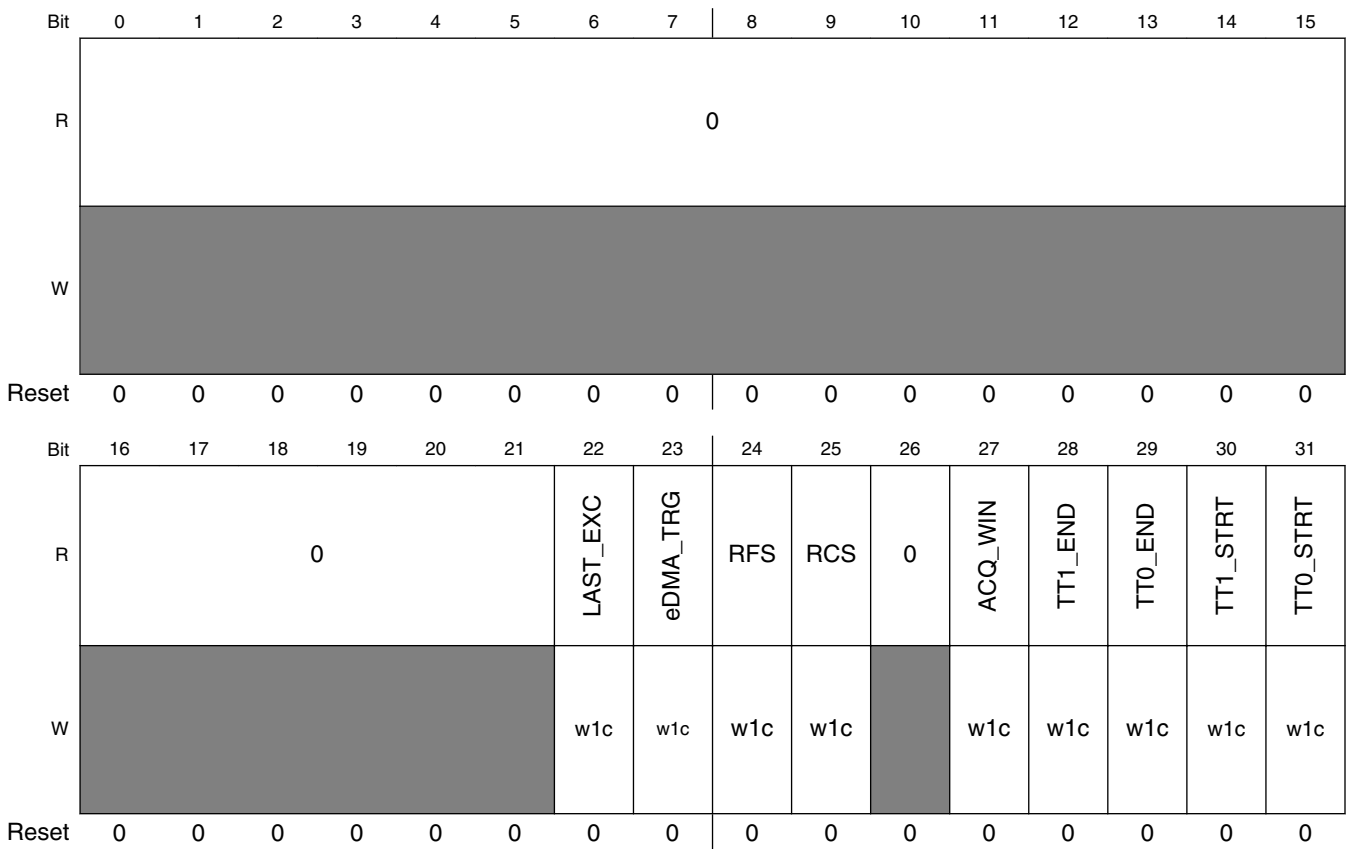
CTE_INTEN field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 LST_EXEN	Last Table Execution Enable 0 Disabled. 1 An interrupt will be generated when the execution of the timing table is finished for the final time as configured.
23 eDMA_TEN	eDMA Trigger Interrupt Enable 0 Disabled 1 An interrupt will be generated on the rising edge of the eDMA trigger.
24 RFS_EN	RFS interrupt enable (rising edge) 0 Disabled. 1 An interrupt will be generated on the rising edge of the RFS.
25 RCS_EN	RCS interrupt enable (rising edge) 0 Disabled. 1 An interrupt will be generated on the rising edge of the RCS.
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 AC_WD_EN	Acquisition window (rising) 0 Disabled. 1 An interrupt will be generated on the rising edge of the acquisition window signal.
28 TT1_EDEN	Timing table end (rising) 0 Disabled. 1 An interrupt will be generated on the rising edge of the second timing table end signal.
29 TT0_EDEN	Timing table end (rising) 0 Disabled. 1 An interrupt will be generated on the rising edge of the first timing table end signal.
30 TT1_STEN	Timing table start (rising) 0 Disabled. 1 An interrupt will be generated on the rising edge of the second timing table start signal.
31 TT0_STEN	Timing table start (rising) 0 Disabled. 1 An interrupt will be generated on the rising edge of the first timing table start signal.

46.7.10 CTE Interrupt Status Register (CTE_INTSTAT)

This is the interrupt status register which contains flags that are set when events occur that generate interrupts, if the corresponding mask bit is set. These bits are set on the events and can be cleared by w1c strategy. If an event is in CTE clock domain, it will take 1 CTE clock + 3 IPG clock cycles for the corresponding status bit in this register to be set. In case of CTE running in divided clock, the timing taken will be 1 divided CTE clock + 3 IPG clock cycles. For a signal which is in IPG clock domain, it will take 2 IPG clock cycles for the corresponding event to be set.

Address: 0h base + 224h offset = 224h



CTE_INTSTAT field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 LAST_EXC	Last Execution This bit is set and remains set until w1c when the timing table is executed for the last time as per the configuration. For example if CNTRL[REP_CNT] is 5 and CNTRL[OPMOD_SL] = "10", this bit will be set

Table continues on the next page...

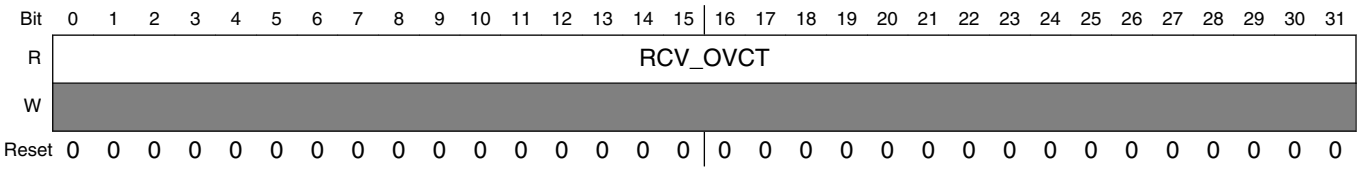
CTE_INTSTAT field descriptions (continued)

Field	Description
	when the last entry of the TT0 is executed for the 5th time. An interrupt is generated when the corresponding enable bit is set in the interrupt enable register.
23 eDMA_TRG	eDMA Trigger This bit is set and remains set until w1c when a rising edge of the eDMA trigger signal is detected. An interrupt is generated when the corresponding enable bit is set in the interrupt enable register.
24 RFS	Radar Frame Synchronization This bit is set and remains set until w1c when a rising edge of the RFS signal is detected. An interrupt is generated when the corresponding enable bit is set in the interrupt enable register.
25 RCS	Radar Chirp Synchronization This bit is set and remains set until w1c when a rising edge of the RCS signal is detected. An interrupt is generated when the corresponding enable bit is set in the interrupt enable register.
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 ACQ_WIN	Acquisition window (rising) This bit is set and remains set until w1c when acquisition signal from CTE to the SPT is asserted. An interrupt is generated when the corresponding enable bit is set in the interrupt enable register.
28 TT1_END	TT1 end This bit is set and remains set until w1c when TT1 execution reaches the end. **NOTE:** The end of table is generated when the entry address counter reaches the last valid entry. An interrupt is generated when the corresponding enable bit is set in the interrupt enable register.
29 TT0_END	TT0 end This bit is set and remains set until w1c when TT0 execution reaches the end. **NOTE:** The end of table will be generated when the entry address counter reaches the last valid entry. An interrupt is generated when the corresponding enable bit is set in the interrupt enable register.
30 TT1_STRT	TT1 start This bit is set and remains set until w1c when timing table execution for TT1 is started. An interrupt is generated when the corresponding enable bit is set in the interrupt enable register.
31 TT0_STRT	TT0 start This bit is set and remains set until w1c when timing table execution for TT0 is started. An interrupt is generated when the corresponding enable bit is set in the interrupt enable register.

46.7.11 Receiver Overflow Counter (CTE_RCVOFCNT)

This register contains the Receiver overflow event counter.

Address: 0h base + 22Ch offset = 22Ch



CTE_RCVOFCNT field descriptions

Field	Description
0–31 RCV_OVCT	Receiver Overflow counter This counter increments on every CTE clock when the RCV overflow mask bit in the timing table is set and there is an receiver overflow event at the input. **NOTE:** Since this counter is running in CTE clock domain, read to this will be associated with the wait cycles caused because of the asynchronous nature of CTE and IPG clocks.

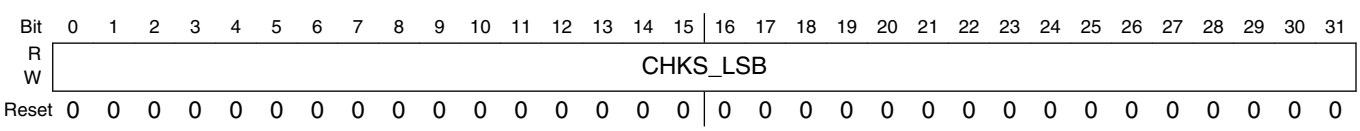
46.7.12 LUT Checksum Register (CTE_CKSM_LSB)

The following register contains the checksum value for the signal definition bits in the CTE_LUT0/CTE_LUT1_LSB and CTE_LUT0/CTE_LUT1_MSB registers. Please refer to Checksum for LUT0/LUT1 section for details of Checksum.

NOTE

A portion of 40:0 is reflected back on read of this register.

Address: 0h base + 270h offset = 270h



CTE_CKSM_LSB field descriptions

Field	Description
0–31 CHKS_LSB	Checksum Result LSB This value is the result of the checksum calculation for 16 timing signals in the LUT0/LUT1_LSB register ([31:16]) and 16 timing signals in LUT0/LUT1_MSB register([15:0]). The checksum result is updated every time these timing signals are updated.

46.7.13 LUT Checksum Register (CTE_CKSM_MSB)

Following register contains the checksum value for the remaining signal definition bits the LUT0/LUT1_MSB register. Please refer to Checksum for LUT0/LUT1 section for details of Checksum.

NOTE

A portion of 40:0 is reflected back on read of this register.

Address: 0h base + 274h offset = 274h

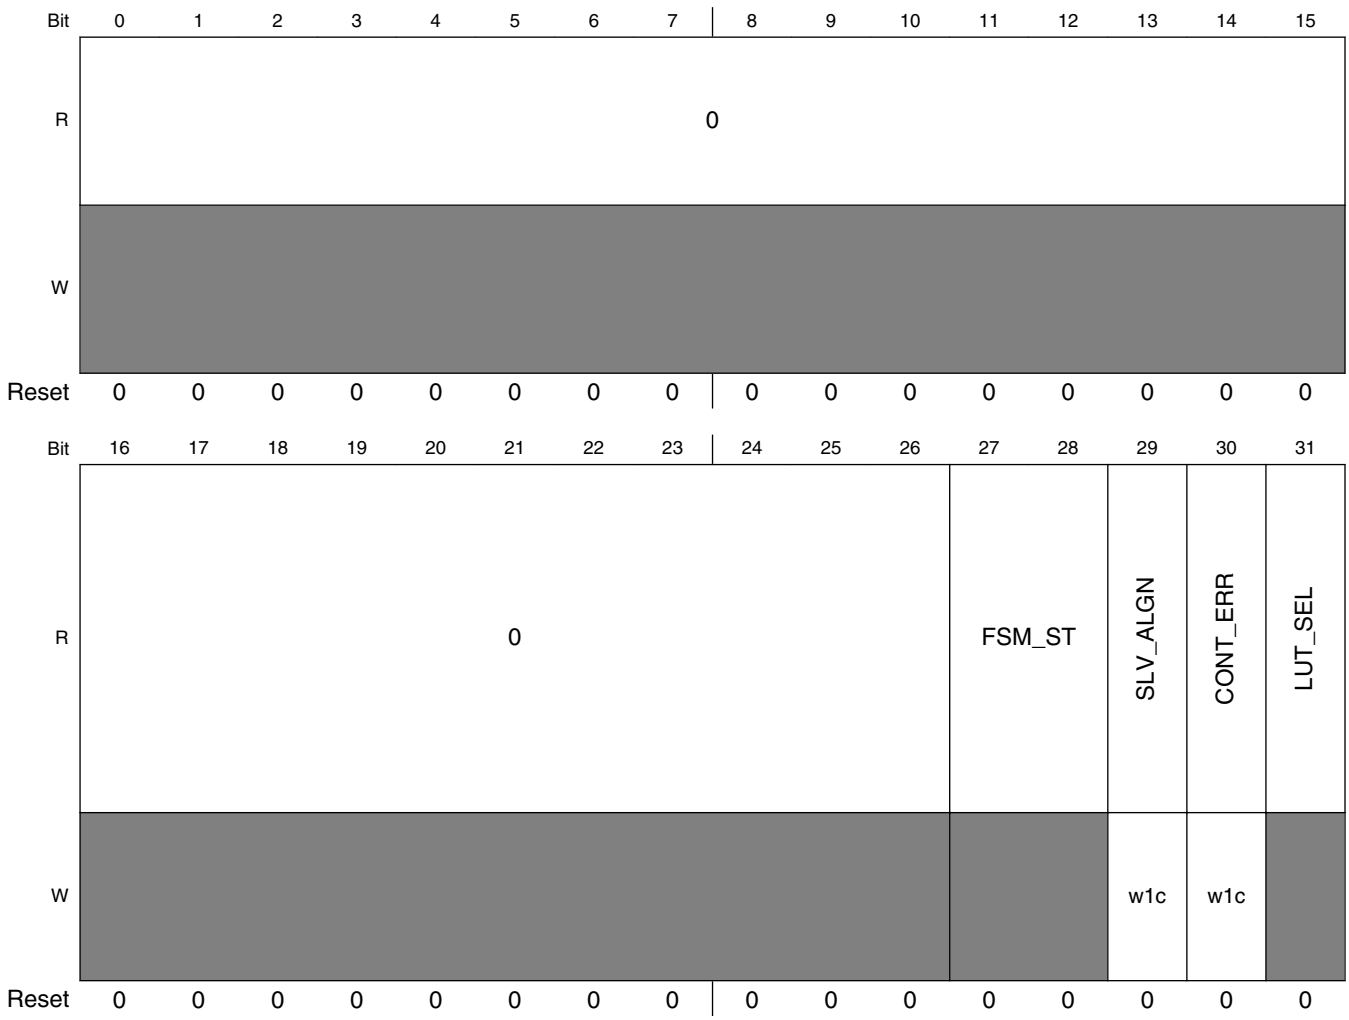
CTE_CKSM_MSB field descriptions

Field	Description
0–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 CHKS_MSB	Checksum Result LSB This value is the result of the checksum calculation for 8 timing signals in the LUT0/LUT1_MSB[24:16]. The checksum result is updated every time these timing signals are updated.

46.7.14 Debug Register (CTE_DBG_REG)

Following register is used for the debugging purpose.

Address: 0h base + 278h offset = 278h



CTE_DBG_REG field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–28 FSM_ST	OPMOD FSM state These bits reflect the state of the operation mode FSM. These can be used for debugging purpose. 00 FSM is in HALT. 01 FSM is in CRUN Table 0 10 FSM is in CRUN Table 1

Table continues on the next page...

CTE_DBG_REG field descriptions (continued)

Field	Description
29 SLV_ALGN	RFS/RCS align status This bit is set when the CTE is configured to work in slave mode (CNTRL[MA_SL_ST] is set) and first RCS pulse delayed by CTE_CNTRL[RCS_DLY] value, is received. This bit is valid in slave mode only. This bit will be reset using w1c strategy. **NOTE:** The RCS pulse is the synchronized and delayed i.e. the input RCS pulse is first synchronized using a 2 flop mechanism and then fed to the delay block which will delay the pulse as per configured value of CNTRL[RCS_DLY]. 0 RFS and RCS input are not aligned. 1 RFS and RCS input are aligned.
30 CONT_ERR	Timing Table contention error This bit is set when a timing table, which is currently active, is attempted to be programmed/written by CPU, eDMA, or by any other means. It is cleared by writing a 1 on it. 0 No timing table contention has occurred. 1 Contention has occurred on the active timing table.
31 LUT_SEL	TT Select This bit reflects which timing table out of the 2 available is currently selected. This field is read only, it will be toggling when toggle mode (CTE_CNTRL[OPMOD_SL] is "11") is selected. 0 TT0 is currently being used for signal definitions. 1 TT1 is currently being used for signal definitions.

46.7.15 TT0 Execution Duration Register (CTE_LUT_DUR)

This register contains the counter value which dictates for how many clock cycles the active TT0 is executed.

NOTE

In Toggle mode, if one of the CTE LUT duration registers (CTE_LUT_DUR or CTE_LUT_DUR1) is programmed zero and other is programmed less than 32, then the CTE timing table executes all 32 entries in for *both* LUTs.

Specifically, in Toggle mode (CNTRL[OPMOD_SL] =="2'b11"), when both LUTs are running, and if either the CTE_LUT_DUR or the CTE_LUT_DUR1 register is programmed "0", then following behavior is expected:

- If CTE_LUT_DUR == "0" and CTE_LUT_DUR1 != "0", then both LUTs are executed in full. A total of 64 entries are executed (32 for LUT0 and 32 for LUT1).
- If CTE_LUT_DUR != "0" and CTE_LUT_DUR1 == "0", then:
  - Only on the first run only, LUT0 is executed to programmed delay as specified by CTE_LUT_DUR.
  - On all further runs, all 32 entries are executed. A total of 64 entries are executed (32 for LUT0 and 32 for LUT1).

To run the 32 entries for the intended LUT, the user must not program either of the CTE LUT duration registers to “0”. The user has to program the correct value to *both* the CTE_LUT_DUR or CTE_LUT_DUR1 registers.

Address: 0h base + 27Ch offset = 27Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	TT0_DUR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CTE_LUT_DUR field descriptions

Field	Description
0–31 TT0_DUR	TT0 Duration This counter defines the duration in terms of the CTE clock cycles for which the first timing table is executed. It starts decrementing as soon as the timing table execution is started and once it reaches 0, timing table end is considered. If it is 0, all the 32 table entries in TT0 will be executed before declaring the end of table.

46.7.16 TT1 Execution Duration Register (CTE_LUT_DUR1)

This register contains the counter value which dictates for how many clock cycles the active TT1 is executed.

NOTE

In Toggle mode, if one of the CTE LUT duration registers (CTE_LUT_DUR or CTE_LUT_DUR1) is programmed zero and other is programmed less than 32, then the CTE timing table executes all 32 entries in for *both* LUTs.

Specifically, in Toggle mode (CNTRL[OPMOD_SL] =="2'b11"), when both LUTs are running, and if either the CTE_LUT_DUR or the CTE_LUT_DUR1 register is programmed "0", then following behavior is expected:

- If CTE_LUT_DUR == "0" and CTE_LUT_DUR1 != "0", then both LUTs are executed in full. A total of 64 entries are executed (32 for LUT0 and 32 for LUT1).
- If CTE_LUT_DUR != "0" and CTE_LUT_DUR1 == "0", then:
  - Only on the first run only, LUT0 is executed to programmed delay as specified by CTE_LUT_DUR.
  - On all further runs, all 32 entries are executed. A total of 64 entries are executed (32 for LUT0 and 32 for LUT1).

To run the 32 entries for the intended LUT, the user must not program either of the CTE LUT duration registers to “0”. The user has to program the correct value to *both* the CTE_LUT_DUR or CTE_LUT_DUR1 registers.

Address: 0h base + 280h offset = 280h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CTE_LUT_DUR1 field descriptions

Field	Description
0–31 TT1_DUR	TT1_DURATION This register contains the counter value which dictates for how many CTE clock cycles the TT1 is executed. If it is 0, all 32 entries in TT1 will be executed.

46.7.17 Clock Select Register (CTE_CLKSEL)

Following register is used to select which one of the 4 independent clock dividers is used to send the clock on CTEP[7:0], RCS and RFS signals when these are defined as clock type.

Address: 0h base + 284h offset = 284h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

CTE_CLKSEL field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–13 CLK_SEL9	Clock Select These bits are used to select one of the 4 available clock dividers for RFS when it is defined as clock type. 00 1st clock divider will be used for generating the clock type signal on RFS. 01 2nd clock divider will be used for generating the clock type signal on RFS. 10 3rd clock divider will be used for generating the clock type signal on RFS. 11 4th clock divider will be used for generating the clock type signal on RFS.
14–15 CLK_SEL8	Clock Select These bits are used to select one of the 4 available clock dividers for RCS when it is defined as clock type. 00 1st clock divider will be used for generating the clock type signal on RCS. 01 2nd clock divider will be used for generating the clock type signal on RCS. 10 3rd clock divider will be used for generating the clock type signal on RCS. 11 4th clock divider will be used for generating the clock type signal on RCS.
16–17 CLK_SEL7	Clock Select These bits are used to select one of the 4 available clock dividers for ctep7 when it is defined as clock type. 00 1st clock divider will be used for generating the clock type signal on ctep7. 01 2nd clock divider will be used for generating the clock type signal on ctep7. 10 3rd clock divider will be used for generating the clock type signal on ctep7. 11 4th clock divider will be used for generating the clock type signal on ctep7.
18–19 CLK_SEL6	Clock Select These bits are used to select one of the 4 available clock dividers for ctep6 when it is defined as clock type. 00 1st clock divider will be used for generating the clock type signal on ctep6. 01 2nd clock divider will be used for generating the clock type signal on ctep6.

Table continues on the next page...

CTE_CLKSEL field descriptions (continued)

Field	Description
	10 3rd clock divider will be used for generating the clock type signal on ctep6. 11 4th clock divider will be used for generating the clock type signal on ctep6.
20–21 CLK_SEL5	Clock Select These bits are used to select one of the 4 available clock dividers for ctep5 when it is defined as clock type. 00 1st clock divider will be used for generating the clock type signal on ctep5. 01 2nd clock divider will be used for generating the clock type signal on ctep5. 10 3rd clock divider will be used for generating the clock type signal on ctep5. 11 4th clock divider will be used for generating the clock type signal on ctep5.
22–23 CLK_SEL4	Clock Select These bits are used to select one of the 4 available clock dividers for ctep4 when it is defined as clock type. 00 1st clock divider will be used for generating the clock type signal on ctep4. 01 2nd clock divider will be used for generating the clock type signal on ctep4. 10 3rd clock divider will be used for generating the clock type signal on ctep4. 11 4th clock divider will be used for generating the clock type signal on ctep4.
24–25 CLK_SEL3	Clock Select These bits are used to select one of the 4 available clock dividers for ctep3 when it is defined as clock type. 00 1st clock divider will be used for generating the clock type signal on ctep3. 01 2nd clock divider will be used for generating the clock type signal on ctep3. 10 3rd clock divider will be used for generating the clock type signal on ctep3. 11 4th clock divider will be used for generating the clock type signal on ctep3.
26–27 CLK_SEL2	Clock Select These bits are used to select one of the 4 available clock dividers for ctep2 when it is defined as clock type. 00 1st clock divider will be used for generating the clock type signal on ctep2. 01 2nd clock divider will be used for generating the clock type signal on ctep2. 10 3rd clock divider will be used for generating the clock type signal on ctep2. 11 4th clock divider will be used for generating the clock type signal on ctep2.
28–29 CLK_SEL1	Clock Select. These bits are used to select one of the 4 available clock dividers for ctep1 when it is defined as clock type. 00 1st clock divider will be used for generating the clock type signal on ctep1. 01 2nd clock divider will be used for generating the clock type signal on ctep1. 10 3rd clock divider will be used for generating the clock type signal on ctep1. 11 4th clock divider will be used for generating the clock type signal on ctep1.
30–31 CLK_SEL0	Clock Select These bits are used to select one of the 4 available clock dividers for ctep0 when it is defined as clock type. 00 1st clock divider will be used for generating the clock type signal on ctep0.

Table continues on the next page...

CTE_CLKSEL field descriptions (continued)

Field	Description
	01 2nd clock divider will be used for generating the clock type signal on ctep0. 10 3rd clock divider will be used for generating the clock type signal on ctep0. 11 4th clock divider will be used for generating the clock type signal on ctep0.

46.8 Functional description

46.8.1 Timing Table (TT) execution

Once a timing table is configured, it is executed by the CTE to generate the required signals. A Finite State Machine (FSM) is responsible for the execution. The FSM has the following states.

- Halt
- Continuous run, single table
- Continuous toggle, two tables

For details, see the following figure.

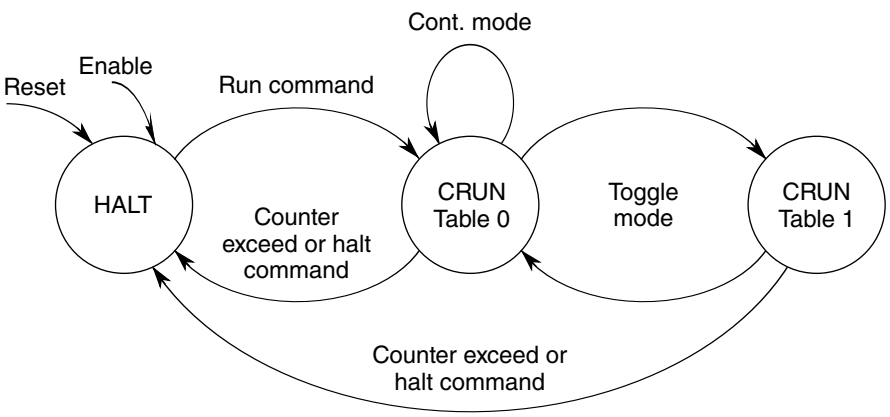

Figure 46-10. Operation mode state diagram

NOTE

Even if the FSM goes back to halt state after counter exceeds, but the CTE_CNTRL[OPMOD_SL] bits will remain as configured by software. Software can read the CTE_DBG_REG[FSM_ST] bits to know the state of the FSM.

In Halt state, timing generation is stopped. All signals are in their default level. HALT state is exited as soon as the CNTRL[CTE_RST] is de-asserted, CNTRL[OPMOD_SL] is set to either 01/10/11, and CNTRL1[CTE_EN] is set.

In CRUNTable0 and CRUNTable1 states, the timing tables are executed for a predefined number of repetitions or forever until the halt state is enforced depending upon the value of CNTRL[REP_CNT]. The maximum count of repetitions is 2^16-1, where the value of 0 is used to repeat forever.

End of timing table is considered either after the last timing entry is reached or when timing table execution duration counter LUT_DUR/LUT_DUR1 expires. In case when the table is executed only once, the signal states will retain their states as according to the last entry of the table which is decided by the timing table execution duration counter (LUT_DUR/LUT_DUR1). If table execution is configured for more than one execution, after reaching the last entry in the timing table, entry address will roll back to 0 driving the signal states as per timing entry 0.

Once the timing table reaches the end, the next timing table is activated (toggle mode) or the same timing table runs again depending on the CNTRL[OPMOD_SL] setting. In toggle mode, an automatic update by the eDMA is possible. The timing tables are toggled either after the last valid timing entry is reached or when LUT_DUR/LUT_DUR1 counter expires. This timing table duration counter is initialized at the beginning of each table along with the time-out value and decrements by 1 on each CTE clock (divided clock if configured).

46.8.2 Timing table

The timing table defines times and signal levels. The times can be defined as absolute intervals from the start of table or relative to previous time entry. Signals generated by CTE can be activated and deactivated with each timing table. The inactive level can be defined separately (0/1/Z). The signal state Z is only valid for signals connected to pads, where pad output is set to high impedance. The time entries define moments, where a change in one of the activated signals happens. It is possible to change the signal mode with each timing table. The last entry in a timing table has at least one clock pulse effect. The supported modes are different for external and internal signals.

46.8.3 Time base

The time base for CTE is derived from its clock. The clock for the CTE is 80MHz. A 6 bit clock divider can be programmed for each timing table using CNTRL[CTECK_DV] in order to modify the scale of time entries.

The divided clocks on which the timing tables are executed are counted with a 16 bit counter, which is compared to the time entries in the table. Once the 16 bit counter matches the time entry value, signal value for all the signals defined in timing table

registers (CTE_LUT0/CTE_LUT1 LSB and CTE_LUT0/CTE_LUT1 MSB) is stored. Based on the type of the signal defined in signal type register (CTE_SIGTYPE0/1), signals at that particular time instant are generated. See the following figure for details:

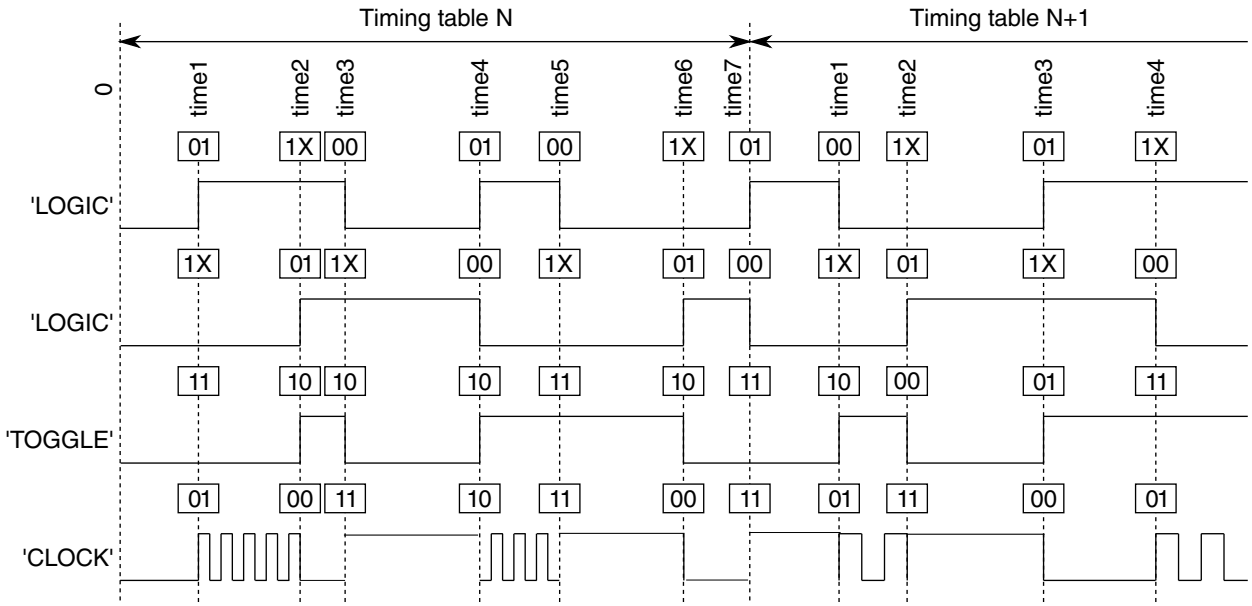

Figure 46-11. Timing generation

46.8.4 Timing generation

The generation of signals is based on configuring timing tables which define the assertion/ de-assertion of signals at specific instants of time. Two timing tables are provided which can be toggled seamlessly without interruption of the timing generation. The signal generation logic works in either the relative mode in which the signal generation logic treats the timing entry in the table as relative to the previous entry or in absolute mode in which each timing entry is treated at absolute time.

46.8.5 CTE clock divider

There are total 5 clock dividers present in CTE module. These are shown in the figure below.

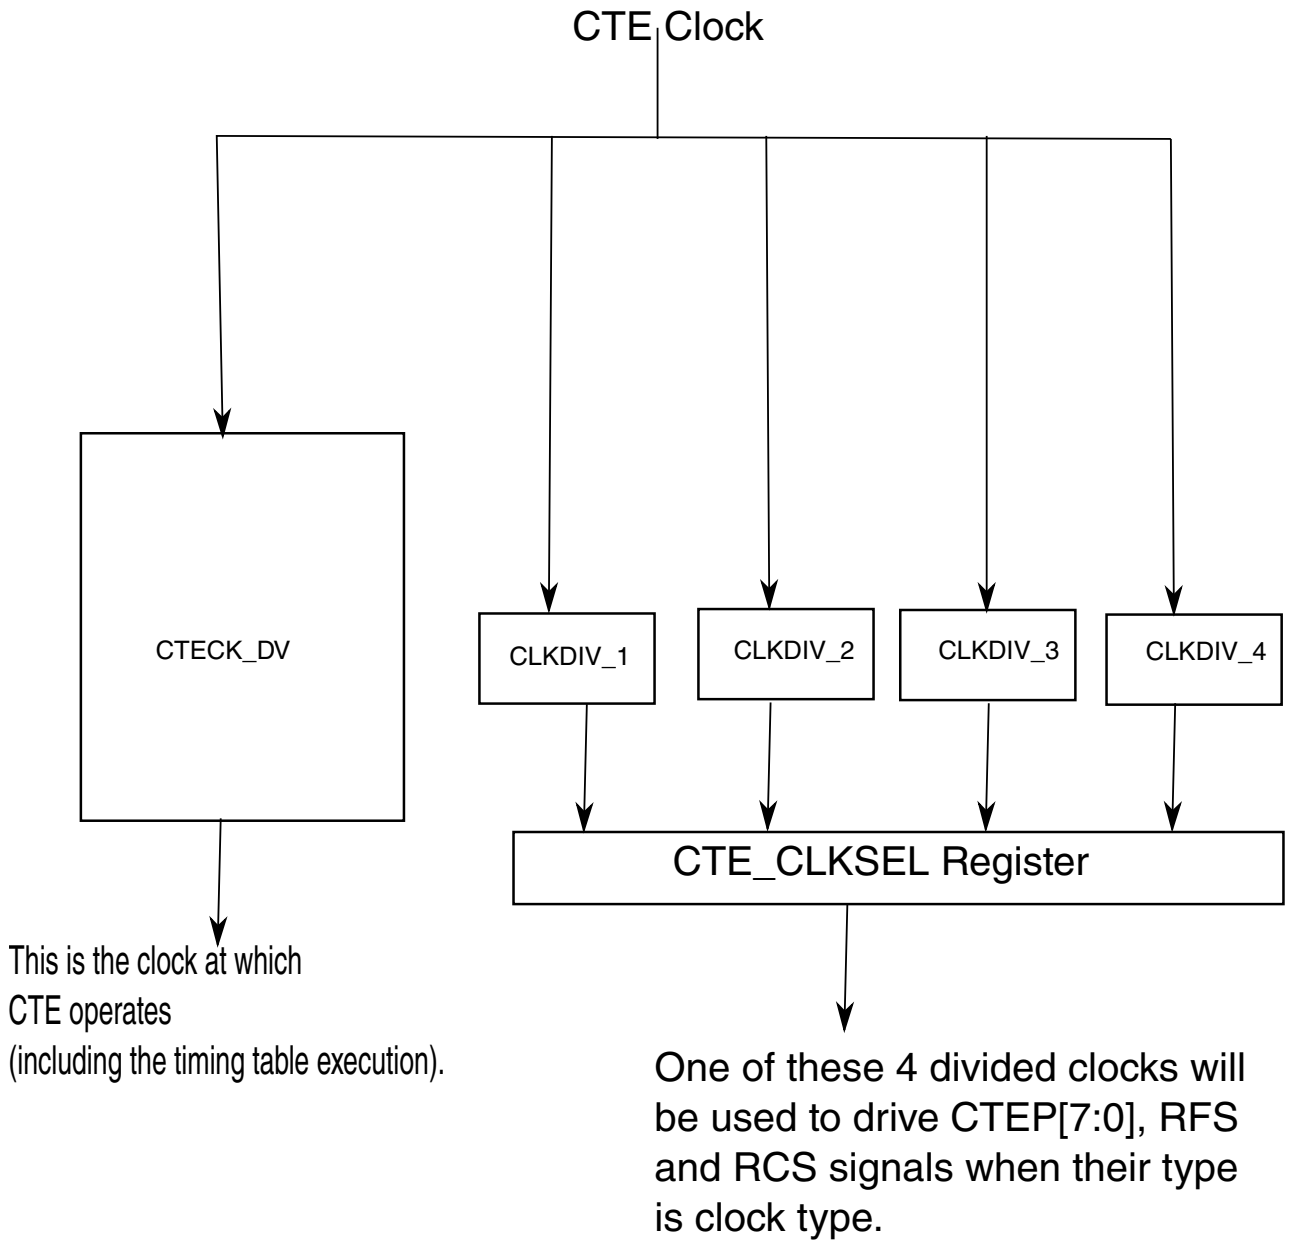

Figure 46-12. CTE Clock divider architecture

The main clock divider derives its frequency from register bits CTE_CNTRL1[CTECK_DV]. The duty cycle of this divided clock is not 50%. The other 4 independent clock dividers derive their frequencies from CTE_CNTRL1[CLKDIV_1], CTE_CNTRL1[CLKDIV_2, CTE_CNTRL1[CLKDIV_3] and CTE_CNTRL1[CLKDIV_4] respectively. The duty cycle of these divided clocks are 50%. These clocks are used to send the periodic signals of defined frequencies on CTEP[7:0], RCS and RFS ports when their type is defined as clock (through CTE signal type0/1 register settings). Please refer the example in initialization sequence to get the details of how user can configure CTE to generate periodic signals on CTEP[7:0], RCS and RFS outputs.

46.8.6 Timing table configuration

The timing tables can be configured either directly by the CPU or through the DMA using the eDMA trigger functionality described below. Note that the timing entries in LUT0_LSB[15:0] and LUT1_LSB[15:0] are the timing instances. The signals will be driven on that particular instance depending upon the relative or absolute mode. Timing entry 0 is not valid and it is the responsibility of the SW that timing entry should not be programmed as 0. If SW enters timing entry as 0, the signal will be driven after 65536 clock cycles because the internal 16 bit timing counter will roll over after these many clock cycles. Similarly in absolute mode, it is the responsibility of the SW to ensure that the next timing entry is always greater than the previous. If this is not maintained, the signal will be driven after 65536+ the value written in the timing entry. See the figure below for details.

First signal output is in absolute mode. The timing entry in the table are 3, 5 and 7 for 3 consecutive locations. Now in absolute mode, the signal state is driven when the internal timecounter reaches the 3rd, 5th and 7th clock. In relative mode, when the internal time counter reaches to 3, signal state is driven and the counter resets to 0. It then takes 5 more clocks to drive the next signal state value.

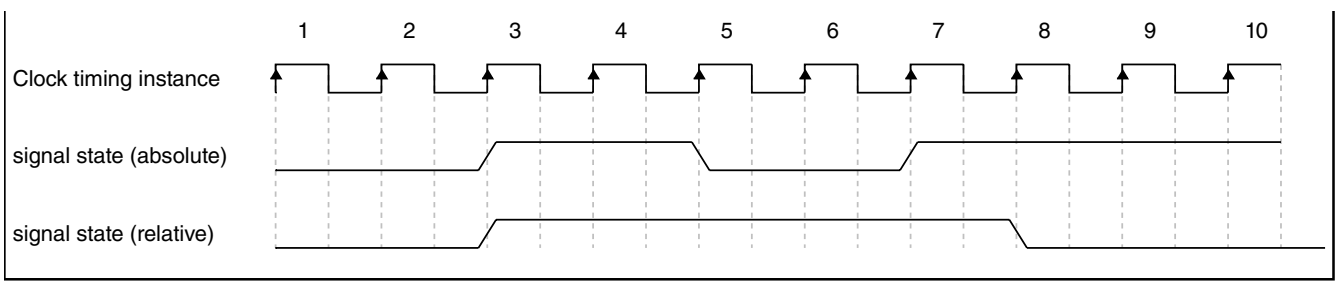

Figure 46-13. Timing entry effect on signal state in relative and absolute mode

46.8.6.1 CPU configuration

CPU can configure one of the two available timing tables so as to enable the CTE to generate various internal and external signals. The CPU always updates the table which is not active. If it tries to update the active timing table, timing table contents will be overwritten and a contention error flag (lut_contn_err) of the Debug Register (CTE_DBG_REG, bit 1) will be asserted. Each timing table will have 32 entries containing timing instances and the signal states corresponding to that particular timing instance for the internal and external signals.

46.8.6.2 eDMA trigger

Timing tables can also be configured using the eDMA trigger functionality. CTE can generate eDMA triggers to the eDMA engine to start a DMA transfer. These trigger events can be configured to occur on toggling of the timing table and the start/end of the timing table. On any of the above events, a DMA trigger will be generated by the CTE. It is the responsibility of the DMA controller to make sure that the correct timing table is configured.

46.8.7 Overflow counter

The overflow counter is a 32bit counter, counting the time of the overflow flags. The counter is reset with radar frame synchronization (RFS) signal at the beginning of each frame start. Two such counters exist, one for ADC overflows and the other for receiver overflows.The implementation of both counters is identical, only the overflow input is connected to different sources as described below.

46.8.7.1 Receiver overflow counter

The receiver overflow input is one selected GPIO input and synchronized to CTE clock domain by two flop stages. It is qualified with LUT0_LSB[rcv_ovf], in order to generate a window in which the overflow is valid. The counter is enabled with this combined signal and counts while it is '1'. The counter value is mapped to configuration register. See the figure below for more details:

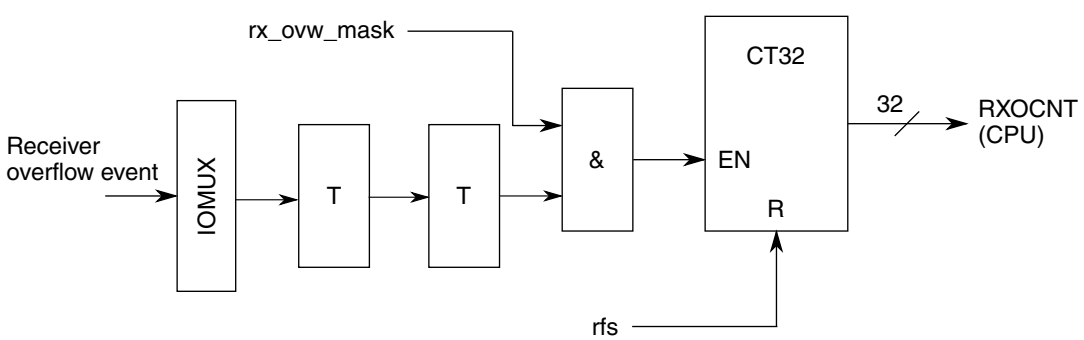

Figure 46-14. Receive overflow counter

46.8.7.2 ADC Overflow Counter

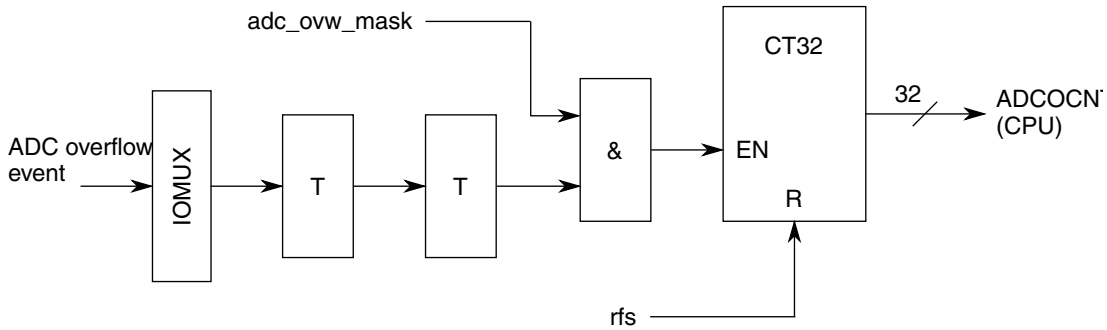

Figure 46-15. ADC Overflow Counter

The ADC overflow counter signal is the result of the OR operation on all the ADC overflow flags. It is qualified with LUT0_LSB[adc_ovf] to generate the counter enable signal.

46.8.8 CrossTrigger Timing

The cross-triggering ensures a timing correlation between the output of the DAC and the capturing of antenna input. Depending on the RADAR system, the generation of timing signals may completely change between RADAR measurement cycles. It may also vary within phases, e.g. to modulate the timing of chirp waveform within a couple of clock cycles.

The following picture shows a typical timing for ADC and DAC triggering for two un-modulated chirp waveforms. See the figure below for more details:

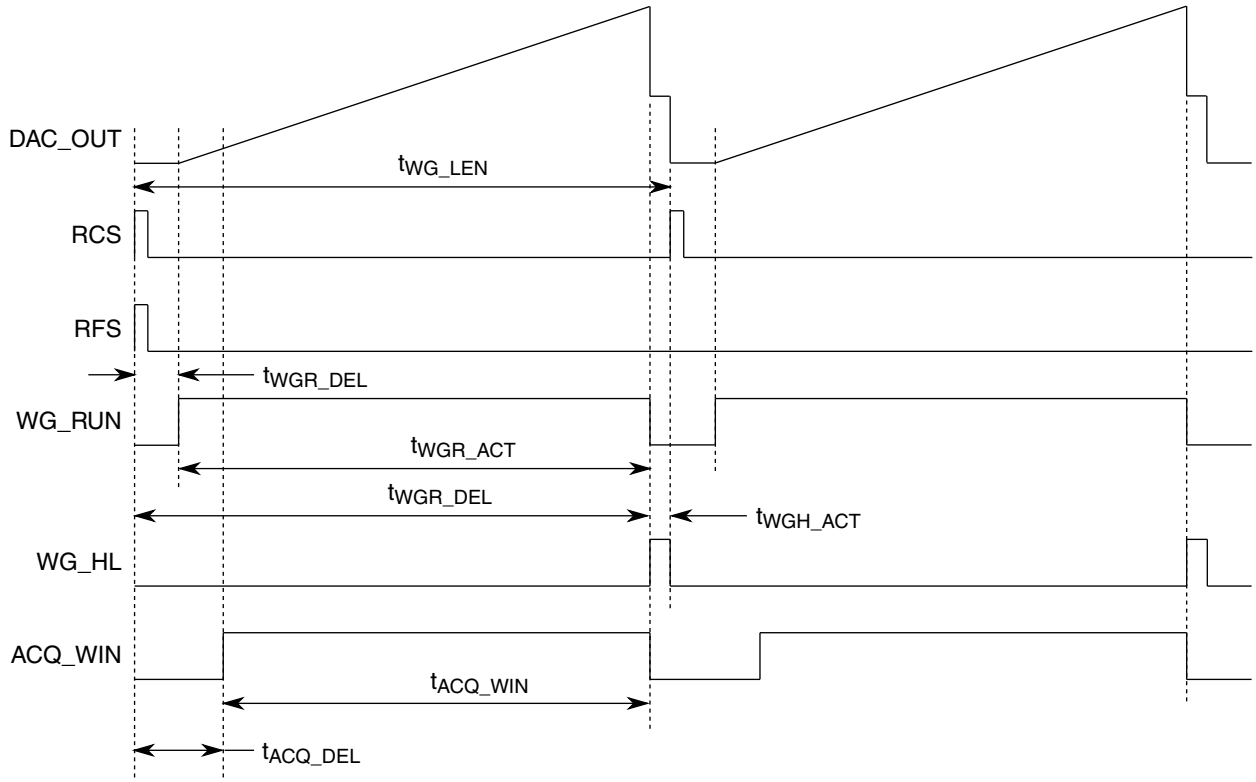

Figure 46-16. Cross Trigger Timing

46.9 Interrupts

CTE can generate interrupts to the CPU on various events e.g. start of each timing table, end of each timing table or by rising edge of selected timing signals. See the interrupt status register CTE_INTSTAT for details. The interrupts can be masked using the corresponding enable bits in interrupt enable register CTE_INTEN. An interrupt is indicated by the event flag if corresponding enable bit is set and cleared by W1C strategy.

46.10 Checksum for LUT0/LUT1

The Checksum register carry the most recent calculated checksum for LUT0 and LUT1. It is calculated on LUT content and signal mode content. The Checksum is updated on each update on any LUT content.

The Checksum registers are in read/write mode. The start Checksum value can be written into the register before making update to the LUT content. The updated content can be read back from the same registers.

Checksum is calculated in two modes:

1. Checksum is calculated for 39:0 bits and carryover at bit 40 is dropped.
2. Checksum is calculated for 39:0 bits and carryover at bit 40 is added back to LSB that is bit0.

Thus, the initial Checksum is loaded into internal registers in the following way:

- Initial_Checksum[40:0] = {1'b0, CTE_CKSM_MSB.CKSM_MSB[7:0], CTE_CKSUM_LSB.CHKS_LSB[31:0]}

The final Checksum is calculated in the following way:

- Final_Checksum[40:0] = Initial_Checksum[40:0] + {1'b0,CTE_SIGTYPE0n[24],CTE_SIGTYPE0n[22:0],CTE_LUT0_LSBn[15:0]};

This Final_Checksum is again updated to Initial_Checksum and on the next write, new Initial_Checksum is taken. On resetting the Checksum, the entire Checksum is reset.

46.11 Timing table configuration example

The modification of active timing table values is possible, but is not recommended. If this is attempted by the SW, the contents in the timing table will be replaced but the behavior of CTE will not be defined (a contention error bit also sets in debug register CTE_DBG_REG.

The recommended way to update the timing table values is to temporarily stop timing generation by disabling the CTE and updating the timing table or update currently inactive timing table by configuring CTE in toggle mode and using timing table end interrupts. With the first method, CPU can prepare all required timing data in main SRAM as a linked list. The timing tables are then loaded by eDMA into the CTE automatically. With the second method, CPU can calculate the next timing data and load it directly into the current unused CTE timing table using the "table_sel" bit in the debug register to know which timing table is currently in use. The minimum time covered by a single timing table is mainly limited by the latency of the eDMA in the first approach and the response time of the CPU in the second approach. See the following figure for more details.

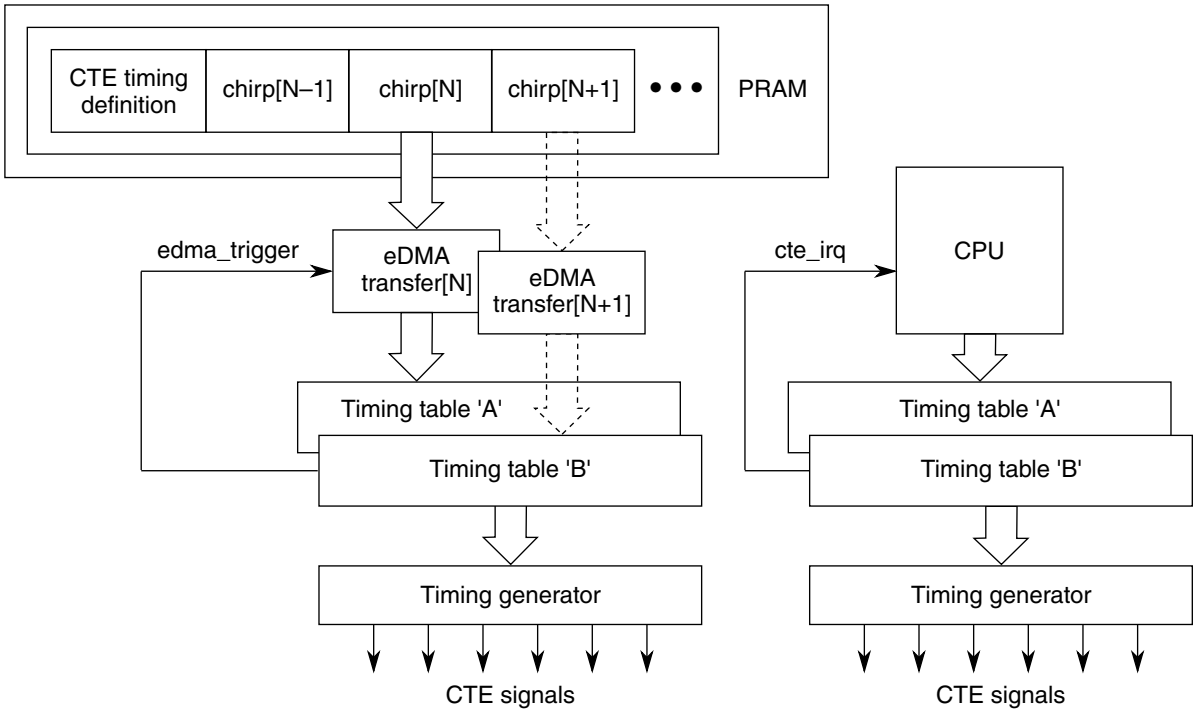

Figure 46-17. eDMA and CPU Programming Model

46.12 Initialization sequence

CTE supports different modes in which the timing table is executed, eDMA trigger is generated etc. Following is the sequence which should be followed by the user in order to configure CTE:

1. Configure time instances and corresponding signal states in the timing table register LUT_LSB_0.
2. Configure remaining signal states in the timing table register LUT_MSB_0.
3. Configure time instances and corresponding signal states in the timing table register LUT_LSB_1.
4. Configure remaining signal states in the timing table register LUT_MSB_1.
5. Configure signal types in signal type registers CTE_SIGTYPE0/1.
6. Configure MA_SL_ST bit in control register CTE_CNTRL.
7. Configure REP_CNT value in control register CTE_CNTRL.
8. Configure OPMOD_SL bits in control register CTE_CNTRL to define continuous run mode or toggle mode.
9. Configure the duration counter for TT0 and TT1 execution in registers CTE_LUT_DUR and CTE_LUT_DUR1 respectively.

NOTE

The user must not program either of the CTE LUT duration registers to "0". See the NOTEs in TT0 Execution Duration Register (CTE_LUT_DUR) and TT1 Execution Duration Register (CTE_LUT_DUR1).

10. Configure timemode bit in CTE_CNTRL1 to define absolute/relative mode of timing table execution.
11. Configure CTECK_DV in CTE_CNTRL1 to define the CTE data path clock.
12. Configure CLKDIV_1-CLKDIV_4 in CTE_CNTRL1 to define clocks for external signals.
13. Configure CLK_SEL0-CLK_SEL9 in clock select register CTE_CLKSEL to select the clock divider for the external signals.
14. Enable CTE by setting CTE_EN bit in CTE_CNTRL1.

Note that steps 1-4 can be done using either eDMA or CPU. Following are the steps for CPU configuration:

- Since there are separate interrupts to the CPU on start and end of both the timing tables, CPU can easily find out which one is being used and which one is free. Using this info, CPU can configure the table which is not being used by the CTE for timing generation without any contention.

In case of eDMA configuration following are the steps:

- configure eDMA_CTL bits in control register CTE_CNTRL. This will configure CTE to generate the trigger either on start or end of the table execution. If start of execution is being used as a trigger, eDMA will have to make sure that it updates the other table in order to avoid contention. In case when end is being used as a trigger, eDMA will have to update the same table.

Configuring Clock type ports

CTE enables user to configure any of the CTEP[7:0], RCS and RFS ports as clock and send periodic signals which are aligned to one of the 4 clock dividers. Suppose user wants to send 10 M signal on CTEP[0] and RCS, 5 MHz signal on RFS and CTEP[1], 2.5 MHz signal on CTEP[4:2] and 1.25 MHz signal on CTEP[7:5]. Following steps should be used:

- Configure CTE_SIGTYPE0 register to define CTEP[7:0] as clock type signals. CTE_SIGTYPE0[CTE_TYPE0] = 0x10, this will configure CTEP[0] as clock, similarly configure rest of the CTEP[7:1] as clock.
- Configure CTE_SIGTYPE1 register to define RCS and RFS as clock type signals. CTE_SIGTYPE1[RCS] = 0x10 and CTE_SIGTYPE1[RFS] = 0x10.

- Configure clock divider 1 to generate 10 MHz clock. CTE_CNTRL1[CLKDIV_1] = 0x011".
- Configure clock divider 2 to generate 5 MHz clock. CTE_CNTRL1[CLKDIV_2] = 0x100".
- Configure clock divider 3 to generate 2.5 MHz clock. CTE_CNTRL1[CLKDIV_3] = 0x101".
- Configure clock divider 4 to generate 1.25 MHz clock. CTE_CNTRL1[CLKDIV_4] = 0x110".
- Configure clock select register so that RCS and CTEP[0] are aligned to clock divider 1 and are sending 10 MHz signal. CTE_CLKSEL[CLK_SEL8] = 0x00 and CTE_CLKSEL[CLK_SEL0] = 0x00.
- Configure clock select register so that RFS and CTEP[1] are aligned to clock divider 2 and are sending 5 MHz signal. CTE_CLKSEL[CLK_SEL9] = 0x01 and CTE_CLKSEL[CLK_SEL1] = 0x01.
- Configure clock select register so that CTEP[4:2] are aligned to clock divider 3 and are sending 2.5 MHz signal. CTE_CLKSEL[CLK_SEL2] = 0x10, CTE_CLKSEL[CLK_SEL3] = 0x10 and CTE_CLKSEL[CLK_SEL4] = 0x10.
- Configure clock select register so that CTEP[7:5] are aligned to clock divider 4 and are sending 1.25 MHz signal. CTE_CLKSEL[CLK_SEL5] = 0x11, CTE_CLKSEL[CLK_SEL6] = 0x11 and CTE_CLKSEL[CLK_SEL7] = 0x11.

- Enable CTE by setting CTE_EN bit in CTE_CNTRL1.

Chapter 47
Waveform Generation Module (WGM)

47.1 Introduction

The WGM generates the digital output using one of the four configurable look-up tables (LUT), to be converted into the waveforms by the DAC module. The waveforms can be programmed by means of four configurable LUTs. The timing and control signals for generating these LUT outputs to the DAC is provided by the Cross Triggering Engine (CTE) module.

The following table lists various acronyms and their description that are used in WGM module.

Table 47-1. Acronyms

Acronym	Description
WGM	Waveform Generator Module
DAC	Digital-to-Analog Converter
LUT	Look-up Table
CTE	Cross Triggering Engine
FSM	Finite State Machine
GPIO	General Purpose I/O
PWM	Pulse-width modulation
SW	Software
LFSR	Linear Feedback Shift Registers
FADR	Fixed Address
CVAL	Counter Value
MISR	Multi Input Shift Register

47.2 Block Diagram

The block diagram of the WGM module is shown below:

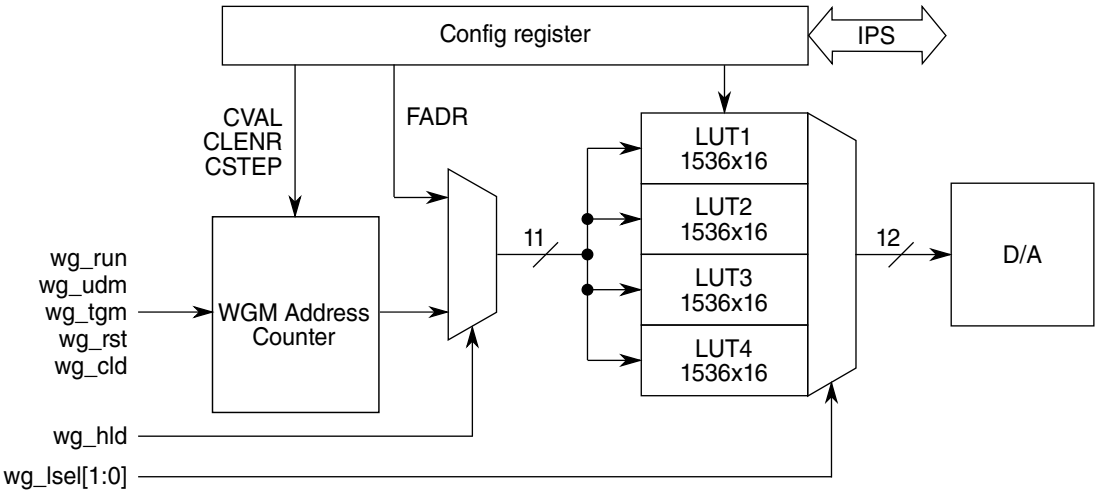

Figure 47-1. WGM Block Diagram

47.3 Features

The WGM module has the following key features

- Programmable LUT based chirp generation.
- Up to four 16x1536 configurable LUTs provided.
- 5 Programmable PWM waveform generation modules.
- WGM LUT does not have ECC protection.
- Automatic update of waveform data by eDMA.
- Stand alone mode supported.

47.4 Interrupts

The WGM module can generate interrupts to the CPU on the following events:

- At the start of LUT execution i.e. when WGM starts reading the LUT and WGM address counter is 0.
- At the end of the LUT execution when WGM is reading the LUT and WGM address counter either equals or exceeds last entry in the LUT or (WGM Control Register 1 (WGM_CTRL_1) [VALID_CNT]).

These interrupts are masked and will show on the interrupt line only when the corresponding enable bit is set in the INT_EN [31:30] and the event occurs. Clearing of the interrupts follows w1c strategy.

47.5 Modes of operation

There are different scenarios under which different types of data from a selected LUT has to be sent to the DAC from the WGM. Based on the wg_lsel bits coming from the CTE, active LUT for sending the data to the DAC is selected. The data to be sent to the DAC is stored in LUTs. An 11-bit WGM address counter is used to read the data from the LUT. For generating different types of data to the DAC, WGM address counter needs to be controlled.

Following are the modes in which WGM logic operates to generate different values of WGM address counter and hence different types of data to the DAC:

- Hold Mode
- Off Mode
- Stop Mode
- Run Mode
- Stand alone mode

Different modes are described below:

47.5.1 Hold Mode

In this mode, a constant value is sent to the DAC module. This constant value is stored in specific locations of all the LUTs. WGM address counter keeps on running the way it is configured but the address for reading the LUT data is loaded with the Fixed address from the CPU (FADR) which corresponds to the above specific location. In this way a particular LUT location is selected to send a fixed value to the DAC. There is a Multiplexer which ensures that the FADR is used as the LUT read address instead of the WGM address counter in hold mode.

47.5.2 Off Mode

In this mode, output to DAC is disabled i.e. all zeroes are transmitted to the DAC from WGM. WGM address counter is in reset. WGM enters in this mode after reset and remains in this mode until WGM is enabled by software.

47.5.3 Stop Mode

In this mode, a fixed value is transmitted to the DAC from WGM. This is achieved by freezing the WGM address counter once the Stop mode is entered causing the same value to be transmitted until the WGM is in this mode.

47.5.4 Run Mode

In this mode the LUT address counter runs in control of the CTE (Cross Triggering Engine). Following signals shown in the table, for example, wg_udm, wg_tgm, wg_rst, wg_cld decide in which mode the LUT address counter should be running. Depending upon the signals coming from CTE module, WGM address counter value is generated.

Table 47-2. WGM Address Counter Mode Table

Signal Name	Description
wg_udm	When this signal is '0, WGM address counter decrements by step size "cstep" on every clock and then rounds off to 0 after reaching the end address1535. When "wg_udm" is '1', WGM address counter resets to 1535 and then starts incrementing by "cstep" on every clock until it reaches 0 where it rounds off to 1535 again. Please note that in either mode, round off will take the counter to 0 e.g. suppose wg_udm is 1 and cstep is 30. Counter reaches 1530 then the next value will be 0 and then 30 and so on. Similar will be the case when wg_udm is 0. Please see WGM Address Counter Example where some examples are shown depicting various WGM address counter run scenarios.
wg_tgm	When this signal is '1', the counter increments by "cstep" on one clock and then decrements by the same on the next clock.
wg_rst	When this signal is asserted, WGM address counter will be reset to 0 on the next WGM clock cycle.
wg_cld	When this is set, WGM address counter will be loaded with "cval" on the next WGM clock.
cval	This is the value with which the counter will be loaded on the next WGM clock when "wg_cld" signal is asserted.
cstep	This is the step size with which the counter will increment or decrement depending upon the "wg_udm".
clenr	This the factor which limits the data rate from WGM to DAC. By default, this is 0 which means that the data rate will be 80 Mega samples per seconds. Value of clenr is taken in power of 2 which means that if it is 1, the data rate will become 40 Mega samples per seconds, if it is 2, data rate will become 20 Mega samples per seconds, if it is 3, data rate will become 10 Mega samples per seconds and so on. The Supported Data Rates are 10 Msps and Lower. User should configure it in a way that the rate should remain 10 Msps or Lower for a DAC.

47.5.5 Standalone Mode

Normally the WGM modes of operation is controlled by CTE but there is a provision to control the WGM operation by CPU in stand alone mode (by setting CTRL_1[11]). In this case, the WGM operation is started and stopped by CPU. Once started, WGM address counter increments until it reaches the end value and then rounds off to value 0. It always runs in incremental mode and increments always by 1.

NOTE

Please note that only LUT1 is available in this mode.

47.6 WGM Address Counter Example

The time at which the control signals become effective on the address counter and the DAC data is different depending upon states of the signals. Following table lists the number of clock cycles it takes for a particular control signal to affect the address counter. From the time address counter is changed, DAC data takes 3 WGM clock cycles to show up. LUT number and location depends upon the "wg_lsel[1:0]" and address counter value respectively. The following table shows the number of clock cycles required by the control signals from CTE, to affect the WGM address counter.

Table 47-3. Timing table relating to address counter and control signals

Control Signal	Required clock cycles to change the address counter
wg_run	1
wg_tgm	1
wg_cld	1
wg_udm	1
wg_rst	1
wg_hld	0

It can be seen from the table above that except "wg_hld" which affects the counter immediately/asynchronously, all the other control signal affect the counter synchronously i.e. take effect on the next clock cycle.

Following example diagrams show the counter output dependent upon the signals coming from the CTE. Please note that the frequency of clock shown below in all the diagrams will be according to the CLENR value programmed in CTRL_1 [26:29].

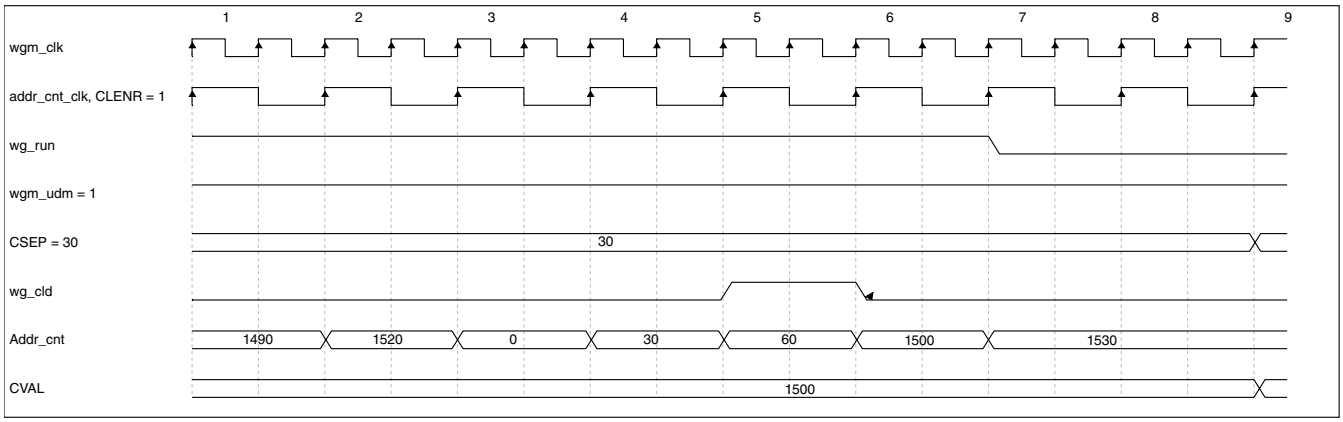

Figure 47-2. Incremental mode with CSTEP as 30 and wg_cld

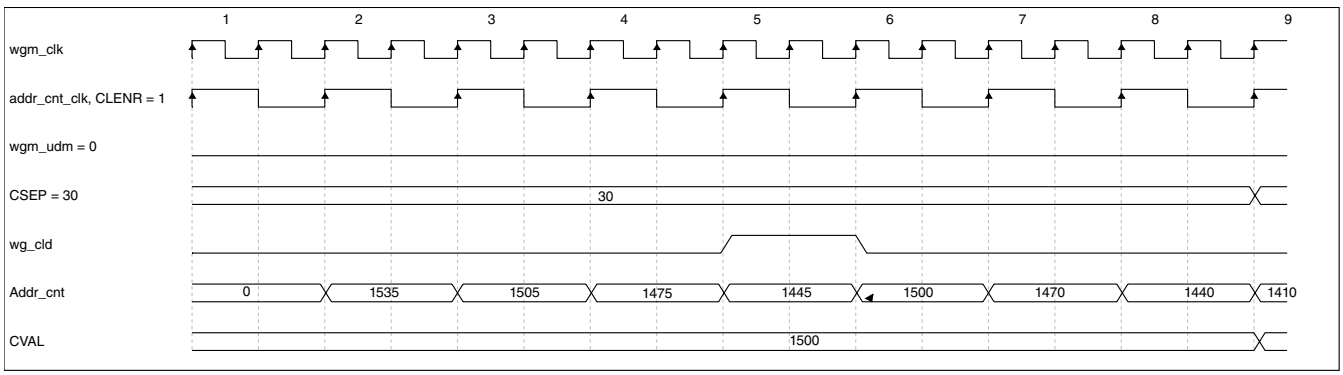

Figure 47-3. Decremental mode with CSTEP as 30 and wg_cld

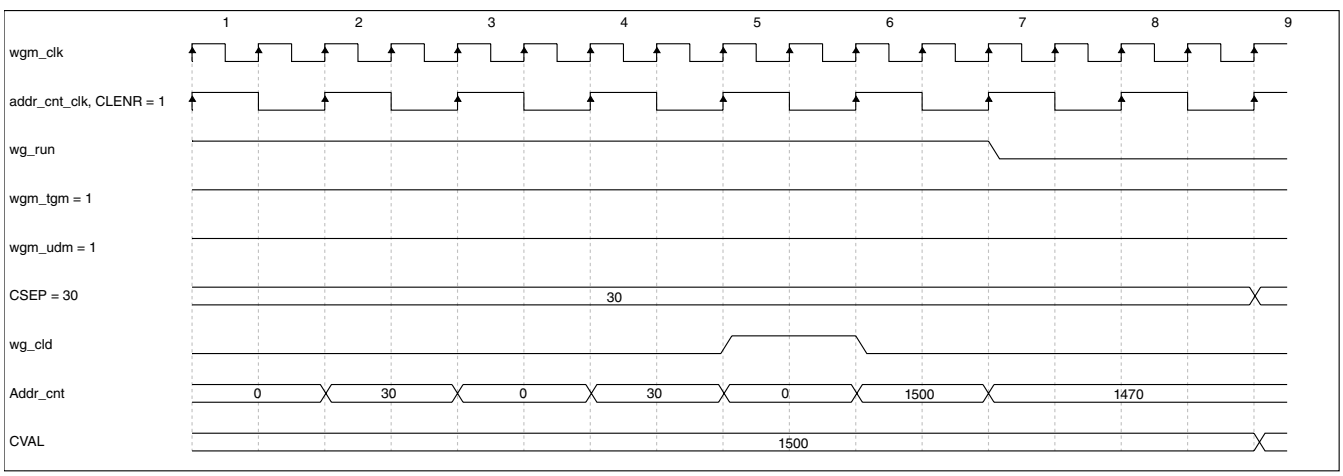

Figure 47-4. Incremental mode with CSTEP as 30 and wg_tgm and wg_cld

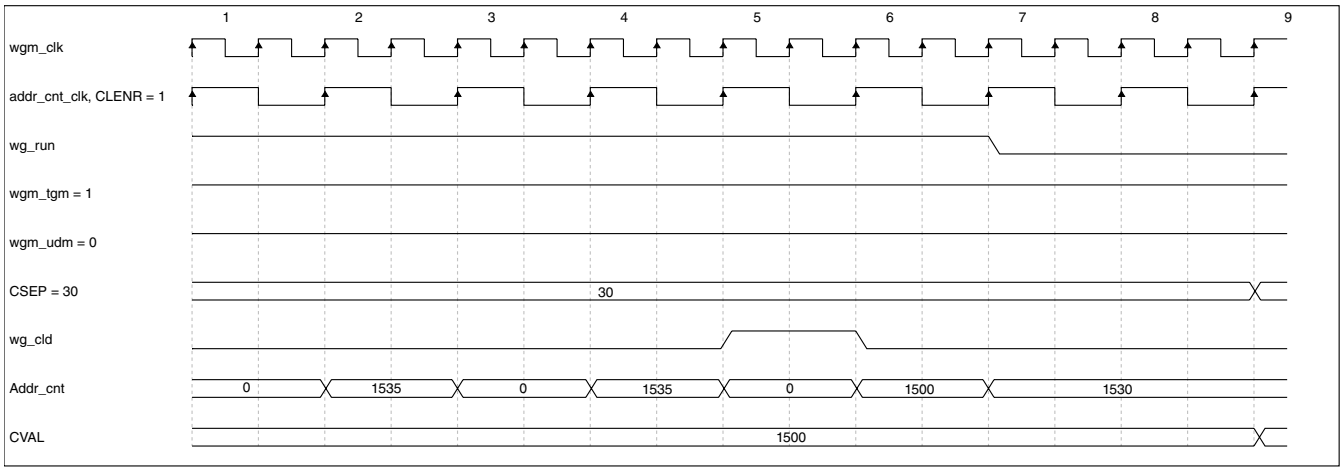

Figure 47-5. Decremental mode with CSTEP as 30 and wg_tgm and wg_cld

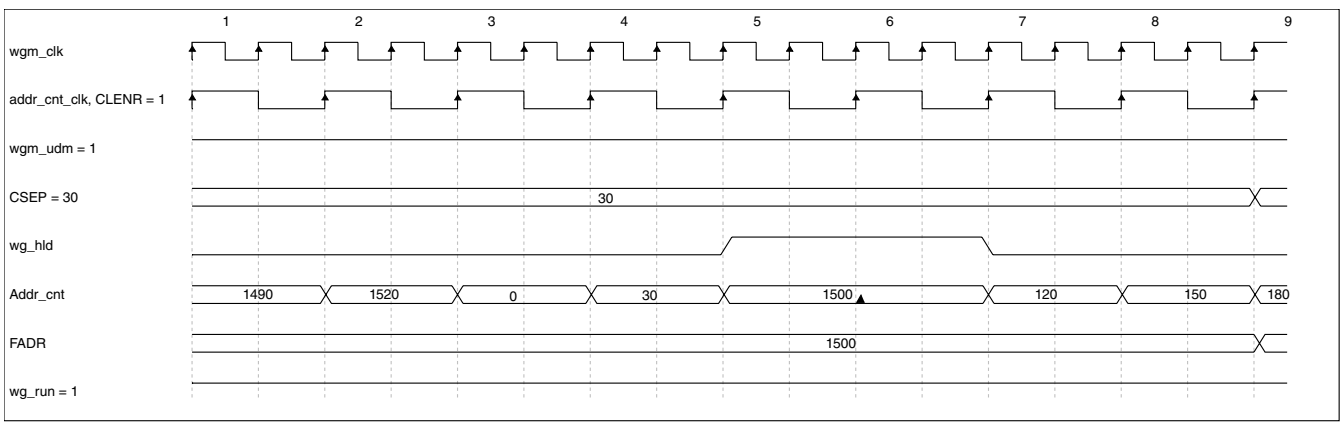

Figure 47-6. Incremental mode with CSTEP as 30 and wg_hld and wg_run = 1

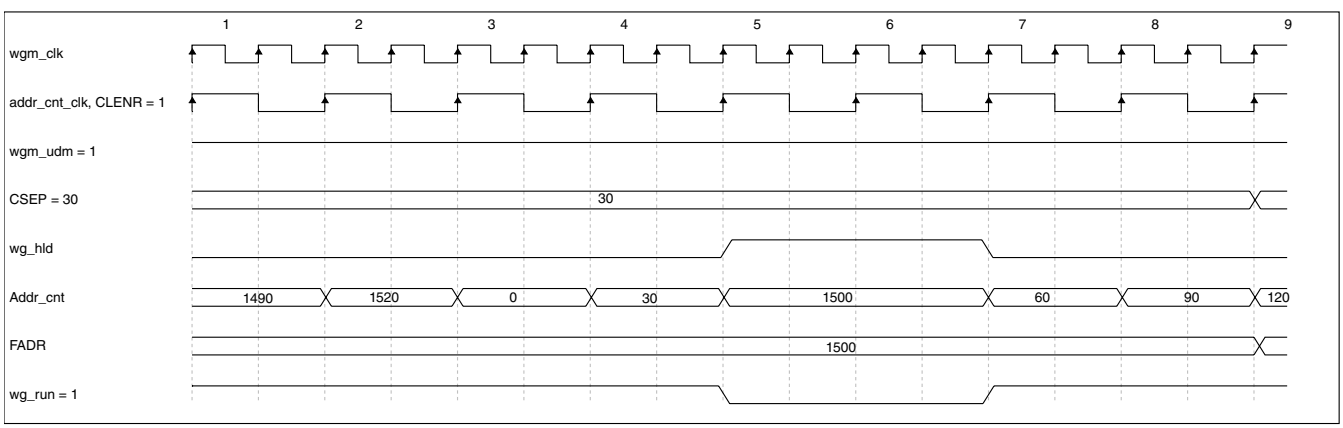

Figure 47-7. Decremental mode with CSTEP as 30 and wg_hld and wg_run = 0

Figure 47-8 below shows that the WGM module starts sending data to the DAC module after three clock cycles as soon as it is enabled by software. Which LUT will be used, is decided by "wg_lsel[1:0]" value and LUT address location will be decided, based on the address counter value which is 0 by default.

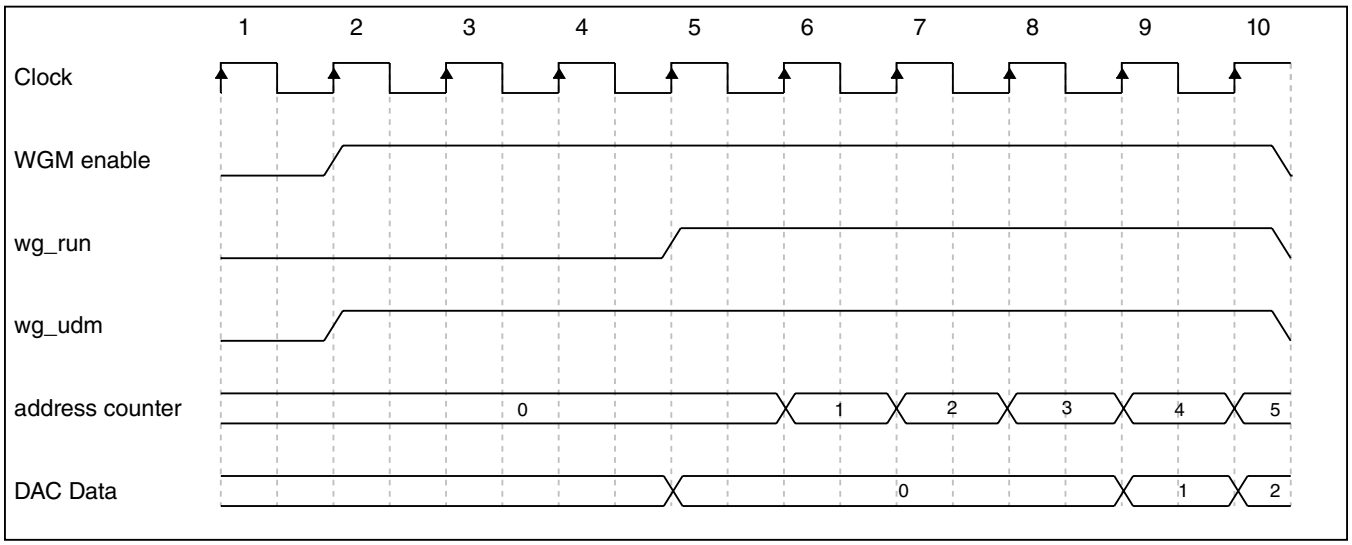

Figure 47-8. DAC data behavior with WGM enable, wg_run

Figure 47-9 below shows the address counter behaviour and the data which will be sent to the DAC when the LSEL along with other control signals are changing. Please note that after WGM is enabled, it will take 3 WGM clocks for WGM module to send data to the DAC if dac_ade is 0. If dac_ade is 1, it will take 4 clock cycles.

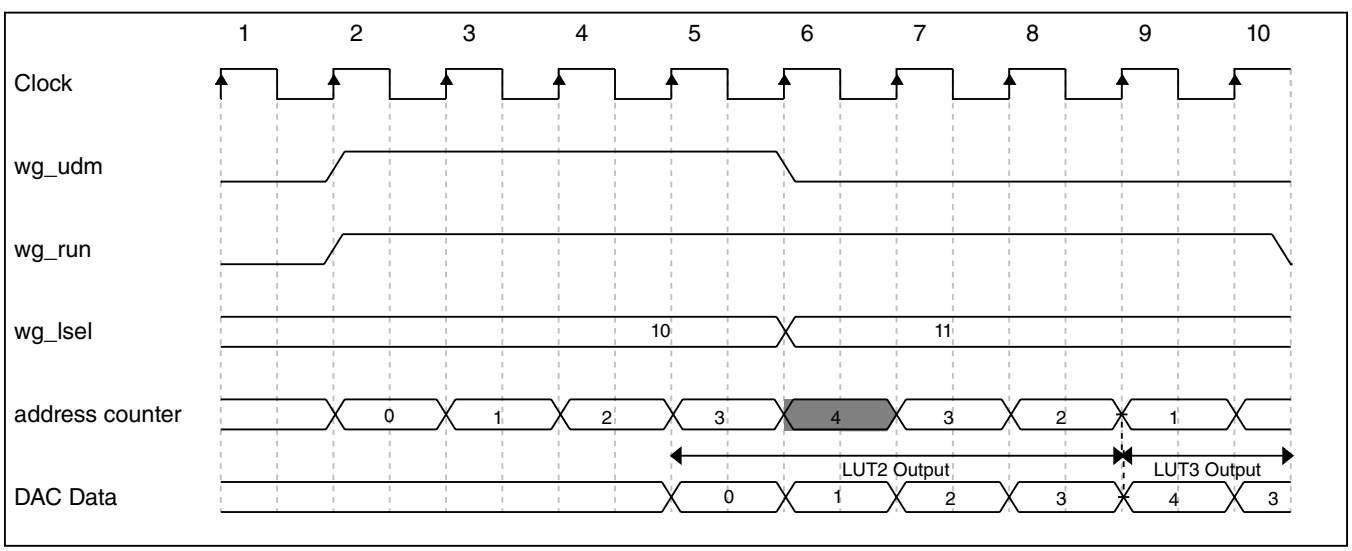

Figure 47-9. Address counter and DAC data relation in case of LSEL change

Figure 47-10 below shows the address counter behavior and the data which will be sent to the DAC when the wg_rst is asserted. Since address counter is already at 0, it is appearing that wg_rst is taking effect for more than 4 clocks. Shaded area of the DAC data output shows the values which was sent corresponding to reset.

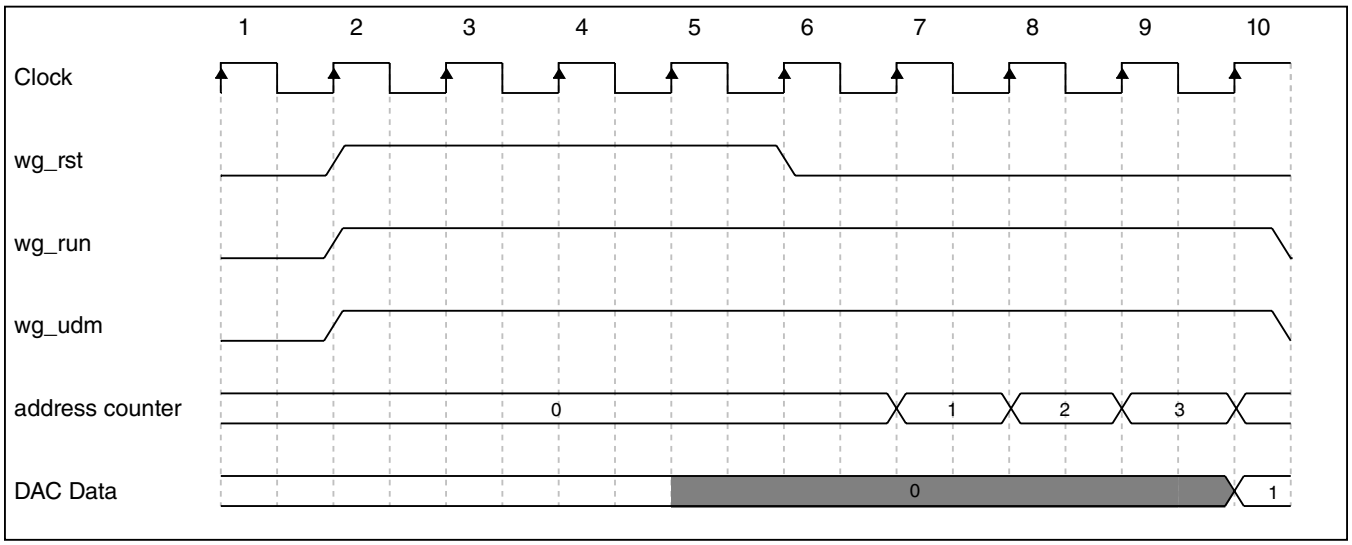

Figure 47-10. Address counter and DAC data relation with wg_rst

Figure 47-11 shows when wg_rst is asserted when address counter has a non-zero value.

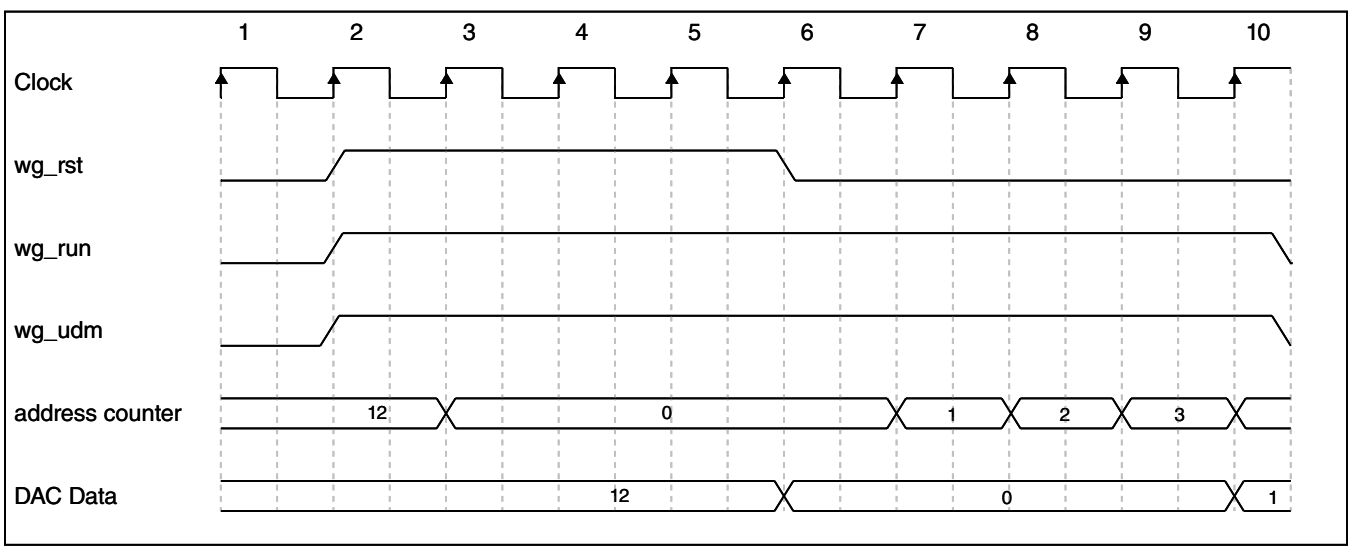

Figure 47-11. Address counter and DAC data relation with wg_rst and non-zero count value

Figure 47-12 shows the address counter and associated DAC data output behavior when wg_cld is asserted.

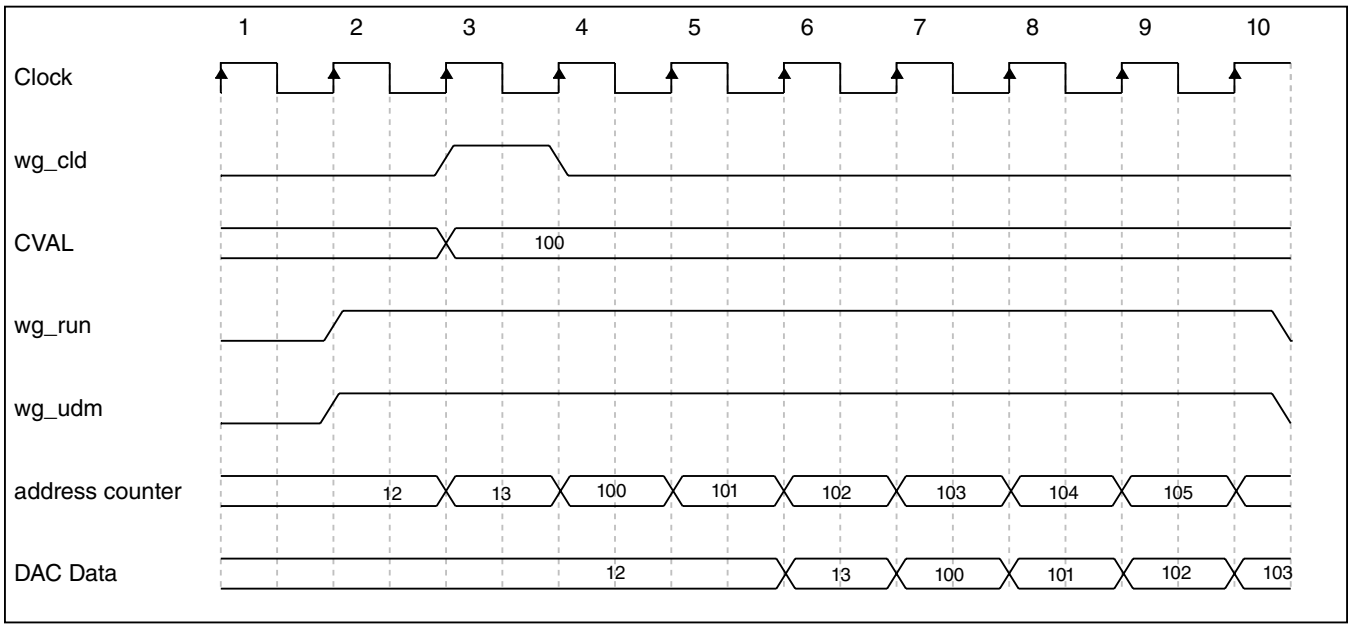

Figure 47-12. Address counter and DAC data relation with wg_cld

Figure 47-13 shows the case where in "wg_run" signal from CTE is high just for 1 WGM clock and CLENR is 2 meaning that the address counter is running at divide by 4 clock. wg_run fails to increment the address counter but wg_run1 increments it. It is the responsibility of the SW to ensure that the timing signal is high for at least one divided clock period as per CLENR value.

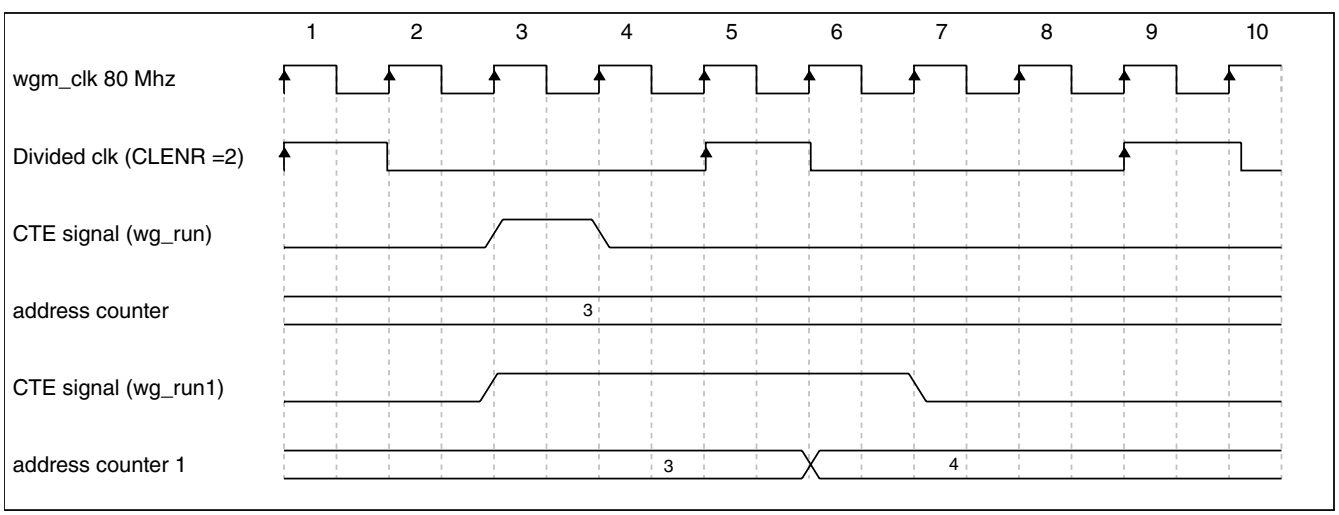

Figure 47-13. Address counter behaviour with timing signal when CLENR is high

Figure 47-14 below show the effect of WGM_CTRL_1[WG_HLD_S]. When this bit is '1', wg_hld signal's behavior becomes synchronous, that is, it's effect is delayed by one clock. This means that when wg_lsel[1:0] is changing from 0 to 1, data corresponding to FADR starts showing up after one clock and for that clock data from LUT0 shows up at

the DAC data output. When WGM_CTRL_1[WG_HLD_S] is '0', the effect of wg_hld is asynchronous and hence the data corresponding to FADR starts showing up at the data output on the same clock.

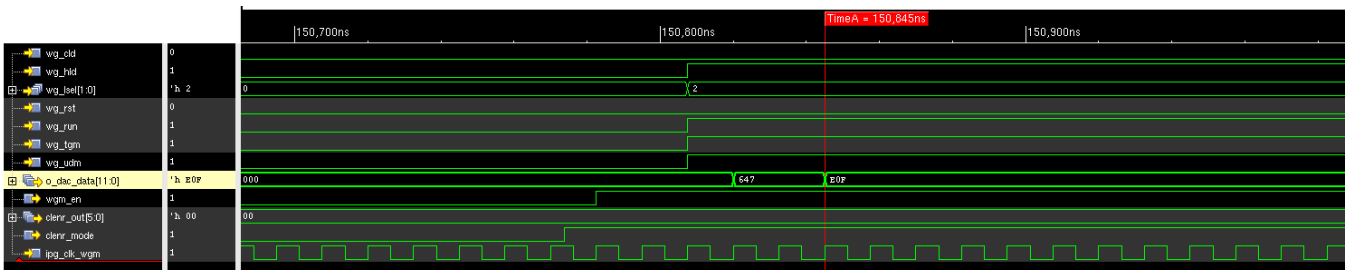

Figure 47-14. wg_hld synchronous behavior

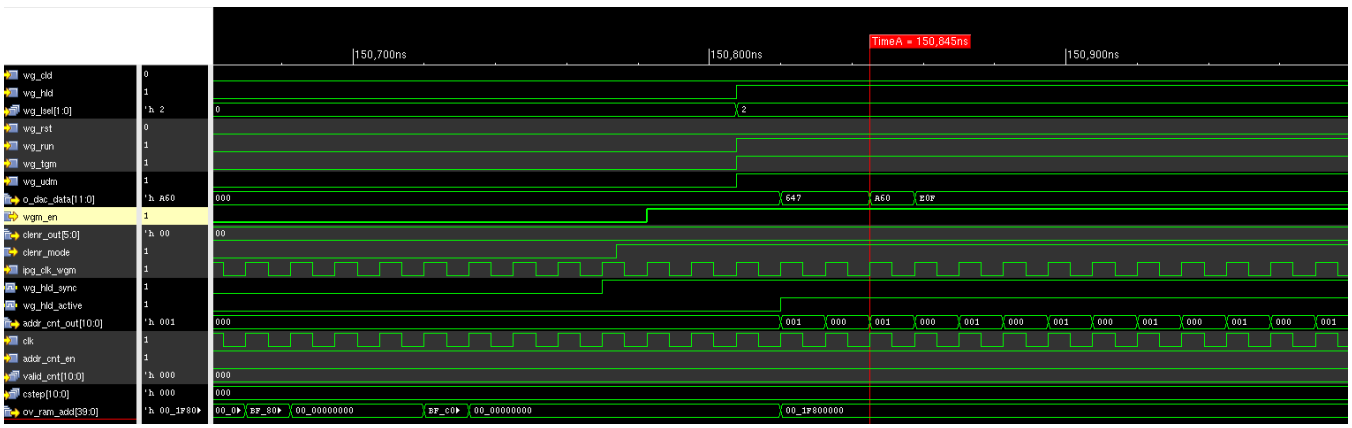

Figure 47-15. wg_hld asynchronous behavior

47.7 Memory Map and Register Description

WGM memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	WGM Control Register (WGM_CTRL)	32	R/W	0000_0000h	47.7.1/2168
4	WGM Control Register 1 (WGM_CTRL_1)	32	R/W	0000_0000h	47.7.2/2171

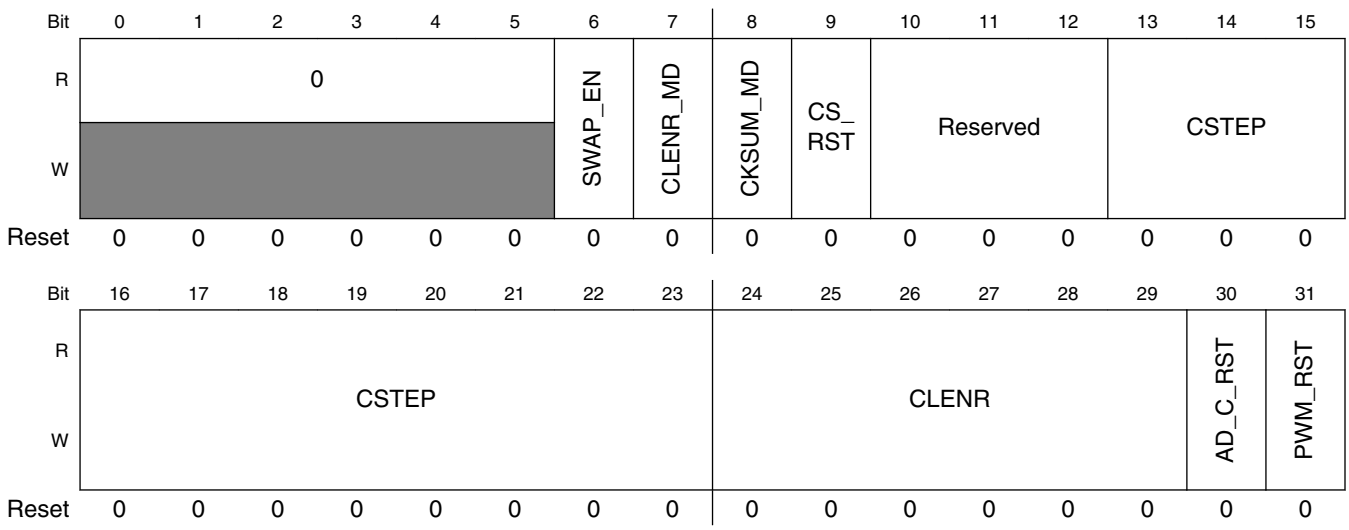
47.7.1 WGM Control Register (WGM_CTRL)

This is the first control register of WGM module.

Address: 0h base + 0h offset = 0h



WGM_CTRL field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 SWAP_EN	SWAP Enable This bit is used to swap the endianness of the data which is programmed into the WGM LUTs. 0 No swapping is done while programming the data onto the LUTs. 1 Swapping is performed on 16-bit boundary while programming the data on LUTs. For example, if swapping is enabled and the content 0xabcdbcda is written on WGM_LUT_Data, then the content which will be written onto the LUT will be 0xbcdaabcd.
7 CLENR_MD	CLENR Mode

Table continues on the next page...

WGM_CTRL field descriptions (continued)

Field	Description
	Thit bit decides the mode in which the value of WGM_CTRL [CLENR] is taken to limit the rate at which WGM transmits data to the DAC. The maximum data rate supported is 10 Msps. User should configure in a way that the maximum data rate does not exceed 10Msps. 0 CLENR value is taken in power of 2 i.e. the way it is described in CLENR bit field description. Only 4 lower bits are used in this case. 1 CLENR value is taken in decimal e.g. when WGM_CTRL[CLENR] is "101000", the data rate to DAC is limited to 2 Mega samples per second.
8 CKSUM_MD	Checksum Calculation Mode This bit decides whether checksum calculator block works in checksum mode or MISR (multi input shift register) mode. 0 Checksum mode. Carry on MSB is dropped. For example: current value = 1000000000000000 next write value = 1000000000000000 checksum result = 0000000000000000 (Carry on MSB is dropped). 1 MISR mode, carry from MSB is added to the LSB. For example: current value = 1000000000000000 next write value = 1000000000000000 checksum result = 0000000000000001 (carry on MSB is added to LSB).
9 CS_RST	Checksum Reset This bit when asserted causes the Checksum calculation block to reset synchronously on the next IPG clock. 0 De-asserted. 1 Checksum block will be synchronously reset on the next IPG clock cycle.
10–12 Reserved	This field is reserved.
13–23 CSTEP	Counter Step CSTEP defines the step by which WGM address counter should increment/decrement depending upon the wg_run and wg_udm signals from CTE. It can have values from 0 to 2047. **NOTE:** Please note that if the value of CSTEP is programmed to be more than the LUT DEPTH and the current value of wgm address counter is non-zero, it will roll over to 0 and stay there. If the current value is 0, the counter anyways will stay at 0. 0000 Address counter increments/decrements by 1. .. 1111 Address counter increments/decrements by 16 and so on.
24–29 CLENR	Counter LENR CLENR defines the rate at which the WGM transmits data to the DAC. Depending upon the CLENR mode bit (WGM_CTRL[CLENR_MD], either only 4 lower bits are taken in the power of 2 as per the table below, or all 6 bits are taken in decimal. For example if user programmes WGM_CTRL[CLENR] = "101000" and WGM_CTRL[CLENR_MD] is 0, then the value taken will be 2**8 which is 256 and DAC data will be limited to 80/256 = 0.3125 MSPS. IF WGM_CTRL[CLENR_MD] is 1, then value will be taken as 40 and DAC data will be limited to 80/40 = 2 MSPS. **NOTE:** Please note that it is the responsibility of the SW to ensure that the CLENR is correctly programmed in order to match the data rate of WGM to the internal DAC in order to avoid data loss. The maximum data rate supported is 10 Msps. User should configure in a way that the maximum data rate does not exceed 10 Msps. 0000 Reserved

Table continues on the next page...

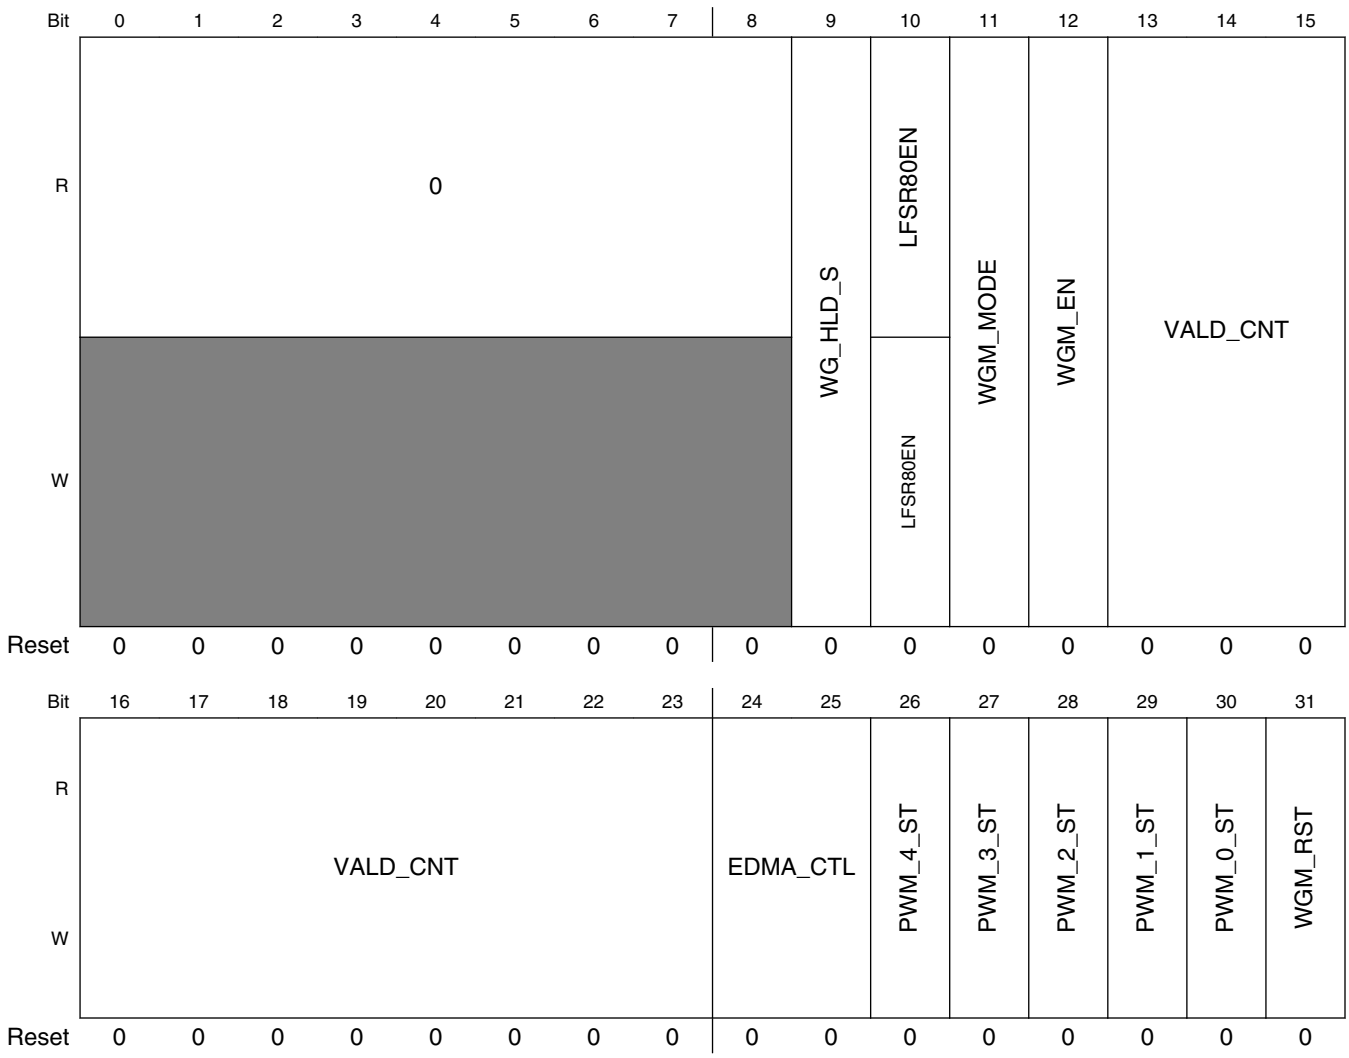
WGM_CTRL field descriptions (continued)

Field	Description
	0001 Reserved 0010 Reserved 0011 Data rate is 10 M Samples per second. 0100 Data rate is 5 M Samples per second. 0101 Data rate is 2.5 M Samples per second and so on.
30 AD_C_RST	Address Counter Reset This bit is used to reset the WGM address counter separately. This bit does not have any effect on other modules. This can be used for debugging purpose. 0 De-asserted. 1 WGM address counter is reset synchronously on the next WGM clock cycle.
31 PWM_RST	PWM Reset This bit is used to reset the 5 LFSR modules. This bit does not have any effect on other modules. This can be used for debugging purpose. **NOTE:** Please note that this bit does not reset the PWM module start bits (PWM_4_ST, PWM_3_ST, PWM_2_ST, PWM_1_ST and PWM_0_ST) in the WGM_CTRL1 register. Hence user should first reset the individual PWM start bit before asserting the PWM_RST and then set it individually after de-asserting the PWM_RST. 0 De-asserted. 1 All the 5 PWM generator modules are reset synchronously on the next LFSR clock cycle.

47.7.2 WGM Control Register 1 (WGM_CTRL_1)

This is the second control register of WGM module.

Address: 0h base + 4h offset = 4h



WGM_CTRL_1 field descriptions

Field	Description
0–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 WG_HLD_S	WG_HLD Synchronous/Asynchronous This bit decides if the effect of wg_hld signal coming from CTE will be synchornous or asynchronous. **NOTE:** Please see the example figure at section "WGM Address Counter Example" for details.

Table continues on the next page...

WGM_CTRL_1 field descriptions (continued)

Field	Description
	0 Effect of wg_hld will be asynchronous i.e. the address to the LUT will be replaced by FADR on the same WGM clock. 1 Effect of wg_hld will be synchronous i.e. the address to the LUT will be replaced by FADR on the next WGM clock.
10 LFSR80EN	LFSR 80 Mhz Clock Enable This bit is used to select the clock at which LFSRs operate. 0 LFSRs operate at 40 Mhz. 1 LFSRs operate at 80 Mhz.
11 WGM_MODE	WGM mode This bit is used to select the mode in which the WGM address counter operates. 0 WGM operation is dependent upon the control signals coming from CTE. 1 WGM operates in stand alone mode. In this mode, the address counter starts from 0 and increments by 1 until the it reaches 1535 and then rolls back to 0. It always runs in incremental mode. Only one LUT (LUT1) is available in this case.
12 WGM_EN	WGM Enable This bit is used to enable the transmission of data to the DAC. When this is 0, zeroes are transmitted to the DAC. WGM address counter will retain its value and the operation mode will go back to OFF mode. 0 WGM operation will remain in OFF mode meaning that zeroes will be transmitted to the DAC. WGM address counter will retain the current value. 1 WGM operation is started. In normal mode the operation will be dependent upon the control signals coming from the CTE.
13–23 VALD_CNT	Valid Entry Counter This field describes how many entries in the LUT are valid. The value of WGM address counter will be rolled over to 0 once it becomes greater than or equal to this value. If this value is 0, it is considered as 1535 meaning all the entries in the table are valid. **NOTE:** Please note that the value of "VALD_CNT" should always be <=LUT DEPTH.
24–25 EDMA_CTL	eDMA trigger control These 2 bits decide which event is used to send the eDMA trigger for LUT configuration. 00/11 eDMA trigger generation disabled. 01 eDMA trigger is generated when the active LUT which is being used to send data to the DAC is started i.e. the value of WGM address counter is 0. 10 eDMA trigger is generated when the active LUT which is being used to send data to the DAC reaches the end i.e. the value of WGM address counter is either >= 1535 or it is >= WGM_CTRL_1[VALD_CNT] at 0x0004).
26 PWM_4_ST	5th PWM module start This bit is used for starting/stopping the PWM generator. For configuring the seed, it should first be stopped. 0 Third 360-bit PWM generation module is stopped. 1 Third 360-bit PWM generation module is running.

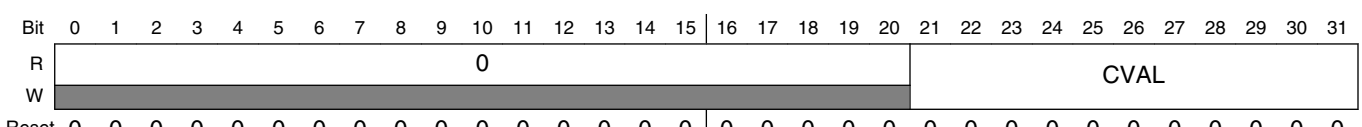
Table continues on the next page...

WGM_CTRL_1 field descriptions (continued)

Field	Description
27 PWM_3_ST	4th PWM module start This bit is used for starting/stopping the PWM generator. For configuring the seed, it should first be stopped. 0 Second 360-bit PWM generation module is stopped. 1 Second 360-bit PWM generation module is running.
28 PWM_2_ST	3rd PWM module start This bit is used for starting/stopping the PWM generator. For configuring the seed, it should first be stopped. 0 First 360-bit PWM generation module is stopped. 1 First 360-bit PWM generation module is running.
29 PWM_1_ST	2nd PWM module start This bit is used for starting/stopping the second PWM generator. For configuring the seed, it should first be stopped. 0 Second 128-bit PWM generation module is stopped. 1 Second 128-bit PWM generation module is running.
30 PWM_0_ST	1st PWM module start This bit is used for starting/stopping the first 128 bit PWM generator. For configuring the seed, it should first be stopped. 0 First 128-bit PWM generation module is stopped. 1 First 128-bit PWM generation module is running.
31 WGM_RST	WGM Reset This bit is used to reset the WGM module synchronously. 0 Reset is de-asserted. 1 All the WGM modules will be reset synchronously on their next respective clocks.

47.7.3 CVAL Register (WGM_CVAL)

Address: 0h base + 8h offset = 8h



WGM_CVAL field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

WGM_CVAL field descriptions (continued)

Field	Description
21–31 CVAL	Counter Value This is the value to which counter is initialized on the next WGM clock cycle when "wg_cld" signal is asserted by the CTE. **NOTE:** Please note that the value of CVAL should always be less than or equal to the LUT DEPTH in order to send a valid data to the DAC.

47.7.4 Fixed Address Register (WGM_FADR)

Address: 0h base + Ch offset = Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																					FADR_VAL										
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

WGM_FADR field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–31 FADR_VAL	Fixed Address Normally wgm address counter value is used as the address for reading the data from active LUT (depending upon the "wg_lsel" value). But when "wg_hld" signal from CTE is 1, FADR_VAL is used as the address counter on the same clock. **NOTE:** Please note that the value of FADR should always be less than or equal to the LUT DEPTH in order to send a valid data to the DAC.

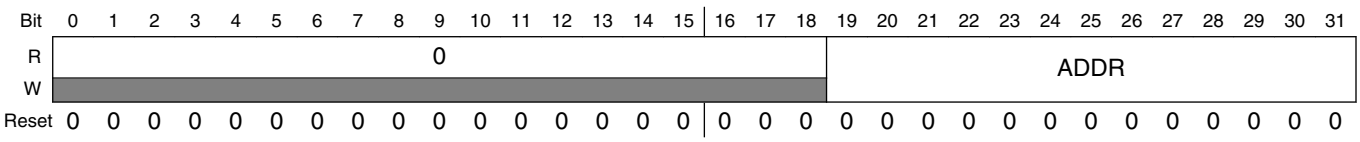
47.7.5 LUT Address Register (WGM_LUT_ADDR)

This register contains the address along with the LUT select bits corresponding to the 2 data values in the LUT_DATA register.

NOTE

Do not access this register when the WGM_CLK is disabled. As this clock is derived from the Sigma Delta PLL (SDPLL) the SDPLL must be on in the current mode before accessing this register.

Address: 0h base + 10h offset = 10h



WGM_LUT_ADDR field descriptions

Field	Description
0–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–31 ADDR	LUT address value This address is used for updating the LUT by the CPU. LUT depth is 768 which means 10 bits are required for addressing the LUT. ADDR [22:31] will be used for LUT addressing and ADDR [20:21] will be used as LUT select and ADDR [19] is unused. So the location of the LUT select bit is not fixed but is dependent upon the LUT DEPTH. Next 2 bits after the addressing bits are always taken as the LUT select bits. For example, suppose LUT DEPTH is 64, then ADDR [26:31] will be used for addressing, ADDR [24:25] will be used as LUT select, and ADDR [19:23] will be unused. Address is loaded by the CPU only once and then, auto-increments by 1 after every write to the LUT_DATA register. **NOTE:** The implemented LUT dimension is 1536 deep and 16-bit wide (1536x16). However, since the CPU data bus width is 32, in order to minimize the time taken by the CPU to configure the LUT, the dimension is taken as 768 deep and 32-bit wide.

47.7.6 LUT Data Register (WGM_LUT_DATA)

This register is accessed by the CPU to configure the LUTs. The value written in this register gets loaded into the LUT at location mentioned in the LUT address register. This register contains data for 2 locations of LUT selected by the LUT select bits and address counter. For example, if CPU writes 0x000 in the address register, internal address counter will be loaded with 0 and LUT0 will be selected. DAC_VALUE [16:27] will be written to LUT location 0 and DAC_VALUE [0:11] will be written to LUT location 1. Then on every write on the data register, internal address counter increments by 1 and the data is similarly written on the next LUT location.

NOTE

In case of 16-bit writes to the data register, skip writing will take place. Please refer Lookup Table Configuration.

NOTE

Do not access this register when the WGM_CLK is disabled. As this clock is derived from the Sigma Delta PLL (SDPLL) the SDPLL must be on in the current mode before accessing this register.

Address: 0h base + 14h offset = 14h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

WGM_LUT_DATA field descriptions

Field	Description
0–31 DAC_VAL	DAC value for LUT

47.7.7 WGM LFSR128 Register (WGM_LFSR_128)

This register is used to program the seed for the PWM modules. The contents of this register update the LFSR seed depending upon which LFSR is selected and which DWORD, i.e., 32-bit chunk of the selected LFSR is selected. Please see LFSR select register at address 0x001C for details. Normally for configuring 128 LFSR seed it requires four 32-bit write access + some wait states (introduced because IPG clock and WGM clocks are asynchronous). In 8-bit mode, it will take 16 write access + wait states. For configuring 360-bit LFSR in 8/16-bit mode will take even longer. Hence this register is designed to be accessed in 32-bit mode only.

NOTE

CPU should always configure the seed register in 32-bit write access mode. If CPU tries to access this register in 8/16-bit mode, entire 32-bit seed will be modified by the write data bus content leading to incorrect results. Hence it is recommended to programme the seed in 32-bit write mode only.

Address: 0h base + 18h offset = 18h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	LFSR_VAL																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

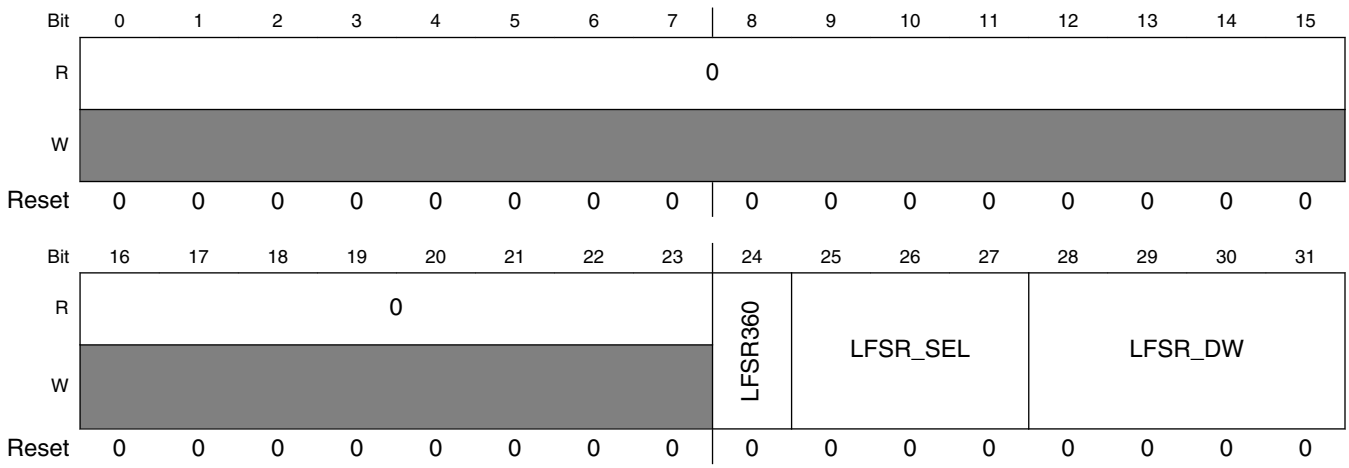
WGM_LFSR_128 field descriptions

Field	Description
0–31 LFSR_VAL	1st LFSR128 Value This value/pattern is loaded by the CPU as seed to the selcted PWM module. Corresponding "pwm_start" bit in WGM_CTRL1 should be 0 for programming the seed value. The PWM generator runs forever once it is started and is stopped only for loading the new seed value.

47.7.8 LFSR Select Register (WGM_LFSR_SEL)

There are total 5 PWM/LFSRs modules. 3rd, 4th and 5th are 360-bit and 1st and 2nd are 128-bit. This register selects which LFSR module out of the 5 is used for updating the seed.

Address: 0h base + 1Ch offset = 1Ch



WGM_LFSR_SEL field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 LFSR360	LFSR360 MUX Select This bit is used to select between the positive output of the second 360-bit LFSR and negative output of the third 360-bit LFSR. 0 Positive (p) output of third 360-bit LFSR module is connected to forth LFSR360 output of the WGM module. Please see PWM Generator section under Functional Description for details. 1 Negative (n) output of second 360-bit LFSR module is connected to forth LFSR360 output of the WGM module. Please see PWM Generator section under Functional Description for details.
25–27 LFSR_SEL	LFSR Select These bits will select which LFSR will be updated out of the 5 available LFSRs. 000 No LFSR is selected for updating the seed. 001 First 128-bit LFSR is selected for updating the seed. 010 Second 128-bit LFSR is selected for updating the seed. 011 First 360-bit LFSR is selected for updating the seed. 100 Second 360-bit LFSR is selected for updating the seed. 101 Third 360-bit LFSR is selected for updating the seed. 110-111 No LFSR is selected for updating the seed.
28–31 LFSR_DW	LFSR Double Word Select These 4 bits select which double word of the selected LFSR gets configured.

Table continues on the next page...

WGM_LFSR_SEL field descriptions (continued)

Field	Description	
	0000	Content of the LFSR_128_REG0 will configure the first double word [31:0] of the LFSR selected by the "LFSR_SEL" bits.
	0001	Content of the LFSR_128_REG0 will configure the first double word [63:32] of the LFSR selected by the "LFSR_SEL" bits.
	0010	Content of the LFSR_128_REG0 will configure the first double word [95:64] of the LFSR selected by the "LFSR_SEL" bits.
	0011	Content of the LFSR_128_REG0 will configure the first double word [127:96] of the LFSR selected by the "LFSR_SEL" bits.
	0100	Content of the LFSR_128_REG0 will configure the first double word [159:128] of the LFSR selected by the "LFSR_SEL" bits (only valid for 360-bit LFSRs).
	0101	Content of the LFSR_128_REG0 will configure the first double word [191:160] of the LFSR selected by the "LFSR_SEL" bits (only valid for 360-bit LFSRs).
	0110	Content of the LFSR_128_REG0 will configure the first double word [223:192] of the LFSR selected by the "LFSR_SEL" bits (only valid for 360-bit LFSRs).
	0111	Content of the LFSR_128_REG0 will configure the first double word [255:224] of the LFSR selected by the "LFSR_SEL" bits (only valid for 360-bit LFSRs).
	1000	Content of the LFSR_128_REG0 will configure the first double word [287:256] of the LFSR selected by the "LFSR_SEL" bits (only valid for 360 bit LFSRs).
	1001	Content of the LFSR_128_REG0 will configure the first double word [319:288] of the LFSR selected by the "LFSR_SEL" bits (only valid for 360-bit LFSRs).
	1010	Content of the LFSR_128_REG0 will configure the first double word [351:320] of the LFSR selected by the "LFSR_SEL" bits (only valid for 360-bit LFSRs).
	1011	Content of the LFSR_128_REG0 will configure the first double word [359:352] of the LFSR selected by the "LFSR_SEL" bits (only valid for 360-bit LFSRs).
	1100-1111	Unused. Writing these bits will have no effect on the LFSR configuration.

47.7.9 WGM Interrupt Enable Register (WGM_INT_EN)

This is the interrupt enable register for WGM.

Address: 0h base + 20h offset = 20h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0														L_END_EN	L_STR_EN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

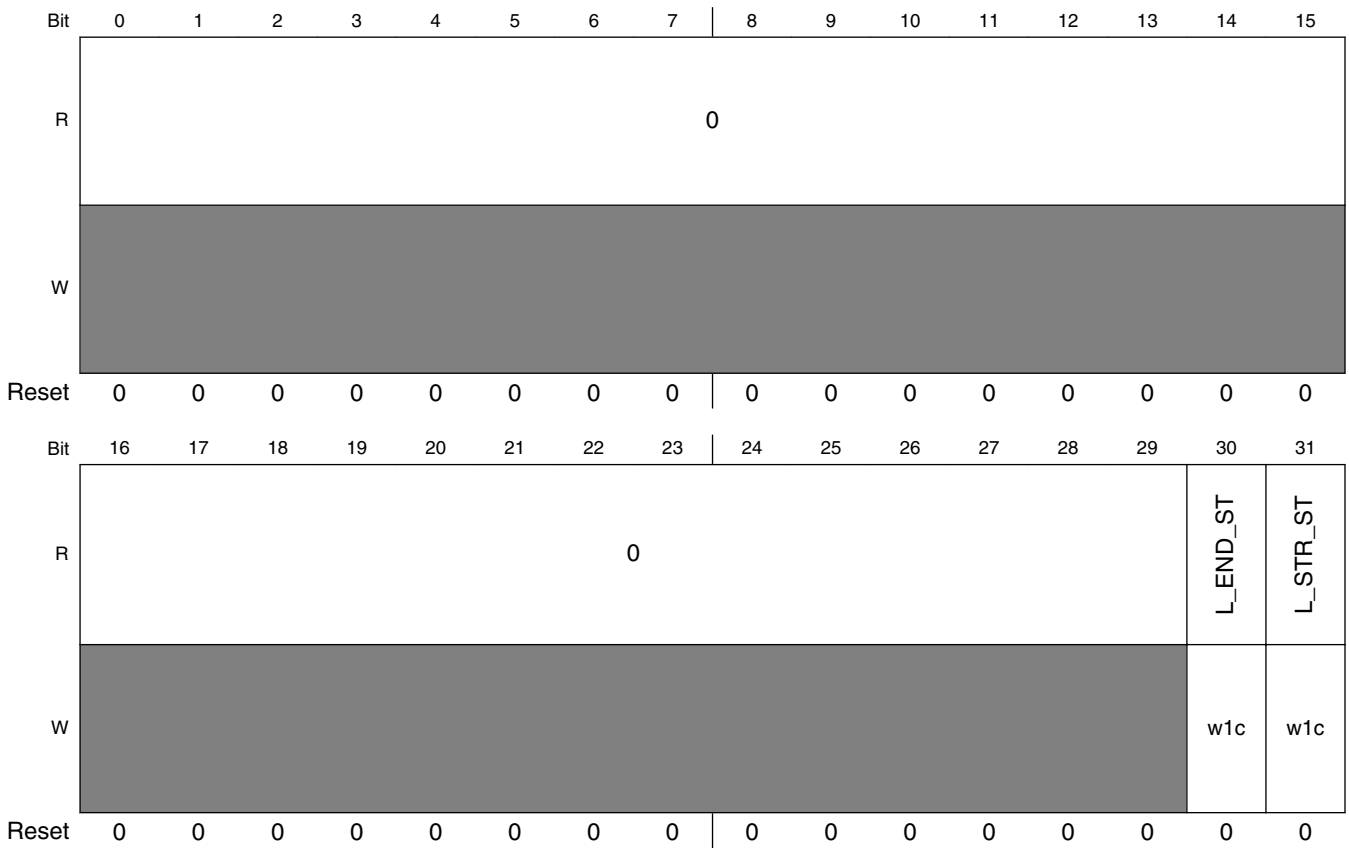
WGM_INT_EN field descriptions

Field	Description
0–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 L_END_EN	LUT end enable When this bit is set along with the corresponding event on WGM_INT_STAT an interrupt is generated to the CPU. 0 Disabled. 1 LUT end interrupt will be generated on the corresponding event.
31 L_STR_EN	LUT start enable When this bit is set along with the corresponding event on WGM_INT_STAT register, an interrupt is generated to the CPU. 0 Disabled. 1 LUT start interrupt will be generated on the corresponding event.

47.7.10 WGM Interrupt Status Register (WGM_INT_STAT)

This is the interrupt status register for WGM. All the bits in this register are sticky bits which set on the corresponding events defined in the Interrupt enable register and are cleared by writing a '1'. If the corresponding enable bit in the INT_EN register is set, an interrupt is generated to the CPU.

Address: 0h base + 24h offset = 24h



WGM_INT_STAT field descriptions

Field	Description
0–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 L_END_ST	LUT end This bit is set when the WGM is reading the LUT's and the address counter value becomes >= LUT DEPTH or valid entry counter (WGM_CTRL_1 [VALD_CNT]). It is cleared by writing a '1' on it. 0 LUT execution has not finished. 1 LUT execution has finished.
31 L_STR_ST	LUT start

Table continues on the next page...

WGM_INT_STAT field descriptions (continued)

Field	Description
	This bit is set when WGM starts reading the LUT and the address counter value is 0. This can be cleared by writing a 1 on it. 0 LUT execution has not been started. 1 LUT execution has started.

47.7.11 LUT Checksum Register (WGM_LUT_CKSM)

This register contains the 32-bit checksum value for a particular location of the LUT. Its purpose is for the CPU to ensure if the contents were correctly programmed into the LUTs. After the LUT is programmed, CPU reads the checksum value and compares against its own calculated value to ensure correct LUT programming.

Address: 0h base + 28h offset = 28h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	CKSUM																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

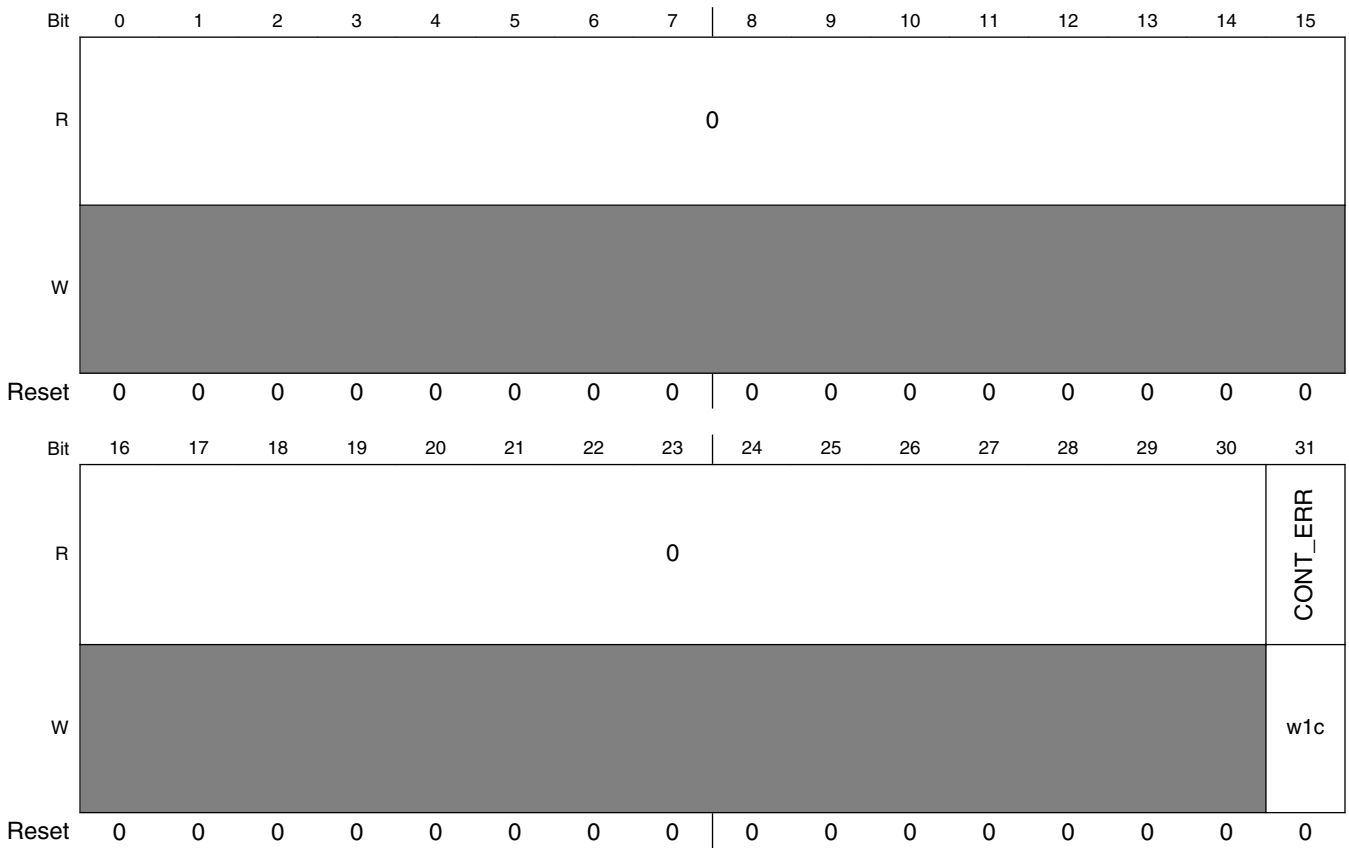
WGM_LUT_CKSM field descriptions

Field	Description
0–31 CKSUM	Checksum These 32-bit contain the checksum corresponding to the bits programmed in the LUT. CPU uses this checksum value to ensure that the LUT was properly configured. Please see Checksum Calculation block for more details.

47.7.12 Debug Register (WGM_DEBUG)

This register is used for the debug purpose.

Address: 0h base + 2Ch offset = 2Ch



WGM_DEBUG field descriptions

Field	Description
0–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 CONT_ERR	LUT contention error This bit is set when a LUT, which is currently being read by the WGM for sending the data to the DAC, is attempted to be programmed/written by CPU, eDMA,or by any other means. It is cleared by writing a 1 on it. 0 No LUT contention has occurred. 1 LUT contention has occurred.

47.8 Functional Description

Main functionality of WGM module is to run under the supervision of the CTE module and generate the DAC output from one of the 4 programmed LUTs. Main blocks of this module are address counter block and the PWM generator block.

47.8.1 Waveform LUT

The WGM module contains 4 LUTs and multiplexer for LUT output. The LUTs contain the binary numbers for the DAC. Each LUT has 1536 entries of unsigned numbers. The bit-width of the numbers in LUT is 12 bits. Only write operation can be supported from IPS bus, in order to update the LUT values.

47.8.2 Waveform LUT configuration

It is possible to configure the contents of the LUTs using either the CPU or the eDMA.

47.8.2.1 CPU Configuration

It is possible to configure the contents of any of the four LUTs using the CPU. The CPU should ensure that the LUT is inactive before modifying its contents. If it tries to update a LUT while it is active, new data will be loaded but the behavior of WGM will not be guaranteed so this should be avoided by the CPU. In order to let CPU know if any such event occured, a contention error flag (WGM_DEBUG [31] of Debug register) will be asserted. To optimize the performance of the WGM it is possible to update one of the LUTs while any of the other three are active.

47.8.3 eDMA Trigger

There are situations in which the LUT in WGM module need to be directly updated by the eDMA. This is accomplished using a DMA channel using eDMA interface. The WGM module request the eDMA transfer by sending trigger events to the DMA engine. These triggers are configurable (using CTRL_1 [24:25]) and can be sent out on either on the start or end of the LUT (address counter 0 or 1535) or a fixed configurable value of address counter (CTRL_1 [VALID_CNT]). When WGM_CTRL_1[24:25] is not "00/11",

a DMA request signal will be asserted which will cause DMA to configure the LUT. Once DMA is done, it will generate acknowledgement signal which will clear the DMA request signal.

47.8.4 Resets

In order to give control to the SW, there is a provision to assert a software reset bit (WGM_CTRL_1 [WGM_RST]) which will reset the entire WGM module. The effect of this bit is same as the hardware reset. Sometimes, it is required to reset some modules separately. There is a provision to reset the PWM/LFSR generator and Address counter block separately by SW. There are three separate reset signals which are provided for PWM generator WGM_CTRL [PWM_RST], address counter WGM_CTRL[AD_C_RST] and checksum calculation block WGM_CTRL[CS_RST] for this purpose. This may also be useful in debugging.

47.8.5 PWM Generator

There are 5 different Linear Feedback Shift Registers (LFSR) available in WGM module. Two of them (LFSR1-0) are 128 bits and rest are 360 bits (LFSR4-2). There is a provision to stop/start the shifting operation using WGM_CTRL_1 [26:30]. Shifting always happens from MSB to LSB and hence LSB gets shifted out first. Stop is used to load the LFSR and then it is started.

Total 6 outputs are coming out of the LFSR modules. LFSR0 and LFSR1(128 bits) have single bit output. LFSR2 has 2 different output. Positive output of LFSR3 and negative output of LFSR4 are multiplexed (360 bits) to have 2 different outputs. Second output is the inverted of the first output.

Table 47-4. LFSR module connection to the port

LFSR Output port	LFSR Module
lfsr[0]	LFSR0 output
lfsr[1]	LFSR1 output
lfsr[2]	LFSR2 normal output
lfsr[3]	LFSR2 inverted output
lfsr[4]	LFSR3 positive output
lfsr[5]	Multiplexed between the inverted output of LFSR3 and normal output of LFSR4. Inverted output of LFSR4 is unconnected. Please see the figure below for more details.

All these outputs can be enabled/disabled using the GPIO (general purpose input/output) pin multiplexing.

The clock source of this module is 40 MHz, which is achieved by dividing the waveform generator clock (80 MHz) by 2. Please see figure below for more details.

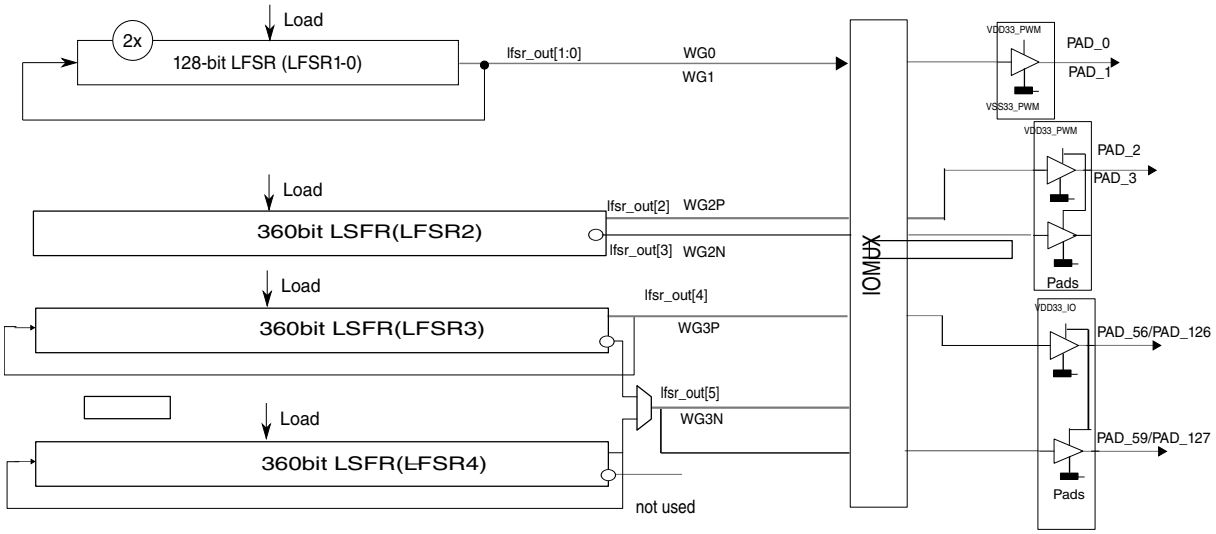


Figure 47-16. PWM Generator

47.8.6 Checksum Calculation

The checksum calculator block is to enable CPU, to validate the contents programmed into the LUTs. Checksum calculation is based on a simple bitwise addition. There are two modes in which the checksum calculation works.

- Checksum mode
- MISR (Multi Input Shift Register) mode

In checksum mode, carry on the MSB ([0] in this case) is dropped. In MISR mode, carry on MSB is added back to the LSB ([31]).

Please see the following example in the figure to see how checksum is calculated in checksum mode on every write on the LUT:

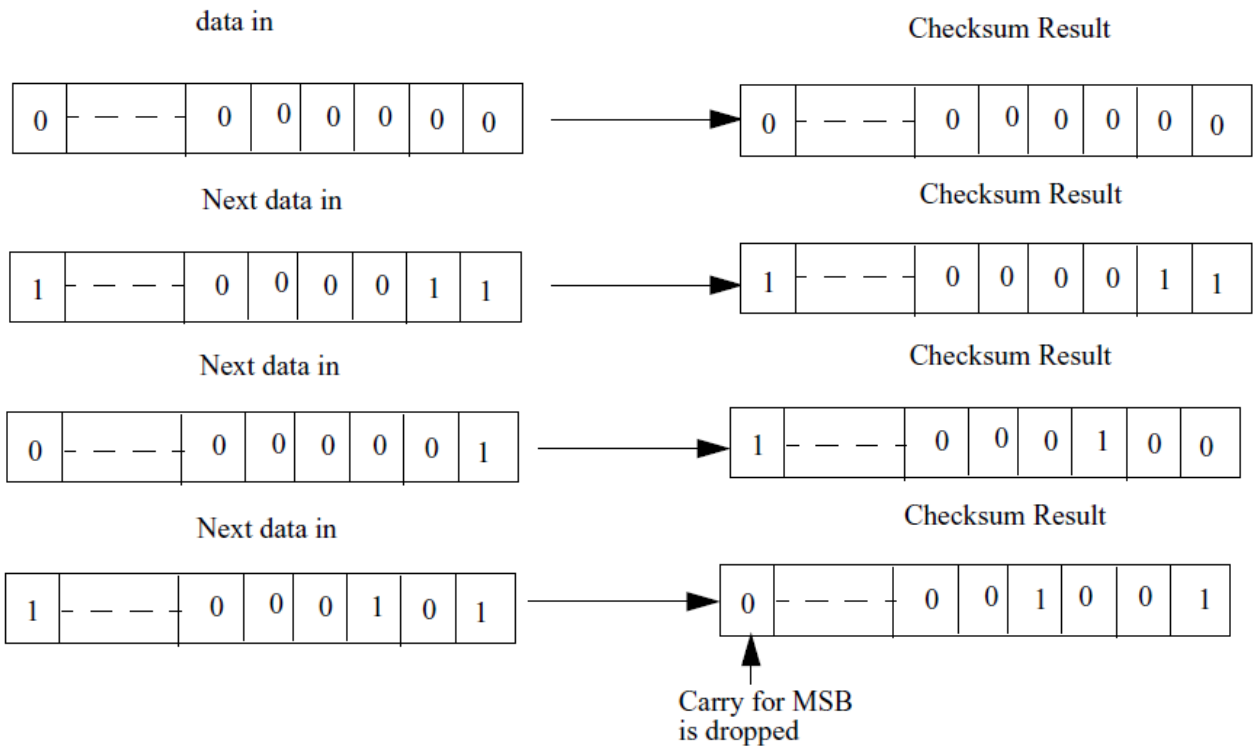

Figure 47-17. Checksum Calculation Example

47.9 Lookup Table Configuration

The following two figures show the examples of LUT configuration. The starting location depends upon the value of the WGM Address register, which is used to load an internal address counter which then increments on every write to the LUT data register. There are 2 modes in which the LUT can be configured.

- 32-bit ([0:11] are for 12-bit DAC and [12:15] are unused)
- 16-bit ([16:27] are for 12-bit DAC and [28:31] are unused)

Following is the example with 32-bit write:

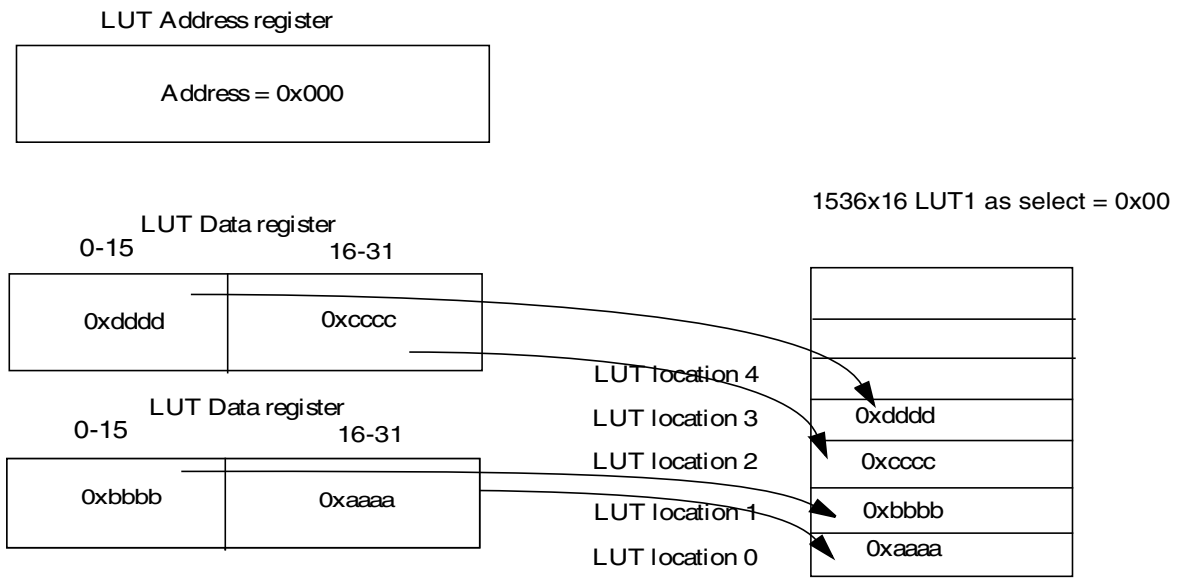

Figure 47-18. 32-bit LUT Configuration Example

Following is the example with 16-bit write:

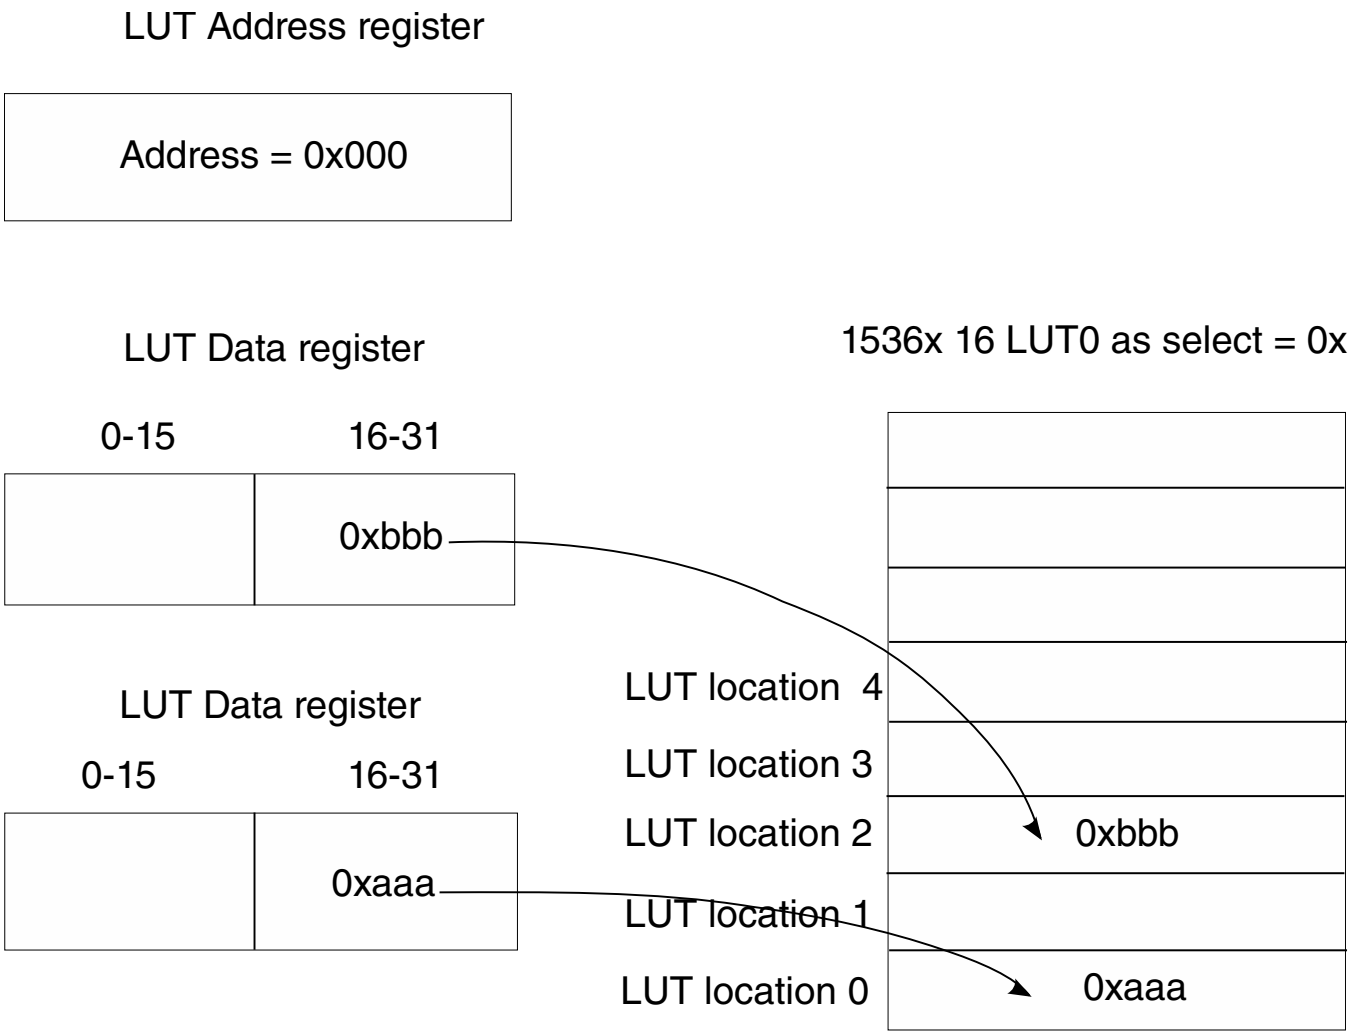

Figure 47-19. 16-bit LUT Configuration Example

47.10 WGM Initialization Sequence

Following section describes how various modules/interfaces of WGM should be configured in order to achieve the required functionality.

47.10.1 WGM-DAC Initialization Sequence

For programming the LUTs, CPU will need to take the following steps:

- Check that DEBUG[CONT_ERR] is low.
- Configure the LUT_ADDR. Current depth of LUT is 768 meaning that WGM_LUT_ADDR [22:31] will be used for addressing. WGM_LUT_ADDR [20:21] will select among the 4 available LUTs.

- Write the data to be written in the LUT_DATA [0:31]. This causes the logic to transfer the data contents [16:31] into the selected LUT location as per the address register content and data contents [0:15] to the next LUT location. Logic then uploads an internal counter with the address register content. This counter increments by 1 on every write on the WGM_LUT_DATA. Please note that the CPU write enable signal is used to increment the counter. This will ensure that the next write to the data register will transfer the contents into the next LUT location. The counter will roll over once it reaches 767. This is how the entire LUT or a selected portion of the LUT is configured.
- Verify if the data contents were written properly by comparing the checksum result with WGM_LUT_CKSM.
- Configure the CTRL([CLENR] of CTRL register) value so as to match the DAC capacity.
- Configure the CTRL([CSTEP] of CTRL register. The maximum data rate supported in 10 Msps. User should configure in a way that the maximum data rate does not exceed 10 Msps.
- Configure CTRL1[EDMA_CTL] in CTRL_1 register.
- Configure VALD_CNT on the basis of how many entries in a LUT is to be used to send data to the DAC.
- Configure CVAL register.
- Configure FADR_VAL in CTRL_1 register.
- Configure WGM_INT_EN [31] and WGM_INT_EN [30] for address counter start and end interrupts in INT_EN register.
- Configure WGM Control Register 1 (WGM_CTRL_1) [WGM_MODE]. This should be set to 1 for stand alone mode operation.
- Enable WGM by setting of WGM Control Register 1 (WGM_CTRL_1) [WGM_EN].

47.10.2 LFSR 128/360 Initialization Sequence

Following are the steps which are required to configure the LFSR modules.

- Configure "lfsr_sel" in LFSR Select Register to decide which LFSR module out of the five, needs to be configured.
- Configure "lfsr_dw_sel" in LFSR Select Register to select which 32 bit chunk needs to be updated.
- Configure first 32 bits of seed in WGM LFSR128 Register.

Chapter 48
RADAR Analog Front-End (AFE)

48.1 Chip specific AFE information

48.1.1 AFE filter phase select logic

It is possible to trigger the AFE filter logic based to sequence the AFE filters in a sequential order. This triggering mechanism can be used in two modes as shown in the figure below:

- Trigger after a wait cycle(recommended mode)
- Trigger without a wait state

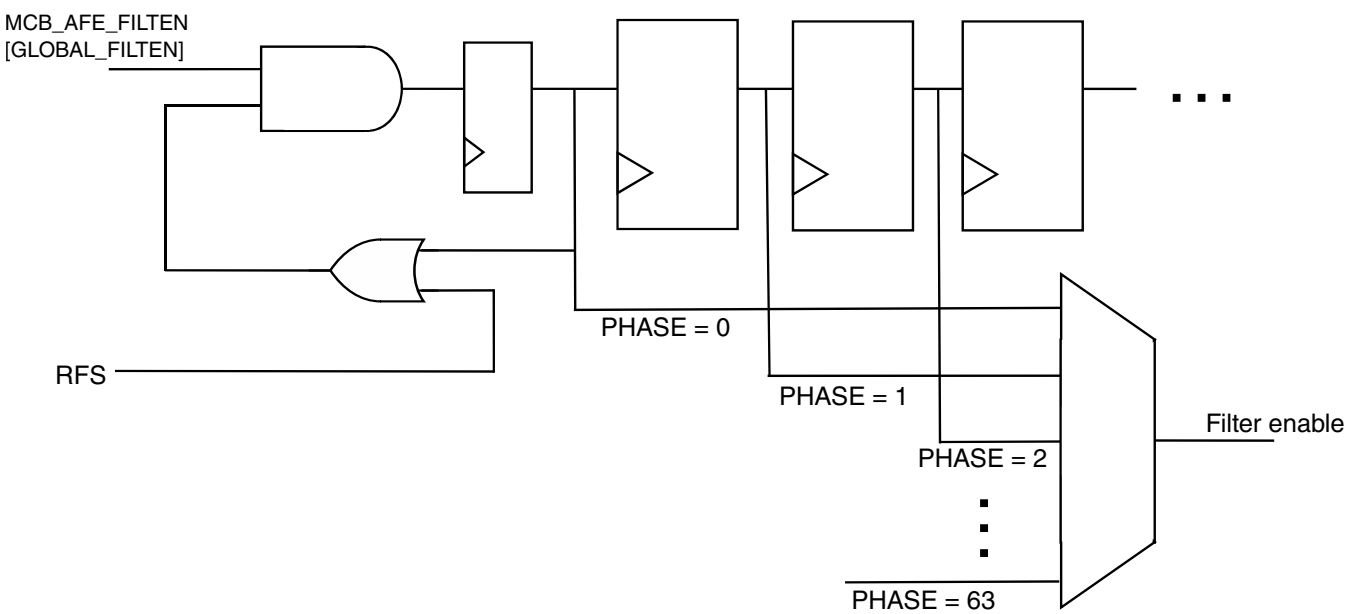

Figure 48-1. Decimation filter phase delay with MCB_AFE_FILTn_PHASE[MODE] = 0

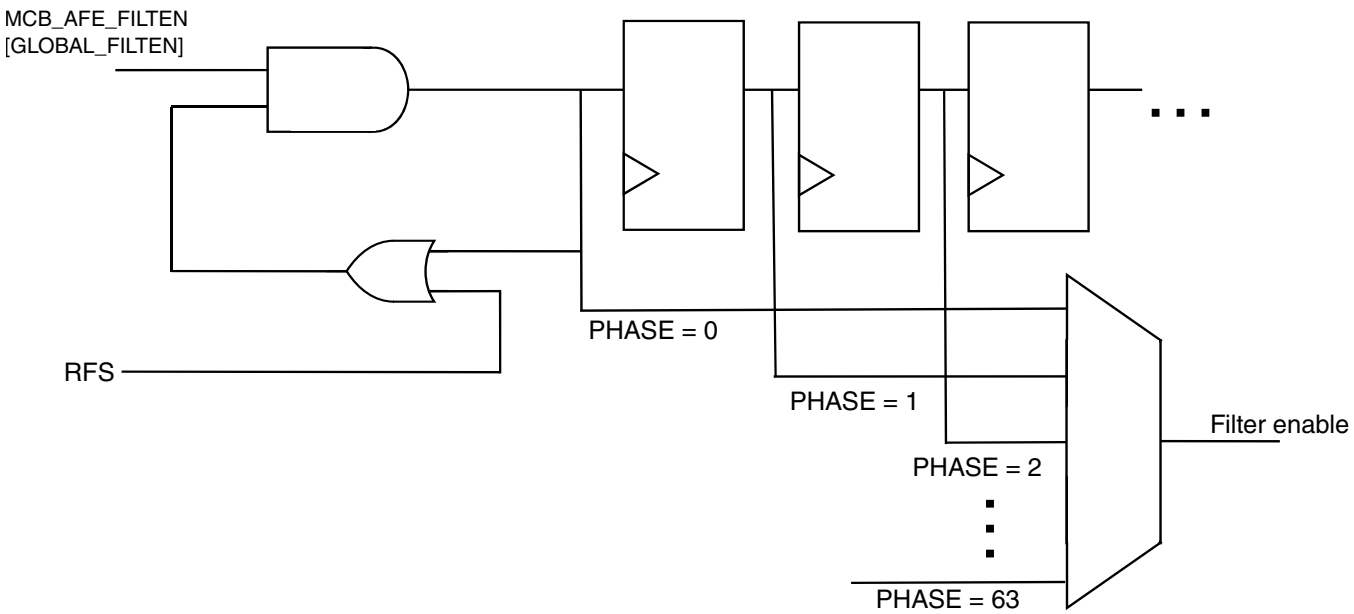

Figure 48-2. Decimation filter phase delay with MCB_AFE_FILTn_PHASE[MODE] = 1

- The Global Filter enable bit shown in the diagram above is controlled by MCB_AFE_FILTEN[GLOBAL_FILTEN].
- The Mode bit is controlled by MCB_AFE_FILT*n*_PHASE[MODE].
- The Phase is controlled by MCB_AFE_FILT*n*_PHASE[PHASE].

Using the AFE decimation filters :

Generic description for the AFE decimation filters is provided in Control and Operation .

Specifically for this device, follow the steps below to operate the AFE decimation filters:

1. Clear MCB_AFE_FILTEN to ensure decimation filters are not operating.
2. Write desired values to the AFE_FLnCOEFn registers and the AFE_FILTnCTRL[OSR] bits to configure decimation filters.
3. Set MCB_AFE_FILTEN to enable the filters once RFS is received.
4. The filters will start producing output words after the CTE module asserts the filter enables (RFS).

48.1.2 AFE filter phase select logic

To obtain clean SD-ADC data, the user needs to ensure that the minimum time between RFS, which enables the decimation filter, and assertion of acquisition window from CTE (ACQ_WIN) to be as follows:

$T_{filt\_en} + T_{phase\_mode}$ + 8 sample times

Similarly the minimum time between start of stable analog input and ACQ_WIN must be as follows:

9 sample times

T_{filt_en} depends on the OSR value in AFE_FILTCTRLn. Based on 80 MHz clock:
- OSR = 00: 19 cycles
- OSR = 01: 27 cycles
- OSR = 10: 43 cycles
- OSR = 11: 75 cycles

T_{phase_mode} depends on the Filter Phase setting in MCB_AFE_FILTn_PHASE.Example based on 80 MHz clock: When MODE = 0 (one cycle delay), PHASE = 2;T_{phase_mode} = 1 + 2 = 3 cycles

48.2 RADAR Analog Front-End (AFE) Wrapper

The AFE wrapper module contains control registers for use with the AFE hard block. The wrapper also contains decimation filters for the outputs of the 4 ADC's in the AFE hard block. The filter results are fed to the Signal Processing Toolbox (SPT) module. The control registers use a peripheral bus interface to communicate with the device. The AFE generates 320 MHz, 160 MHz, and 80 MHz clocks from the 320 MHz SDPLL output.

48.2.1 Features

The AFE analog block has the following features:
- Generates 320 MHz, 160 MHz, and 80 MHz clocks using the SDPLL output
- Four continuous-time sigma delta ADCs
- The AFE provides differential inputs for four separate high dynamic range sigma delta modulators with two poles of built in anti-aliasing filter performance and 5 MHz bandwidths to allow for multichannel simultaneous processing of sensitive analog signals
- The AFE provides high accuracy calibrated 12-bit DAC with accurate rise and fall times for improved accuracy and low step error offsets
- Provides low jitter and low phase noise 320 MHz clock as well as a low jitter 40 MHz crystal reference clock
- Tuning and mismatch shaping algorithms are part of the analog hard block. These algorithms provide feedback data for tuning the ADC coefficients and improving the ADC performance
- Sigma delta ADCs each have separate mismatch shaping algorithms for improved distortion performance

- The AFE is self contained with local regulation of analog and digital supplies using a combination of on-chip and off-chip bypassing to obtain optimal supply rejection and isolation performance
- The AFE provides for accurate trimmed bias currents as well as a trimmed bandgap voltage
- The AFE provides for bypassing the 40 MHz crystal reference clock

The AFE wrapper has the following features:

- Generates phase indicator to maintain alignment between the DAC and WGM
- Generates an interrupt based on ADC input overvoltage condition
- Provides decimation filtering of Sigma-Delta ADC outputs
- Individual power down controls for the SDADCs and DAC. Power down of the XOSC and SDPLL is controlled through the Mode Entry Module Mode Configuration registers.

48.2.2 Modes of Operation

The AFE has many modes of operation to enable proper processing of signals with high dynamic range accurately. The various modes of operation also include various test modes for testing DC bias conditions within the AFE to ensure proper operation of the various analog processing blocks. The AFE includes modes to calibrate the high precision analog blocks as well as one bypass mode of operation.

- Run Mode

  XOSC and SDPLL are enabled. SDPLL is locked at 320MHz.
  Up to four channels of the ADC are enabled and ready to process signals.
  The 12-bit DAC is ready to process data from the main processor in the IC.

- Calibration Mode (enabled during initial testing and possibly during a given period of inactivity for the AFE).

  In calibration mode, a trim comparator is enabled to accurately trim to an external resistor. The ADC uses the trim codes provided by the trim comparator to tune the resistor array within the ADC. The ADC sends corrected trim codes for the ADC coefficients in this mode of operation.

- SDPLL Calibration Mode

  SDPLL must run calibration routine to lock at 320 MHz.

- XOSC Bypass Mode

In this mode, the crystal oscillator can be bypassed allowing a single-ended external 40MHz clock to be supplied via the extal input pad or a differential external 40MHz clock to be supplied via the extal and xtal input pads.

- Power down Modes

  The Power down modes enable power down of individual modules and sub-blocks.

48.2.3 AFE Wrapper Block Diagram

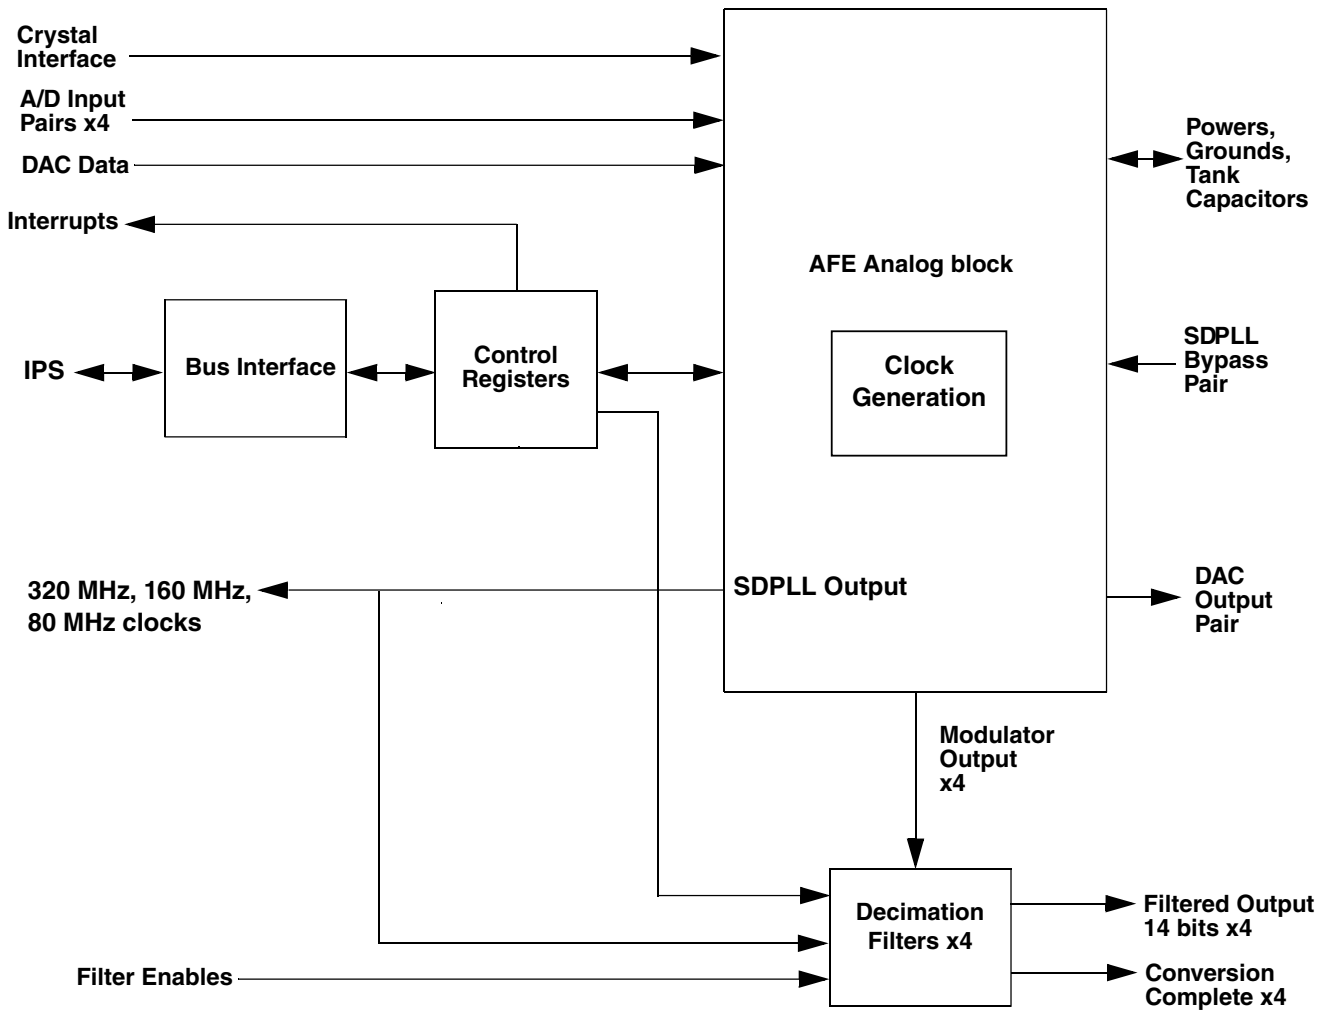

Figure 48-3. AFE Wrapper Block Diagram

48.2.4 AFE Analog Block Diagram

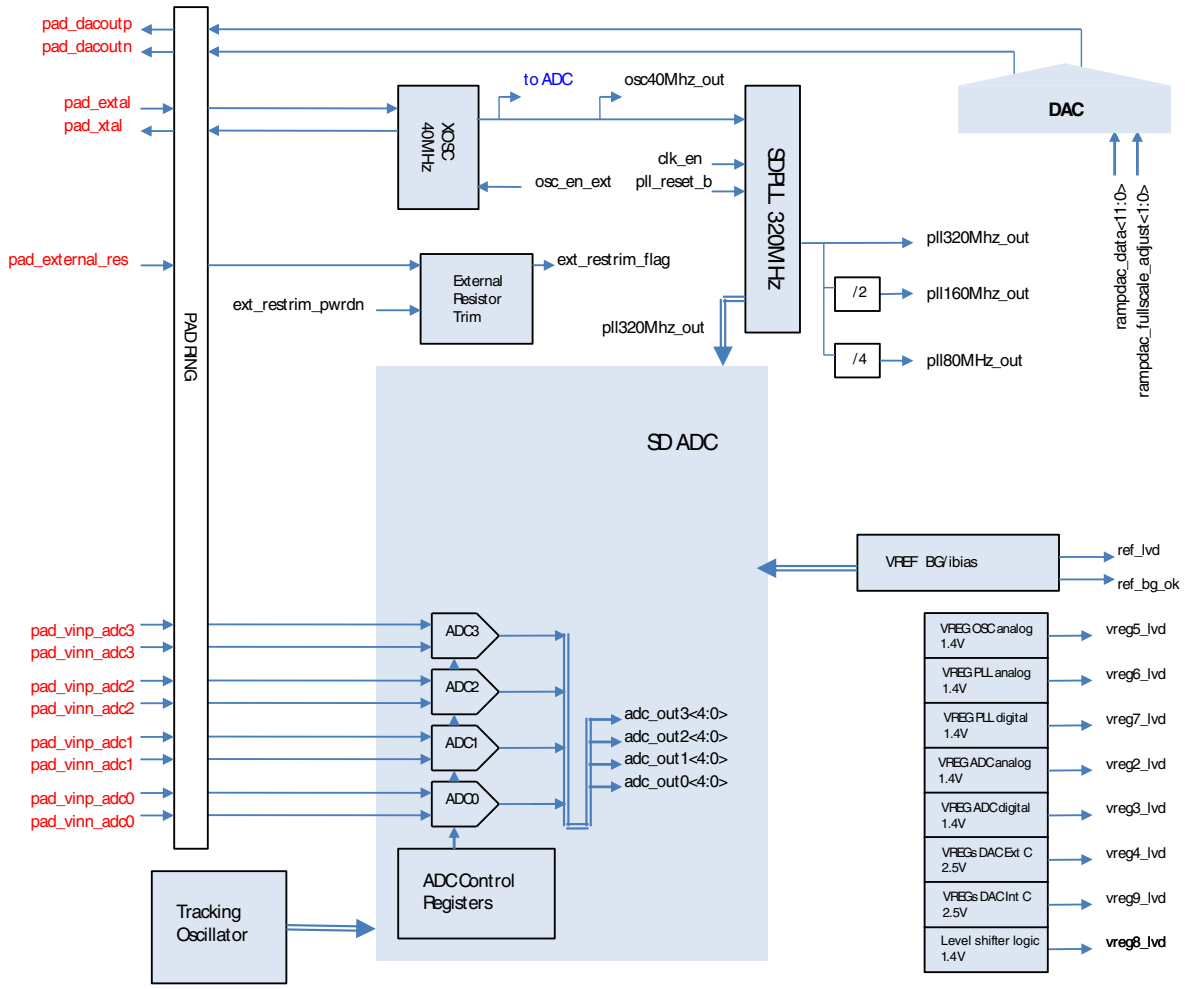

Figure 48-4. AFE Analog Block Diagram

48.2.5 Trimming

48.2.5.1 Resistor Trimming

The following steps are used to trim the external resistor.

NOTE

If no external resistor is connected to the SD_R pin, then this procedure must not be executed and the SDADCs and the DAC cannot be used.

1. Clear ADCTRIM[RMASK].

2. Clear ADCCTRL2[RT_PWRDN].
3. Wait for ADCTRIM[RESRDY] to go high.
4. Set ADCCTRL2[RT_PWRDN] to turn off the external resistor trim block.

48.2.5.2 Capacitor Trimming

The following steps are used to trim the tracking oscillator.

1. Perform resistor trimming. Without resistor trimming capacitor trimming will not work.
2. Write the value 011 to ADCTRIM[OVRD_CAP] and then set ADCTRIM[COVRD].

48.2.6 Initialization

When exiting reset, use the following procedure to turn on the AFE and start processing. If not starting from a reset condition, make sure all registers are set to their reset values before starting this procedure.

VREF/IREF and VREG8 will power-on automatically on power supply (VDD_HV_RAW and VDD_HV_DAC) ramp.

Voltage regulators other than VREG8 will power-on automatically on power supply ramp (VDD_HV_RAW and VDD_HV_DAC) when VREF LVD and LVDSTS[BGOK] are both logic 1.

When the voltage regulator low voltage detects output a high (no low voltage), the other modules (such as the ADC, DAC, SDPLL, OSC, etc.) can be powered-up.

If VREF LVD or LVDSTS[BGOK] are logic 0, all voltage regulators (except VREG8) are automatically powered down and their LVD's output a logic 0.

Start initialization:

1. Clear VRFCTRL1[PWRDN] to make sure Vref is on
2. Wait for LVDSTS[BGOK] to be set to make sure Vref is present

Steps to turn on oscillator:

If using a crystal:

1. Clear OSCCTRL[EN_EXT].
2. Set OSCCTRL[ICAL] to 0110.

3. Write the desired oscillator settling time into OSCDLY[EOCV]. (Reset value is 0x80 and is recommended.)
4. Enable the oscillator in the Mode Entry module.
5. Wait for OSCSTS[STS] to get set.
6. Write OSCSTS[STS] to clear interrupt.

If using single-ended bypass mode:

1. Set MCB_MISC1[SIN_END_BYP].
2. Set OSCCTRL[EN_EXT].
3. Set OSCCTRL[ICAL] to 0110.
4. Write the desired oscillator settling time into OSCDLY[EOCV]. (Reset value is 0x80 and is recommended.)
5. Set MC_ME_mode_MC[XOSCON] in the Mode Entry module and perform a mode transition.
6. Wait for OSCSTS[STS] to get set.
7. Write OSCSTS[STS] to clear interrupt.

If using differential bypass mode:

1. Set OSCCTRL[EN_EXT] and clear OSCCTRL[31] in one register write command.
2. Set OSCCTRL[ICAL] to 0110.
3. Write the desired oscillator settling time into OSCDLY[EOCV]. (Reset value is 0x80 and is recommended.)
4. Set MC_ME_mode_MC[XOSCON] in the Mode Entry module and perform a mode transition.
5. Wait for OSCSTS[STS] to get set.
6. Write OSCSTS[STS] to clear interrupt.

Steps to turn on and calibrate SDPLL:

1. Clear MC_ME_(D)RUNn_MC[SDPLLON] in Mode Entry Module and perform mode change in order to make sure SDPLL is reset and off.
2. Clear PLLCTRL1[RST_B] in AFE.
3. Set PLLCTRL1[CLKGEN_EN].
4. Write 0x7 to PLLCTRL1[DCBIAS_HI_LIM] and 0x4 to PLLCTRL1[DCBIAS_LO_LIM].
5. Write 0x3f to PLLCTRL2[FCAP_HI_LIM] and 0x00 to PLLCTRL2[FCAP_LO_LIM].
6. Set PLLCTRL8[REFCLK_CNT] to 0xF and set PLLCTRL8[FCLKBY2_CNT] to 0x0F0.
7. Set PLLCTRL3[CP_I_SEL] to 100.

8. Turn on SDPLL using the Mode Entry module and perform a mode change (do not yet check for mode change completion as next steps are required before mode change can complete).
9. Set PLLCTRL1[RST_B] to take SDPLL out of reset.
10. Enable SDPLL calibration by setting PLLCTRL2[START].
11. Wait for PLLSTS[LOCK] to get set which indicates completion of calibration (500µsec) and lock (75µsec).
12. If desired set PLLCTRL3[LCKLOIE] to enable loss of lock interrupt.
13. If desired set PLLCTRL3[LORIE] to enable loss of reference interrupt.
14. Check for mode change completion.

Steps to turn on analog circuits:

1. Perform resistor array trimming as described in Resistor Trimming section and Capacitor array trimming as described in Capacitor Trimming section.
2. Turn on ADC protection circuitry by clearing and ADCCTRL7[OVPWRDN]. Wait 3 microseconds before the next step.
3. Turn on the ADC's by clearing the ADCCTRL7[PWRDN] bits for the ADC channel's that are to be used. It is recommended to not power up all ADC's simultaneously.
4. Set ADCCTRL1[MM_SEL] to 10.
5. Set ADCCTRL1[MM_DTHEN] to 0011.
6. Set ADCCTRL1[MM_BYP] to 0 to select mismatch shaping or 1 to de-select mismatch shaping.
7. Clear any ADCOVLD[OVERVOLTS] or flags by writing 1's to those bit positions.
8. Turn on DAC circuitry by clearing DACCTRL[PWRDN].
9. Set DACCTRL[FS_ADJ] to 01 or 10.
10. Initialize ADC by setting ADCRST[INTRST], ADCRST[DFFRST], and ADCCTRL1[MM_RST]. Next, clear ADCRST[INTRST], then clear ADCRST[DFFRST], and then clear ADCCTRL1[MM_RST].

Steps to turn on decimation filters:

1. Clear MCB_AFE_FILTEN to make sure the decimation filters are not working.
2. Configure decimation filters by writing desired values to the FLnCOEFn registers.
3. Write desired values to FILTnCTRL[OSR] bits.
4. Write desired values to FILTnCTRL[USE14] bits.
5. Set MCB_AFE_FILTEN to enable the filters once RFS is received.
6. The filters will start producing output words after the CTE module asserts the filter enables.

48.3 Memory map and register description

Transfer errors are generated for accesses beyond the largest register address but within the 16 KB block of addresses reserved for the AFE module.

NOTE

AFE does not support transfer error for memory holes.

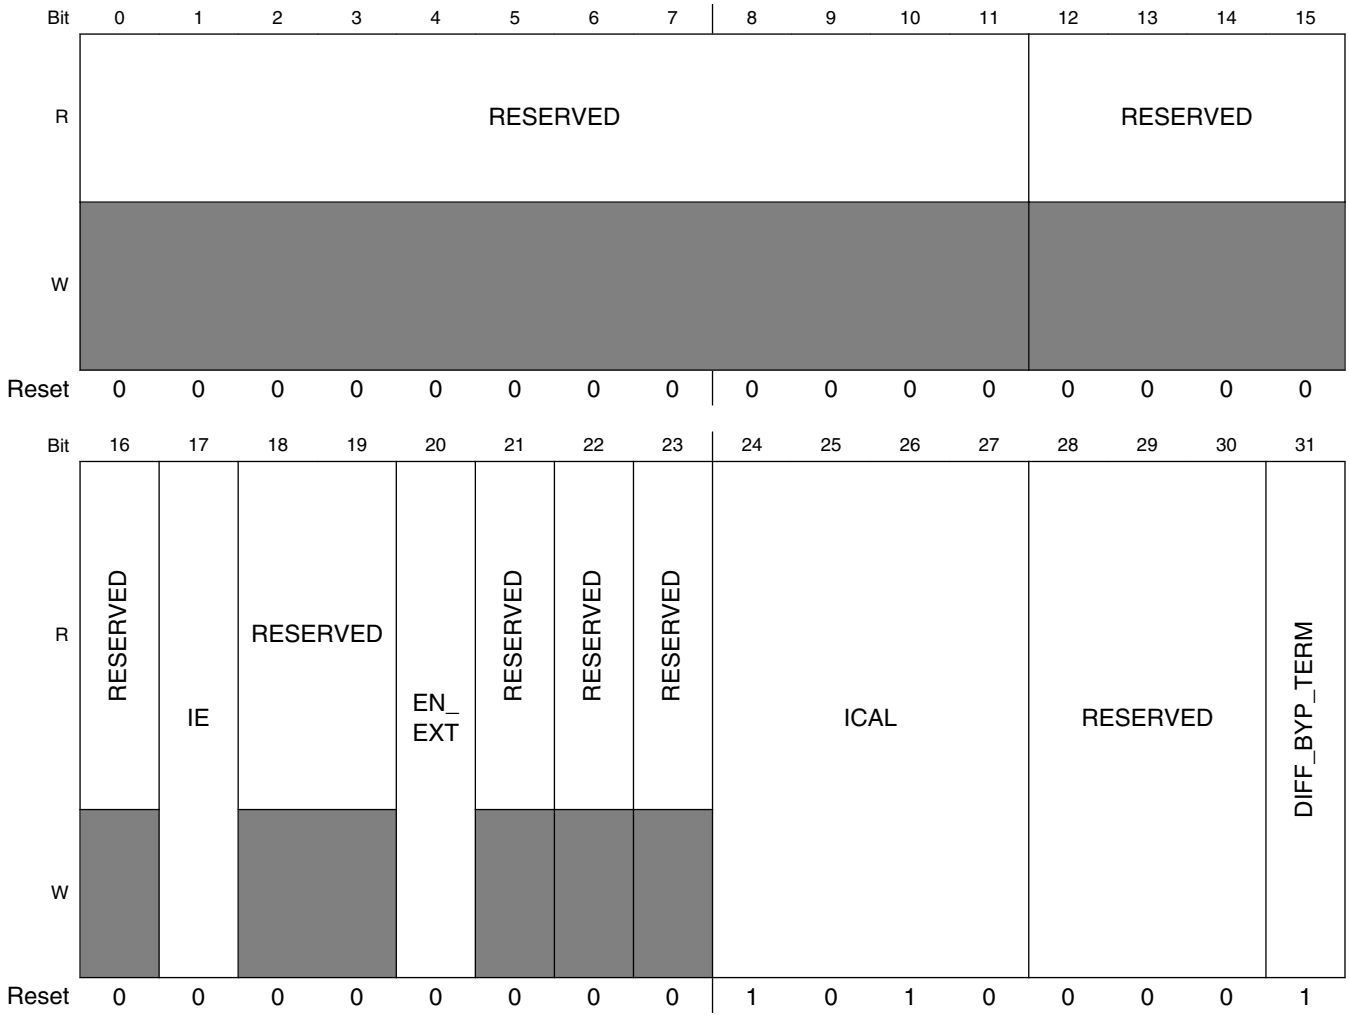
48.3.1 Oscillator Control Register (AFE_OSCCTRL)

Address: 0h base + 0h offset = 0h



AFE_OSCCTRL field descriptions

Field	Description
0–11 RESERVED	This field is reserved.
12–15 RESERVED	This field is reserved.
16 RESERVED	This field is reserved.
17 IE	Oscillator interrupt enable. This bit allows the rising edge of the OSCSTS[STS] flag to create an interrupt. 0 Oscillator interrupt disabled. 1 Oscillator interrupt enabled.

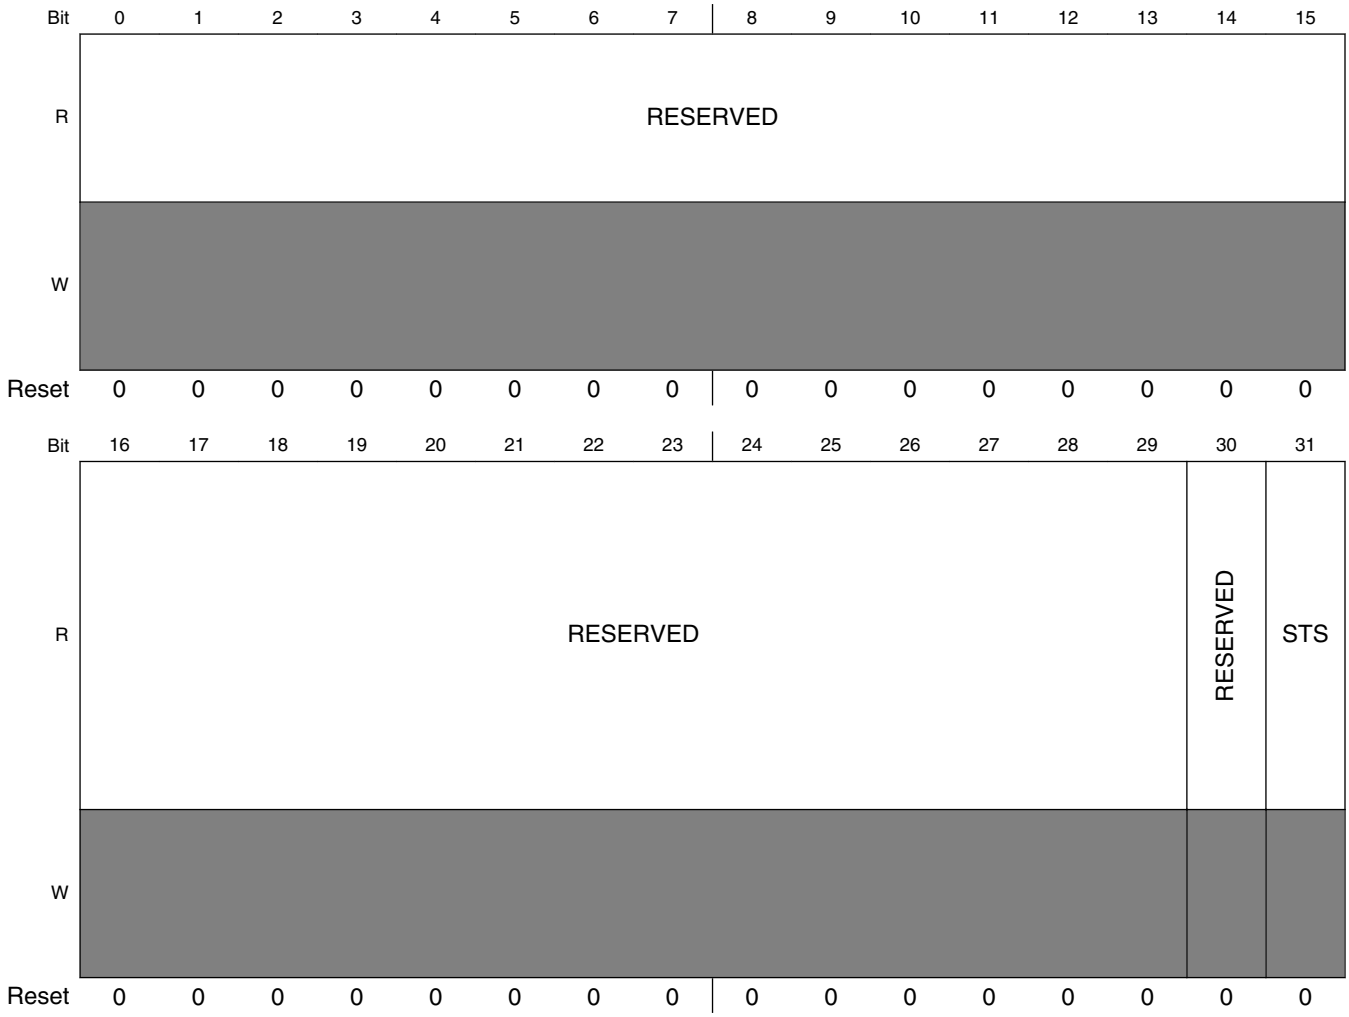
Table continues on the next page...

AFE_OSCCTRL field descriptions (continued)

Field	Description
18–19 RESERVED	This field is reserved.
20 EN_EXT	Crystal oscillator bypass control. This bit controls the crystal oscillator bypass function which allows an external 40 MHz clock to be supplied. 0 Crystal mode, no bypass. 1 40 MHz external clock enabled. Do not set this bit when the crystal oscillator is operating.
21 RESERVED	This field is reserved.
22 RESERVED	This field is reserved.
23 RESERVED	This field is reserved.
24–27 ICAL	Variable current select bits. This field controls the oscillator's and buffer's variable currents. xx00 Oscillator bias 10µA. xx01 Oscillator bias 15µA. xx10 Oscillator bias 20µA. xx11 Oscillator bias 25µA. 00xx Buffer bias 50µA. 01xx Buffer bias 100µA. 10xx Buffer bias 150µA. 11xx Buffer bias 200µA.
28–30 RESERVED	This field is reserved. This field is reserved. Always write the reset value to this field.
31 DIFF_BYP_ TERM	Termination control for differential bypass mode. Clear this field according to the procedure in the "If using differential bypass mode" instructions in Initialization. Keep it set in all other cases. 0 Termination on for differential bypass mode. 1 Termination off for all other modes.

48.3.2 Oscillator Status Register (AFE_OSCSTS)

Address: 0h base + 4h offset = 4h



AFE_OSCSTS field descriptions

Field	Description
0–29 RESERVED	This field is reserved.
30 RESERVED	This field is reserved.
31 STS	Oscillator status This bit is set when the oscillator is powered up and enough transitions have occurred to allow an internal counter to reach a value of OSCDLY[EOCV] x 256. This bit cannot be set unless the oscillator is powered up. A rising edge on this bit will create an interrupt if OSCCTRL[IE] is set. Writing a 1 to this position will clear the oscillator interrupt but will leave this bit set. **NOTE:** STS gets cleared when XOSC is turned off using MC_ME and STS gets set when oscillator has completed transition count after being turned ON by MC_ME.

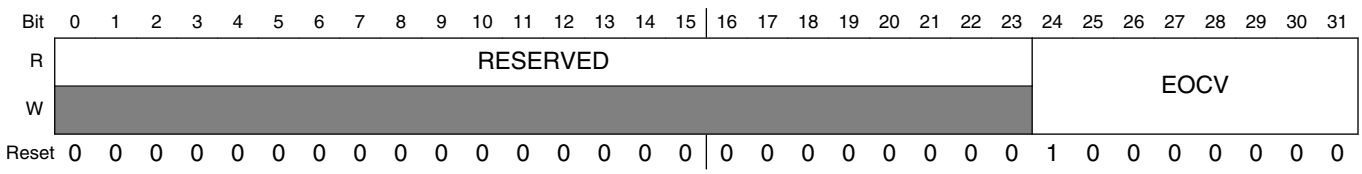
Table continues on the next page...

AFE_OSCSTS field descriptions (continued)

Field	Description
	0 Oscillator has not completed transition count. 1 Oscillator has completed transition count.

48.3.3 Oscillator Delay Register (AFE_OSCDLY)

Address: 0h base + 8h offset = 8h

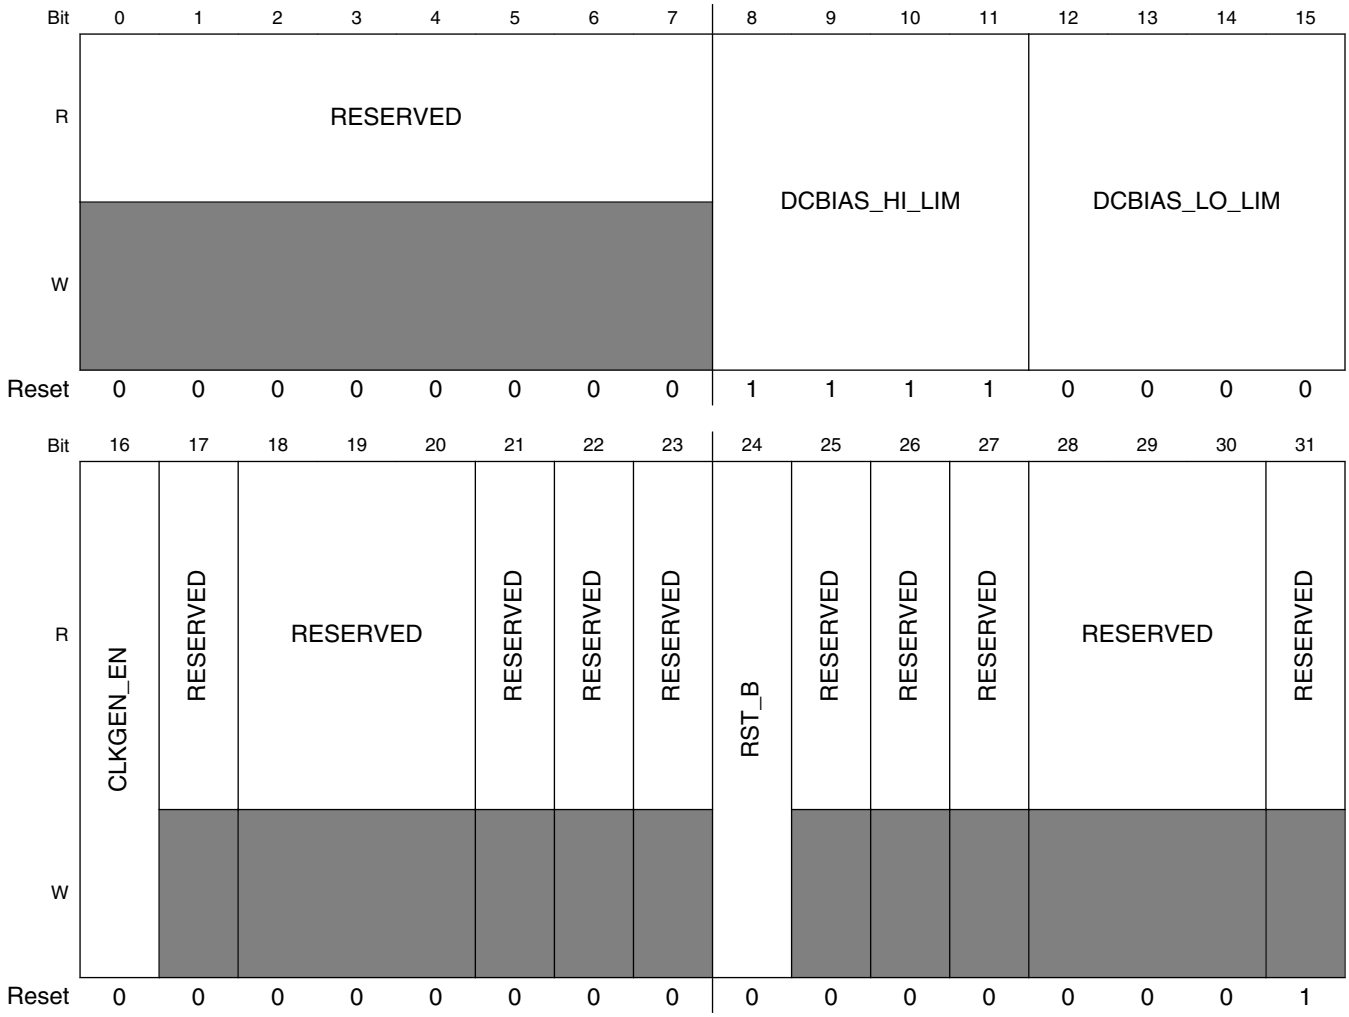


AFE_OSCDLY field descriptions

Field	Description
0–23 RESERVED	This field is reserved.
24–31 EOCV	End of count value. This field specifies the end of count value to be used for comparison by the oscillator stabilization counter whenever the oscillator is switched on. This counter period ensures that the external oscillator clock signal has completed the required number of transitions before it can be selected by the system. When the oscillator counter reaches the value EOCV x 256, OSCSTS[STS] is set and may generate an interrupt. The counter is reset when the oscillator is powered down or bypassed. Changes to this register can be made before or after the oscillator is turned on (through mode entry procedure), but the user must check for OSCSTS[STS] bit after EOCV completion in both conditions after oscillator is enabled.

48.3.4 SDPLL Control Register 1 (AFE_PLLCTRL1)

Address: 0h base + Ch offset = Ch



AFE_PLLCTRL1 field descriptions

Field	Description
0–7 RESERVED	This field is reserved.
8–11 DCBIAS_HI_LIM	This field is used to limit the high (maximum) value of the DC bias bus used during the SDPLL calibration. It is used in conjunction with the DCBIAS_LO_LIM field. By default this field is 0xF and therefore does not limit the value of DC bias. This field is used during both automatic and manual calibration procedures.
12–15 DCBIAS_LO_LIM	This field is used to limit the low (minimum) value of the DC bias bus used during the SDPLL calibration. It is used in conjunction with the DCBIAS_HI_LIM field. By default this field is 0x0 and therefore does not limit the value of DC bias. This field is used during both automatic and manual calibration procedures.
16 CLKGEN_EN	Clock generation enable. This bit turns on the clock generation circuit which uses the 320 MHz output of the SDPLL to generate 160 MHz and 80 MHz clocks. This bit must be set in order for the decimation filters to operate.

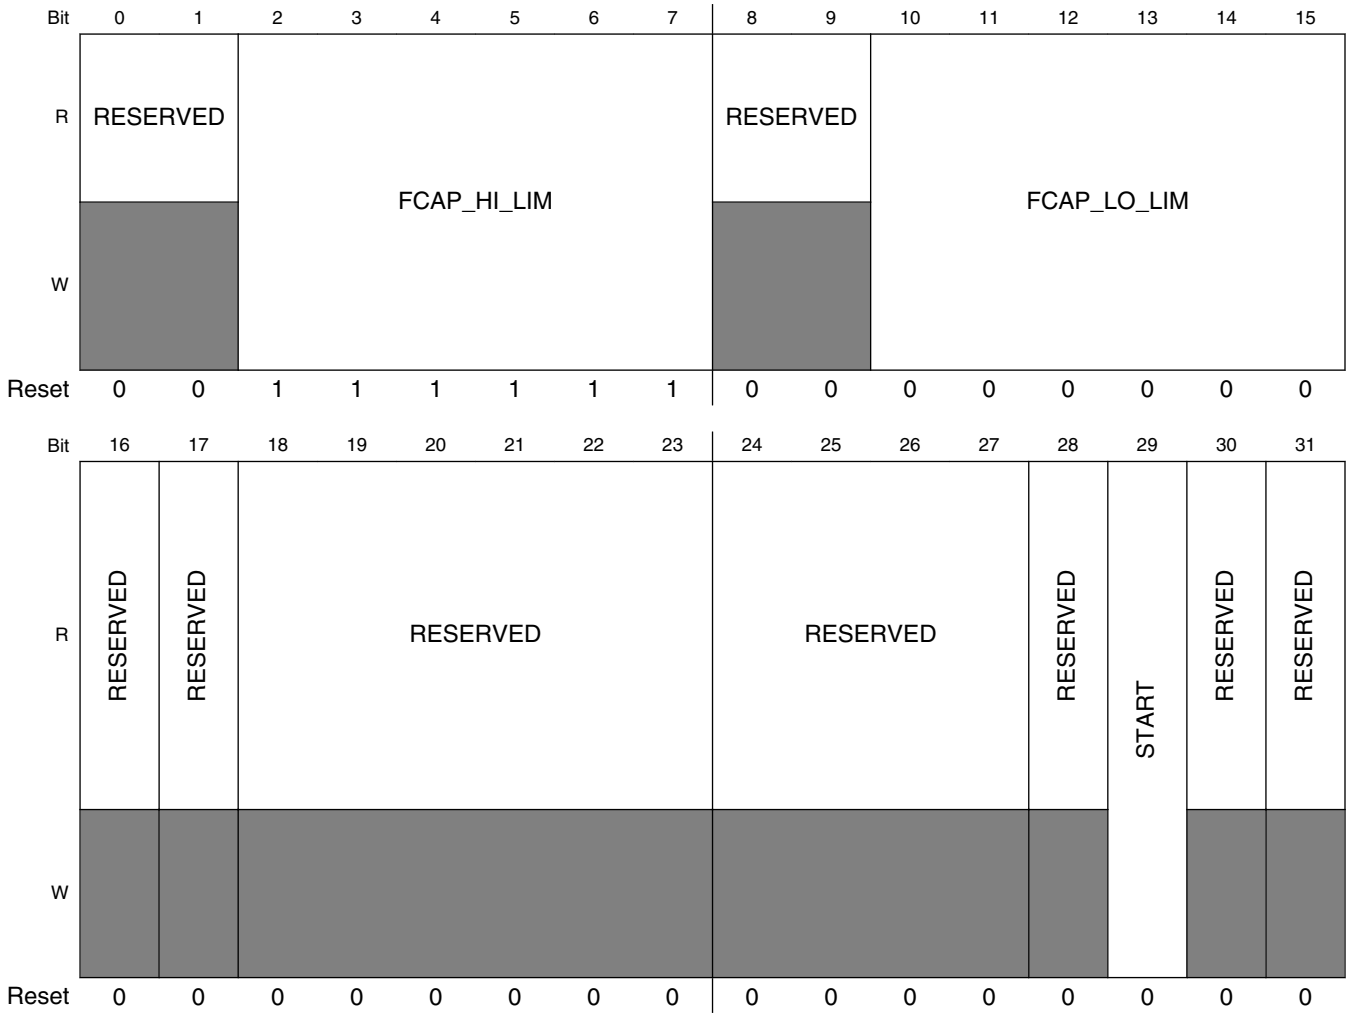
Table continues on the next page...

AFE_PLLCTRL1 field descriptions (continued)

Field	Description
	0 Disable clock generation. 1 Enable generation of 160 MHz and 80 MHz clocks.
17 RESERVED	This field is reserved.
18–20 RESERVED	This field is reserved.
21 RESERVED	This field is reserved.
22 RESERVED	This field is reserved.
23 RESERVED	This field is reserved.
24 RST_B	Lock reset. This bit resets the SDPLL lock detect and test circuitry. 0 Reset the SDPLL lock detect and test circuits. 1 Normal operation.
25 RESERVED	This field is reserved.
26 RESERVED	This field is reserved.
27 RESERVED	This field is reserved.
28–30 RESERVED	This field is reserved.
31 RESERVED	This field is reserved.

48.3.5 SDPLL Control Register 2 (AFE_PLLCTRL2)

Address: 0h base + 10h offset = 10h



AFE_PLLCTRL2 field descriptions

Field	Description
0–1 RESERVED	This field is reserved.
2–7 FCAP_HI_LIM	This field is used to limit the high (maximum) value of the FCAP bus used during the SDPLL calibration. It is used in conjunction with the FCAP_LO_LIM field. By default this field is 0x3F and therefore does not limit the value of FCAP. This field is used during both automatic and manual calibration procedures.
8–9 RESERVED	This field is reserved.
10–15 FCAP_LO_LIM	This field is used to limit the low (minimum) value of the FCAP bus used during the SDPLL calibration. It is used in conjunction with the FCAP_HI_LIM field. By default this field is 0x00 and therefore does not limit the value of FCAP. This field is used during both automatic and manual calibration procedures.

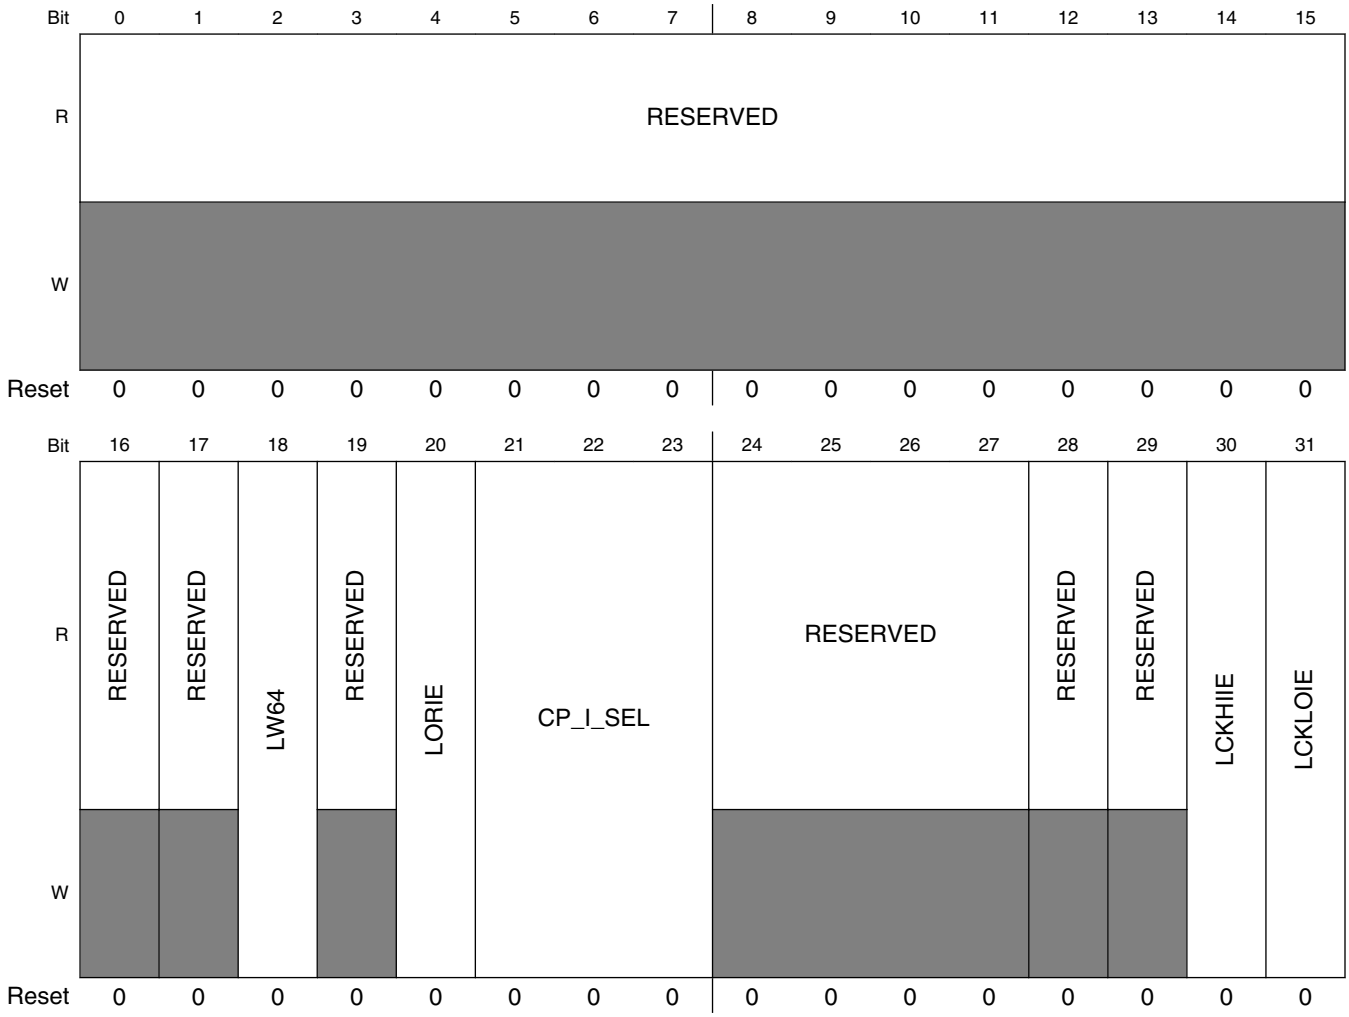
Table continues on the next page...

AFE_PLLCTRL2 field descriptions (continued)

Field	Description
16 RESERVED	This field is reserved.
17 RESERVED	This field is reserved.
18–23 RESERVED	This field is reserved.
24–27 RESERVED	This field is reserved.
28 RESERVED	This field is reserved.
29 START	Start DCbias and Fcap calibration in SDPLL. Once set, this bit should remain set as long as the SDPLL is being used in order to maintain calibration settings. 0 Stop DCbias and/or Fcap calibration in SDPLL 1 Start DCbias and/or Fcap calibration in SDPLL.
30 RESERVED	This field is reserved.
31 RESERVED	This field is reserved.

48.3.6 SDPLL Control Register 3 (AFE_PLLCTRL3)

Address: 0h base + 14h offset = 14h



AFE_PLLCTRL3 field descriptions

Field	Description
0–15 RESERVED	This field is reserved.
16 RESERVED	This field is reserved.
17 RESERVED	This field is reserved.
18 LW64	SDPLL calibration wait time adjustment. 0 Default wait time of 256 reference clock cycles is used. 1 A wait time of 64 reference clock cycles is used.

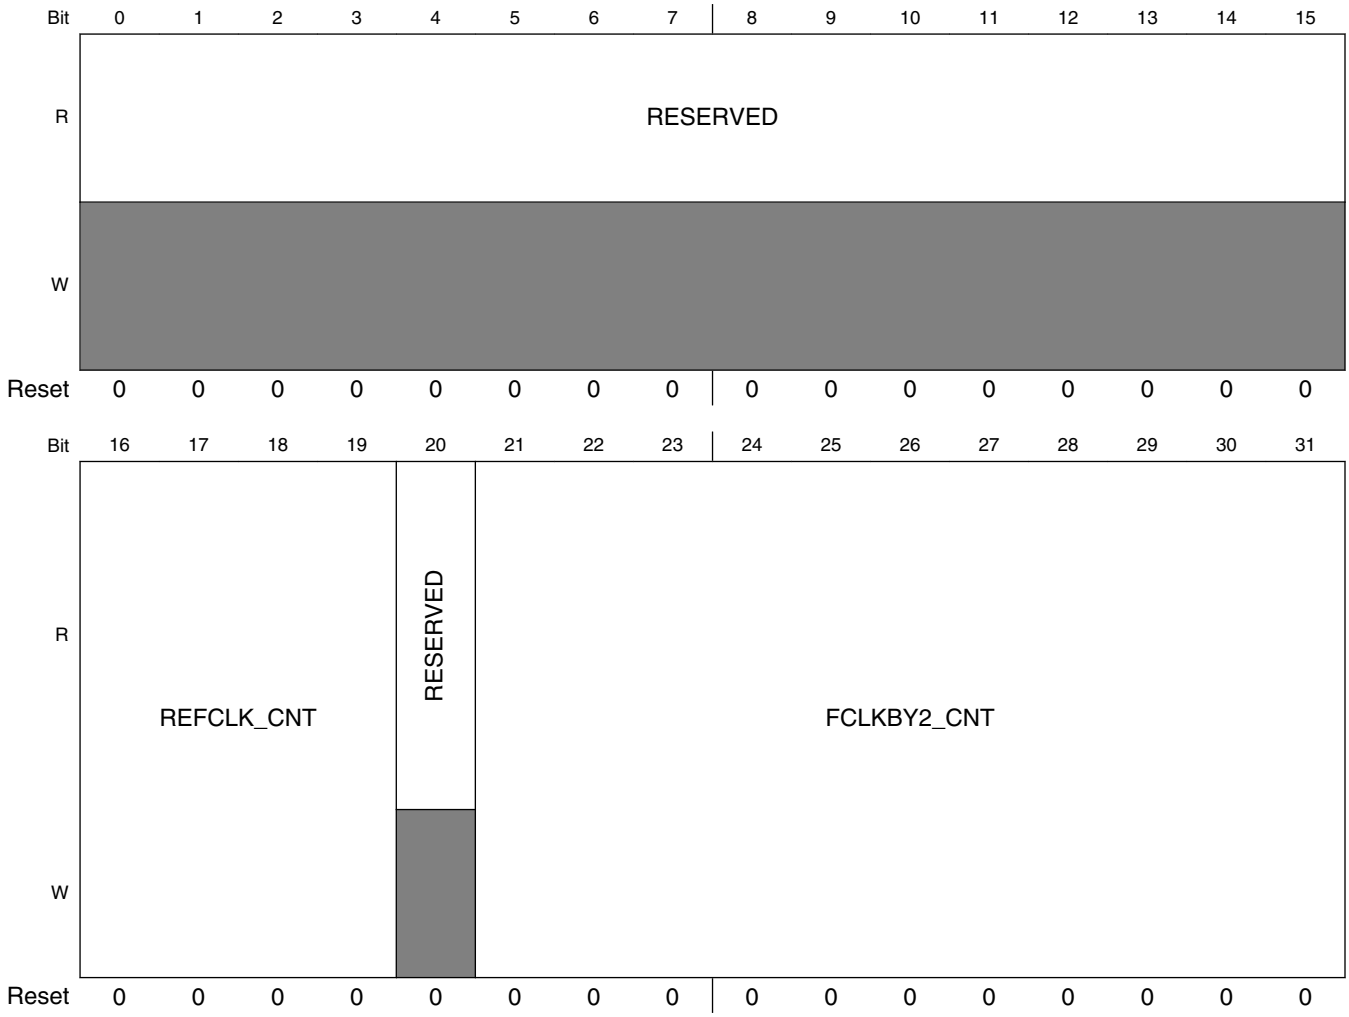
Table continues on the next page...

AFE_PLLCTRL3 field descriptions (continued)

Field	Description
19 RESERVED	This field is reserved.
20 LORIE	Loss of reference interrupt enable. This bit enables the SDPLL loss of reference interrupt to be generated when PLLSTS[LOR] is set. 0 SDPLL loss of reference interrupt disabled. 1 SDPLL loss of reference interrupt enabled.
21–23 CP_I_SEL	Charge pump current select bits. 000 001 010 011 100 Recommended value. 101 110 111
24–27 RESERVED	This field is reserved.
28 RESERVED	This field is reserved.
29 RESERVED	This field is reserved.
30 LCKHIIE	SDPLL lock high interrupt enable. This bit enables the SDPLL lock interrupt to be generated when the PLLSTS[LOCK] bit is high. This indicates when the SDPLL has achieved lock. 0 SDLL interrupt disabled. Interrupt will not assert when SDPLL locks. 1 SDPLL interrupt enabled. Interrupt will assert when SDPLL locks.
31 LCKLOIE	SDPLL lock loss interrupt enable. This bit enables the SDPLL lock loss interrupt to be generated when the PLLSTS[LCKLOSS] bit is high. This indicates when the SDPLL has lost lock. 0 SDPLL lock loss interrupt disabled. Interrupt will not assert when SDPLL loses lock. 1 SDPLL lock loss interrupt enabled. Interrupt will assert when SDPLL loses lock.

48.3.7 SDPLL Control Register 8 (AFE_PLLCTRL8)

Address: 0h base + 28h offset = 28h

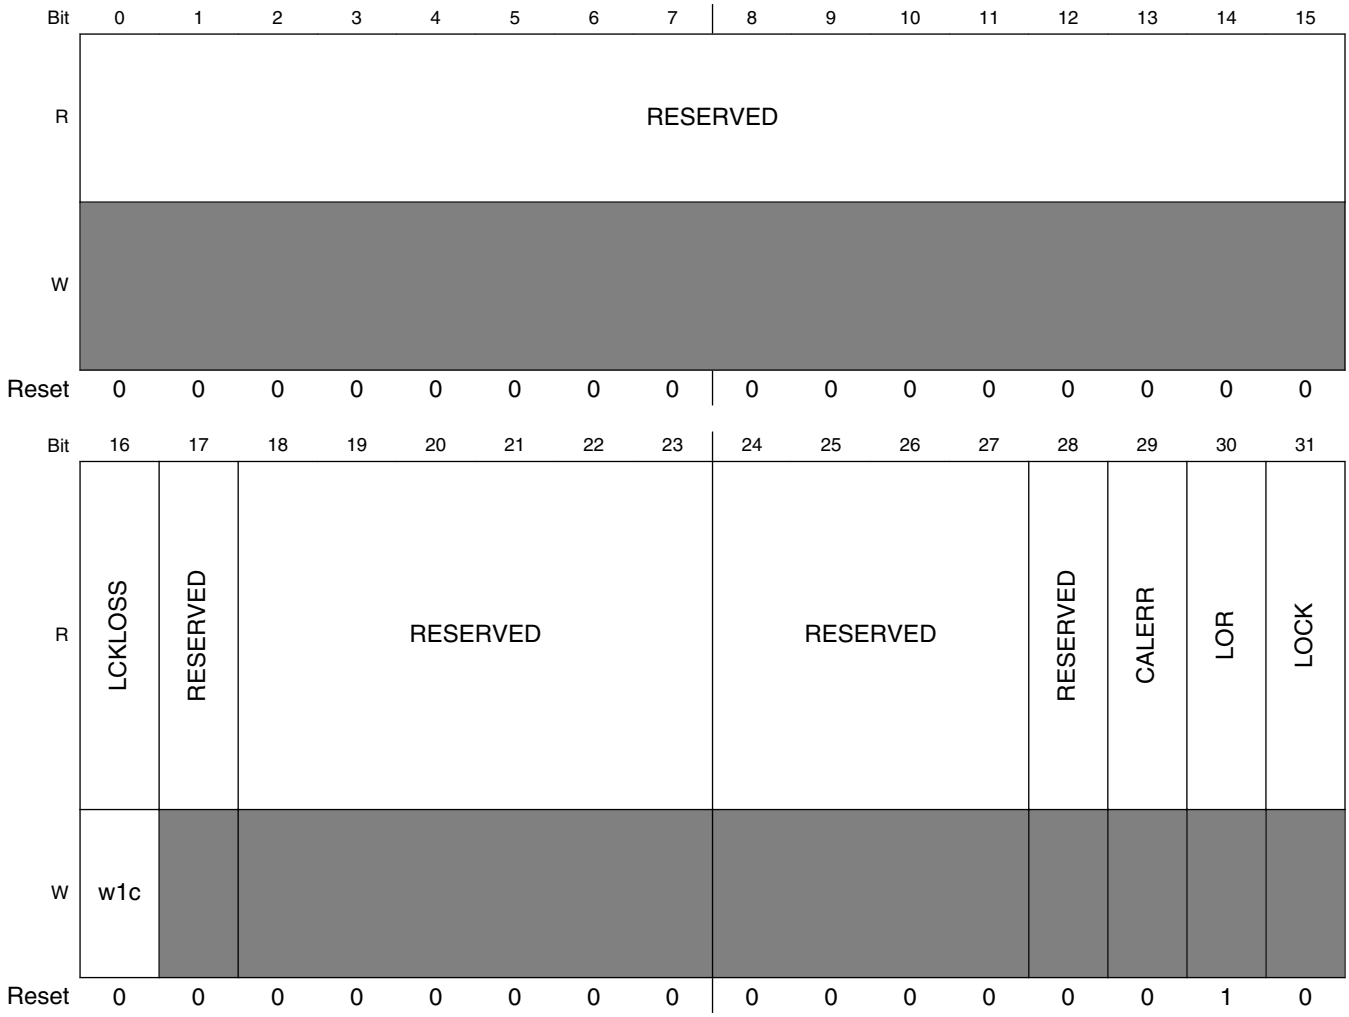


AFE_PLLCTRL8 field descriptions

Field	Description
0–15 RESERVED	This field is reserved.
16–19 REFCLK_CNT	Programmable reference clock count This field determines the number of 40MHz clock periods over which the SDPLL output is counted during calibration.
20 RESERVED	This field is reserved.
21–31 FCLKBY2_CNT	Programmable Fvco/2 clock count This field is the target count for the SDPLL VCO during calibration.

48.3.8 SDPLL Status Register (AFE_PLLSTS)

Address: 0h base + 2Ch offset = 2Ch



AFE_PLLSTS field descriptions

Field	Description
0–15 RESERVED	This field is reserved.
16 LCKLOSS	SDPLL loss of lock indicator. This bit is set when the SDPLL falls out of lock. This is determined by looking for a falling edge of PLLSTS[LOCK] while the SDPLL is powered up. When this bit is high, it can create the SDPLL loss of lock interrupt if PLLCTRL3[LCKLOIE] is set. Clear this bit by writing a 1 to this position. 0 SDPLL has not fallen out of lock. 1 SDPLL has fallen out of lock.
17 RESERVED	This field is reserved.
18–23 RESERVED	This field is reserved.

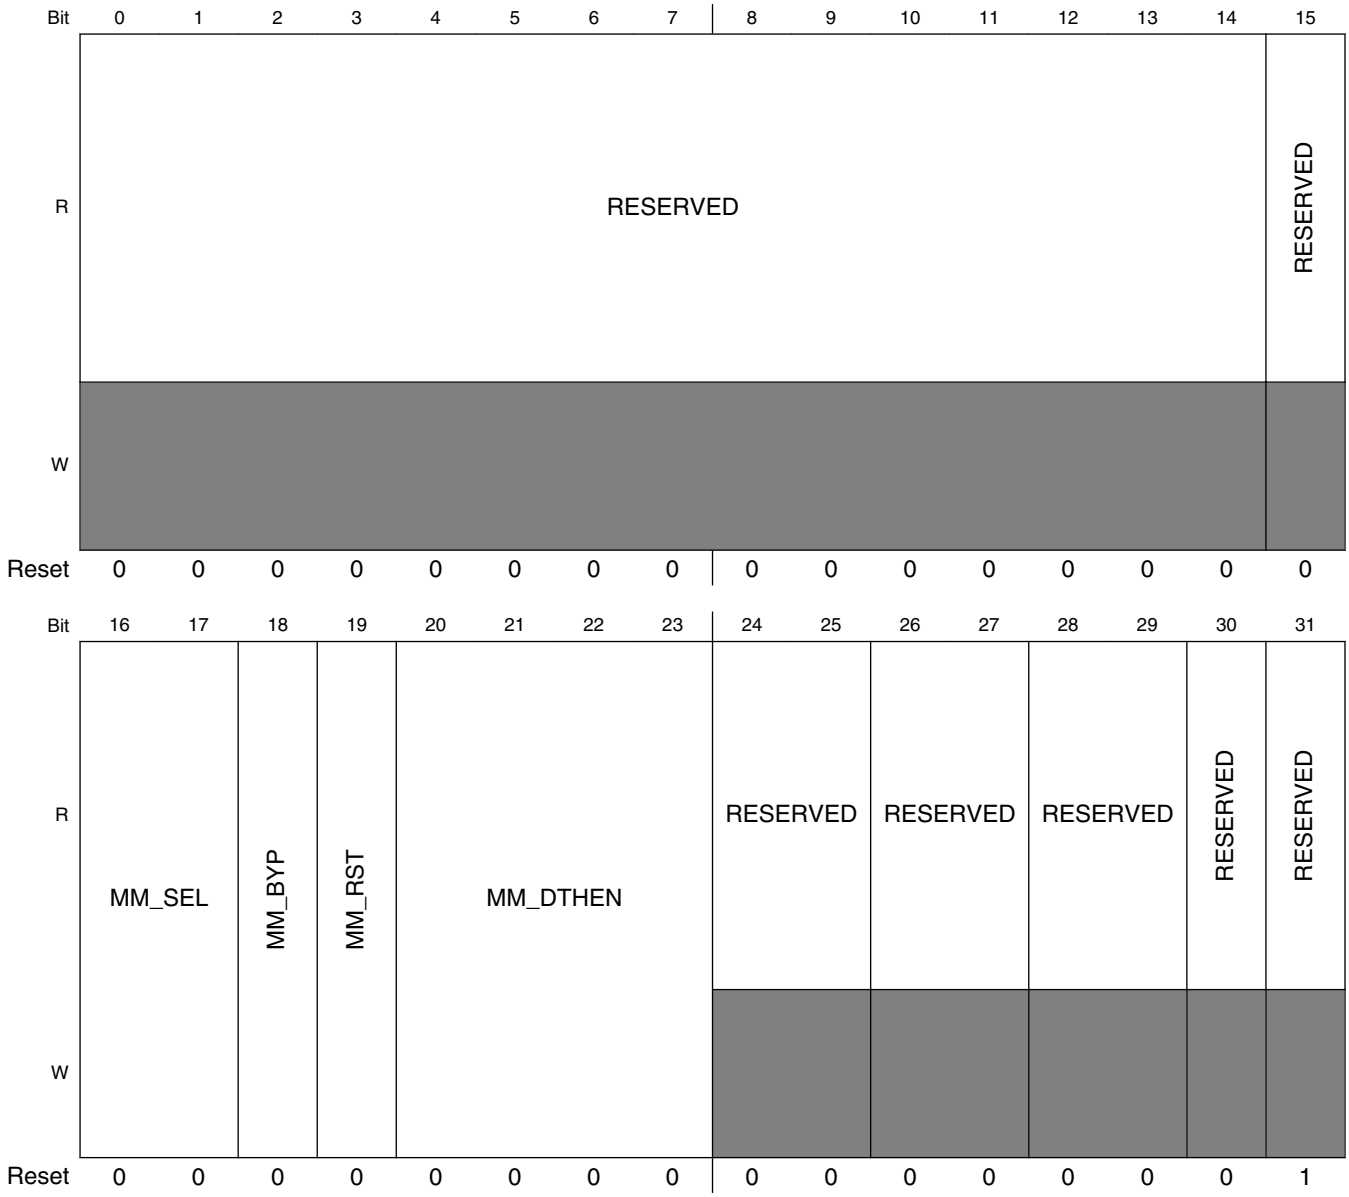
Table continues on the next page...

AFE_PLLSTS field descriptions (continued)

Field	Description
24–27 RESERVED	This field is reserved.
28 RESERVED	This field is reserved.
29 CALERR	SDPLL calibration error. 0 SDPLL calibration successful. 1 An error occurred during SDPLL calibration.
30 LOR	SDPLL loss of reference. This bit indicates that the SDPLL reference clock (crystal oscillator) is not toggling. This bit will be asserted about 25 clock cycles after the last edge on the reference clock. This bit will be cleared when the reference clock toggles again. This bit can be used with PLLCTRL3[LORIE] to create the SDPLL loss of reference interrupt. 0 SDPLL reference clock is toggling. 1 SDPLL reference clock is not toggling.
31 LOCK	SDPLL lock indicator This bit indicates that the SDPLL is locked. 0 SDPLL has not locked. 1 SDPLL has calibrated and locked.

48.3.9 ADC Control Register 1 (AFE_ADCCTRL1)

Address: 0h base + 30h offset = 30h



AFE_ADCCTRL1 field descriptions

Field	Description
0–14 RESERVED	This field is reserved.
15 RESERVED	This field is reserved.
16–17 MM_SEL	Mismatch shaper clock select.

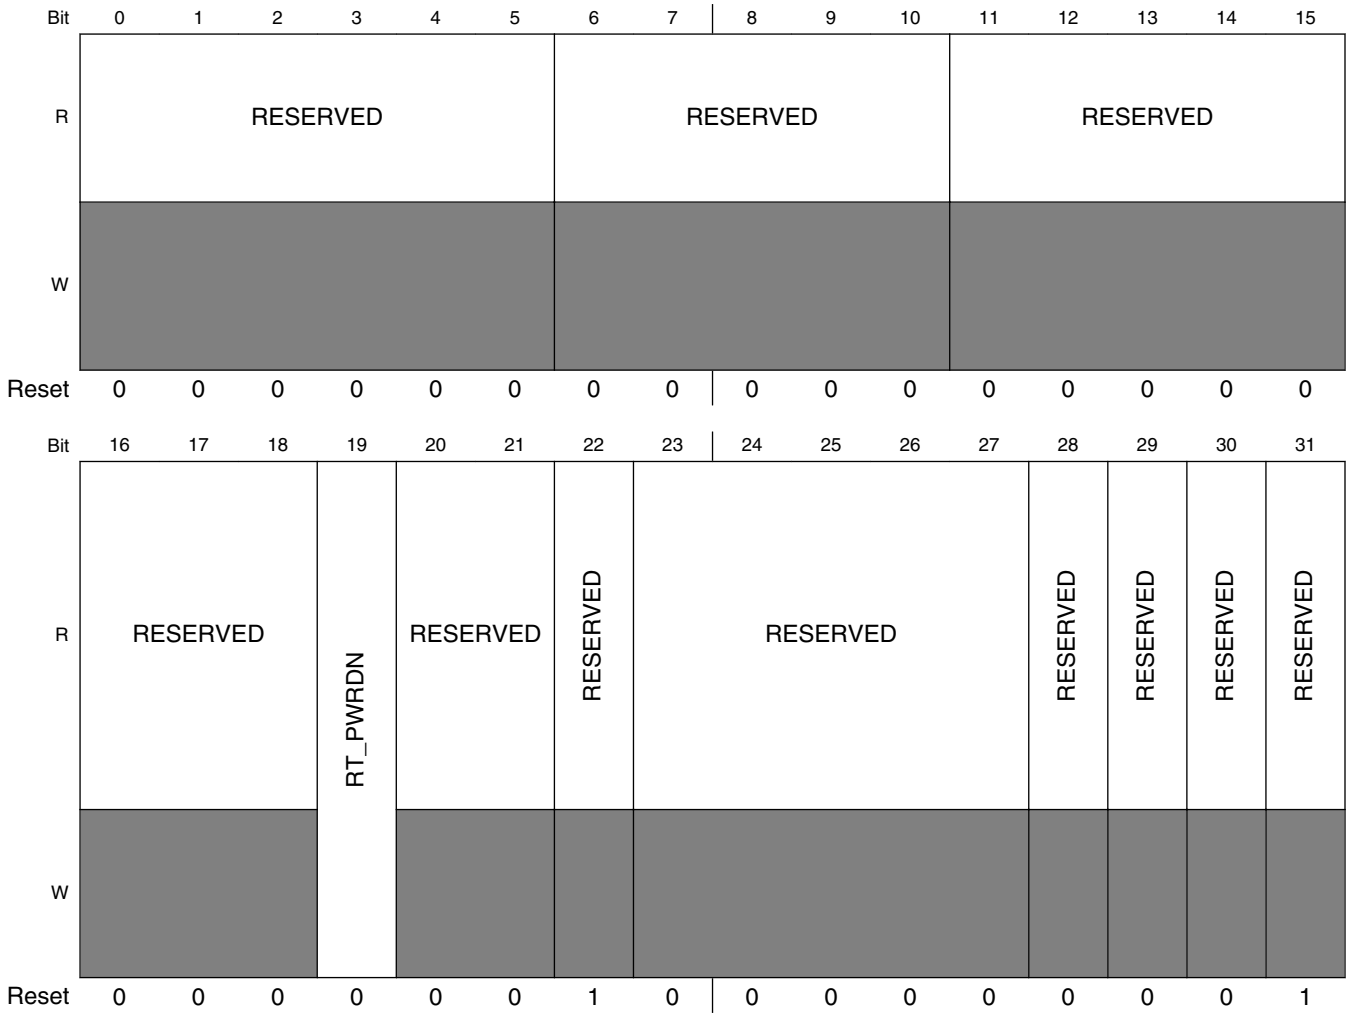
Table continues on the next page...

AFE_ADCCTRL1 field descriptions (continued)

Field	Description
	00 Bypass = 320 MHz 01 Divide by 2 = 160 MHz 10 Divide by 4 = 80 MHz 11 Unused
18 MM_BYP	Mismatch shaping algorithm bypass. 0 Mismatch shaper is enabled. 1 Mismatch shaper is bypassed.
19 MM_RST	Mismatch shaper reset. 0 Normal operation. 1 Output of mismatch shaper is taken to midscale.
20–23 MM_DTHEN	Mismatch shaper dither enable. This field is a 4-bit thermometer code to enable dither within the mismatch shaper. Each bit enables a different point in the algorithm to add dither.
24–25 RESERVED	This field is reserved.
26–27 RESERVED	This field is reserved.
28–29 RESERVED	This field is reserved.
30 RESERVED	This field is reserved.
31 RESERVED	This field is reserved.

48.3.10 ADC Control Register 2 (AFE_ADCCTRL2)

Address: 0h base + 34h offset = 34h



AFE_ADCCTRL2 field descriptions

Field	Description
0–5 RESERVED	This field is reserved.
6–10 RESERVED	This field is reserved.
11–15 RESERVED	This field is reserved.
16–18 RESERVED	This field is reserved.
19 RT_PWRDN	External resistor trim circuit powerdown control bit. **NOTE:** Do not set this bit if there is no external resistor connected to the SD_R pin.

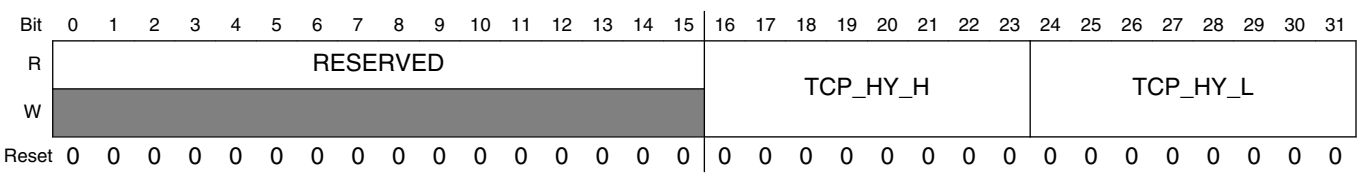
Table continues on the next page...

AFE_ADCCTRL2 field descriptions (continued)

Field	Description
	0 Enable external resistor trim. 1 Disable, powerdown. Forces ADCTRIM[RESRDY] low.
20–21 RESERVED	This field is reserved.
22 RESERVED	This field is reserved.
23–27 RESERVED	This field is reserved.
28 RESERVED	This field is reserved.
29 RESERVED	This field is reserved.
30 RESERVED	This field is reserved.
31 RESERVED	This field is reserved.

48.3.11 ADC Tracking Oscillator Trim Register (AFE_ADCTOT)

Address: 0h base + 38h offset = 38h

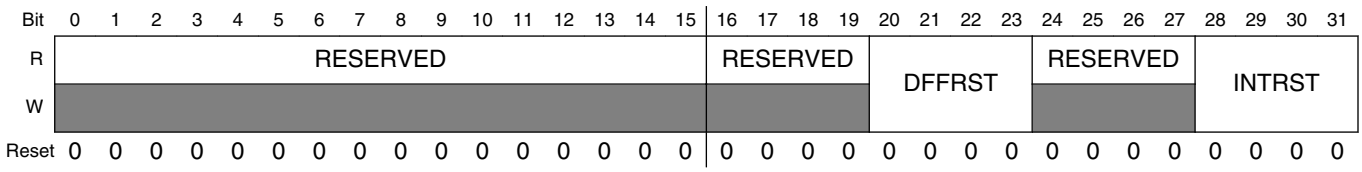


AFE_ADCTOT field descriptions

Field	Description
0–15 RESERVED	This field is reserved.
16–23 TCP_HY_H	Provides trim capability to improve accuracy of the tracking oscillator.
24–31 TCP_HY_L	Provides trim capability to improve accuracy of the tracking oscillator.

48.3.12 ADC Reset Register (AFE_ADCRST)

Address: 0h base + 3Ch offset = 3Ch

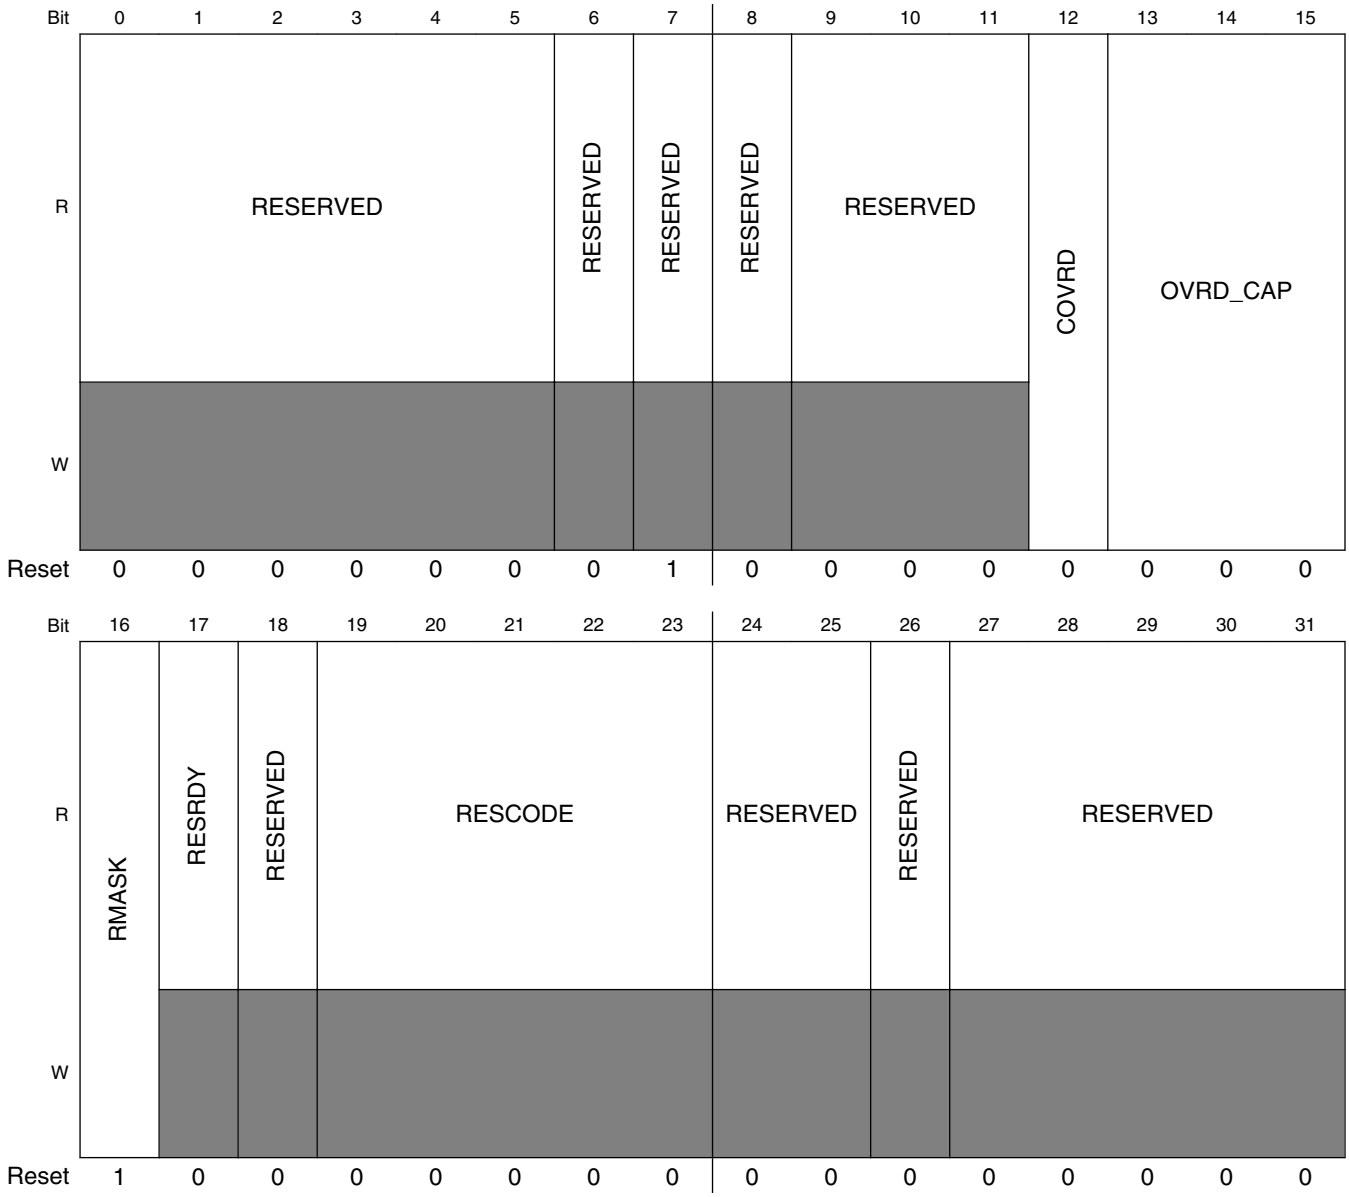


AFE_ADCRST field descriptions

Field	Description
0–15 RESERVED	This field is reserved.
16–19 RESERVED	This field is reserved.
20–23 DFFRST	Reset control for the flip flops for the digital word to the DAC's in the eight ADC's. 0 Normal operation. 1 Reset code word of a specific ADC to midscale of the DAC's.
24–27 RESERVED	This field is reserved.
28–31 INTRST	Zeros integrator capacitor charge of each of the four ADC's. 0 Normal operation. 1 Sets the output of the integrator of a specific ADC at analog ground.

48.3.13 ADC Trim Register (AFE_ADCTRIM)

Address: 0h base + 40h offset = 40h



AFE_ADCTRIM field descriptions

Field	Description
0–5 RESERVED	This field is reserved.
6 RESERVED	This field is reserved.
7 RESERVED	This field is reserved.

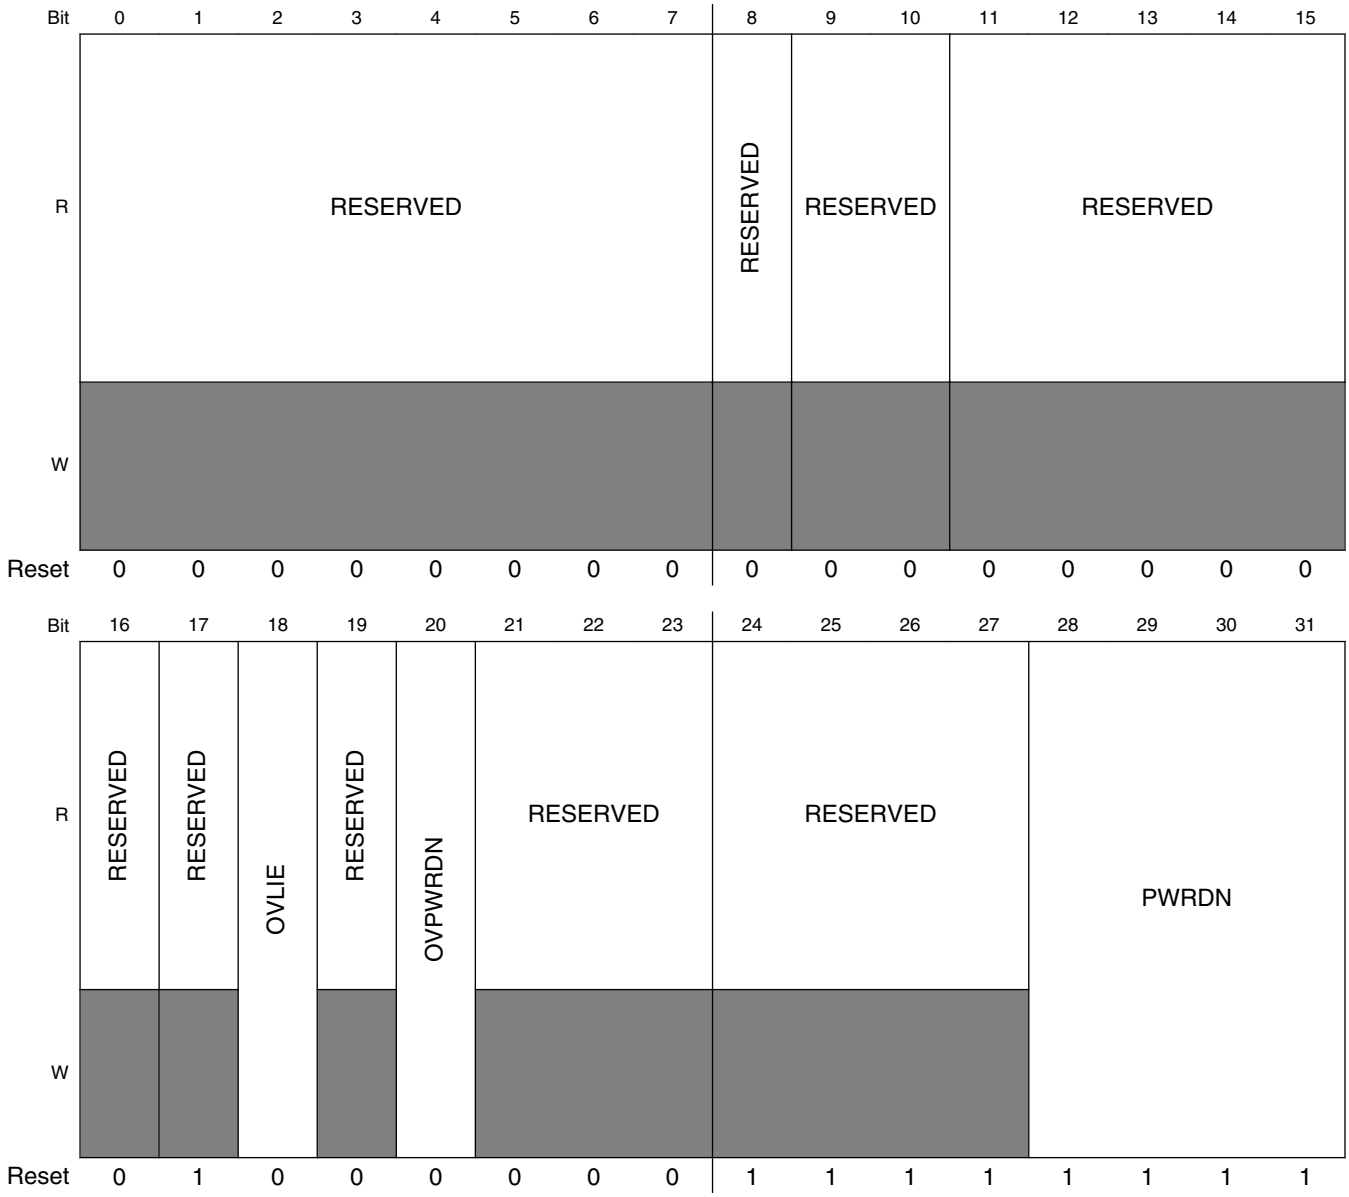
Table continues on the next page...

AFE_ADCTRIM field descriptions (continued)

Field	Description
8 RESERVED	This field is reserved.
9–11 RESERVED	This field is reserved.
12 COVRD	Capacitor Trim override control bit. 0 Normal operation. 1 Override Capacitor Trim value with ADCTRIM[OVRD_CAP].
13–15 OVRD_CAP	Capacitor trim override value. This value is only used when ADCTRIM[COVRD] is set. It is then driven into the capacitor trim circuitry for use in place of the value computed from the trimming.
16 RMASK	Resistor arrays trim mask. To start the ADC trim procedure set this bit to 1 and then clear it. Trimming can only be performed when ADCCTRL2[RT_PWRDN] is 0. 0 Enables the resistor arrays to be trimmed. 1 The resistor array is set to default midcode setting.
17 RESRDY	External resistor trim flag. This bit is the output from the restrim comparator to indicate when the correct resistor trim value has been reached. 0 Resistor trim routine is not complete. 1 Resistor trim routine is complete.
18 RESERVED	This field is reserved.
19–23 RESCODE	The correct trim value for the resistor arrays within the Vref and the resistor trim.
24–25 RESERVED	This field is reserved.
26 RESERVED	This field is reserved.
27–31 RESERVED	This field is reserved.

48.3.14 ADC Control Register 7 (AFE_ADCCTRL7)

Address: 0h base + 48h offset = 48h



AFE_ADCCTRL7 field descriptions

Field	Description
0–7 RESERVED	This field is reserved.
8 RESERVED	This field is reserved.
9–10 RESERVED	This field is reserved.

Table continues on the next page...

AFE_ADCCTRL7 field descriptions (continued)

Field	Description
11–15 RESERVED	This field is reserved.
16 RESERVED	This field is reserved.
17 RESERVED	This field is reserved.
18 OVLIE	ADC overvoltage detect interrupt enable. 0 Disable overvoltage detect interrupt. 1 Create overvoltage detect interrupt if any of ADCOVLD[OVERVOLTS] is set.
19 RESERVED	This field is reserved.
20 OVPWRDN	ADC overvoltage protection circuitry powerdown. 0 Overvoltage protection on (channels 0-3). 1 Overvoltage protection circuitry off and powered down (channels 0-3).
21–23 RESERVED	This field is reserved.
24–27 RESERVED	This field is reserved.
28–31 PWRDN	ADC powerdown enables for ADC 3 down to 0 (also referred to as ADC D down to A). 0 Enable one of the four ADC's. 1 Disable, powerdown one of the four ADC's. **NOTE:** It is recommended to not power up all ADCs simultaneously.

48.3.15 ADC Overload Detect Register (AFE_ADCOVLD)

Address: 0h base + 4Ch offset = 4Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	RESERVED				OVERVOLT				RESERVED				OVERVOLTS				RESERVED															
W													w1c																			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

AFE_ADCOVLD field descriptions

Field	Description
0–3 RESERVED	This field is reserved.
4–7 OVERVOLT	ADC overvoltage detect flag for each of the four ADC's. These bits reflect the realtime status of the ADC overvoltage detect circuits. An overvoltage condition (ADC absolute input voltage greater than 1.2V) will be acted upon immediately by the analog circuitry but must last at least 12.5nsec to cause a flag to set. A flag will clear once the overvoltage condition has gone away for at least 12.5nsec.

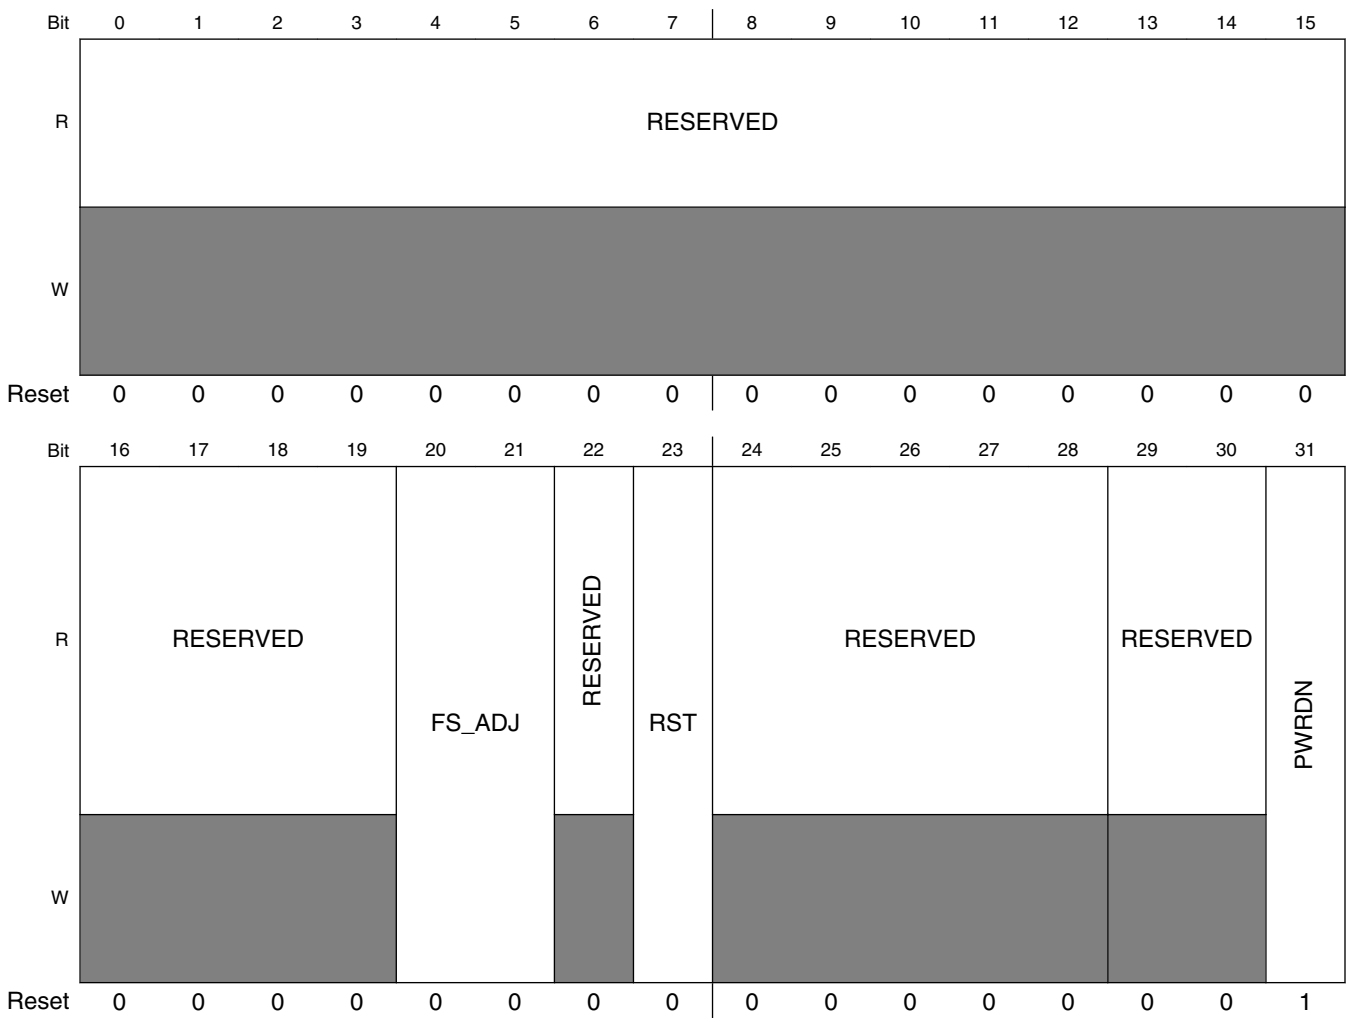
Table continues on the next page...

AFE_ADCOVLD field descriptions (continued)

Field	Description
8–11 RESERVED	This field is reserved.
12–15 OVERVOLTS	ADC overvoltage detect flag for each of the four ADC's. These bits are sticky and will remain asserted once set. Clear each bit by writing a 1 to that bit position.
16–31 RESERVED	This field is reserved.

48.3.16 DAC Control Register (AFE_DACCTRL)

Address: 0h base + 50h offset = 50h

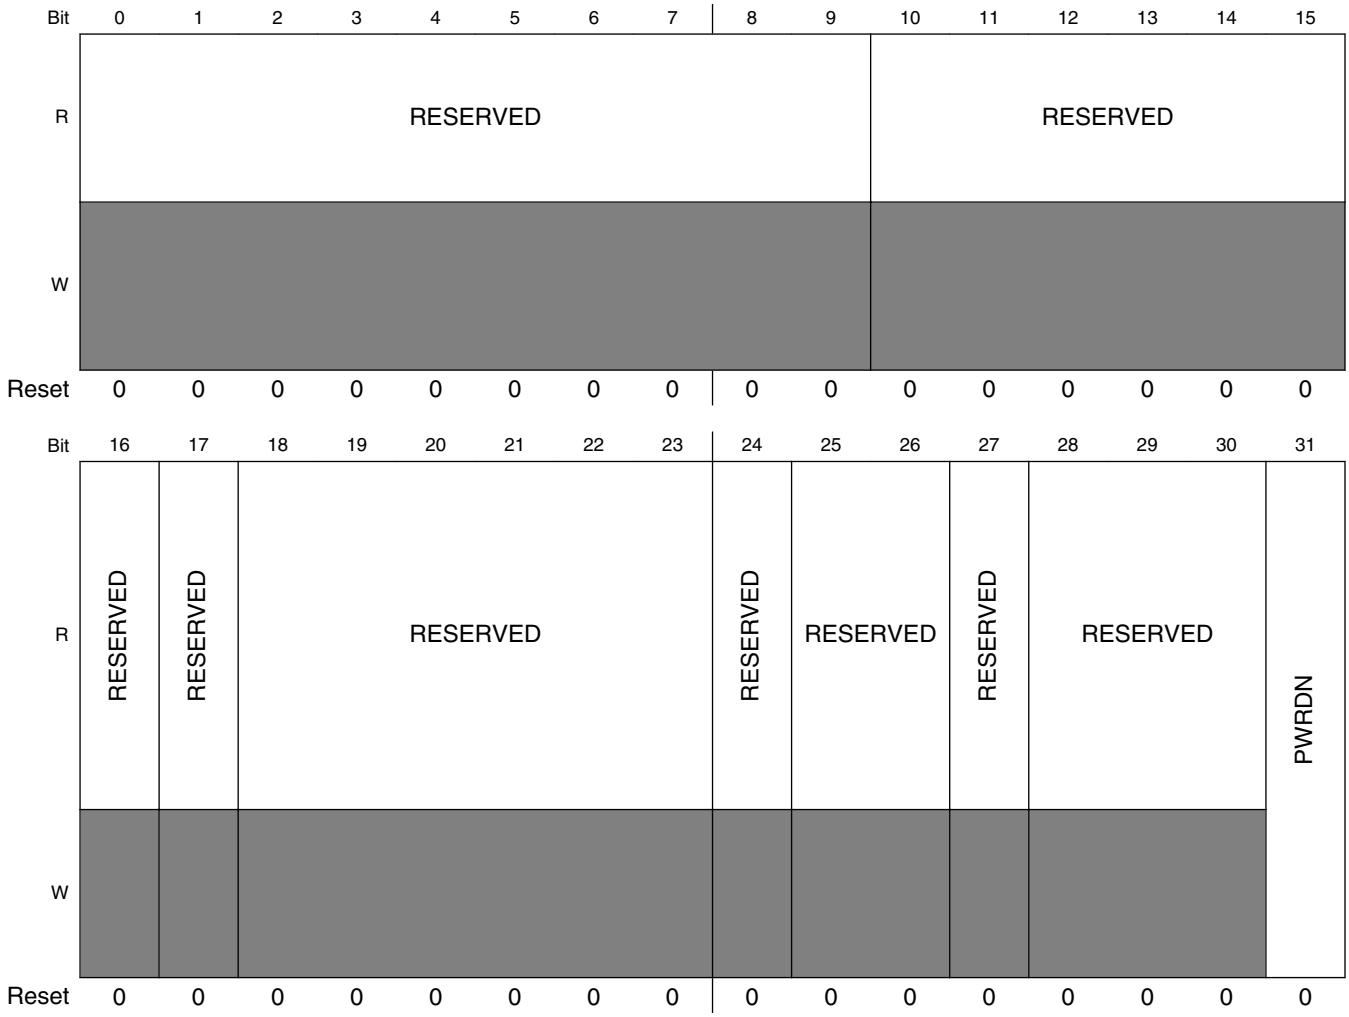


AFE_DACCTRL field descriptions

Field	Description
0–19 RESERVED	This field is reserved.
20–21 FS_ADJ	DAC full scale adjust. Increases the full scale current to overcome the DAC region overlaps. 00 Additional 240µA will flow to dacoutm. 01 Additional 120µA will flow to dacoutp and to dacoutm. 10 Additional 120µA will flow to dacoutp and to dacoutm. 11 Additional 240µA will flow to dacoutp.
22 RESERVED	This field is reserved.
23 RST	DAC reset. Resets the DAC outputs to 1.272V and 0.04V when the DAC is clocked. 0 Normal operation. 1 Resets DAC to midscale.
24–28 RESERVED	This field is reserved.
29–30 RESERVED	This field is reserved.
31 PWRDN	DAC powerdown. 0 Enable DAC. 1 Disable, powerdown.

48.3.17 VREF Control Register 1 (AFE_VRFCTRL1)

Address: 0h base + 54h offset = 54h



AFE_VRFCTRL1 field descriptions

Field	Description
0–9 RESERVED	This field is reserved.
10–15 RESERVED	This field is reserved.

48.4 Functional Description

48.4.1 Crystal Oscillator (XOSC)

The oscillator used on the AFE module is a low voltage, very low jitter 40MHz crystal oscillator. It features:

- Low RF emissions with peak to peak swing limited dynamically
- External crystal load capacitance is required
- Integrated internal bias resistor
- AC-coupled, non-hysteresis output buffer to provide very high immunity to jitter caused by power supply noise
- Clock monitor
- RMS jitter <1pS (100 Hz–5 MHz)
- External bypass mode
- Input 40 MHz only

This circuit is a loop amplitude controlled Pierce oscillator with programmable current settings. The optimum settings are determined in characterization, and have default settings that do not require adjustment. It is self-starting upon power-up. It is designed to work specifically with a 40MHz crystal with a Q>25,000. The oscillator's termination resistors are enabled by default.

48.4.2 Voltage Regulators (VREG)

Each of the voltage regulators in the AFE present low voltage detect flags to the system. In general the low voltage conditions do not immediately affect operation, but instead indicate an out of specification condition. VREG2 and VREG3, however, control the powerdown of the SDADC common mode circuit. If either of these two low voltage conditions is engaged, then the common mode circuitry will powerdown and the common mode voltage will decay to 0V and the SDADC's will be non-functional.

48.4.3 Sigma Delta Phase Locked Loop (SDPLL)

The SDPLL module is a calibrated, LC oscillator-based PLL generating only a 320 MHz clock. It features:

- Dual-path architecture
- LC oscillator with built-in inductor
- Self-calibration
- Non-programmable divider
- Phase Detector
- Lock detect
- Loss of reference clock detect
- It requires a 40 MHz reference clock

This circuit is an LC-based, calibrated PLL. It requires a 40 MHz reference, oscillates at 1.28 GHz, which is divided to the 320 MHz reference for the AFE. The oscillator is calibrated to be near the desired frequency by incrementally adding fixed capacitance to the oscillator and measuring the frequency. This allows a much lower oscillator frequency gain (Kv) than one which is not calibrated. The oscillator is thus much less sensitive to power supply or other noise. The calibration sequence is internally implemented, and occurs automatically when following the steps described in the Initialization section. The exact frequency is obtained by controlling the bias on voltage variable capacitors (VVC).

Dual path charge pumps are employed: a conventional (integral) charge pump to generate a frequency control voltage for the oscillator, and a feed forward (proportional) charge pump to reduce ripple and reference spurs on the control voltage.

48.4.4 Analog to Digital Converters (ADC's)

The 4 AFE ADC's are designed using a continuous time sigma delta modulator topology. The topology utilizes the accuracy of time to improve the accuracy in voltage by oversampling the input signal and filtering the results. The continuous time topology is used for the inherent benefits of built-in anti-aliasing filtering, immunity to substrate noise, and larger SNR over traditional Nyquist conversion at a less costly area and power budget comparatively. The topology requires a low jitter (less than 10 ps) 320 MHz clock and can achieve targeted SNR of 70 dB over a 5 MHz bandwidth. In addition, the topology of the continuous time ADC provide inherent anti-aliasing filtering. Because of this built-in AAF of the architecture there is no need for additional expensive active filtering in front of the ADC if a discrete time Nyquist rate or oversampled version of the ADC was implemented.

The sigma delta modulator topology is a fully differential cascade of integrators feedback form (CIFB) that utilizes active RC integrators to reduce sensitivities to layout parasitics. In addition, the feedback DAC currents of the ADC utilize NRZ DAC pulses to reduce the jitter requirements of the clock source. The sigma delta modulator along with the digital decimation filtering compose a complete ADC. The ADC described provides for final sampling rates from 1.25 Ms/sec to 10 Ms/sec with an effective accurate 12-bit resolution output.

48.4.5 Digital to Analog Converter (DAC)

The 12-bit DAC is designed for generating a ramp that is used to drive the VCO which is used to generate the frequency chirp for the RADAR system. The DAC uses current steering (steers current from negative side to positive side and vice versa) architecture to generate the analog step from digital input. The DAC's sample rate is 10MHz. The DAC is divided into two sub-DAC’s, one for the MSB’s which has 5-bits of input and the one for the LSB’s which has 7-bits of input. There is a binary to thermometer decoder for each section. The LSB section has 127 equally weighted current sources (ideal weight is 1uA for each current source). The MSB section has 31 equally weighted current sources (ideal weight should be 128uA for each current source). During the transition of all LSB current sources to one of the MSB sources (for example if the DAC digital input switches from 00000 1111111 to 00001 0000000) , the most significant current source

needs to be matched to the sum of all LSB current sources so that the DAC output increases only by 1uA. This is difficult to achieve with respect to power and area constraint.

The system can handle higher negative DNL(differential nonlinearity = (actual step-ideal step)/ideal step) i.e. the difference in output current can go negative during the LSB to MSB transition. So the DAC has been designed with an 12 LSB overlap between the LSB to MSB transitions throughout the DAC output range. The overlap is realized by setting the nominal value of the each MSB current sources to 116uA instead of the ideal 128uA.

Now due to the overlap, total loss of the current will be 12uA*31 = 372uA. In order to compensate for the loss two additional MSB current sources are added (2*116uA = 232uA, still DAC will have 140uA loss which will be compensated for by factory trim settings applied at device reset . This extra two MSB sources are controlled by DACCTRL[FS_ADJ].

Every current source inside the DAC is connected to a dedicated pair of switches S1 and notS1, all of the S1 switches connect the current sources to DAC_OUTP and are controlled by DATA (DAC digital inputs) and all of the notS1 switches connect the current sources to DAC_OUTN and are controlled by notDATA . Now, if DACCTRL[FS_ADJ] bits are both set to logic “low” then the 232uA will flow to the DAC_OUTN. If one of the FS_ADJ bits is set to logic “low” and the other one logic “high” then the one set to logic “high” will provide 116uA to the DAC_OUTP and the other one (set to logic “low”) will provide 120uA to the DAC_OUTN. If both FS_ADJ bits are set to logic “high” then the 232uA will flow to the DAC_OUTP.

48.4.6 Decimation Filters

48.4.6.1 Introduction

The AFE radar sigma-delta decimation filter is a digital block that low-pass filters and decimates the 320MHz 5-bit sigma-delta modulator output to generate a lower rate 14-bit signed two’s complement output. The decimation filter supports oversampling ratios (OSR) from 32 to 256 to produce a 10 to 1.25 MHz output sample rate. It includes two stages of filtering: a fourth order sinc filter followed by a programmable 32-tap FIR filter as shown in Figure 48-5. The sinc filter down samples the input by a factor of OSR/4 with the final decimate by 4 done by the FIR filter. The sinc filter output is scaled to a 14-bit signed value for filtering by the FIR filter. The FIR filter has programmable coefficients which are set to yield the desired overall frequency response and digital gain.

After FIR filtering, digital limiting is performed to clip signals with amplitudes greater than the full scale digital output. The output (filt_out[13:0]) is a signed 14-bit, two's complement value that can be optionally rounded to 12-bits.

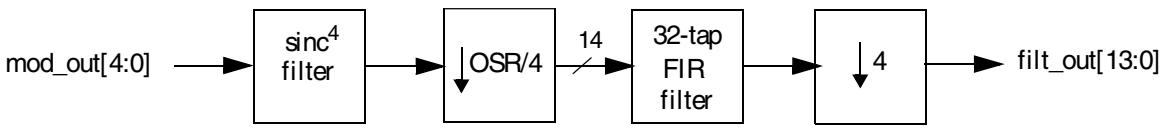

Figure 48-5. Decimation Filter Block Diagram

Table 48-1. OSR Selection

FILTnCTRL[OSR]	OSR	Sample Rate (320 MHz)
00	32	10
01	64	5
10	128	2.5
11	256	1.25

48.4.6.2 Filter Parameters

The combined effects of the sinc filter and the default FIR filter coefficient values are shown in Table 48-2

Table 48-2. Filter Parameters

filt_osr[1:0]	OSR
Modulator Frequency	320 MHz
Output Sample Rate (Fs)	10 - 1.25 MHz
Output Resolution	12 / 14 bits
FIR Filter Length	32
FIR Coefficient Size	14 bits
OSR	32 - 256
Pass-band	0 - 0.4 Fs
Pass-band Ripple	< +/- 0.3 dB[1]
Stop-band Attenuation > 0.7 Fs	> 60 dB
Phase Response	Linear
Group Delay	4.3 / Fs

1. When using 320 MHz sampling mode.

48.4.6.3 Control and Operation

The filter state is reset and filtering operations are stopped when reset is asserted. Out of reset, the filter is disabled until the filt_en signals from the CTE are asserted. When the filt_en signals are negated, the state of the filter is reset and the filter effectively enters a low power mode by negating the enables to most registers allowing for internal clock gating of the registers. The FIR filter coefficient values are not reset and can be read/ written when the filt_en signals are negated.

The FIR filter coefficients have default values which give the filter the characteristics shown in Table 48-2 and described in Frequency Response . The coefficients are programmable and can be modified. The FIR filter is symmetrical with FLnCOEF0 corresponding to FIR coefficients h[0] and h[31], FLnCOEF1 corresponding to FIR coefficients h[1] and h[30], up to FLnCOEFF corresponding to coefficients h[15] and h[16]. Transfers take one clock cycle and may be performed on consecutive clock cycles.

After the coefficients are programmed and the OSR is selected, operation of the filter is started by the AFE_FILT_PHASE block of the MISC module asserting the filt_en signals. This assertion establishes the sampling phase for the channels. The timing of the filt_en signals for each channel can be used to synchronize sampling of multiple channels or introduce a phase delay between channels. The coefficients, OSR, and rounding mode should not be modified while the filter is operating.

The mod_out data is sampled on the rising edge of mod_clk. This 5-bit signed, two's complement input signal is filtered by the sinc filter which has a 29-bit internal word width. The sinc filter output it scaled based on the OSR and rounded to produce a 14-bit signed output which further processed by the FIR filter.

The FIR filter is a symmetrical with 16 programmable coefficients that are 14-bit signed, Two's complement, fractional values which can range in value from -1.0 (0x2000) to 0.9999 (0x1FFF). The FIR filter is implemented with a full 14-bit multiplier and 29-bit accumulator. The FIR filter accumulator has two guard bits which provide headroom for large amplitude signals. The output of the FIR filter is limited and rounded to produce a 12-bit two's complement output with the 2 least significant bits always zero. The pass-band gain of the filter establishes the digital gain which sets the full scale analog input level. A gain of 1.22 (1.7dB) is required to produce the specified full scale analog input range. When the FIR filter processing is finished, the conversion complete (filt_cc) output is asserted for one clock cycle to indicate the filt_out[13:0] value is valid. The first 8 samples generated after the filter is enabled are not valid due to the memory of the filter. The FIR filter processing adds 55 mod_clk (320MHz) clock cycles of delay to the filter, in addition to the filter group delay (4.3 sample times for the default coefficients).

48.4.6.4 Frequency Response

The filter frequency response scales with the output sample rate which is a function of the modulator clock (mod_clk) frequency and the OSR. The overall frequency response is the combined response of the sinc4 filter and the 32 tap FIR filter. The sinc4 filter frequency response which is given in equation 1-1 has significant pass-band droop and a wide transition band.

$H(z)=((1-z^{-OSR}) /(1-z^{-1}))^4$

An example of the $sinc^4$ filter frequency response with OSR=32 is shown in the figure below. In this, case the sample frequency is 10 MHz, so frequency components above 5 MHz are aliased back into the band from 0 to 5 MHz.

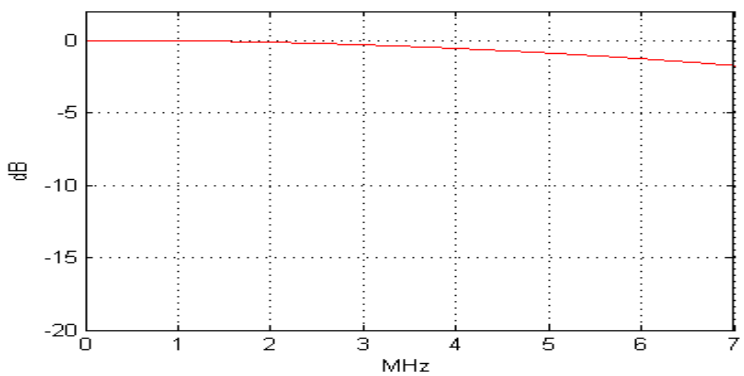

Figure 48-6. Sinc Filter Frequency Response OSR=32

The FIR filter is used to compensate for the pass-band droop of the sinc filter and narrow the transition band. The specifications for the combined response of the two filters is given in Filter parameters table and shown in the following figure for the default FIR filter coefficients.

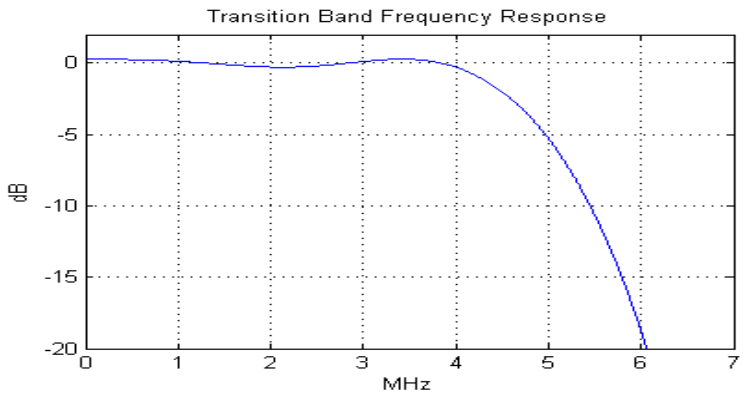

Figure 48-7. Overall Filter Frequency Response OSR=32

48.5 Resets

All wrapper registers are forced to their reset state upon the assertion of the reset input to the AFE wrapper.

48.6 Clocks

The SDPLL in the AFE analog block generates 320 MHz, 160 MHz, and 80 MHz outputs via non-configurable dividers. These clocks are used in the wrapper by the decimation filters. The analog block also produces a low jitter 40 MHz crystal reference clock.

48.7 Interrupts

The AFE wrapper has several interrupts. All flags are sticky and will remain set. Flags are cleared by writing a 1 to that bit position except for SDPLL lock flag and loss of reference flag.

Table 48-3. AFE Interrupt Sources

Interrupt Source/Flag	Local Enable	Description
ADCOVLD[OVERVOLT]	ADCCTRL7[OVLIE]	ADC input overvoltage detected. One combined interrupt for all ADC's.

Table continues on the next page...

Table 48-3. AFE Interrupt Sources (continued)

Interrupt Source/Flag	Local Enable	Description
OSCSTS[STS]	OSCCTRL[IE]	Oscillator status. Only activated by rising edge of STS bit.
PLLSTS[LOR]	PLLCTRL3[LORIE]	SDPLL loss of reference clock.
PLLSTS[LOCK]	PLLCTRL3[LCKHIIE]	SDPLL lock achieved.
PLLSTS[LCKLOSS]	PLLCTRL3[LCKLOIE]	SDPLL lock lost.

Chapter 49
MIPICSI2

49.1 Chip specific MIPICSI2 information

49.1.1 CSI signals pin assignment

The following table provides the device IO pin mapping.

Table 49-1. CSI signals pin assignment

Signal description	Pin name
CKP (clock lane differential positive signal)	CSI_CLKP
CKN (clock lane differential negative signal)	CSI_CLKN
DP0 (data lane 0 differential positive signal)	CSI_LANE0P
DN0 (data lane 0 differential negative signal)	CSI_LANE0N
DP1 (data lane 1 differential positive signal)	CSI_LANE1P
DN1 (data lane 1 differential negative signal)	CSI_LANE1N
DP2 (data lane 2 differential positive signal)	CSI_LANE2P
DN2 (data lane 2 differential negative signal)	CSI_LANE2N
DP3 (data lane 3 differential positive signal)	CSI_LANE3P
DN3 (data lane 3 differential negative signal)	CSI_LANE3N
REXT (to connect to external reference resistor for auto-calibration)	REXT

49.2 About this module

49.2.1 Definition

MIPICSI2 is a hardware module that:

- Provides a low-cost, high speed, serial receive interface between a MIPICSI2 serial input data and the on chip Video Interface Unit (VIU) high speed radar data and signal processing tool box(SPT).
- Incorporates a four lane physical layer and one clock lane, compliant with the MIPI Alliance Standard for D-PHY. DPHY RX is high-frequency, low-power, low-cost, and source-synchronous.
- Incorporates a receiver controller core that is flexible, high-performance, easy-to-use and MIPICSI2 compliant. It interfaces with DPHY RX on one side and the VIU Signal Processing Toolbox (SPT) module at the user interface side.
- Incorporates a VIU gasket.

49.2.2 MIPICSI2 Copyright

49.2.3 Features

MIPICSI2 subsystem features include:

- Support for up to four lanes on the DPHY RX side for data transfer.
- Data rate up to 1 Gbit/s1 Gbit/s . supported on each individual DPHY RX lane. It is expected that the throughput when all lanes are being used will not exceed 1Gb/s.
- Short and long packet decoding.
- Support for generic short packet data types for passing any timing related information from the transmitter side to the software.
- Frame and line synchronization packet signaling.
- Input side data types: RGB888, RGB666, RGB565, YUV422 8- and 10-bit, RAW8, RAW10, RAW12, RAW14, user defined, embedded
- Output side data types: RGB888, RGB666, RGB565, YUV444 8-bit
- 1 pixel output per user interface clock.
- Error management and handling:
  - DPHY level errors
  - Packet level errors
  - Protocol decoding level errors

all of which are MIPICSI2 specification compliant with *MIPI Alliance D-PHY Specification* and *MIPI Alliance CSI-2 Specification*, v01-01-00 by MIPI® Alliance.

49.2.4 MIPICSI2 compliance

MIPICSI2 module complies with the MIPI® Alliance Specification for MIPICSI2 (Version 1.01.00, 9-Nov-2010), available from the MIPI Alliance.

49.2.5 Modes of operation

MIPICSI2 supports the following mode of operation:

Mode	Description
Normal	MIPICSI2 subsystem operates as an interface between the external video dataradar data and the Video Interface Unit (VIU)Signal Processing Toolbox (SPT) module.

49.2.6 Clocking

The table below lists the frequency requirements on the clocks for this module.

Table 49-2. Clock Description

Clock Name	Frequency Requirement(MHz)
controller_li_clk	Should be greater than equal to lane frequency /8
controller_ui_clk	Should be greater than equal to 2/3 x controller_li_clk
DPHY_ESCAPE_CLK	60(Min) 80(Max)

49.3 MIPICSI2

49.3.1 MIPICSI2 block diagram

This diagram below shows the components of MIPICSI2:

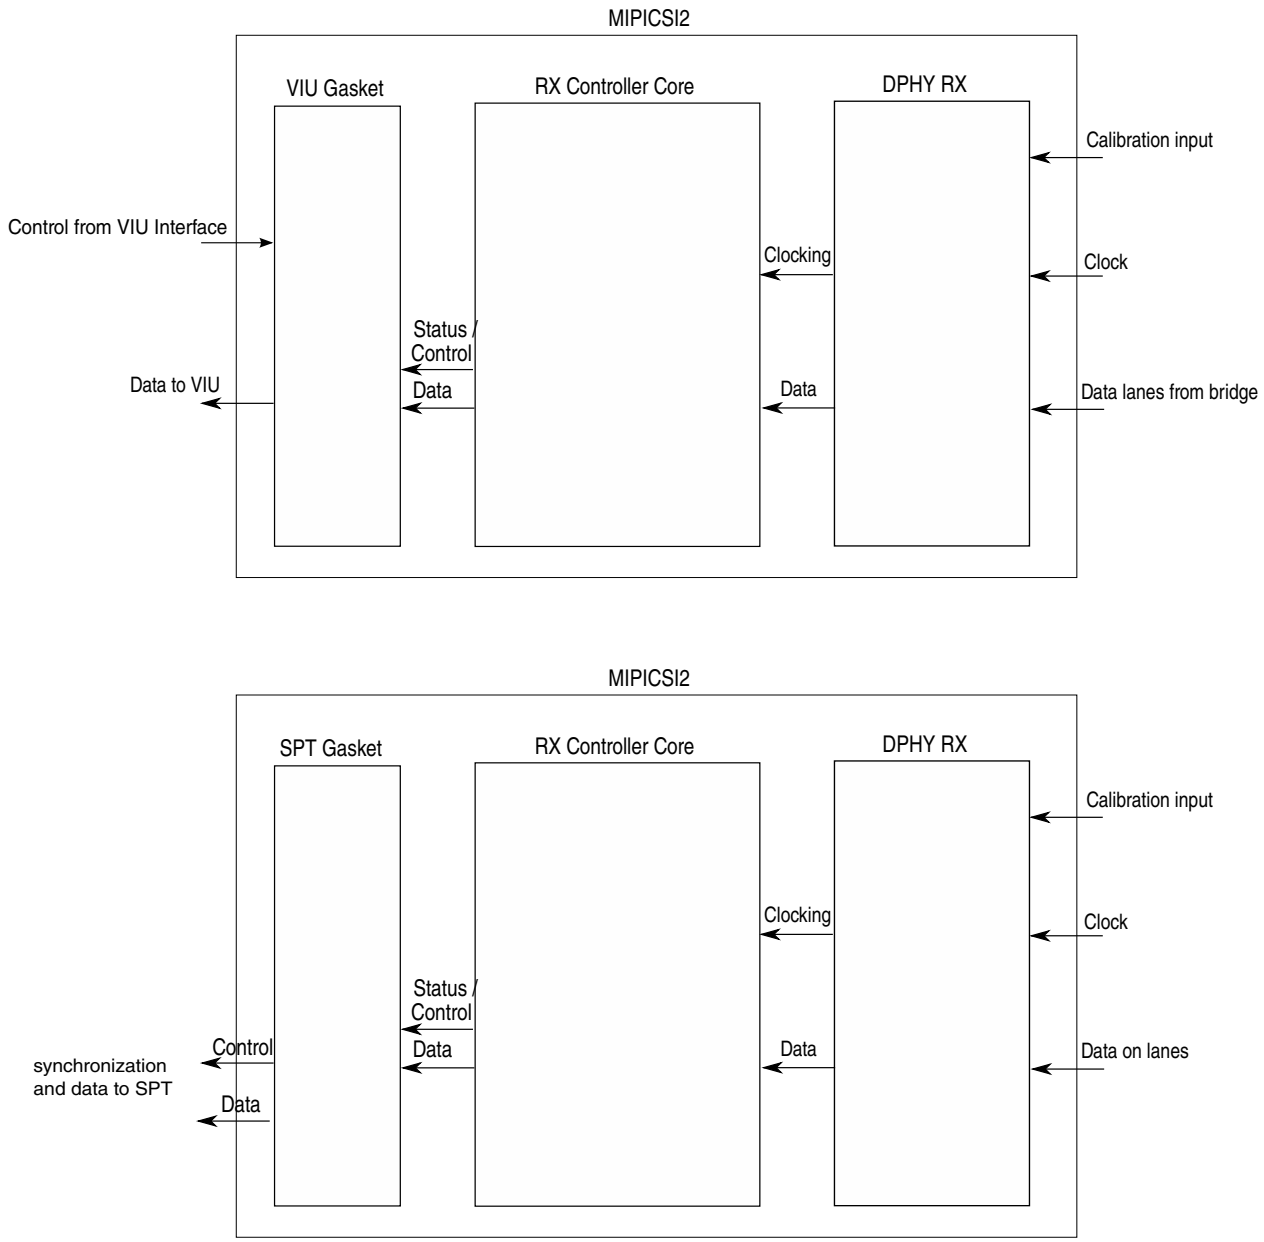

Figure 49-1. MIPICSI2 block diagram

49.3.2 MIPICSI2 components

This table below describes the functions of the main components of the MIPICSI2 subsystem:

Component	Function
DPHY RX	Receives off-chip data over the MIPICSI2 compliant physical layer interface, de-serializes the radar data in to bytes, and sends the bytes to the RX controller core.
RX controller core	Receives MIPICSI2 packetized data as bytes from DPHY RX, provides lane management and low level protocol functionality, and then sends the de-packetized pixels to the VIU gasket.
VIUSPT gasket	Receives the de-packetized data from the RX controller core and sends it out with associated synchronization and blanking information to the Video Interface Unit (VIU)SPT module.

49.3.3 MIPICSI2 signals

This table below describes the signals on the boundary of the MIPICSI2 subsystem:

Signal	Function	Direction	Level of signal after reset	Clocking
PHY interface				
Calibration input	Pin to connect an external reference resistor for auto-calibration. 15K ohm precise resistor with 1% variation or lower is required.	Input/Output	—	—
Clock	Receives the differential clock.	Input	—	—
Data lanes	Receives the differential data.	Input	—	—
Pixel data	Provides the formatted pixel data through a 24-bit parallel interface to the VIU module.	Output	000000h	controller_ui_clk
Sync and enable	Provides a horizontal and vertical synchronization pulses and a data enable signal to the VIU module.	Output	1	controller_ui_clk

49.4 DPHY RX

49.4.1 DPHY RX block diagram

This diagram below shows the components of DPHY RX:

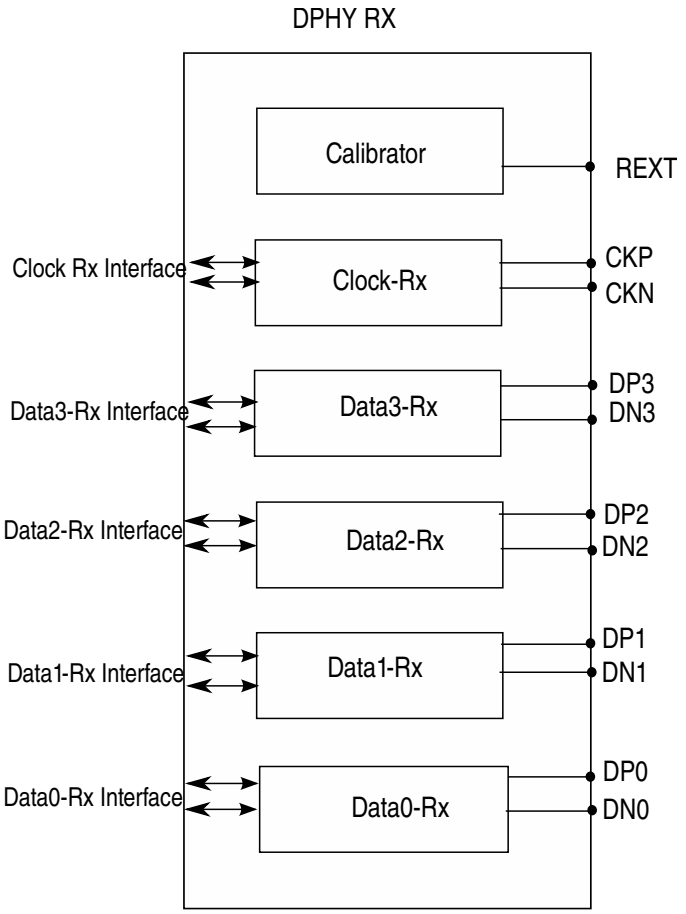

Figure 49-2. DPHY RX block diagram

NOTE

The DPHY RX used on this chip consists of four data lanes.

49.4.2 DPHY RX components

This table below describes the functions of the main components of DPHY RX:

Component	Function
Data0-Rx Data1-Rx Data2-Rx Data3-Rx	Receives off chip data through unidirectional receiver lane. Consists of a high-speed receiver (HS-RX), a low-power receiver (LP-RX), a low-power contention detector (LP-CD), and a deserializer.
Clock_Rx	Receives off chip clock through unidirectional receiver lane and consist of a high-speed receiver (HS-RX), a low-power receiver (LP-RX), and a low-power contention detector (LP-CD).
Calibrator	Calibrates the receiver termination after the block is powered-up to ensure that the transmitter and receiver meet the required specifications. Runs in auto-calibration mode or user programmable mode.

49.4.3 DPHY RX signals

The table below described the DPHY RX signals:

Table 49-3. DPHY RX signals

Signal	Function	Direction
CKP	Receives the differential positive clock lane.	Input
CKN	Receives the differential negative clock lane.	Input
DP0	Receives the differential positive data lane 0.	Input
DN0	Receives the differential negative data lane 0.	Input
DP1	Receives the differential positive data lane 1.	Input
DN1	Receives the differential negative data lane 1.	Input
DP2	Receives the differential positive data lane 2.	Input
DN2	Receives the differential negative data lane 2.	Input
DP3	Receives the differential positive data lane 3.	Input
DN3	Receives the differential negative data lane 3.	Input
REXT	Pin to connect an external reference resistor to for auto-calibration. An accurate 15K ohm resistor with 1% variation or lower is required.	Input/Output

NOTE

Please refer to IO Signal Description Input Multiplexing sheet (Excel file) attached to this document for external signals multiplexing.

49.4.4 Calibrator

Calibrator is used to calibrate the RX termination.

DPHY RX supports one of the following receiver termination modes:

Table 49-4. DPHY RX supports description

Mode	Description
Auto calibration	Termination resistors are automatically configured by calibration circuit with reference resistor connected between REXT and VSSA. NOCAL field is set to zero for such purposes.
User programmable	NOCAL is set to one for manual calibration. RCALI is programmed by the user through registers.

When calibration completes, CALCOM is set indicating that the calibration is complete.

Table 49-5. Calibrator specifications

Symbol	Parameter	Min	Typ	Max	Unit
R_{EXT}	External reference resistor, 1% accuracy, for auto-calibration.		15		KΩ
T_{cal}	Time from when PD_RX signal goes low to when CALCOM goes high		2		µs

49.4.5 Receiver

The receiver blocks within the DPHY RX module consists of unidirectional receive (RX) data and clock lanes.

The RX data lanes consist of:

- a High Speed Receiver
- a Low-Power Receiver
- a Low-Power Contention Detector
- a Deserializer

The clock lane consists of:

- a High Speed Receiver
- a Low-Power Receiver
- a Low-Power Contention Detector

The high-frequency signals have a low voltage swing, whereas low-power signals have a large voltage swing. The high speed function is used for high-frequency data traffic, and the low-power functions (10 Mbit/s data rate) are typically used for control commands.

After the MIPICSI2 subsystem has been initialized, as described in Initializing the MIPICSI2 subsystem, the data lanes are ready to receive low-power data. The transmitter side needs to drive stop state on the lanes for a predetermined time, indicated by the clock and data lanes having stop state asserted which completes the initialization of the link. The steps required to place the receiver in to high-speed and ultra low-power modes are described in Place receiver in high-speed mode and Place receiver in ultra low-power mode.

49.5 RX controller core

49.5.1 RX controller core block diagram

This diagram below shows the components of RX core controller:

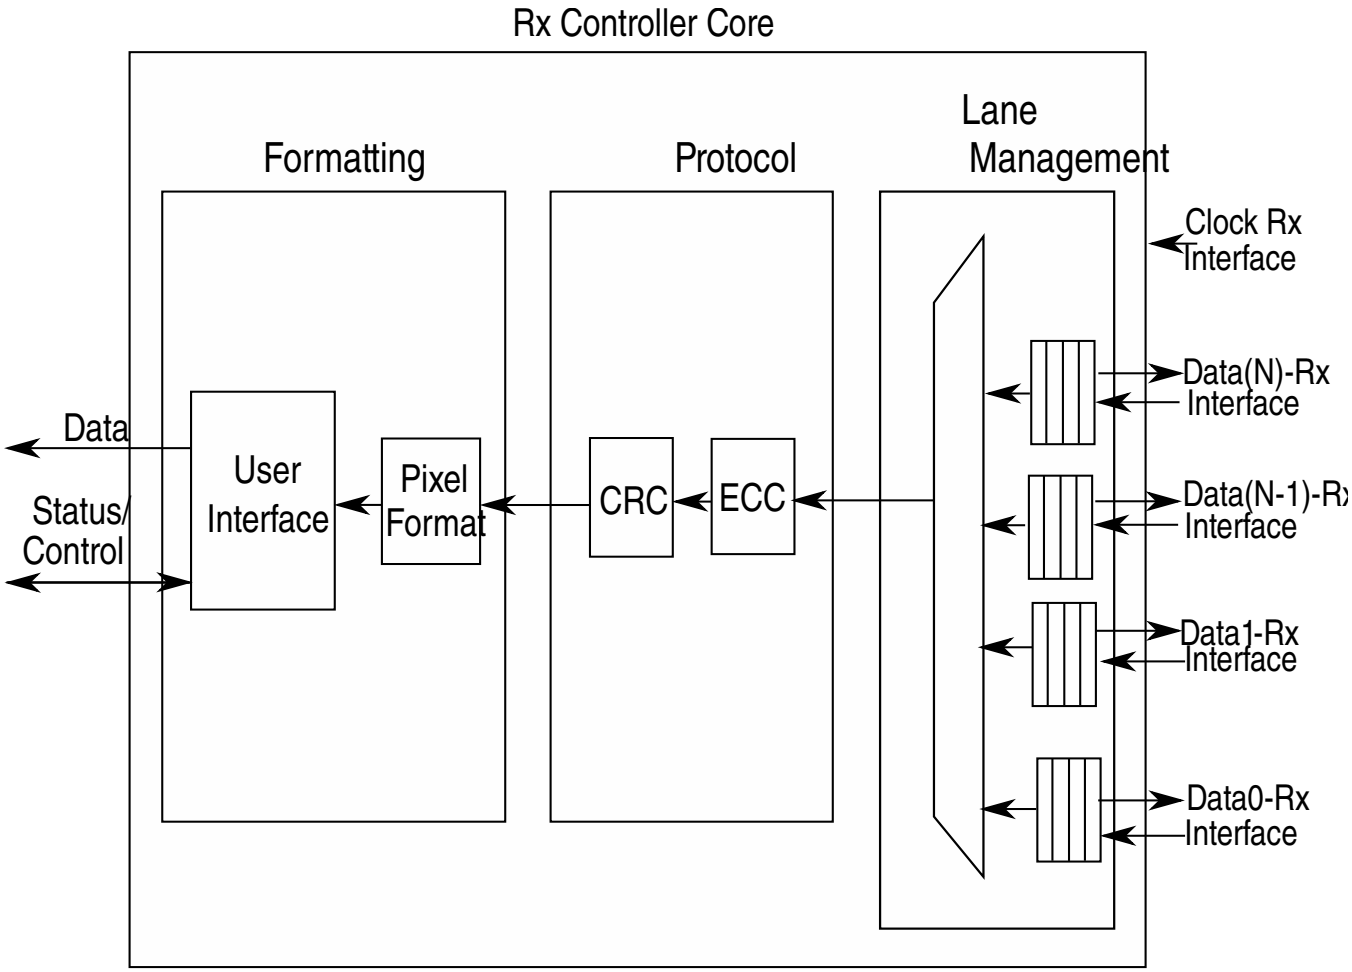

Figure 49-3. RX controller core block diagram

NOTE

The RX controller core used on this chip consists of four data lanes.

49.5.2 RX controller core components

This table below describes the functions of the main components of RX core controller:

Component	Function
Lane management	Controls lane management as defined by the MIPICSI2 specification.
Protocol	Controls low level protocol, including error handling, as defined by the MIPICSI2 specification.
Formatting	Controls byte to pixel packing as defined by the MIPICSI2 specification.

49.5.3 RX controller core signals

This table below describes the RX controller core signals:

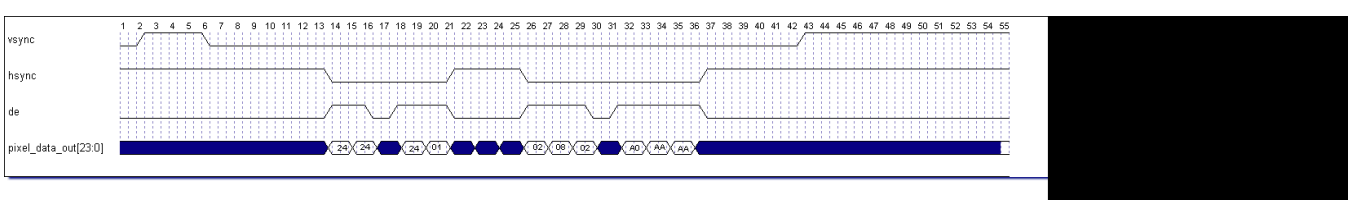
Table 49-6. RX controller core signals

Signal	Function	Direction
Data0-Rx Interface	Receives the output from Data0-Rx of DPHY RX.	Input
Data1-Rx Interface	Receives the output from Data1-Rx of DPHY RX.	Input
Data2-Rx Interface	Receives the output from Data2-Rx of DPHY RX.	Input
Data3-Rx Interface	Receives the output from Data3-Rx of DPHY RX.	Input
Clock Rx Interface	Detects any lane transitions in low power mode.	Input
Status/control	Provides status and control information to the VIU gasket.	Input/Output
Data	Provides the formatted pixel data to the VIU gasket.	Output

49.6 VIUSPT gasket

49.6.1 MIPICSI2 subsystem output data format

This timing diagram shows example signals from the output of the MIPICSI2 subsystem from the Video Interface Unit (VIU) gasket state machine:



The below table shows the organization of image data at the output of the MIPICSI2 subsystem:

Table 49-7. MIPICSI2 subsystem output data

Data formats	Bit Wise Alignment																							
—	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

RGB888	R[7:0]								G[7:0]								B[7:0]							

This table shows the output data format for RGB888 type data:

Pixel out at the controller interface pixel_data_out [23:0]			Pixel out at the controller interface pixel_data_out [23:0]		
[23:16]	[15:8]	[7:0]	[23:16]	[15:8]	[7:0]
{red[7:0]}	{green[7:0]}	{blue[7:0]}	{red[7:0]}	{green[7:0]}	{blue[7:0]}

This table shows the output data format for RGB888 type data:

Pixel out at the controller interface pixel_data_out [23:0]			Pixel out at the controller interface pixel_data_out [23:0]		
[23:16]	[15:8]	[7:0]	[23:16]	[15:8]	[7:0]
{red[7:0]}	{green[7:0]}	{blue[7:0]}	{red[7:0]}	{green[7:0]}	{blue[7:0]}

This table shows the output data format for RGB666 type data:

Pixel out at the controller interface pixel_data_out [23:0]			Pixel at the VIU interface pixel_pixel_data_out [23:0]		
[23:16]	[15:8]	[7:0]	[23:16]	[15:8]	[7:0]
{6'b0,red[5:4]}	{red[3:0],green[5:2]}	{green[1:0]] , blue[5:0]}	{red[5:0],2'b00}	{green[5:0],2'b00}	{blue[5:0],2'b00}

This table shows the output data format for RGB565 type data:

Pixel out at the controller interface pixel_data_out [23:0]			Pixel at the VIU interface pixel_pixel_data_out [23:0]		
[23:16]	[15:8]	[7:0]	[23:16]	[15:8]	[7:0]

Table continues on the next page...

Pixel out at the controller interface pixel_data_out [23:0]			Pixel at the VIU interface pixel_pixel_data_out [23:0]		
{8'b0}	{red[4:0],green[5:3] }	{green[2:0]] , blue[4:0]}	{red[4:0],3'h0}	{green[5:0],2'b00}	{blue[4:0],3'h0}

This table shows the output data format for YUV422 8-bit type data:

Pixel number	Pixel out at the controller interface data_out[23:0]			Pixel out at the controller interface data_out[23:0]		
	[23:16]	[15:8]	[7:0]	[23:16]	[15:8]	[7:0]
1	8'b0	Y1	U1	—	—	—
2	8'b0	Y2	V1	Y1	U1	V1

This table shows the output data format for YUV422 10-bit type data:

Pixel number	Pixel out at the controller interface data_out[23:0]			Pixel out at the controller interface data_out[23:0]		
	[23:16]	[15:8]	[7:0]	[23:16]	[15:8]	[7:0]
1	{4'b00,Y1[9:6]}	{Y1[5:0],U1[9:8]}	U1[7:0]	—	—	—
2	{4'b00,Y2[9:6]}	{Y2[5:0],V1[9:8]}	V1[7:0]	Y1[9:2]	U1[9:2]	V1[9:2]

49.7 Using MIPICSI2

49.7.1 Initializing the MIPICSI2 subsystem

To enable the MIPICSI2 subsystem after the Power supply/connection to the MIPI Receiver has been disconnected or chip has been reset:

1. Configure the number of data lanes (NULANE).
2. Bring the receiver module in DPHY RX out of reset (PDRX).
3. Enable the clock and data lanes of the DPHY (RXEN).
4. Wait until auto calibration is completed (CALCOM) and the DPHY RX is ready to monitor the low-power data from the transmitter, usually 2 us after DPHY RX exits reset.
5. Write the required settle time (HSSETL) and the DPHY lane high speed receive settle time (D0HSET). The settle time should be calculated as described in Calculate the required settle time for DPHY RX.

49.7.2 Calculate the required settle time for DPHY RX

The time in which the high-speed receiver will ignore any high-speed transitions on the data lane is dependent on DPHY_ESCAPE_CLK frequency and the data rate.

1. Calculate the required settle time using the formula **Settle time = (HSSETL + 1) × (Tperiod of DPHY_ESCAPE_CLK)**, where DPHY_ESCAPE_CLK is 80 MHz (12.5ns).

The settle time value varies in the range 85+6×UI (minimum) to 145 +10×UI (maximum) as per the formula shown in the table below.

For example, keeping data rate as 1 Gb/s , the unit interval (UI) is 1ns.

Taking a mid value of settle time (120 ns) the value of HSSETL must be programmed as:

Table 49-8. Settle time for DPHY RX

	Minimum	Typical	Maximum
T_{HS_SETL}	85ns + 6×UI	120ns	145ns +10×UI
HSSETL	(91/15.04) -1 = 5	(120/15.04) -1 = 6.97 ~ 7	(155/15.04)-1 = 9.3058 ~9
HSSETL	(91/12.5) -1 = 6	(120/12.5) -1 = 8.6 ~ 9	(155/12.5)-1 = 11

49.7.3 Override auto calibration values

Termination resistors are automatically configured by the calibration circuit with a reference resistor connected between REXT and VSSA. The auto calibration procedure is performed every time DPHY RX is powered-up.

To override the auto calibration values and enter another value in user programmable mode:

1. Enter user programmable mode (NOCAL).
2. Override the calibration value (RCALI).
3. Wait until calibration has completed (CALCOM).

49.7.4 Place receiver in high-speed mode

After DPHY RX has been initialized for receiving data, the data lanes are ready to receive low-power data.

The transmitter side needs to drive the stop state on the lanes for a predetermined time. High-speed receive is enabled by the transmitter driving the high-speed command on the respective lane, as per MIPI D-PHY standard *LP11-LP01-LP00*.

The following steps are performed to receive high-speed data:

1. Once in the bridge state (LP00), the receiver side will wait for the programmed settle time, HSSETL before it starts to monitor the data lane.
2. RXACTH indicates that high-speed transmission is active on the data lane.
3. At the start of a high speed transmission, the receiver looks for the synchronization pattern sent by the transmitter.
4. When DPHY RX has received one byte of deserialized data, it sends it to RX controller core and updates RXVALH indicating that the current data is valid.

Once a complete packet of high-speed data has been received the lanes return to stop state.

49.7.5 Place receiver in ultra low-power mode

Ultra low-power (ULP) mode is entered through a sequence of low-power commands from the transmitter on the lane.

DPHY RX reacts to the command sequence in the following way:

- DPHY RX indicates that ULP mode is active on the lane once the command sequence is complete (ULPSC).
- DPHY RX indicates that ULP mode is exited when CULPMA is cleared.

Once ULP mode has been exited the lanes return to stop state.

49.7.6 Understanding MIPICSI2 compliant error levels

Due to the layered structure of the MIPICSI2 subsystem, errors can occur at different levels. This table described the levels.

Table 49-9. MIPICSI2 compliant error levels

Error Level	[1]Description
DPHY	Any DPHY related transmission error. Unrelated to the transmission's content. The recommended behavior for handling this error level covers only those errors generated by the data lane since an implementation can assume that the clock lane is running reliably as provided by the expected bit-error-rate (BER) of the link.
Packet	Data integrity of the received packet header and payload data. The behavior for this error level covers only errors recognized by decoding the packet header's ECC byte and computing the CRC of the data payload.

Table continues on the next page...

Table 49-9. MIPICSI2 compliant error levels (continued)

Error Level	[1]Description
Protocol Decoding	Errors present in the decoded packet header or errors resulting from an incomplete sequence of events. The recommended behavior for this error level covers errors caused by decoding the packet header information and detecting a sequence that is not allowed by the MIPICSI2 protocol or a sequence of detected errors by the previous layers.

49.7.7 Decipher error sources and interrupt signals

The MIPICSI2 subsystem provides an error based interrupt signaltwo MIPI protocol based errors.[1]. This interrupt can have a variety of sources.

Table 49-10. Decipher error sources and interrupt signals

Source of error		Details	Error Level	Associated ERRPPST field	Associated ERRPHYS field[1]
Start-of-Transmission (SoT)		A recoverable error that is asserted for one cycle if the high-speed SoT leader sequence is corrupted, but in such a way that proper synchronization can still be achieved. This is considered to be a “soft error” in the leader sequence and confidence in the payload data is reduced.	DPHY	—	
SoT synchronization		An unrecoverable error that is asserted for one cycle if the high-speed SoT leader sequence is corrupted in a way that proper synchronization cannot be expected.	DPHY		or
Control		This error is asserted when the DPHY has detected an illegal control sequence, and remains high until the next change in line state. For example, if a turn-around request or escape mode request is immediately followed by a stop state instead of the required bridge state.	DPHY	—	or
Double bit-error		Asserted when an ECC syndrome was computed and two bit-errors are detected in the received header.	Packet		—
Single bit-error		Asserted when an ECC syndrome was computed and a single bit-error in the header was detected and corrected. Error Position (MIPICSI2_ERRPOS) register contains the location where the single bit error was detected, but is only valid if is 1.	Packet		—

Table continues on the next page...

1. Copyright © 2005-2010 MIPI Alliance, Inc. All rights reserved.

Table 49-10. Decipher error sources and interrupt signals (continued)

Source of error		Details	Error Level	Associated ERRPPST field	Associated ERRPHYS field[1]
Packet payload error		Asserted when the computed CRC code of the message payload is different than the received CRC code.	Packet		—
Frame sync[2]		Asserted when Frame End (FE) is not paired with Frame Starts (FS).Several error cases can be identified for this type of error, such as, when a FS is followed by a second FS, the frame corresponding to the first FS is considered an error,or an FE is followed by a second FE, or when a packet level double bit-error was signaled from the protocol layer the whole transmission until the first DPHY stop state should be ignored since it contains no information that can be safely decoded and cannot be qualified with a data valid signal.	Protocol Decoding		—
Unrecognized ID		Unimplemented or unrecognized ID in the header. Invalid ID Report Register (MIPICSI2_INVID) reports invalid ID was found and what the invalid ID was.	Protocol Decoding		—
Data payload received between FS and FE contains errors		This signal is asserted on any packet payload error and de-asserted on the first FE.	Protocol Decoding		—

1. One field per DPHY RX data lane
2. SoT synchronization also generates this error.

At reset all sources are masked in Interrupt Enable (MIPICSI2_INTREN). Reading the error registers after the interrupt signal is raised will provide the source.

49.7.8 Interrupts

The MIPICSI2 subsystem provides interrupt output that can be error based or status based. A total of one three interrupts can be triggered by the MIPICSI2 subsystem.

1.General MIPICSI2 protocol based interrupt- One interrupt for the protocol based errors and status

- Error based interrupt - This interrupt can have a variety of sources as described in the table below :

Table 49-11. General MIPICSI2 protocol Error based interrupt

Source of error		Details	Error Level	Associated ERRPPST field	Associated ERRPHYS field[1]
Start-of-Transmission (SoT)		A recoverable error that is asserted for one cycle if the high-speed SoT leader sequence is corrupted, but in such a way that proper synchronization can still be achieved. This is considered to be a “soft error” in the leader sequence and confidence in the payload data is reduced.	DPHY	—	
SoT synchronization		An unrecoverable error that is asserted for one cycle if the high-speed SoT leader sequence is corrupted in a way that proper synchronization cannot be expected.	DPHY		or
Control		This error is asserted when the DPHY has detected an illegal control sequence, and remains high until the next change in line state. For example, if a turn-around request or escape mode request is immediately followed by a stop state instead of the required bridge state.	DPHY	—	or
Double bit-error		Asserted when an ECC syndrome was computed and two bit-errors are detected in the received header.	Packet		—

Table continues on the next page...

Table 49-11. General MIPICSI2 protocol Error based interrupt (continued)

Source of error		Details	Error Level	Associated ERRPPST field	Associated ERRPHYS field[1]
Single bit-error		Asserted when an ECC syndrome was computed and a single bit-error in the header was detected and corrected. Error Position (MIPICSI2_ERRPOS) register contains the location where the single bit error was detected, but is only valid if is 1.	Packet		—
Packet payload error		Asserted when the computed CRC code of the message payload is different than the received CRC code.	Packet		—
Frame sync[2]		Asserted when Frame End (FE) is not paired with Frame Starts (FS) on a given virtual channel (VC).Several error cases on the same VC can be identified for this type of error, such as, when a FS is followed by a second FS on the same virtual channel the frame corresponding to the first FS is considered an error, or when a packet level double bit-error was signaled from the protocol layer the whole transmission until the first DPHY stop state should be ignored since it contains no information that can be safely decoded	Protocol Decoding		—

Table continues on the next page...

Table 49-11. General MIPICSI2 protocol Error based interrupt (continued)

Source of error		Details	Error Level	Associated ERRPPST field	Associated ERRPHYS field[1]
		and cannot be qualified with a data valid signal.			
Unrecognized ID		Unimplemented or unrecognized ID in the header. Invalid ID Report Register (MIPICSI2_INVID) reports the VC on which the invalid ID was found and what the invalid ID was.	Protocol Decoding		—
Data payload received between FS and FE contains errors		Asserted after FE when the data payload received between FS and FE contains errors. This signal is asserted on any packet payload error and de-asserted on the first FE.	Protocol Decoding		—

1. One field per DPHY RX data lane
2. SoT synchronization also generates this error.

- Status based interrupt - This interrupt is triggered on any protocol based status update. After reset all sources are masked. Reading the relevant status register will provide the source. The sources are listed below.
  - Generic short packet received

1.General MIPICSI2 PHY based interrupt- One interrupt for the PHY based errors

- Error based interrupt - This interrupt can have a variety of sources as described in the table below :

Table 49-12. General MIPICSI2 PHY Error based interrupt

Source of error		Details	Error Level	Associated ERRPHYS field[1]
Start-of-Transmission (SoT)		A recoverable error that is asserted for one cycle if the high-speed SoT leader sequence is corrupted, but in such a way that proper synchronization can still be achieved. This is	DPHY	

Table continues on the next page...

Table 49-12. General MIPICSI2 PHY Error based interrupt (continued)

Source of error		Details	Error Level	Associated ERRPHYS field[1]
		considered to be a “soft error” in the leader sequence and confidence in the payload data is reduced.		
SoT synchronization		An unrecoverable error that is asserted for one cycle if the high-speed SoT leader sequence is corrupted in a way that proper synchronization cannot be expected.	DPHY	or
Control		This error is asserted when the DPHY has detected an illegal control sequence, and remains high until the next change in line state. For example, if a turn-around request or escape mode request is immediately followed by a stop state instead of the required bridge state.	DPHY	or

1. One field per DPHY RX data lane

2.General MIPICSI2 Packet level interrupt- One interrupt for the packet level errors and status

- Error based interrupt - This interrupt can have a variety of sources as described in the table below :

Table 49-13. General MIPICSI2 Packet level Error based interrupt

Source of error		Details	Error Level	Associated ERRPPST field
Double bit-error		Asserted when an ECC syndrome was computed and two bit-errors are detected in the received header.	Packet	
Single bit-error		Asserted when an ECC syndrome was computed and a single bit-error in the header was detected and corrected. Error Position	Packet	

Table continues on the next page...

Table 49-13. General MIPICSI2 Packet level Error based interrupt (continued)

Source of error		Details	Error Level	Associated ERRPPST field
		(MIPICSI2_ERRPOS) register contains the location where the single bit error was detected, but is only valid if is 1.		
Packet payload error		Asserted when the computed CRC code of the message payload is different than the received CRC code.	Packet	
Frame sync[1]		Asserted when Frame End (FE) is not paired with Frame Starts (FS). Several error cases can be identified for this type of error, such as, when a FS is followed by a second FS the frame corresponding to the first FS is considered an error, or when a packet level double bit-error was signaled from the protocol layer the whole transmission until the first DPHY stop state should be ignored since it contains no information that can be safely decoded and cannot be qualified with a data valid signal.	Protocol Decoding	
Unrecognized ID		Unimplemented or unrecognized ID in the header. Invalid ID Report Register (MIPICSI2_INVID) reports the invalid ID was found and what the invalid ID was.	Protocol Decoding	
Data payload received between FS and FE contains errors		Asserted after FE when the data payload received between FS and FE contains errors. This signal is asserted on any packet payload error and de-asserted on the first FE.	Protocol Decoding	

1. SoT synchronization also generates this error.

- Status based interrupt - This interrupt is triggered on any protocol based status update. After reset all sources are masked. Reading the relevant status register will provide the source. The sources are listed below.
  - Generic short packet received

3.MIPICSI2 data based interrupt. This interrupt is triggered on any error /status based update on the MIPICSI2 data reception

- Error based interrupt - This interrupt can have any of the following sources:

Table 49-14. MIPICSI2 data Error based interrupt

Source of error	Signal	Details	Associated INTRS field
Line Count Error	LCNTE	An error triggered by the hardware if number of lines expected by software are different from the one received by MIPICSI2	LCNT fields in the register Interrupt Status (MIPICSI2_INTRS)
Line Length Error	LLEN	An error triggered by the hardware if length of line expected by software is different from the one received by MIPICSI2	LLEN fields in the register Interrupt Status (MIPICSI2_INTRS)

- Status based interrupt - This interrupt is triggered by any of the following status on MIPICSI2 data reception:

Table 49-15. MIPICSI2 data Status based interrupt

Source of status	Signal	Details	Associated INTRS field
Frame Start	FS	A frame start received by MIPICSI2	FS fields in the register Interrupt Status (MIPICSI2_INTRS)
Frame End	FE	A frame end received by MIPICSI2	FE fields in the register Interrupt Status (MIPICSI2_INTRS)

49.8 Memory map and register definition

NOTE

Only 32-bit access is supported. Non-word accesses do not generate error response and are ignored.

MIPICSI2 memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	RX Controller Configuration Register (MIPICSI2_CONC)	32	R/W	0000_0000h	49.8.1/2286
4	PHY Configuration Register (MIPICSI2_PHYC)	32	R/W	0000_0002h	49.8.2/2287

48	Phy Error Interrupt Enable Register (MIPICSI2_ERPHYIE)	32	R/W	0000_0000h	49.8.15/ 2307
4C	RX Enable Register (MIPICSI2_RXEN)	32	R/W	0000_0000h	49.8.16/ 2310
50	Generic Short Packet Data Register (MIPICSI2_GNSP)	32	R	0000_0000h	49.8.17/ 2310
54	Invalid ID Report Register (MIPICSI2_INVID)	32	R	0000_0000h	49.8.18/ 2311
58	LINE LENGTH (MIPICSI2_LINLEN)	32	R/W	0000_0000h	49.8.19/ 2312
5C	Expected Number of Lines (MIPICSI2_EXPCTDL)	32	R/W	0000_0000h	49.8.20/ 2312
60	Interrupt Enable (MIPICSI2_INTREN)	32	R/W	0000_0000h	49.8.21/ 2313
64	Interrupt Status (MIPICSI2_INTRS)	32	w1c	0000_0000h	49.8.22/ 2314

49.8.1 RX Controller Configuration Register (MIPICSI2_CONC)

This register is used to configure the MIPICSI2 RX Controller.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0														NULANE	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

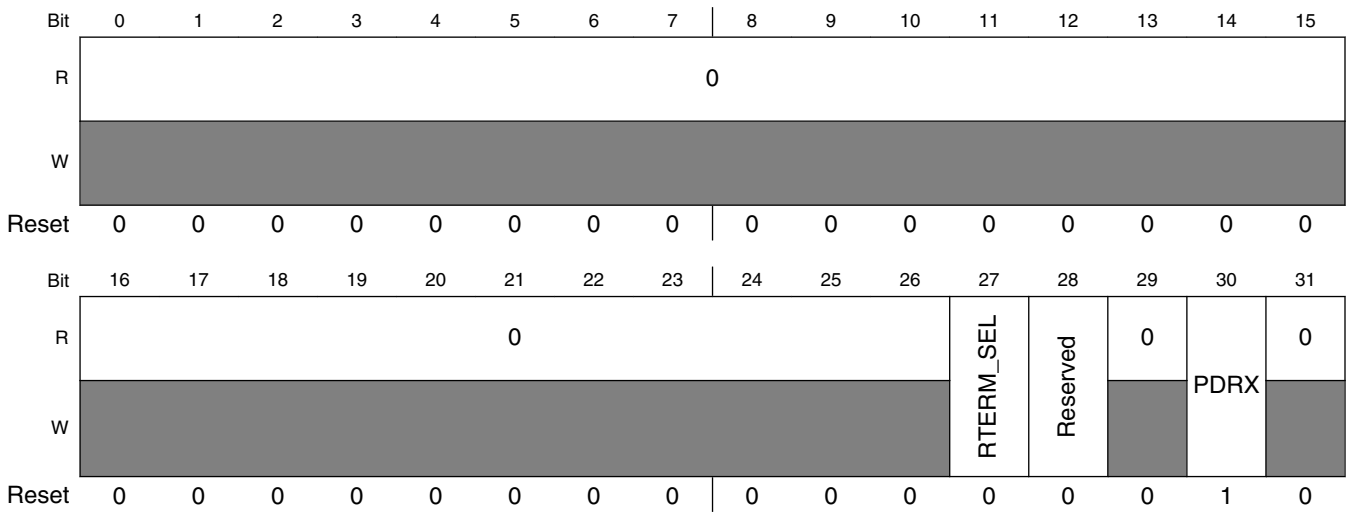
MIPICSI2_CONC field descriptions

Field	Description
0–29 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
30–31 NULANE	Number Of active Lanes being used to receive MIPICSI2 Data This field is to configure the number of data lanes to receive the MIPICSI2 data 00 One Lane to recieve MIPICSI2 data 01 Two Lanes to Receive MIPICSI2 Data 10 Three Lanes to Receive MIPICSI2 Data 11 Four Lanes to Receive MIPICSI2 Data

49.8.2 PHY Configuration Register (MIPICSI2_PHYC)

This register configures the D-PHY.

Address: 0h base + 4h offset = 4h



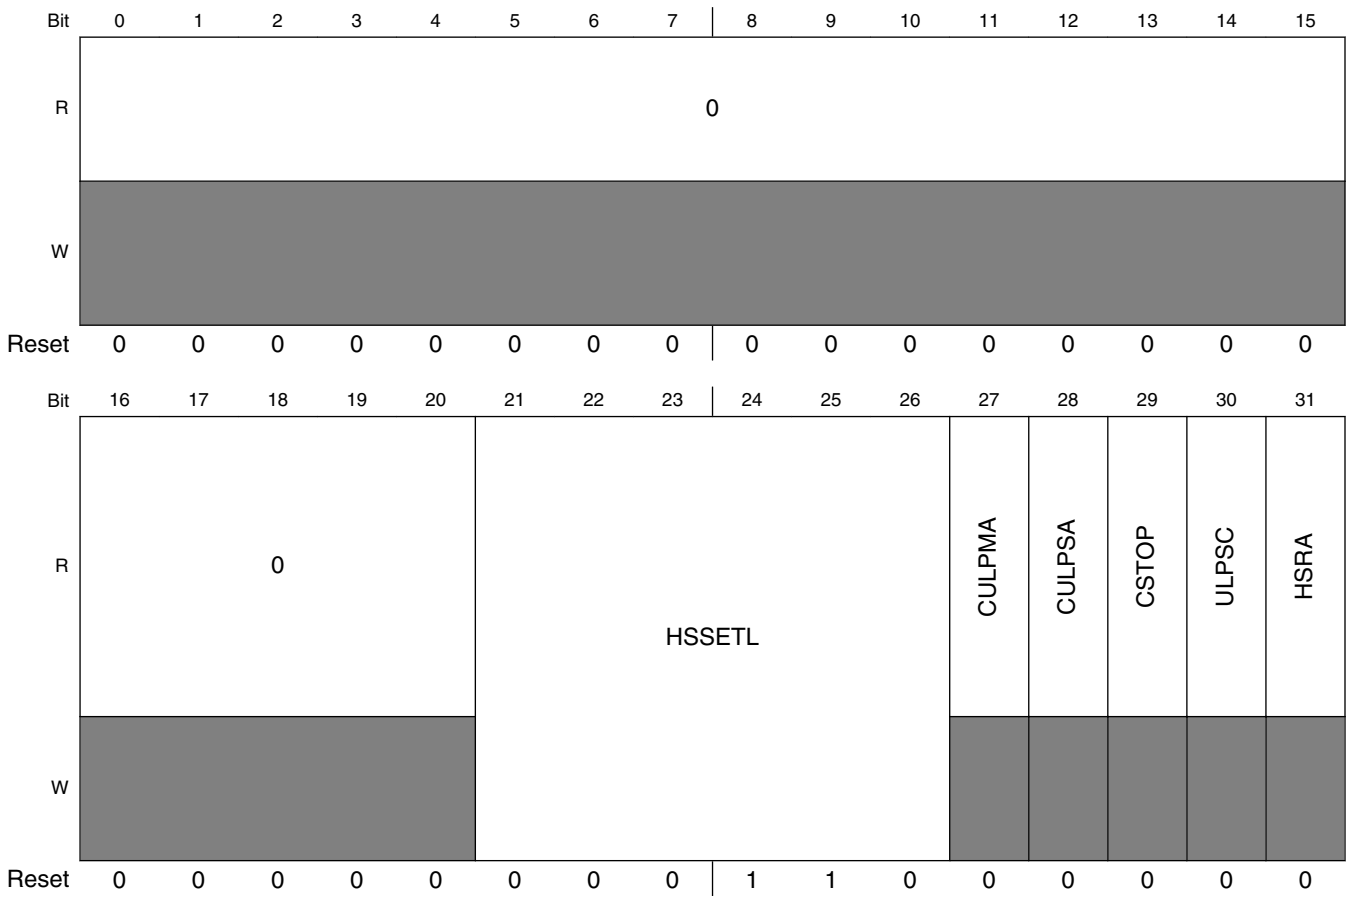
MIPICSI2_PHYC field descriptions

Field	Description
0–26 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
27 RTERM_SEL	Voltage Level selection for HS termination This field allows to select voltage level that enables HS termination 0 Low Power Receive level enables High Speed Termination 1 Low Power Contention Detector level enables High Speed Termination
28 Reserved	This field is reserved.
29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 PDRX	Power Down Receiver This field is the Power Down input for DPHY RX. When high, all blocks are powered down. 0 Power down disabled 1 Power down enabled for all blocks inside PHY
31 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.

49.8.3 Clock Configuration Status Register (MIPICSI2_CLKCS)

This register is used for configuration and status collection of the clock lane of D-PHY.

Address: 0h base + 8h offset = 8h



MIPICSI2_CLKCS field descriptions

Field	Description
0–20 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
21–26 HSSETL	Clock Lane Program RX HS Settle Time interval during which the HS receiver will ignore any Data Lane HS transitions. Refer to Settle Time for DPHY_RX for more details.
27 CULPMA	Clock Lane ULPS mark Active State This one bit field indicates that lane has exited ULPS and entered Mark-1 state[1]. While in Mark-1 state, High Speed data transmission is not allowed.

Table continues on the next page...

MIPICSI2_CLKCS field descriptions (continued)

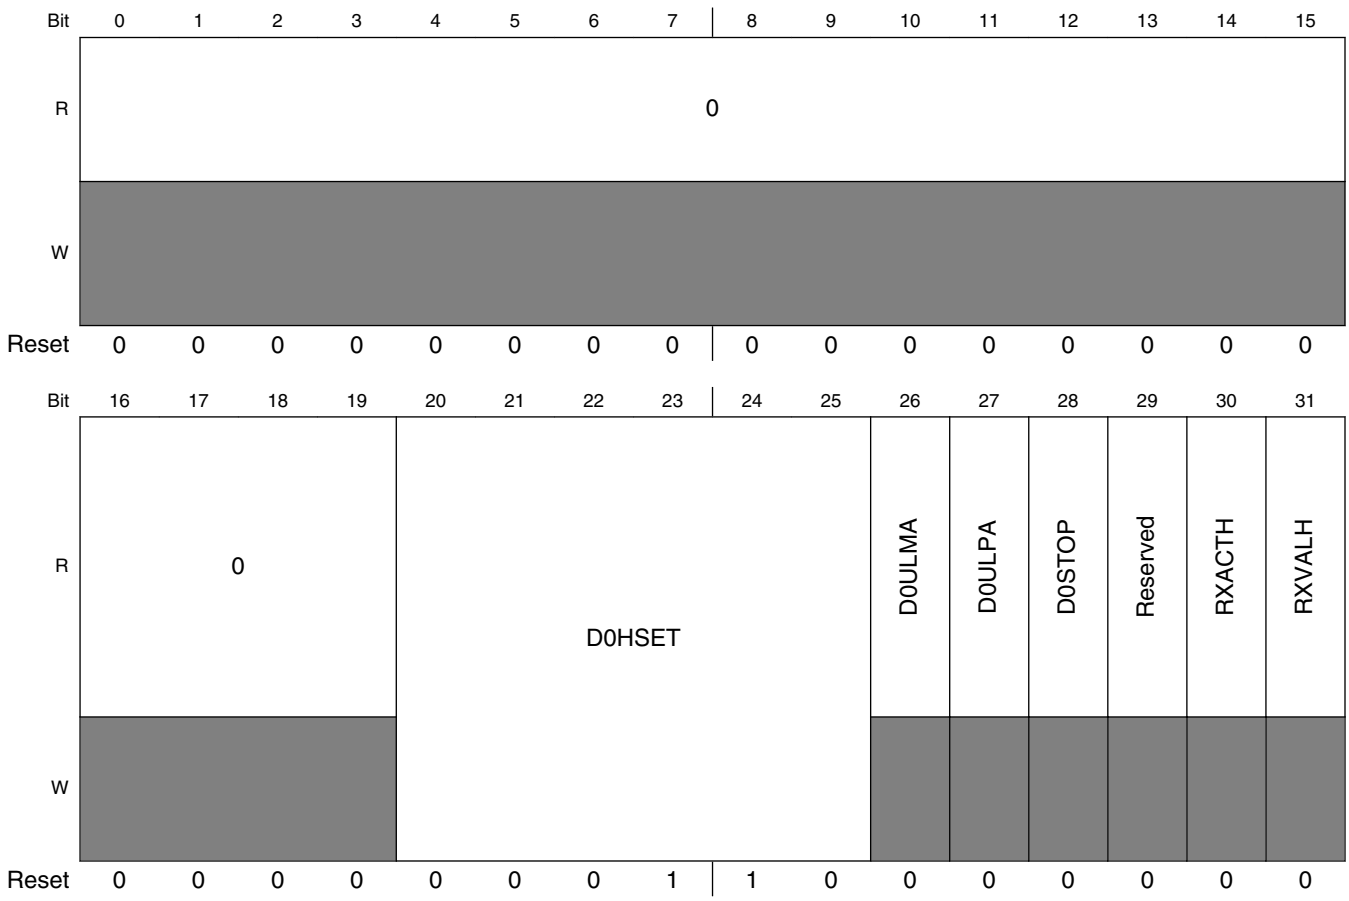
Field	Description
	0 Clock Lane not in Mark active state 1 Clock Lane is in mark active state
28 CULPSA	Clock Lane ULPS Active This one bit field indicates that clock lane is in Ultra Low Power State. This field deasserts the moment the lane enters mark one state. 0 Clock Lane not in ULPS mode 1 Clock Lane in ULPS mode
29 CSTOP	Clock Lane Stop State Clock Lane is in Stop state. This active high signal indicates that the Clock Lane, is currently in Stop state. **NOTE:** Default value would be 0 or 1 depending on when the register is read, before the clock gating is removed or after the clock gating is removed. Refer to Device Clocking Chapter that provides DPHY_ESCAPE_CLK implementation. 0 Clock Lane not in stop state 1 Clock Lane in stop state
30 ULPSC	Clock Lane ULPS This field is asserted to indicate that the Clock Lane Module has entered the Ultra Low-Power State. The Lane Module remains in this mode until a Stop state is detected on the Lane Interconnect. This bit is different from the CULPSA as the CULPSA is deasserted the moment we enter into mark one state, but this field remains asserted after entering the ULPS state till a stop state is detected on the lane. 0 Clock lane not in ultra low power state. 1 Clock Lane in ultra low power state.
31 HSRA	High Speed Clock Receive Active This asynchronous, active high signal indicates that the Clock Lane is receiving a DDR clock signal. 0 DDR clock not being received on the clock lane currently. 1 Clock lane is receiving DDR clock

1. As defined in MIPICSI2 Alliance Specification for D-PHY version 1.1 — 7 November 2011

49.8.4 D-PHY Lane 0 Configuration Status Register (MIPICSI2_LAN0CS)

This register is used for configuring the data lane0 in the D-PHY and for status collection from the lane.

Address: 0h base + Ch offset = Ch



MIPICSI2_LAN0CS field descriptions

Field	Description
0–19 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
20–25 D0HSET	Data lane 0 Program RX HS Settle time Refer to Settle Time for DPHY_RX for more details.
26 D0ULMA	Data Lane 0 ULPS Mark Active

Table continues on the next page...

MIPICSI2_LAN0CS field descriptions (continued)

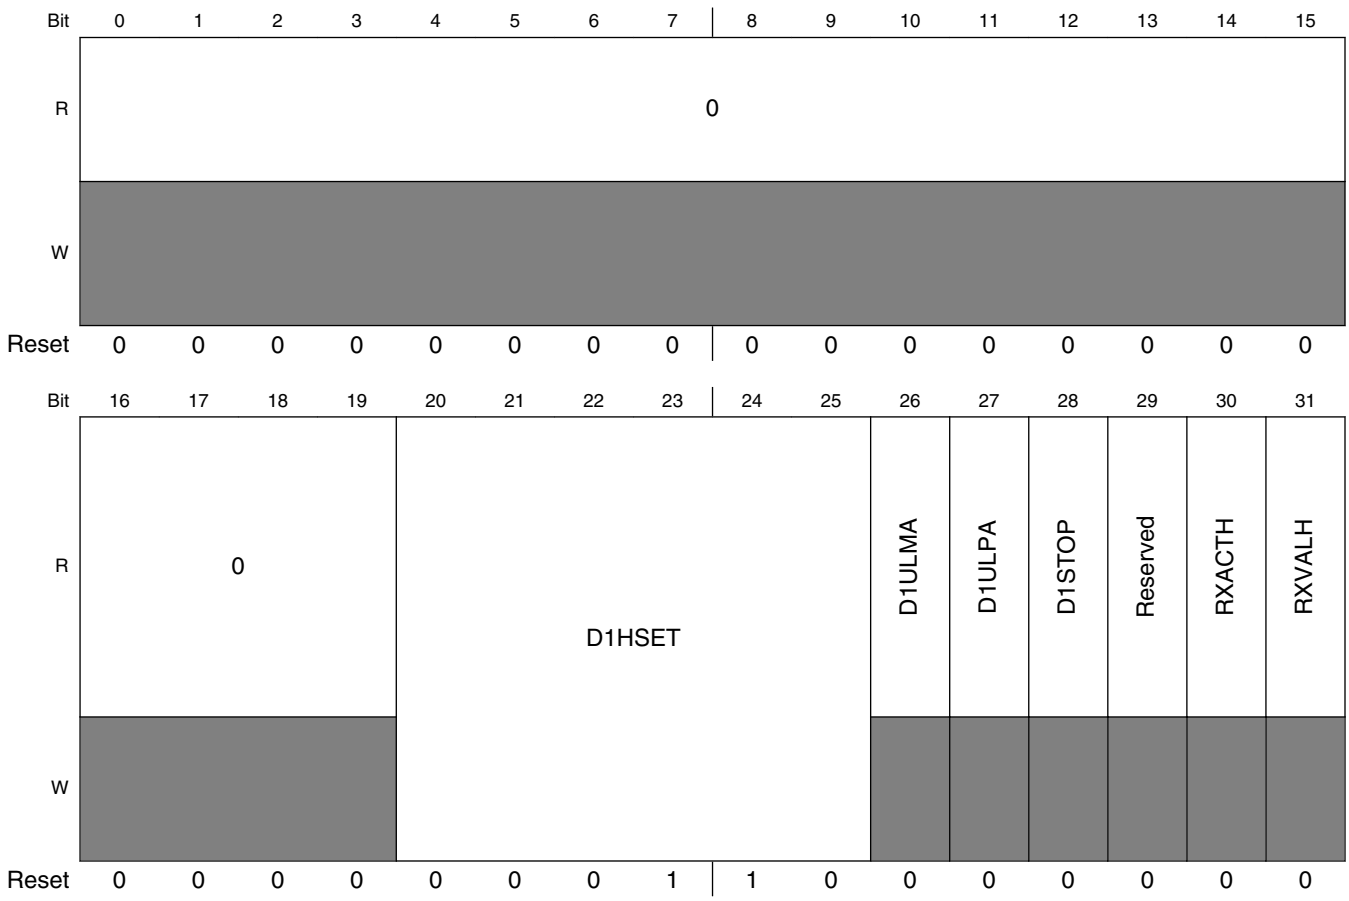
Field	Description
	Receive Ultra Low Power State Mark status. Bit asserts high when data lane 0 has exited ULPS and entered Mark-1 state[1]. While in Mark-1 state, no other active, like High Speed data transmission, is allowed. 0 Data lane 0 is not in Mark 1 state 1 Data lane 0 is in mark 1 state
27 D0ULPA	Data lane 0 ULPS Active Receive Ultra Low Power State active. Bit asserts high when data lane 0 is in ULPS mode. 0 Data Lane 0 ULPS not active 1 Data lane 0 ULPS Active
28 D0STOP	Data Lane 0 Stop State Data Lane 0 is in Stop state. This active high signal indicates that the Data Lane 0, is currently in Stop state. 0 Data lane 0 not in stop state 1 Data lane 0 in stop state.
29 Reserved	This field is reserved.
30 RXACTH	D-PHY Data lane 0 RX active High Speed data This active high field indicates that the lane module is actively receiving high speed data on the lane interconnect. 0 No High Speed data reception ongoing from the lane interconnect. 1 High speed data reception ongoing from lane interconnect.
31 RXVALH	Data Lane 0 RX Valid HS High Speed Receive data on lane 0 is valid. This active high signal indicates that data lane 0 is driving High Speed data on the controller interface. 0 No Valid High Speed data being driven from data lane 0 to MIPICSI2 RX controller 1 Valid High Speed data being driven from data lane 0 to MIPICSI2 RX Controller.

1. As defined in MIPICSI2 Alliance Specification for D-PHY version 1.1 — 7 November 2011

49.8.5 D-PHY Data LANE 1 Configuration Status Register (MIPICSI2_LAN1CS)

This register is used for configuring the Data Lane 1 of D-PHY and collecting the status from this data lane.

Address: 0h base + 10h offset = 10h



MIPICSI2_LAN1CS field descriptions

Field	Description
0–19 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
20–25 D1HSET	D_PHY Data Lane 1 PRG HS Settle time Time interval during which the data lane 1 HS receiver will ignore any HS transitions on the data lane. Refer to Settle Time for DPHY_RX for more details.
26 D1ULMA	D_PHY Data Lane 1 ULPS Mark active

Table continues on the next page...

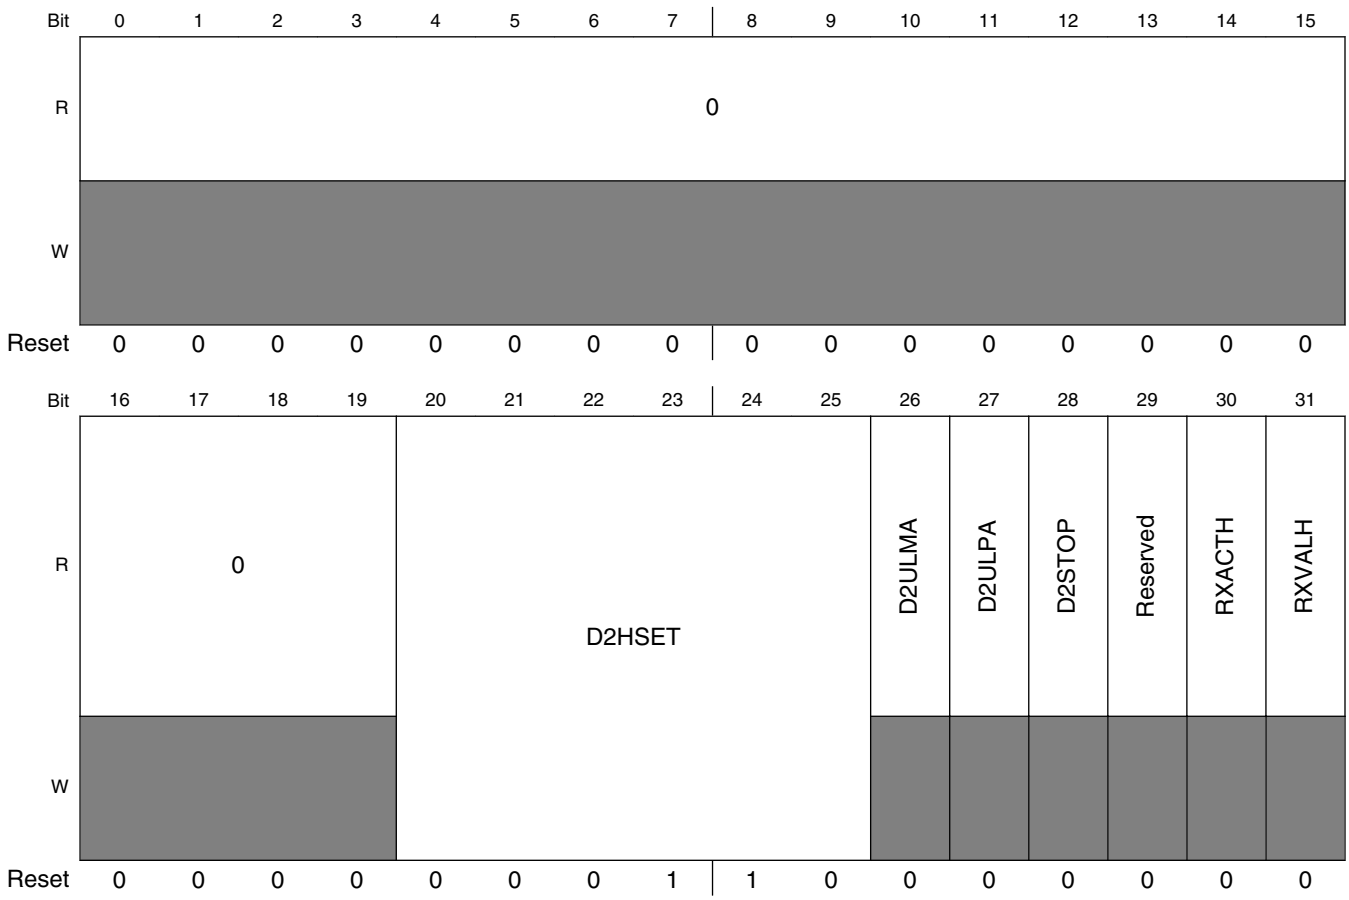
MIPICSI2_LAN1CS field descriptions (continued)

Field	Description
	0 Data Lane 1 not in ULPS mark active state 1 Data Lane 1 in ULPS Mark Active state
27 D1ULPA	D-PHY Data Lane 1 ULPS Active Receive Ultra Low Power State active. Bit asserts high when data lane 1 is in ULPS mode. 0 Data lane not in ULPS state 1 Data Lane 1 in ULPS state
28 D1STOP	D-PHY Data Lane 1 Stop Data Lane 1 is in Stop state. This active high signal indicates that the Data Lane 1 , is currently in Stop state. 0 Data lane 1 is not in stop state 1 Data lane 1 is in stop state
29 Reserved	This field is reserved.
30 RXACTH	D-PHY Data lane 1 Active HS This active high field indicates that the data lane 1 is actively receiving high speed data on the lane interconnect. 0 Data lane 1 not receiving high speed active data on the lane interconnect 1 Data Lane 1 receiving active high speed data on the lane interconnect
31 RXVALH	D-PHY Data lane 1 Receive Valid High speed High Speed Receive data on lane 1 is valid. This active high signal indicates that data lane 1 is driving High Speed data on the controller interface. 0 No Valid High speed data being driven from data lane 1 to the MIPICSI2 RX controller. 1 Valid HS data being transmitted from data lane 1 to the MIPICSI2 RX controller

49.8.6 LANE 2 Configuration/Status Register (MIPICSI2_LAN2CS)

This register is used for configuring the Data Lane 2 of D-PHY and collecting the status from this data lane.

Address: 0h base + 14h offset = 14h



MIPICSI2_LAN2CS field descriptions

Field	Description
0–19 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
20–25 D2HSET	DPHY Data Lane 2 Sette Time Time interval during which the data lane 2 HS receiver will ignore any HS transitions on the data lane. Refer to Settle Time for DPHY_RX for more details.
26 D2ULMA	DPHY Data Lane 2 Mark One state This field indicates that data lane2 is in mark one state.

Table continues on the next page...

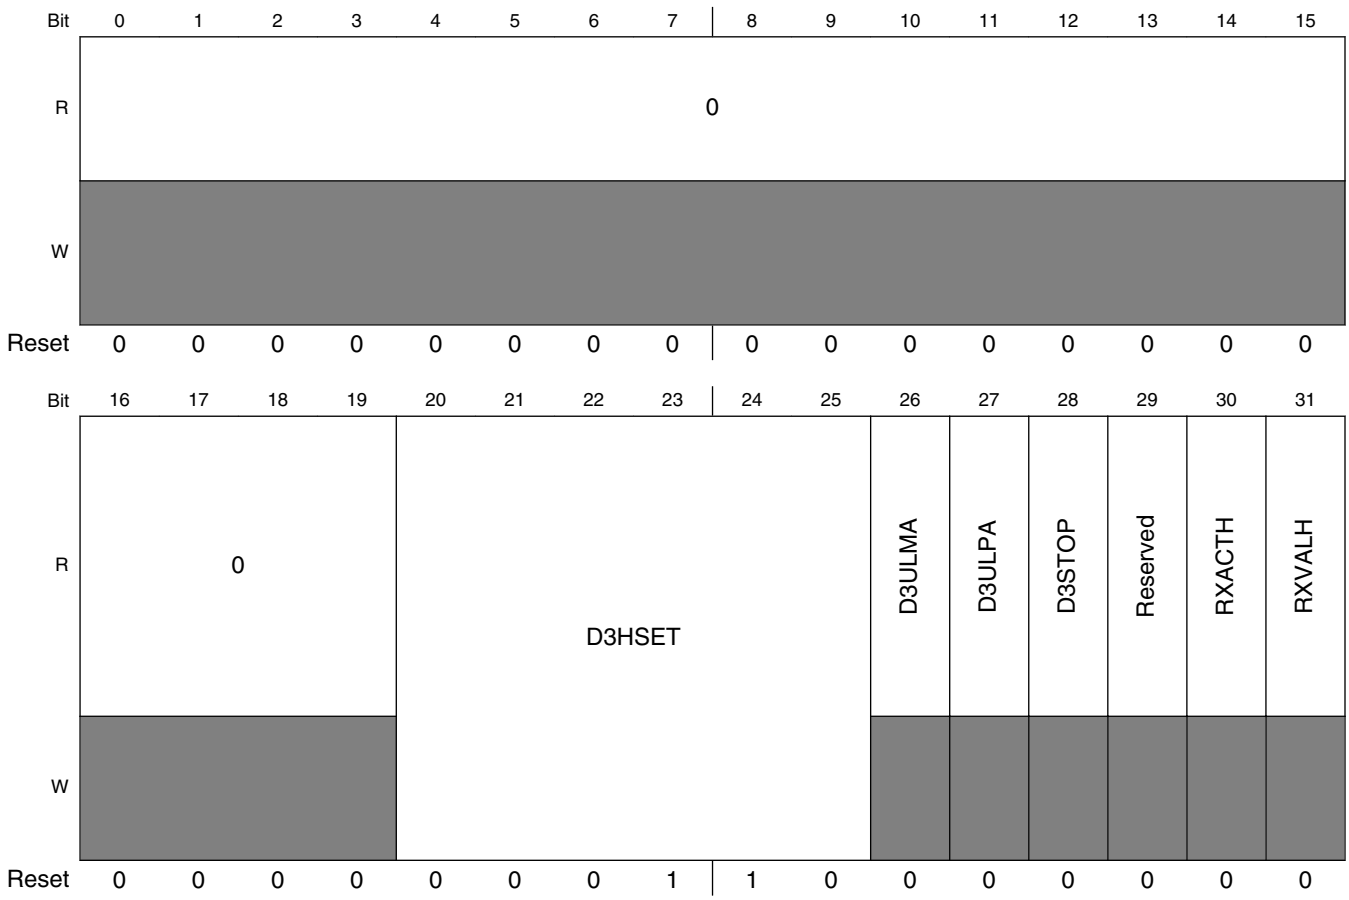
MIPICSI2_LAN2CS field descriptions (continued)

Field	Description
27 D2ULPA	DPHY Dat aLane 2 in Ulps State Receive Ultra Low Power State active. Bit asserts high when data lane 2 is in ULPS mode.
28 D2STOP	DPHY Data Lane 2 Stop State Data Lane 2 is in Stop state. This active high signal indicates that the Data Lane 2 , is currently in Stop state.
29 Reserved	This field is reserved.
30 RXACTH	DPHY Data Lane 2 High Speed Receive Active This active high field indicates that the data lane 2 is actively receiving high speed data on the lane interconnect.
31 RXVALH	High Speed Receive Data Valid High Speed Receive data on lane 2 is vaild. This active high signal indicates that data lane 2 is driving High Speed data on the controller interface.

49.8.7 LANE3 Configuration Status Register (MIPICSI2_LAN3CS)

This register is used for configuring the Data Lane 3 of D-PHY and collecting the status from this data lane.

Address: 0h base + 18h offset = 18h



MIPICSI2_LAN3CS field descriptions

Field	Description
0–19 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
20–25 D3HSET	DPHY Data Lane 3 High Speed Receive Settle Time Time interval during which the data lane 3 HS receiver will ignore any HS transitions on the data lane. Refer to Settle Time for DPHY_RX for more details.
26 D3ULMA	DPHY Data Lane 3 Mark One State This field indicates that data lane3 is in mark one state.

Table continues on the next page...

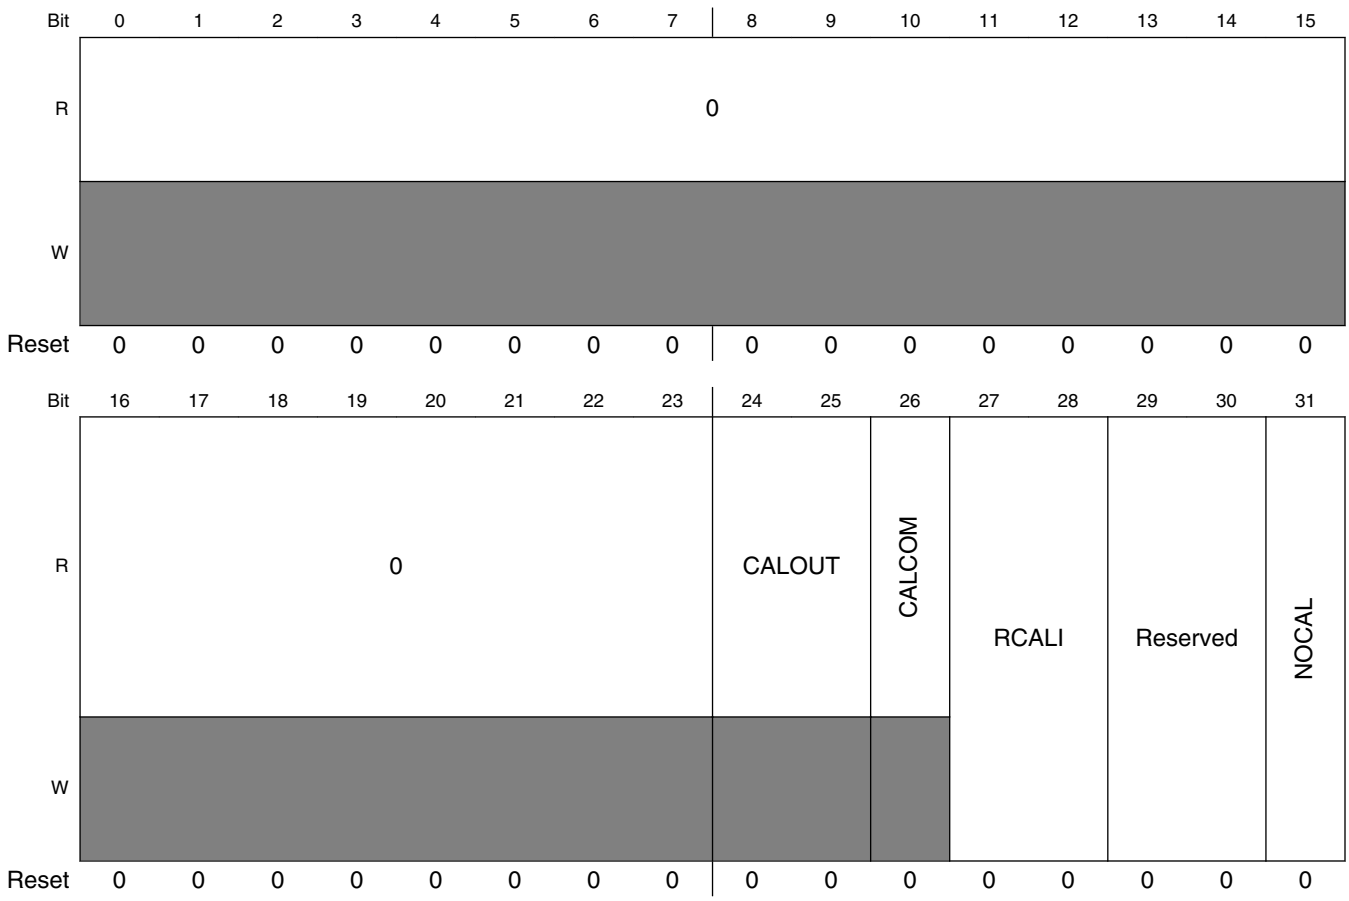
MIPICSI2_LAN3CS field descriptions (continued)

Field	Description
27 D3ULPA	DPHY Data Lane 3 ULPS State Receive Ultra Low Power State active. Bit asserts high when data lane 3 is in ULPS mode.
28 D3STOP	DPHY Data Lane 3 Stop State Data Lane 3 is in Stop state. This active high signal indicates that the Data Lane 3 , is currently in Stop state.
29 Reserved	Reserved This field is reserved. This field is reserved.
30 RXACTH	DPHY Data Lane3 High Speed Receive Active This active high field indicates that the data lane 3 is actively receiving high speed data on the lane interconnect.
31 RXVALH	High Speed Receive Data Vaild High Speed Receive data on lane 3 is vaild. This active high signal indicates that data lane 3 is driving High Speed data on the controller interface.

49.8.8 External Resistor Configuration Status Register (MIPICSI2_RESCS)

This register is used for configuring the external resistor and capturing the status of any calibration done.

Address: 0h base + 20h offset = 20h



MIPICSI2_RESCS field descriptions

Field	Description
0–23 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
24–25 CALOUT	Calibrator output This field gives the Calibrator Outputs
26 CALCOM	Calibration Complete Used for indicating calibration is complete

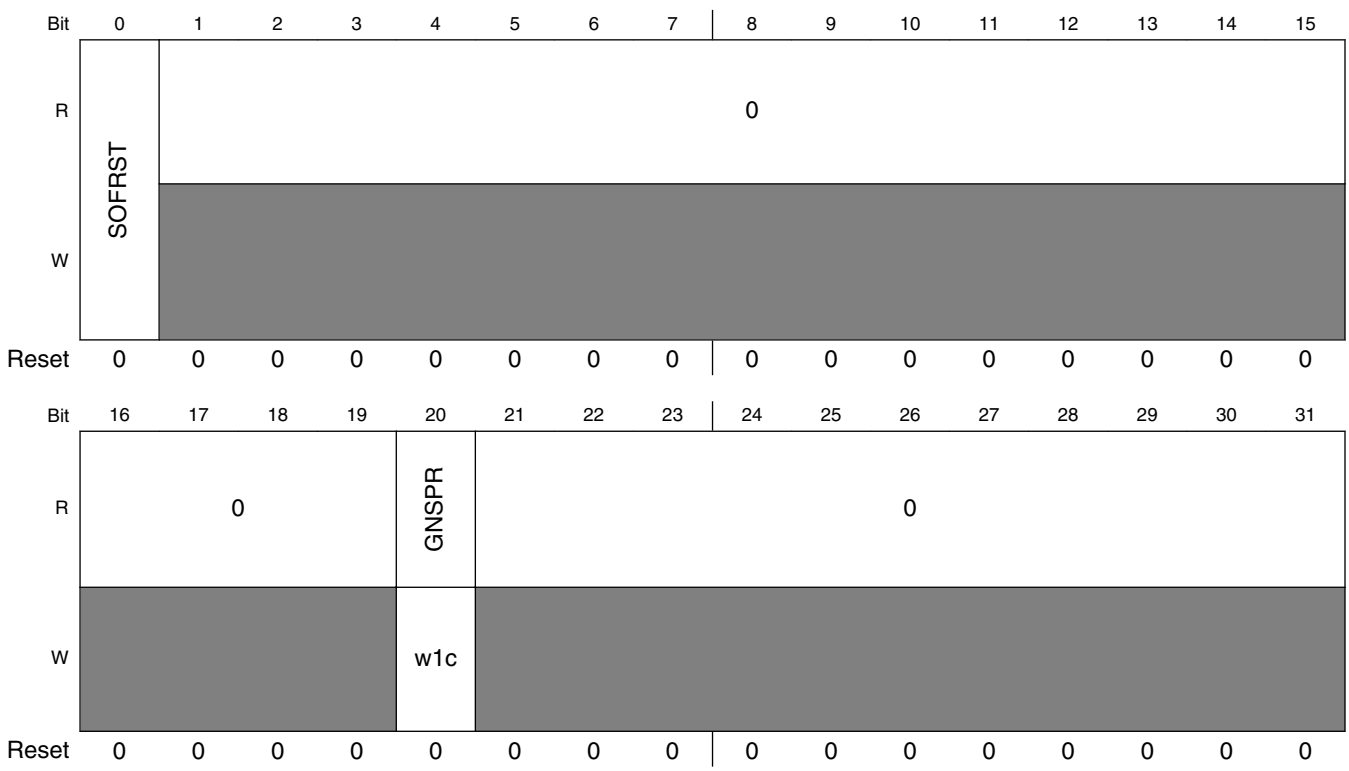
Table continues on the next page...

MIPICSI2_RESCS field descriptions (continued)

Field	Description
	0 Calibration incomplete 1 Calibration Complete
27–28 RCALI	Resistor Calibration Input This field provides On-chip termination control bits for manual calibration. Only active when NOCAL asserted
29–30 Reserved	This field is reserved.
31 NOCAL	No Calibration Used to override calibration value set by auto-calibration circuit with RCALI[1:0]. Set to 0 in auto-calibration operation. 0 Auto Calibration 1 No auto Calibration, manual calibration.

49.8.9 Status Register (MIPICSI2_SR)

Address: 0h base + 28h offset = 28h



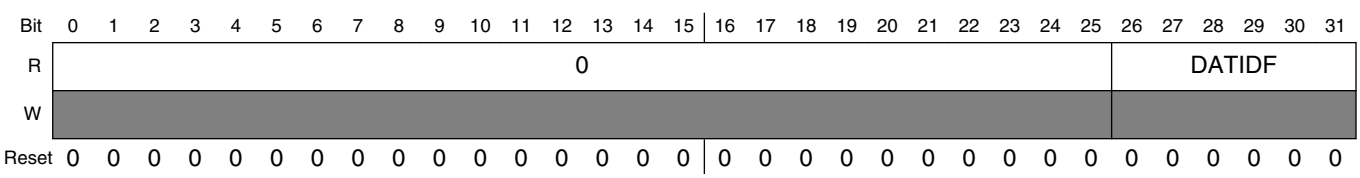
MIPICSI2_SR field descriptions

Field	Description
0 SOFRST	Software reset This field is used to soft reset the IP. The software needs to write a zero to clear this bit. 0 No soft reset requested 1 Soft Reset requested by Software. When set it causes a reset of all the registers and all the FIFOs will be flushed.
1–19 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
20 GNSPR	Generic Short Packet Received This field when set indicates that a generic short packet was received. 0 No generic short packet field was received. 1 Generic Short Packet field was received.
21–31 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.

49.8.10 DataID Report Register (MIPICSI2_DATAID)

This register reports the data type that is being currently received. It is valid only if INVID field in ERRREG is cleared.

Address: 0h base + 2Ch offset = 2Ch



MIPICSI2_DATAID field descriptions

Field	Description
0–25 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
26–31 DATIDF	Data ID Field This six bit field reports the current data type being received by the MIPICSI2 subsystem. This field is valid only when INVID field in error register is not set. 0x00h Frame start 0x01h Frame end

Table continues on the next page...

MIPICSI2_DATAID field descriptions (continued)

Field	Description	
	0x02h	Line start
	0x03h	Line end
	0x04h-0X07h	Unused
	0x10h	Null data
	0x11h	Blanking data
	0X12	Embedded data
	0x1Eh	YUV 422 - 8bit data
	0x1Fh	YUV 422 10 bit data
	0x22h	RGB565 data
	0x23h	Unused
	0x24h	RGB888 data
	0x2Ah	RAW8 data
	0x2Bh	RAW10 data
	0x2Ch	RAW12 data
	0x2Dh	RAW14 data
	0x30h-0x37h	User defined data
	0X38h-0X3Fh	Reserved

49.8.11 Protocol and Packet Error Register (MIPICSI2_ERRPPREG)

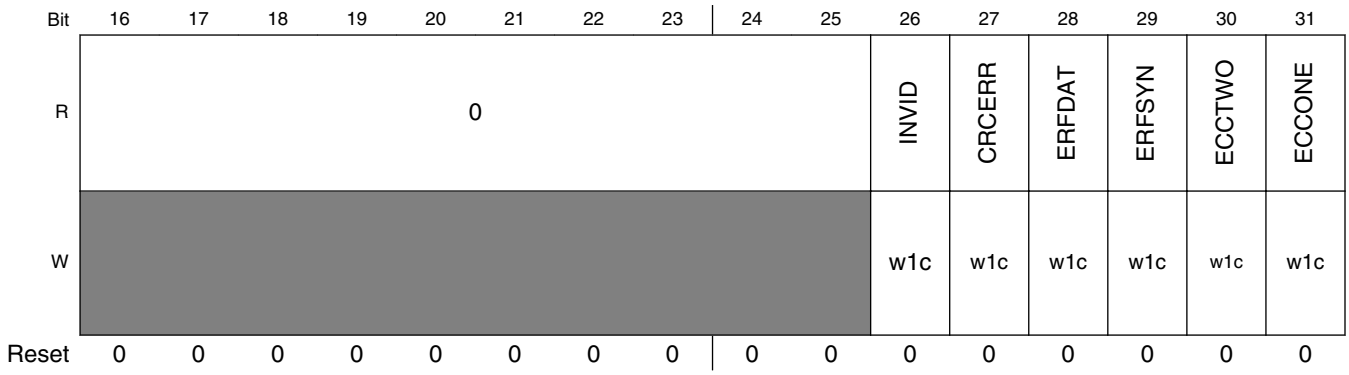
This register stores the errors seen at the receiving side of MIPICSI2 subsystem. It includes protocol and packet level errors.

NOTE

All the bits of this register are W1c , the value of these register fields would indicate: 0 - non occurrence of cause of error or bit cleared 1 - error occurred

Address: 0h base + 34h offset = 34h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0



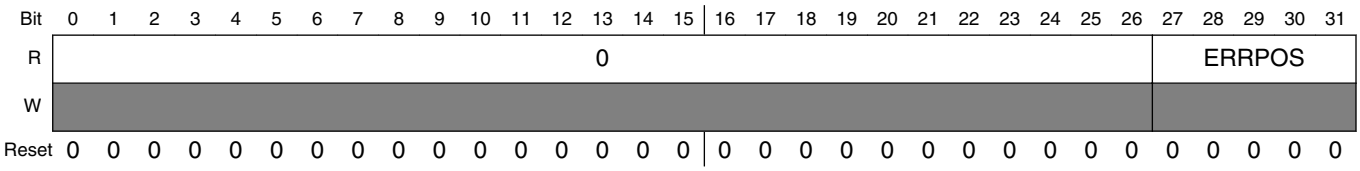
MIPICSI2_ERRPPREG field descriptions

Field	Description
0–25 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
26 INVID	Invalid ID When set, this field indicates an invalid data type was detected.
27 CRCERR	CRC Error When set , this field indicates a CRC error in the received payload.
28 ERFDAT	Frame data error This field indicates an error in the data within a frame. It sets when a CRC error is detcted on the received payload.
29 ERFSYN	Frame synchronization error When set , this field indicates an error in frame Synchronization. It can be set when : 1.frame start is received after frame start without a frame end in between 2.frame end is received after frame end without a frame start in between 3.Double bit ECC error was detected in received packet header 4.Two bit error in high speed Synchronization pattern was detected.
30 ECCTWO	ECC Two Bit Error When this bit is set it indicates that a two bit ECC error was detected in the received packet header.
31 ECCONE	ECC one bit error When set , this bit indicates that a one bit ECC error was detected and corrected in the received packet header

49.8.12 Error Position (MIPICSI2_ERRPOS)

This register indicates the position at which one bit error was detected in ECC.

Address: 0h base + 38h offset = 38h



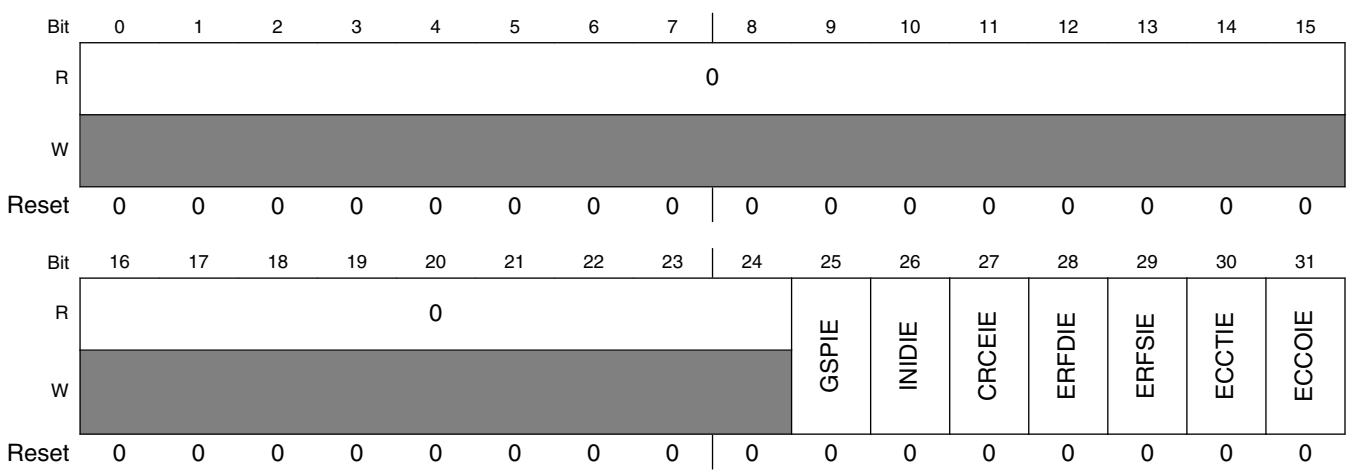
MIPICSI2_ERRPOS field descriptions

Field	Description
0–26 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
27–31 ERRPOS	Error Position This field indicates the location where a one bit error was detected in the ECC by the MIPICSI2 RX controller. The value of this field is valid only if the ECCONE field in the error register is set.

49.8.13 Protocol Packet Error Interrupt Enable (MIPICSI2_ERPPINTEN)

This register is used to enable interrupts corresponding to various errors and status generated at protocol and packet level that are recorded in the error protocol and packet register or status register register.

Address: 0h base + 3Ch offset = 3Ch



MIPICSI2_ERPPINTEN field descriptions

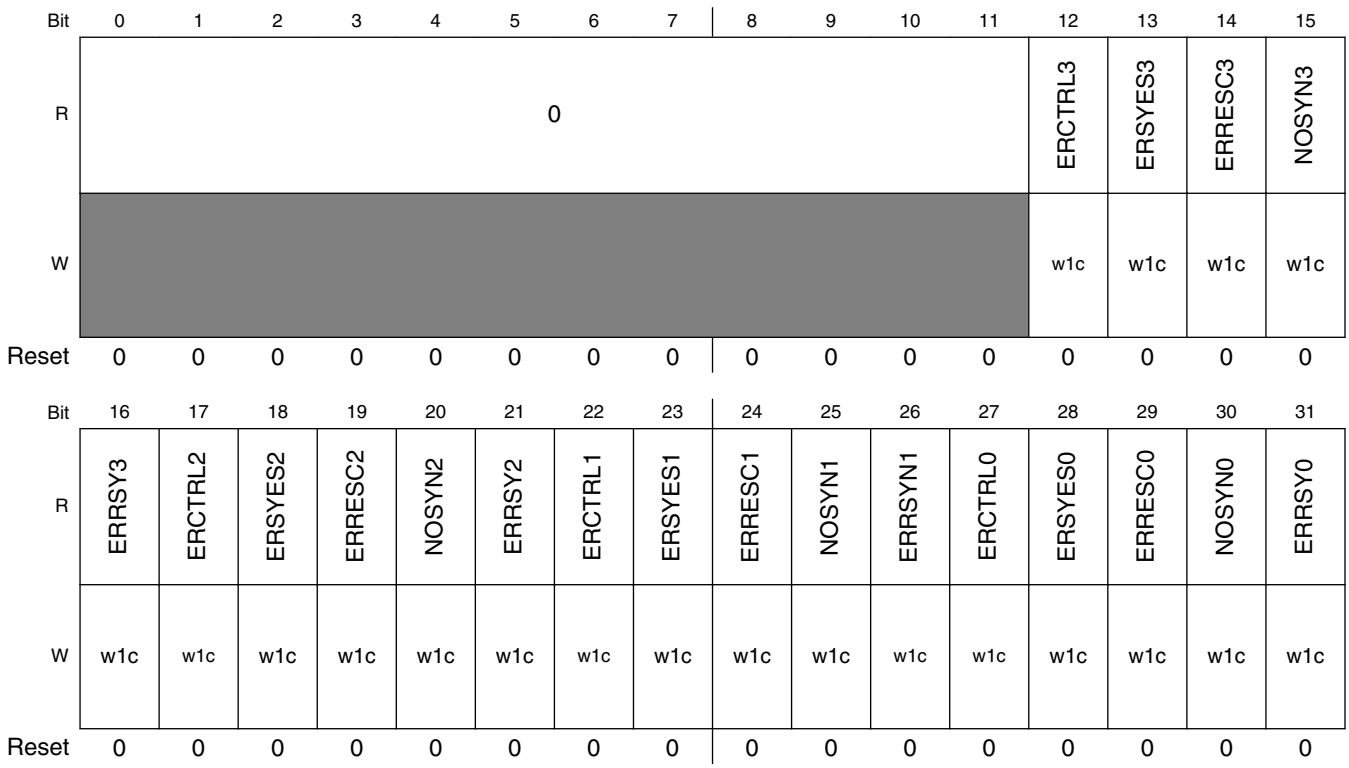
Field	Description
0–24 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
25 GSPIE	Generic Short Packet Interrupt Enable This field enables interrupt generation on reception of a generic short packet . 0 Interrupt on generic short packet reception disabled 1 Interrupt on generic short packet reception enabled
26 INIDIE	Invalid ID Error Interrupt Enable This field enables interrupt generation when the INVID field in the error register is set 0 Interrupt on invalid ID error disabled 1 Interrupt on Invalid ID error enabled
27 CRCEIE	CRC Error Interrupt Enable This field enables interrupt generation when the CRCERR field in the error register is set 0 Interrupt on CRC error disabled 1 Interrupt on CRC error enabled
28 ERFDIE	Error Frame Data Interrupt Enable This field enables interrupt generation when the ERFDAT field in the error register is set 0 Interrupt on frame data error disabled 1 Interrupt on frame data error enabled
29 ERFSIE	Frame Synchronization Error Interrupt Enable This field enables interrupt generation when the ERFSYN field in the error register is set 0 Interrupt on frame Synchronization error disabled 1 Interrupt on frame Synchronization error enabled
30 ECCTIE	ECC Two Interrupt Enable This field enables interrupt generation when the ECCTWO field in the error register is set 0 Interrupt on ECC two bit error disabled 1 Interrupt on ECC two bit error enabled
31 ECCOIE	ECC One Interrupt Enable 0 Interrupt on ECC one bit error disabled 1 Interrupt on ECC one bit error enabled

49.8.14 PHY Error Report Register (MIPICSI2_ERRPHY)

NOTE

All the bits of this register are W1c , the value of these register fields would indicate: 0 - non occurrence of cause of error or bit cleared 1 - error occurred

Address: 0h base + 44h offset = 44h



MIPICSI2_ERRPHY field descriptions

Field	Description
0–11 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
12 ERCTRL3	Control Error on lane 3 When set, this field indicates that an incorrect line state sequence was detected on data lane 3.
13 ERSYES3	Synchronization error in Escape mode on lane 3 When set, this field indicates that a Synchronization error in escape mode on data lane 3 was detected. The field sets if the number of bits received during low power data transmission is not a multiple of eight when the transmission ends.

Table continues on the next page...

MIPICSI2_ERRPHY field descriptions (continued)

Field	Description
14 ERRESC3	Escape Mode Entry Error on lane 3 When set, this field indicates that an error was detected in the escape mode entry sequence on lane 3.
15 NOSYN3	No Synchronization Error Lane 3 When set, this field indicates that more than one bit error was detected in the high speed SoT Synchronization pattern on data lane 3.
16 ERRSY3	Error in the synchronization pattern detected by PHY in lane3 When set , this field indicates that a single bit error in the high speed SOT Synchronization pattern was detected and corrected on data lane 3.
17 ERCTRL2	Control Error on lane 2 When set, this field indicates that an incorrect line state sequence was detected on data lane 2.
18 ERSYES2	Synchronization error in Escape mode on lane 2 When set, this field indicates that a Synchronization error in escape mode on data lane 2 was detected. The field sets if the number of bits received during low power data transmission is not a multiple of eight when the transmission ends.
19 ERRESC2	Escape Mode Entry Error on lane 2 When set, this field indicates that an error was detected in the escape mode entry sequence on lane 2.
20 NOSYN2	No Synchronization Error Lane 2 When set, this field indicates that more than one bit error was detected in the high speed SoT Synchronization pattern on data lane 2.
21 ERRSY2	Error in the synchronization pattern detected by PHY in lane2 When set , this field indicates that a single bit error in the high speed SOT Synchronization pattern was detected and corrected on data lane 2.
22 ERCTRL1	Control Error on lane 1 When set, this field indicates that an incorrect line state sequence was detected on data lane 1.
23 ERSYES1	Synchronization error in Escape mode on lane 1 When set, this field indicates that a Synchronization error in escape mode on data lane 1 was detected. The field sets if the number of bits received during low power data transmission is not a multiple of eight when the transmission ends.
24 ERRESC1	Escape Mode Entry Error on lane 1 When set, this field indicates that an error was detected in the escape mode entry sequence on lane 1.
25 NOSYN1	No Synchronization Error Lane 1 When set, this field indicates that more than one bit error was detected in the high speed SoT Synchronization pattern on data lane 1.
26 ERRSYN1	Error in the synchronization pattern detected by PHY in lane1 When set , this field indicates that a single bit error in the high speed SOT Synchronization pattern was detected and corrected on data lane 1.
27 ERCTRL0	Control Error on lane 0

Table continues on the next page...

MIPICSI2_ERRPHY field descriptions (continued)

Field	Description
	When set, this field indicates that an incorrect line state sequence was detected on data lane 0.
28 ERSYES0	Synchronization error in Escape mode on lane 0 When set, this field indicates that a Synchronization error in escape mode on data lane 0 was detected. The field sets if the number of bits received during low power data transmission is not a multiple of eight when the transmission ends.
29 ERRESC0	Escape Mode Entry Error on lane 0 When set, this field indicates that an error was detected in the escape mode entry sequence on lane 0
30 NOSYN0	No Synchronization Error Lane 0 on HS entry When set, this field indicates that more than one bit error was detected in the high speed SoT Synchronization pattern on data lane 0.
31 ERRSY0	Error in the synchronization pattern detected by PHY in lane0 When set , this field indicates that a single bit error in the high speed SOT Synchronization pattern was detected and corrected on data lane 0.

49.8.15 Phy Error Interrupt Enable Register (MIPICSI2_ERPHYIE)

This register is used to enable interrupts corresponding to various errors and status generated at protocol and packet level that are recorded in the error protocol and packet register or status register.

Address: 0h base + 48h offset = 48h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

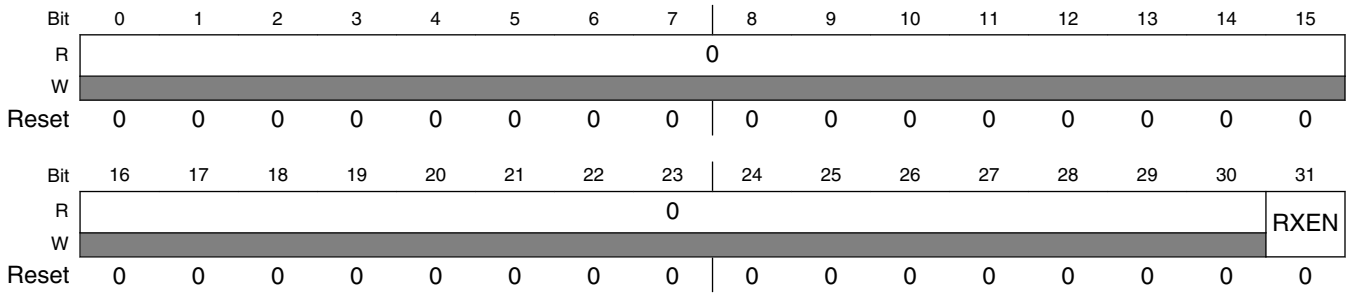
49.8.16 RX Enable Register (MIPICSI2_RXEN)

This register is used to pause the receive data from the MIPICSI2 controller to the user interface on the next packet boundary.

Address: 0h base + 4Ch offset = 4Ch



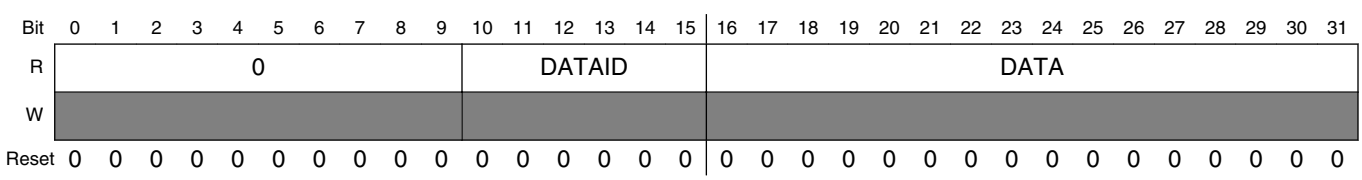
MIPICSI2_RXEN field descriptions

Field	Description
0–30 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
31 RXEN	Receive enable When asserted, this field will enable the receive module for reception of video data from the MIPICSI2 transmitter . When deasserted, the receive module will be disabled . 0 RX disabled 1 RX enabled

49.8.17 Generic Short Packet Data Register (MIPICSI2_GNSP)

This register stores the data field of any generic short packet data received.

Address: 0h base + 50h offset = 50h



MIPICSI2_GNSP field descriptions

Field	Description
0–9 Reserved	Reserved This field is reserved.

Table continues on the next page...

MIPICSI2_GNSP field descriptions (continued)

Field	Description
	This read-only field is reserved and always has the value 0.
10–15 DATAID	Data type This field indicates the type of data in the generic short data packet received. The value of this field is valid only if the field GNSPR in the status register is set. 0x08 Generic short packet code 1 0x09 Generic short packet code 2 0x0A Generic short packet code 3 0x0B Generic short packet code 4 0x0C Generic short packet code 5 0x0D Generic short packet code 6 0x0E Generic short packet code 7 0x0F Generic short packet code 8
16–31 DATA	Data field of a generic short packet This register stores the data field of a generic short packet. The value of this field is valid only if GNSPR field in the status register is set.

49.8.18 Invalid ID Report Register (MIPICSI2_INVID)

This register gives the value of the data id received if the data id is of an unrecognized type.

Address: 0h base + 54h offset = 54h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

MIPICSI2_INVID field descriptions

Field	Description
0–25 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
26–31 INVID	Invalid ID This field reports the invalid ID when an unrecognized data type is received. The value of this field is valid only when INVID in error register is set.

49.8.19 LINE LENGTH (MIPICSI2_LINLEN)

This register indicates the length of each line in MIPICSI2 data

NOTE

Number of lines capture should be programmed to a non zero value.

Address: 0h base + 58h offset = 58h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

MIPICSI2_LINLEN field descriptions

Field	Description
0–15 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
16–31 LINLEN	LINE LENGTH

49.8.20 Expected Number of Lines (MIPICSI2_EXPCTDL)

This register indicates the expected number of lines in a frame .

NOTE

Total lines expected in a frame should be non zero.

Address: 0h base + 5Ch offset = 5Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

MIPICSI2_EXPCTDL field descriptions

Field	Description
0–15 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

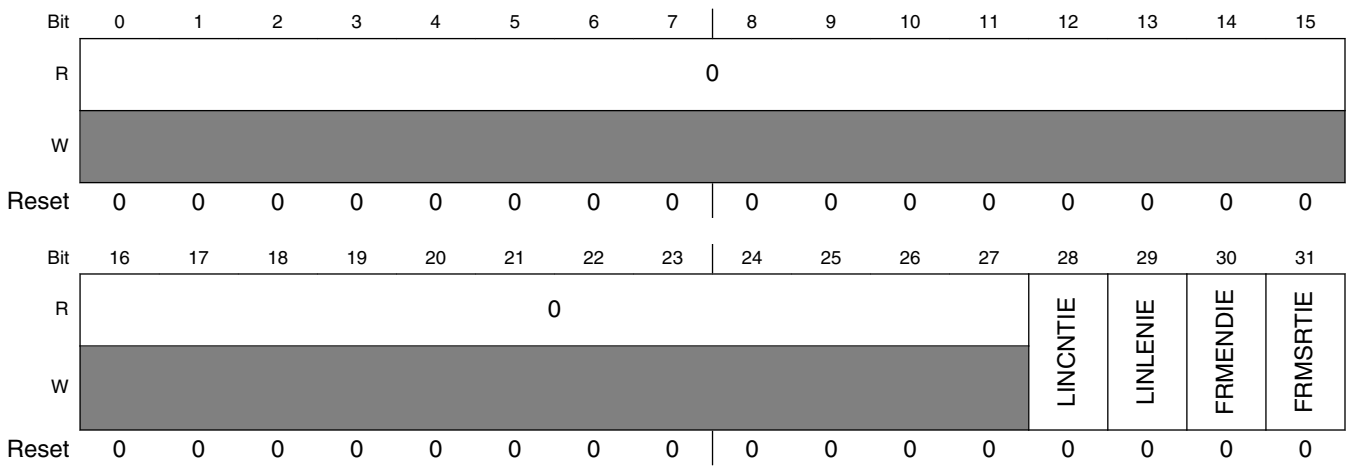
MIPICSI2_EXPCTDL field descriptions (continued)

Field	Description
16–31 EXPLINES	Expected Number Of Lines In a Frame This field allows the programming for the expected number of lines in a frame.

49.8.21 Interrupt Enable (MIPICSI2_INTREN)

This register allows interrupts to be enabled on certain events occurring during MIPICSI2 data capture.

Address: 0h base + 60h offset = 60h



MIPICSI2_INTREN field descriptions

Field	Description
0–27 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
28 LINCNTIE	Line Count Error Interrupt Enable This field allows enabling interrupt on a line count error detection. 0 Interrupt on Line Count Error disabled 1 Interrupt on Line Count Error enabled
29 LINLENIE	Line Length Error Interrupt Enable This field allows enabling of interrupt when incorrect line length is observed . 0 Interrupt on Line Length Error Disabled 1 Interrupt on Line Length Error enabled

Table continues on the next page...

MIPICSI2_INTREN field descriptions (continued)

Field	Description
30 FRMENDIE	Frame End Detection Interrupt Enable This field allows enabling interrupt for frame end detection . 0 Interrupt on frame end indication disabled 1 Interrupt on frame end indication enabled
31 FRMSRTIE	Frame Start Detected Interrupt Enable This field allows enabling interrupt when a frame start is detected. 0 Interrupt on frame start indication disabled 1 Interrupt on frame start indication Enabled

49.8.22 Interrupt Status (MIPICSI2_INTRS)

This register indicates the status of interrupt for the events during MIPICSI2 data capture.

Address: 0h base + 64h offset = 64h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Chapter 50
System Timer Module (STM)

50.1 Chip specific STM information

50.1.1 System Timer Module (STM) Configuration

The System Timer Module (STM) is a 32-bit timer designed to support commonly required system and application software timing functions. The STM includes a 32-bit up counter and four 32-bit compare channels with a separate interrupt source for each channel. The counter is driven by the appropriate system clock divided by an 8-bit prescale value (1 to 256).

This chip includes three STMs, one for each core, with four 32-bit compare channels in each STM.

Table 50-1. System Timer Module (STM) instances

Instance	Description	Number of Channels	Number of Registers (32-bit)
STM_0	Intended for Main Core_0 in the high-speed computational clock domain.	4	14
STM_1	Intended for Main Core_1 in the high-speed computational clock domain.	4	14
STM_2	Intended for Main Core_2 in the high-speed computational clock domain.	4	14

NOTE

An STM interrupt cannot be used for waking up the chip from stop/halt modes.

50.2 Introduction

This section provides an overview, list of features, and modes of operation for the STM.

50.2.1 Overview

The System Timer Module (STM) is a 32-bit timer designed to support commonly required system and application software timing functions. The STM includes a 32-bit up counter and four 32-bit compare channels with a separate interrupt source for each channel. The counter is driven by the system clock divided by an 8-bit prescale value (1 to 256).

50.2.2 Features

The STM has the following features:

- One 32-bit up counter with 8-bit prescaler
- Four 32-bit compare channels
- Independent interrupt source for each channel
- Counter can be stopped in debug mode

50.2.3 Modes of operation

The STM supports two device modes of operation: normal and debug. When the STM is enabled in normal mode, its counter runs continuously. In debug mode, operation of the counter is controlled by the FRZ bit in the STM_CR register. If the FRZ bit is set, the counter is stopped in debug mode, otherwise it continues to run.

50.3 External signal description

The STM does not have any external interface signals.

50.4 Memory map and registers

The STM programming model includes a group of 32-bit registers—a module control register, a counter value register, and three registers for each channel.

The STM registers can only be accessed using 32-bit (word) accesses. Attempted references using a different size or to a reserved address generates a bus error termination.

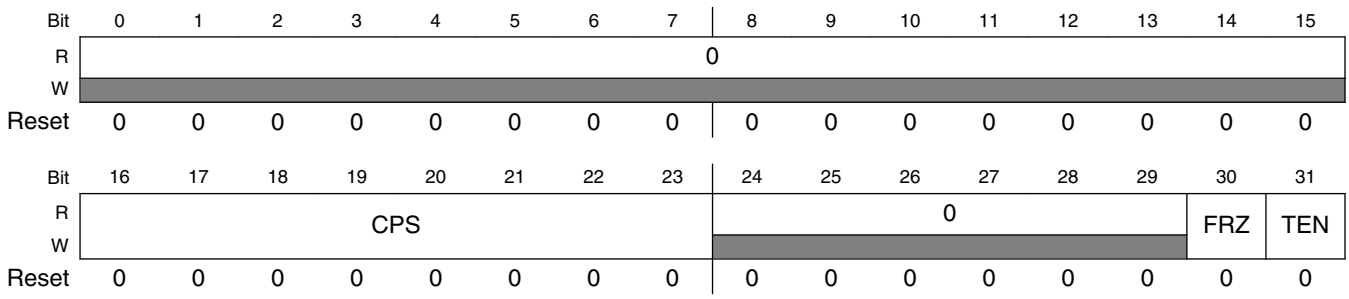
STM memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	STM Control Register (STM_CR)	32	R/W	0000_0000h	50.4.1/2320
4	STM Count Register (STM_CNT)	32	R/W	0000_0000h	50.4.2/2321
10	STM Channel Control Register (STM_CCR0)	32	R/W	0000_0000h	50.4.3/2321
14	STM Channel Interrupt Register (STM_CIR0)	32	w1c	0000_0000h	50.4.4/2322
18	STM Channel Compare Register (STM_CMP0)	32	R/W	0000_0000h	50.4.5/2322
20	STM Channel Control Register (STM_CCR1)	32	R/W	0000_0000h	50.4.3/2321
24	STM Channel Interrupt Register (STM_CIR1)	32	w1c	0000_0000h	50.4.4/2322
28	STM Channel Compare Register (STM_CMP1)	32	R/W	0000_0000h	50.4.5/2322
30	STM Channel Control Register (STM_CCR2)	32	R/W	0000_0000h	50.4.3/2321
34	STM Channel Interrupt Register (STM_CIR2)	32	w1c	0000_0000h	50.4.4/2322
38	STM Channel Compare Register (STM_CMP2)	32	R/W	0000_0000h	50.4.5/2322
40	STM Channel Control Register (STM_CCR3)	32	R/W	0000_0000h	50.4.3/2321
44	STM Channel Interrupt Register (STM_CIR3)	32	w1c	0000_0000h	50.4.4/2322
48	STM Channel Compare Register (STM_CMP3)	32	R/W	0000_0000h	50.4.5/2322

50.4.1 STM Control Register (STM_CR)

The STM Control Register includes the prescale value, freeze control and timer enable bits.

Address: 0h base + 0h offset = 0h



STM_CR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–23 CPS	Counter Prescaler. Selects the clock divide value for the prescaler (1 - 256). 0x00 Divide system clock by 1 0x01 Divide system clock by 2 ---------- 0xFF Divide system clock by 256
24–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 FRZ	Freeze. Allows the timer counter to be stopped when the device enters debug mode. **NOTE:** When the MCU enters debug mode, the STM is notified and uses the FRZ bit to determine counter mode. 0 STM counter continues to run in debug mode. 1 STM counter is stopped in debug mode.
31 TEN	Timer counter Enabled. 0 Counter is disabled. 1 Counter is enabled.

50.4.2 STM Count Register (STM_CNT)

The STM Count Register holds the timer count value.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	CNT																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

STM_CNT field descriptions

Field	Description
0–31 CNT	Timer count value used as the time base for all channels. When enabled, the counter increments at the rate of the system clock divided by the prescale value.

50.4.3 STM Channel Control Register (STM_CCR*n*)

The STM Channel Control Register (STM_CCRn) has the enable bit for channel n of the timer.

Address: 0h base + 10h offset + (16d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

STM_CMP*n* field descriptions

Field	Description
0–31 CMP	Compare value for channel n. If the STM_CCRn[CEN] bit is set and the STM_CMPn register matches the STM_CNT register, a channel interrupt request is generated and the STM_CIRn[CIF] bit is set.

STM_CMP*n* field descriptions (continued)

Field	Description

50.5 Functional description

The STM has one 32-bit up counter (STM_CNT) that is used as the time base for all channels. When enabled, the counter increments at the system clock frequency divided by a prescale value. The STM_CR[CPS] field sets the divider to any value in the range from 1 to 256. The counter is enabled with the STM_CR[TEN] bit. When enabled in normal mode, the counter continuously increments. When enabled in debug mode, the counter operation is controlled by the STM_CR[FRZ] bit. When the STM_CR[FRZ] bit is set, the counter is stopped in debug mode; otherwise, it continues to run in debug mode. The counter rolls over at 0xFFFF_FFFF to 0x0000_0000 with no restrictions at this boundary.

The STM has four identical compare channels. Each channel includes a channel control register (STM_CCR*n*), a channel interrupt register (STM_CIR*n*), and a channel compare register (STM_CMP*n*). The channel is enabled by setting the STM_CCR*n*[CEN] bit. When enabled, the channel will set the STM_CIR*n*[CIF] bit and generate an interrupt request when the channel compare register matches the timer counter. The interrupt request is cleared by writing 1 to the STM_CIR*n*[CIF] bit. A write of 0 to the STM_CIR*n*[CIF] bit has no effect.

NOTE

The STM counter does not advance when the system clock is stopped.

Chapter 51
Software Watchdog Timer (SWT)

51.1 Chip specific SWT information

51.1.1 Software Watchdog Timer (SWT) Configuration

This device contains three SWTs as shown in the following table:

Table 51-1. SWT Configuration Instances

Instance	Description
SWT_0	Intended for Main Core_0 in the high-speed computational clock domain.
SWT_1	Intended for Main Core_1 in the high-speed computational clock domain.
SWT_2	Intended for Main Core_2 in the high-speed computational clock domain. **NOTE:** SWT2 also has a dependency on CORE_0 core reset. CORE_0 must be out of reset for SWT2 to work. Also by this dependency, CORE_2 cannot be used to execute a code which updates the MC_ME_CADDR1[RMC] or the boot vector for CORE_0. If the z4 core RMC needs to be updated, CORE_1 must be used to do this.

NOTE

Stopping a particular core will not stop SWTs corresponding to other cores. Therefore, these other SWTs may time out if they are enabled. For example, both SWT_1 and SWT_2 are accessible from CORE_0, but these SWTs will not receive stop when CORE_0 is stopped, and may therefore time out.

Each SWT has these features:

- 32-bit time-out register to set the time-out period
- Programmable selection of window mode or regular servicing
- Programmable selection of reset or interrupt on an initial time-out
- Programmable selection of the servicing mode
- Master access protection
- Hard and soft configuration lock bits

NOTE

STP bit in SWT_CR can work for HALT mode also.

51.1.2 Default configuration

NOTE

During sequential boot SWTs would be disabled.

On this device, the SWTs come out of reset with the following default values. Minimum timeout value is 256 cycles for SWT0, SWT1, and SWT2.

Table 51-2. Register reset values for z4 booting core

SWT instance	Register	Reset value
SWT0	SWT0 Control Register (SWT_CR)	See Table 51-3
SWT0	SWT0 Time-out (SWT_TO)	0x0003_FDE0
SWT0	SWT0 Counter Output Register (SWT_CO)	See Table 51-3
SWT1	SWT1 Control Register (SWT_CR)	0xFF00_011A
SWT1	SWT1 Time-out (SWT_TO)	0x0003_FDE0
SWT1	SWT1 Counter Output Register (SWT_CO)	Reset value changes when access to soft lock bit is made before reading CO register
SWT2	SWT2 Control Register (SWT_CR)	0xFF00_011A
SWT2	SWT2 Time-out (SWT_TO)	0x0003_FDE0

Table 51-3. SWT0 Reset values

Enable SWT0 dcl_soc_conf_1 Bit 13	SWT0_CR	SWT0_CO
Enable	0xFF00_011B	0x0000_0000
Disable	0xFF00_011A	Reset value changes when access to soft lock bit is made before reading CO register

Table 51-4. Register reset values for z7 booting core

Register rest values	Register	Reset values
SWT0	SWT0 Control Register (SWT_CR)	0xFF00_011A
SWT0	SWT0 Time-out (SWT_TO)	0x0003_FDE0
SWT0	SWT0 Counter Output Register (SWT_CO)	Reset value changes when access to soft lock bit is made before reading CO register
SWT1	SWT1 Control Register (SWT_CR)	See Table 51-5
SWT1	SWT1 Time-out (SWT_TO)	0x0003_FDE0

Table continues on the next page...

Table 51-4. Register reset values for z7 booting core (continued)

Register rest values	Register	Reset values
SWT1	SWT1 Counter Output Register (SWT_CO)	See Table 51-5
SWT2	SWT2 Control Register (SWT_CR)	0xFF00_011A
SWT2	SWT2 Time-out (SWT_TO)	0x0003_FDE0

Table 51-5. SWT1 Reset values

Enable SWT1 dcl_soc_conf_1 Bit 14	SWT1_CR	SWT1_CO
Enable	0xFF00_011B	0x0000_0000
Disable	0xFF00_011A	Reset value changes when access to soft lock bit is made before reading CO register

The SWT_CR register reset value of 0xFF00_011B selects:

- All masters allowed access
- Reset on invalid access
- Oscillator clock selected
- Counter stops in debug mode
- Soft Locked
- Watchdog is enabled

The SWT_CR register reset value of 0xFF00_011A selects:

- All masters allowed access
- Reset on invalid access
- Oscillator clock selected
- Counter stops in debug mode
- Soft Locked
- Watchdog is disabled

51.1.3 Reset assertion

Each SWT can assert a reset when the watchdog timer expires or when an invalid access is made. To generate the reset, the SWT fault source needs to be configured in the FCCU.

This reset causes a system reset equivalent to assertion of the RESET pin.

51.1.4 Service mode watch point input

Each SWT comes out of reset in 'Fixed Service Sequence' mode (SWT_CR[SMD] = 2’b00), but the Instruction Address Compare 8 (IAC8) register (SPR 568) can be used for servicing by using the SWT jd_watchpt input.

To use SWT address execution modes for this purpose, the e200z4 core IAC8 register signal jd_watchpt[15] is connected to the SWT jd_watchpt input. The jd_watchpt[15] signal tells the SWT that an IAC8 compare occurred.

Set SWT_CR[SMD] to one of the following so the SWT is serviced by executing code at the address loaded into the IAC8 register:

- 2’b10 for Fixed Address Execution; the IAC8 register cannot be updated while the watchdog is enabled. If the SWT is in 'Fixed Address Execution' mode, an SWT output signal tells the core; this ‘freezes’ changes to the IAC8 register when the SWT is enabled.
- 2’b11 for Incremental Address Execution; the IAC8 register can be updated.

51.2 Introduction

This section provides an overview, list of features, and modes of operation for the SWT.

51.2.1 Overview

The Software Watchdog Timer (SWT) is a peripheral module that can prevent system lockup in situations such as software getting trapped in a loop or if a bus transaction fails to terminate. When enabled, the SWT requires periodic execution of a watchdog servicing operation. The servicing operation resets the timer to a specified time-out period. If this servicing action does not occur before the timer expires, the SWT generates an interrupt or hardware reset request. The SWT can be configured to generate a reset request or interrupt on an initial time-out. The SWT always generates a reset request on a second consecutive time-out.

51.2.2 Features

The SWT has the following features:

- 32-bit time-out register to set the time-out period

- Programmable selection of window mode or regular servicing
- Programmable selection of reset request or interrupt on an initial time-out
- Programmable selection of the servicing mode
- Master access protection
- Hard and soft configuration lock bits
- Reset configuration inputs allow timer to be enabled out of reset

51.2.3 Modes of operation

The SWT supports these device modes of operation:

- Normal
- Debug
- Stop

When the SWT is enabled in normal mode, its counter runs continuously. In debug mode, operation of the counter is controlled by the FRZ bit in the SWT_CR. If the FRZ bit is set, the counter is stopped in debug mode; otherwise it continues to run. In stop mode, operation of the counter is controlled by the STP bit in the SWT_CR. If the STP bit is set, the counter is stopped in stop mode; otherwise it continues to run.

51.3 External signal description

The SWT module does not have any external interface signals.

51.4 Memory Map and Registers

The SWT programming model has seven 32-bit registers. The programming model can be accessed using only 32-bit (word) accesses.

Any of the following attempted accesses are invalid:

- References using non-32-bit access sizes
- Writes to read-only registers

- Writes of incorrect values to SWT_SR when the SWT is enabled
- Accesses to reserved addresses
- Accesses by masters without permission

For an enabled SWT, an invalid access generates a reset request if SWT_CR[RIA] is 1. An invalid access generates a bus error if SWT_CR[RIA] is 0.

If either HLK or SLK in SWT_CR is 1, then the SWT_CR, SWT_TO, SWT_WN, and SWT_SK registers are read-only.

SWT memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	SWT Control Register (SWT_CR)	32	R/W	See section	51.4.1/2330
4	SWT Interrupt Register (SWT_IR)	32	R/W	0000_0000h	51.4.2/2334
8	SWT Time-out Register (SWT_TO)	32	R/W	See section	51.4.3/2334

SWT_CR field descriptions

Field	Description
0 MAP0	Master Access Protection for Master 0. The platform bus master assignments are device specific. The number of this field corresponds to the logical ID of the bus master. MAP0 corresponds to logical IDs 0 and 8. For the masters with the logical IDs to which the MAP*n* fields correspond, see the chip-specific information for the Crossbar Switch. 0 Access for the master is not enabled 1 Access for the master is enabled
1 MAP1	Master Access Protection for Master 1. The platform bus master assignments are device specific. The number of this field corresponds to the logical ID of the bus master. MAP1 corresponds to logical IDs 1 and 9. For the masters with the logical IDs to which the MAP*n* fields correspond, see the chip-specific information for the Crossbar Switch. 0 Access for the master is not enabled 1 Access for the master is enabled
2 MAP2	Master Access Protection for Master 2. The platform bus master assignments are device specific. The number of this field corresponds to the logical ID of the bus master. MAP2 corresponds to logical IDs 2 and 10. For the masters with the logical IDs to which the MAP*n* fields correspond, see the chip-specific information for the Crossbar Switch. 0 Access for the master is not enabled 1 Access for the master is enabled
3 MAP3	Master Access Protection for Master 3. The platform bus master assignments are device specific. The number of this field corresponds to the logical ID of the bus master. MAP3 corresponds to logical IDs 3 and 11. For the masters with the logical IDs to which the MAP*n* fields correspond, see the chip-specific information for the Crossbar Switch. 0 Access for the master is not enabled 1 Access for the master is enabled
4 MAP4	Master Access Protection for Master 4. The platform bus master assignments are device specific. The number of this field corresponds to the logical ID of the bus master. MAP4 corresponds to logical IDs 4 and 12. For the masters with the logical IDs to which the MAP*n* fields correspond, see the chip-specific information for the Crossbar Switch. 0 Access for the master is not enabled 1 Access for the master is enabled
5 MAP5	Master Access Protection for Master 5. The platform bus master assignments are device specific. The number of this field corresponds to the logical ID of the bus master. MAP5 corresponds to logical IDs 5 and 13.

Table continues on the next page...

SWT_CR field descriptions (continued)

Field	Description
	For the masters with the logical IDs to which the MAP*n* fields correspond, see the chip-specific information for the Crossbar Switch. 0 Access for the master is not enabled 1 Access for the master is enabled
6 MAP6	Master Access Protection for Master 6. The platform bus master assignments are device specific. The number of this field corresponds to the logical ID of the bus master. MAP6 corresponds to logical IDs 6 and 14. For the masters with the logical IDs to which the MAP*n* fields correspond, see the chip-specific information for the Crossbar Switch. 0 Access for the master is not enabled 1 Access for the master is enabled
7 MAP7	Master Access Protection for Master 7. The platform bus master assignments are device specific. The number of this field corresponds to the logical ID of the bus master. MAP7 corresponds to logical IDs 7 and 15. For the masters with the logical IDs to which the MAP*n* fields correspond, see the chip-specific information for the Crossbar Switch. 0 Access for the master is not enabled 1 Access for the master is enabled
8–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–22 SMD	Service Mode 00 Fixed Service Sequence: The watchdog is serviced by writing the fixed sequence 0xA602, 0xB480 to SWT_SR. 01 Keyed Service Sequence: The watchdog is serviced by writing two pseudorandom key values to SWT_SR. 10 Fixed Address Execution: The watchdog is serviced by executing code at the address loaded into the designated IAC register, which cannot be updated while the watchdog is enabled. 11 Incremental Address Execution: The watchdog is serviced by executing code at the address loaded into the designated IAC register, which can be updated.
23 RIA	Reset on Invalid Access **NOTE:** For a description of how this chip implements SWT reset requests resulting from SWT invalid accesses, see the chip-specific SWT information. 0 Invalid access to the SWT generates a bus error 1 Invalid access to the SWT causes a reset request if WEN is 1
24 WND	Window Mode 0 Regular mode: service sequence can be done at any time 1 Windowed mode: service sequence is valid only when the down counter is less than the value in the SWT_WN register
25 ITR	Interrupt Then Reset Request

Table continues on the next page...

SWT_CR field descriptions (continued)

Field	Description
	NOTE: For a description of how this chip implements SWT reset requests and interrupt requests resulting from SWT time-outs, see the chip-specific SWT information. 0 Generate a reset request on a time-out 1 Generate an interrupt on an initial time-out; generate a reset request on a second consecutive time-out
26 HLK	Hard Lock This bit is cleared only at reset. 0 SWT_CR, SWT_TO, SWT_WN and SWT_SK are read/write registers if SLK is 0 1 SWT_CR, SWT_TO, SWT_WN and SWT_SK are read-only registers
27 SLK	Soft Lock This bit is cleared by writing the unlock sequence to the service register. 0 SWT_CR, SWT_TO, SWT_WN and SWT_SK are read/write registers if HLK is 0 1 SWT_CR, SWT_TO, SWT_WN and SWT_SK are read-only registers
28 Reserved	Reserved This field is reserved.
29 STP	Stop Mode Control Allows the watchdog timer to be stopped when the device enters stop mode. 0 SWT counter continues to run in stop mode 1 SWT counter is stopped in stop mode
30 FRZ	Debug Mode Control Allows the watchdog timer to be stopped when the device enters debug mode. 0 SWT counter continues to run in debug mode 1 SWT counter is stopped in debug mode
31 WEN	Watchdog Enabled 0 SWT is disabled 1 SWT is enabled

51.4.2 SWT Interrupt Register (SWT_IR)

The SWT_IR contains the time-out interrupt flag.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

* Notes:

- The reset value of this register is implementation specific. See the chip-specific SWT information.

SWT_TO field descriptions

Field	Description
0–31 WTO	Watchdog time-out period in clock cycles. An internal 32-bit down counter is loaded with , when the service sequence is written or when the SWT is enabled.

51.4.4 SWT Window Register (SWT_WN)

The SWT Window (SWT_WN) register contains the 32-bit window start value. This register is cleared on reset. This register is read-only if either SWT_CR[HLK] or SWT_CR[SLK] is 1.

Address: 0h base + Ch offset = Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	WST																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SWT_WN field descriptions

Field	Description
0–31 WST	Window Start Value When window mode is enabled, the service sequence can only be written when the internal down counter is less than this value.

51.4.5 SWT Service Register (SWT_SR)

The SWT Service (SWT_SR) register is the target for service operation writes used to reset the watchdog timer.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																															
W																	WSC															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SWT_SR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 WSC	Watchdog Service Code This field is used to service the watchdog and to clear the Soft Lock bit (SWT_CR[SLK]). If the SWT_CR[SMD] field is 01b, two pseudorandom key values are written to service the watchdog; see Functional description for details. Otherwise, the sequence 0xA602 followed by 0xB480 is written to the WSC field. To clear the Soft Lock bit (SWT_CR[SLK]), the value 0xC520 followed by 0xD928 is written to the WSC field. When read, the WSC field always returns zero.

51.4.6 SWT Counter Output Register (SWT_CO)

The SWT Counter Output (SWT_CO) register is a read-only register that shows the value of the internal down counter when the SWT is disabled.

Address: 0h base + 14h offset = 14h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	CNT																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

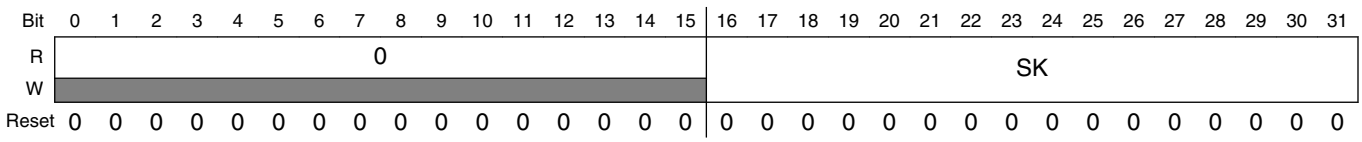
SWT_CO field descriptions

Field	Description
0–31 CNT	Watchdog Count When the watchdog is disabled (SWT_CR[WEN] is 0), this field shows the value of the internal down counter. When the watchdog is enabled (SWT_CR[WEN] is 1), this field is cleared (the value is 0x0000_0000). Values in this field can lag behind the internal counter value for up to 6 system clock cycles plus 8 counter clock cycles. Therefore, the value read from this field immediately after disabling the watchdog may be higher than the actual value of the internal counter.

51.4.7 SWT Service Key Register (SWT_SK)

The SWT Service Key (SWT_SK) register holds the previous (or initial) service key value. This register is read-only if either SWT_CR[HLK] or SWT_CR[SLK] is 1.

Address: 0h base + 18h offset = 18h



SWT_SK field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 SK	Service Key This field is the previous (or initial) service key value used in keyed service mode. If SWT_CR[SMD] is 01b, the next key value to be written to the SWT_SR is (17*SK+3) mod 2^{16} .

51.5 Functional description

51.5.1 Introduction

The SWT is a 32-bit window watchdog timer designed to enable the system to recover in situations such as software getting trapped in a loop or if a bus transaction fails to terminate. It includes:

- a control register (SWT_CR),
- an interrupt register (SWT_IR),
- a time-out register (SWT_TO),
- a window register (SWT_WN),
- a service register (SWT_SR),
- a counter output register (SWT_CO), and
- a service key register (SWT_SK).

Accesses to SWT registers occur with no peripheral bus wait states. (The peripheral bus bridge may add one or more system wait states.) However, due to synchronization logic in the SWT design, recognition of the service sequence or configuration changes may require up to three system plus seven counter clock cycles.

51.5.1.1 SWT_CR register

The SWT_CR register includes bits to enable the timer, set configuration options, and lock configuration of the module. The watchdog is enabled by setting the SWT_CR[WEN] bit. The reset value of the SWT_CR[WEN] bit is device specific.[3] If the reset value of this bit is 1, the watchdog starts operation automatically after reset is released. Some devices can be configured to clear this bit automatically during the boot process.

51.5.1.2 SWT_TO register

The SWT_TO register holds the watchdog time-out period in clock cycles unless the value is less than 0x100, in which case the time-out period is set to 0x100. When the SWT is enabled, the time-out period is loaded into an internal 32-bit down counter each time a valid service operation is performed. See the Configuration section to determine the source that is used to clock the down counter.

51.5.1.3 SWT_CO register

The SWT_CO register shows the value of the down counter when the watchdog is disabled. When the watchdog is enabled this register is cleared. The value shown in this register can lag behind the value in the internal counter for up to six system plus eight counter clock cycles.

The SWT_CO register can be used during a software self test of the SWT. For example, the SWT can be enabled and not serviced for a fixed period of time less than the time-out value. Then the SWT can be disabled (SWT_CR[WEN] cleared) and the value of the SWT_CO register read to determine if the internal down counter is working properly.

3. See the chip-specific SWT information.

51.5.2 Configuration locking

The configuration of the SWT can be locked through use of either a soft lock or a hard lock. In either case, when locked, the SWT_CR, SWT_TO, SWT_WN and SWT_SK registers are read-only.

51.5.2.1 Hard lock

The hard lock is enabled by setting the SWT_CR[HLK] bit, which can only be cleared by a reset.

51.5.2.2 Soft lock

The soft lock is enabled by setting the SWT_CR[SLK] bit and is cleared by writing the unlock sequence to the service register.

51.5.3 Unlock sequence

The unlock sequence is a write of 0xC520 followed by a write of 0xD928 to the SWT_SR[WSC] field. There is no timing requirement between the two writes. The unlock sequence logic ignores service sequence writes and recognizes the 0xC520, 0xD928 sequence regardless of previous writes. The unlock sequence can be written at any time and does not require the SWT_CR[WEN] bit to be set.

51.5.4 Servicing operations

When enabled, the SWT requires periodic execution of a servicing operation that is determined by the SWT_CR[SMD] field. Properly servicing the watchdog loads the internal down counter with the time-out period. The servicing modes are:

- fixed service sequence
- keyed service sequence
- fixed execution address
- incremental execution address

51.5.4.1 Fixed service sequence mode

If the SWT_CR[SMD] field is 00b, the fixed service sequence mode is selected, which requires writing 0xA602, then 0xB480 to the SWT_SR[WSC] field to service the watchdog. There is no timing requirement between the two writes and the service sequence logic ignores unlock sequence writes.

51.5.4.2 Keyed service sequence mode

If the SWT_CR[SMD] field is 01b, then the keyed service sequence mode is selected, which requires writing two pseudorandom keys to the SWT_SR[WSC] field to service the watchdog. The key values are determined by the pseudorandom key generator defined by the equation in the following figure. This algorithm will generate a sequence of 2^{16} different key values before repeating. The state of the key generator is held in the SWT_SK register. For example, if SWT_SK[SK] is 0x0100, then the service sequence keys are 0x1103, 0x2136. In this mode, each time a valid key is written to the SWT_SR register, the SWT_SK register is updated. So, after servicing the watchdog by writing 0x1103 and then 0x2136 to the SWT_SR[WSC] field, SWT_SK[SK] is 0x2136 and the next key sequence is 0x3499, 0x7E2C.

$$SK_{n+1} = (17 \times SK_n + 3) \bmod 2^{16}$$

Figure 51-1. Pseudorandom Key Generator

51.5.4.3 Fixed execution address mode

If the SWT_CR[SMD] field is set to 10b, the fixed execution address mode is selected, which requires executing code at the address loaded into the designated IAC register to service the watchdog. In this mode, the IAC register cannot be updated while the watchdog is enabled.

51.5.4.4 Incremental execution address mode

If the SWT_CR[SMD] field is set to 11b, the incremental execution address mode is selected, which requires executing code at the address loaded into the designated IAC register to service the watchdog. In this mode, the IAC register can be updated while the watchdog is enabled.

51.5.4.5 Window mode

If window mode is enabled (SWT_CR[WND] bit is 1), the service sequence must be applied in the last part of the time-out period defined by SWT_WN.

- The window is open when the down counter is less than the value in SWT_WN.
- Outside this window, service sequence writes are invalid accesses and generate a bus error or reset request depending on the value of SWT_CR[RIA].

For example, if SWT_TO is set to 5000 and SWT_WN is set to 1000, the service sequence must be applied in the last 20% of the time-out period.

Synchronization logic in the watchdog design slightly delays when the window opens. This delay could be up to 3 system clock cycles plus 4 counter clock cycles.

51.5.5 Time-out

The SWT_CR[ITR] bit controls the SWT's action taken when a time-out occurs.

- If the SWT_CR[ITR] bit is 0, the SWT generates a reset request immediately on any time-out.
- If the SWT_CR[ITR] bit is 1, an initial time-out causes the SWT to generate an interrupt and load the down counter with the time-out period.
  - The interrupt is indicated by the Time-out Interrupt Flag (SWT_IR[TIF]).
  - Clear the interrupt by writing 1 to SWT_IR[TIF].

  If the service sequence is not written before the second consecutive time-out, the SWT generates a reset request.

51.5.6 Initialization

All registers should be initialized before setting the SWT_CR[WEN] bit to enable the watchdog. Registers can be initialized in any sequence.

Chapter 52
Periodic Interrupt Timer (PIT)

52.1 Chip-specific PIT information

52.1.1 PIT Instantiations

This device contains two PIT modules each having 4 channels.

52.1.2 PIT/DMA Periodic Trigger Assignments

The PIT generates periodic trigger events to the DMA Mux as shown in the table below. All triggers go to both DMAMUX modules.

Table 52-1. PIT channel assignments for periodic DMA triggering

DMAMUX_0 and DMAMUX_1 Channel Trigger	Source Module	Source Signal
0	PIT_0	Trigger Channel 0
1	PIT_0	Trigger Channel 1
2	PIT_0	Trigger Channel 2
3	PIT_0	Trigger Channel 3
4	PIT_1	Trigger Channel 0
5	PIT_1	Trigger Channel 1
6	PIT_1	Trigger Channel 2
7	PIT_1	Trigger Channel 3

52.2 Introduction

The PIT module is an array of timers that can be used to raise interrupts and trigger DMA channels.

52.2.1 Block diagram

The following figure shows the block diagram of the PIT module.

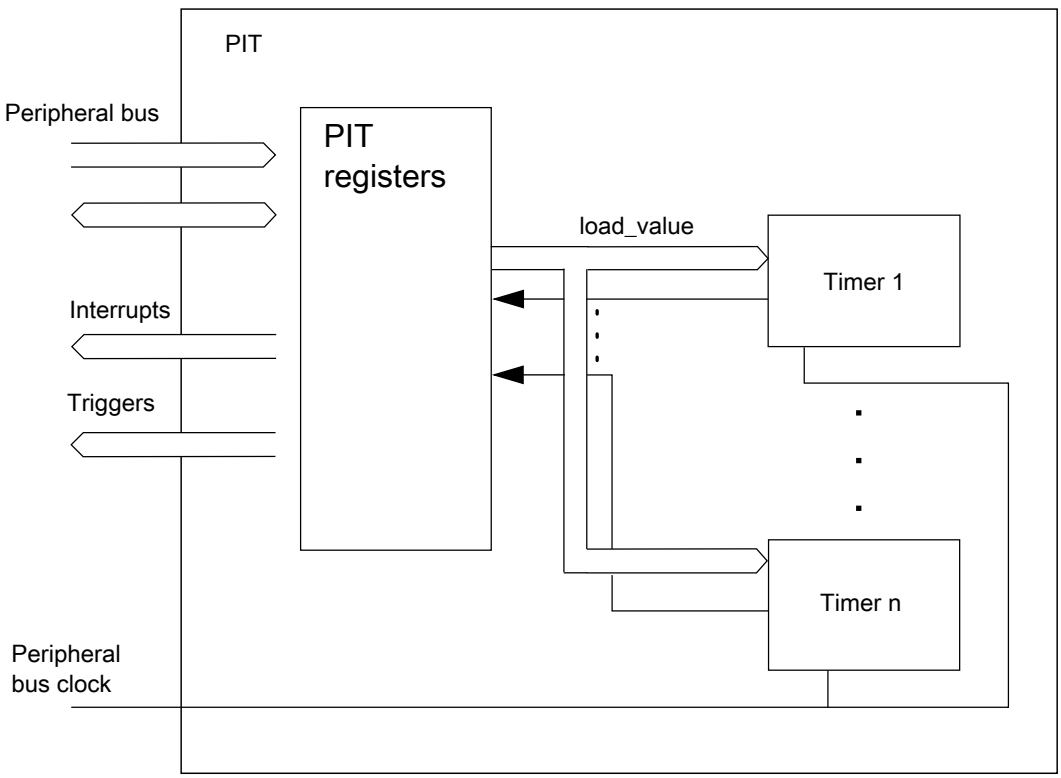


Figure 52-1. Block diagram of the PIT

NOTE

See the chip-specific PIT information for the number of PIT channels used in this MCU.

52.2.2 Features

The main features of this block are:

- Ability of timers to generate DMA trigger pulses
- Ability of timers to generate interrupts
- Maskable interrupts
- Independent timeout periods for each timer

52.3 Signal description

The PIT module has no external pins.

52.4 Memory map/register description

This section provides a detailed description of all registers accessible in the PIT module.

- Reserved registers will read as 0, writes will have no effect.
- See the chip-specific PIT information for the number of PIT channels used in this MCU.

PIT memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	PIT Module Control Register (PIT_MCR)	32	R/W	0000_0000h	52.4.1/2345
E0	PIT Upper Lifetime Timer Register (PIT_LTMR64H)	32	R	0000_0000h	52.4.2/2347

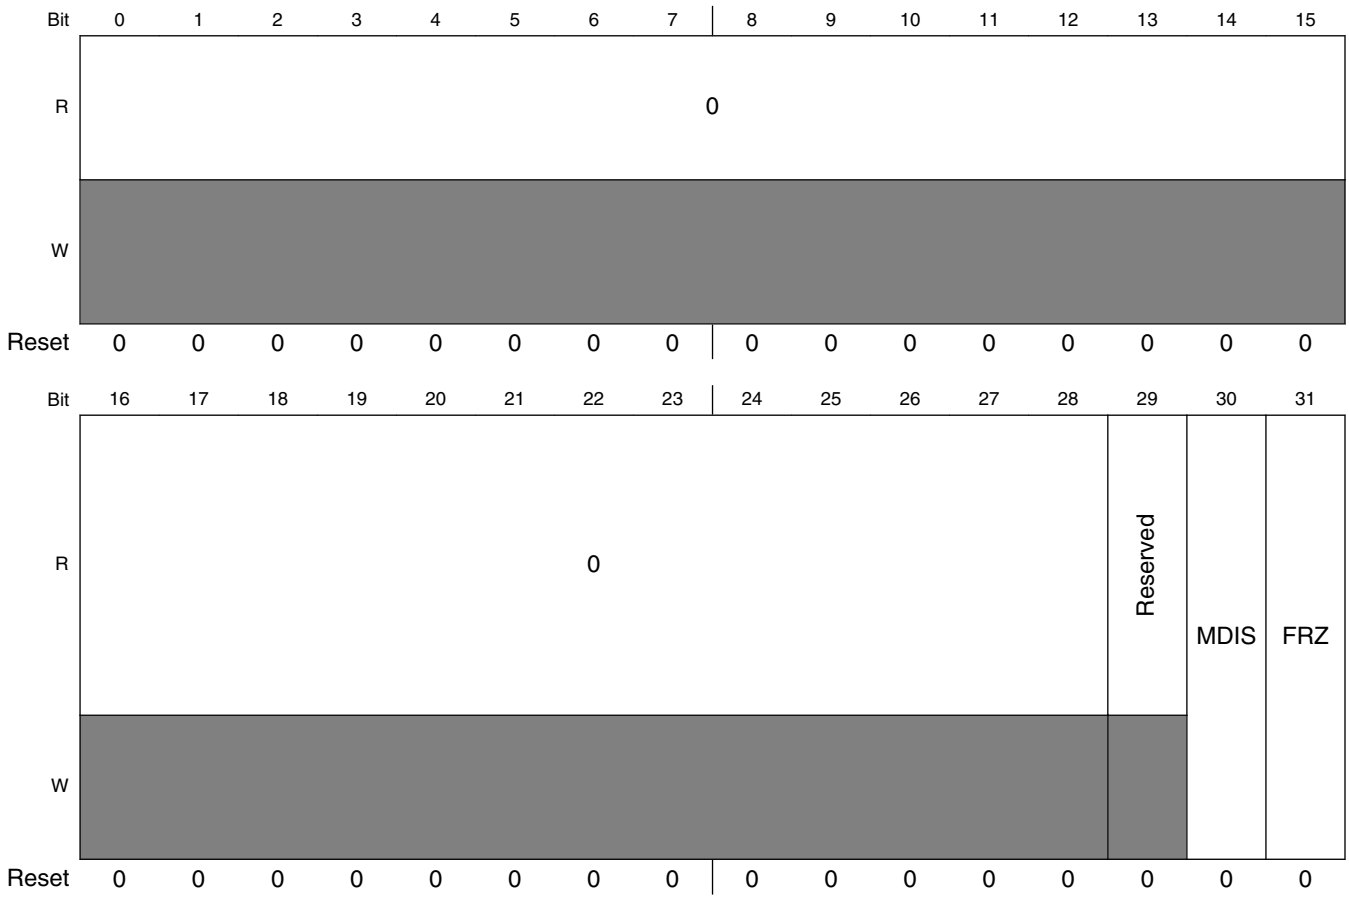
12C	Timer Flag Register (PIT_TFLG2)	32	R/W	0000_0000h	52.4.7/2350
130	Timer Load Value Register (PIT_LDVAL3)	32	R/W	0000_0000h	52.4.4/2348
134	Current Timer Value Register (PIT_CVAL3)	32	R	0000_0000h	52.4.5/2348
138	Timer Control Register (PIT_TCTRL3)	32	R/W	0000_0000h	52.4.6/2349
13C	Timer Flag Register (PIT_TFLG3)	32	R/W	0000_0000h	52.4.7/2350

52.4.1 PIT Module Control Register (PIT_MCR)

This register enables or disables the PIT timer clocks and controls the timers when the PIT enters the Debug mode.

Access: User read/write

Address: 0h base + 0h offset = 0h



PIT_MCR field descriptions

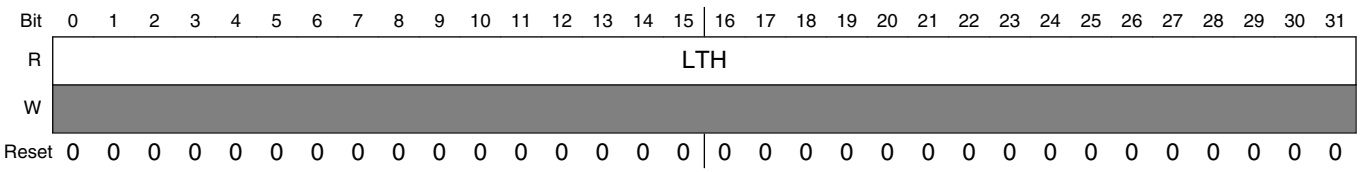
Field	Description
0–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 Reserved	This field is reserved.
30 MDIS	Module Disable - (PIT section) Disables the standard timers. This field must be enabled before any other setup is done. **NOTE:** Always write to this bit after at least 3 bus clock cycles of enabling the PIT clock gate in the device clock generation module. 0 Clock for standard PIT timers is enabled. 1 Clock for standard PIT timers is disabled.
31 FRZ	Freeze Allows the timers to be stopped when the device enters the Debug mode. 0 Timers continue to run in Debug mode. 1 Timers are stopped in Debug mode.

52.4.2 PIT Upper Lifetime Timer Register (PIT_LTMR64H)

This register is intended for applications that chain timer 0 and timer 1 to build a 64-bit lifetimer.

Access: User read only

Address: 0h base + E0h offset = E0h



PIT_LTMR64H field descriptions

Field	Description
0–31 LTH	Life Timer value Shows the timer value of timer 1. If this register is read at a time t1, LTMR64L shows the value of timer 0 at time t1.

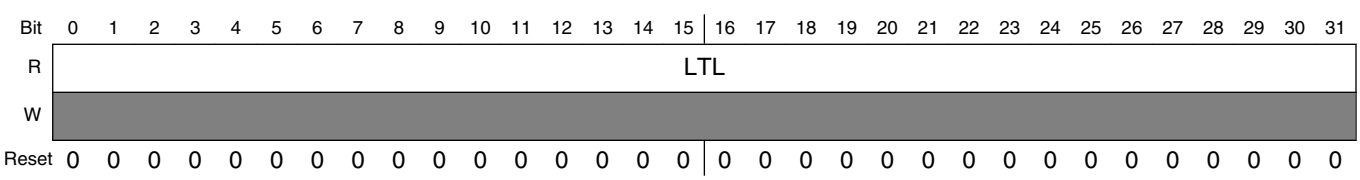
52.4.3 PIT Lower Lifetime Timer Register (PIT_LTMR64L)

This register is intended for applications that chain timer 0 and timer 1 to build a 64-bit lifetimer.

To use LTMR64H and LTMR64L, timer 0 and timer 1 need to be chained. To obtain the correct value, first read LTMR64H and then LTMR64L. LTMR64H will have the value of CVAL1 at the time of the first access, LTMR64L will have the value of CVAL0 at the time of the first access, therefore the application does not need to worry about carry-over effects of the running counter.

Access: User read only

Address: 0h base + E4h offset = E4h



PIT_LTMR64L field descriptions

Field	Description
0–31 LTL	Life Timer value Shows the value of timer 0 at the time LTMR64H was last read. It will only update if LTMR64H is read.

52.4.4 Timer Load Value Register (PIT_LDVAL*n*)

These registers select the timeout period for the timer interrupts.

Access: User read/write

Address: 0h base + 100h offset + (16d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PIT_LDVAL*n* field descriptions

Field	Description
0–31 TSV	Timer Start Value Sets the timer start value. The timer will count down until it reaches 0, then it will generate an interrupt and load this register value again. Writing a new value to this register will not restart the timer; instead the value will be loaded after the timer expires. To abort the current cycle and start a timer period with the new value, the timer must be disabled and enabled again.

52.4.5 Current Timer Value Register (PIT_CVAL*n*)

These registers indicate the current timer position.

Access: User read only

Address: 0h base + 104h offset + (16d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	TVL																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PIT_CVAL*n* field descriptions

Field	Description
0–31 TVL	Current Timer Value Represents the current timer value, if the timer is enabled.

PIT_CVAL*n* field descriptions (continued)

Field	Description
	NOTE: • If the timer is disabled, do not use this field as its value is unreliable. • The timer uses a downcounter. The timer values are frozen in Debug mode if MCR[FRZ] is set.

52.4.6 Timer Control Register (PIT_TCTRL*n*)

These registers contain the control bits for each timer.

Access: User read/write

Address: 0h base + 108h offset + (16d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0													CHN	TIE	TEN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PIT_TCTRL*n* field descriptions

Field	Description
0–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 CHN	Chain Mode When activated, Timer n-1 needs to expire before timer n can decrement by 1. Timer 0 cannot be chained. 0 Timer is not chained. 1 Timer is chained to previous timer. For example, for Channel 2, if this field is set, Timer 2 is chained to Timer 1.
30 TIE	Timer Interrupt Enable When an interrupt is pending, or, TFLGn[TIF] is set, enabling the interrupt will immediately cause an interrupt event. To avoid this, the associated TFLGn[TIF] must be cleared first. 0 Interrupt requests from Timer n are disabled. 1 Interrupt will be requested whenever TIF is set.
31 TEN	Timer Enable Enables or disables the timer. 0 Timer n is disabled. 1 Timer n is enabled.

52.4.7 Timer Flag Register (PIT_TFLG*n*)

These registers hold the PIT interrupt flags.

Access: User read/write

Address: 0h base + 10Ch offset + (16d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0															TIF
W																w1c
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PIT_TFLG*n* field descriptions

Field	Description
0–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 TIF	Timer Interrupt Flag Sets to 1 at the end of the timer period. Writing 1 to this flag clears it. Writing 0 has no effect. If enabled, or, when TCTRLn[TIE] = 1, TIF causes an interrupt request. 0 Timeout has not yet occurred. 1 Timeout has occurred.

52.5 Functional description

This section provides the functional description of the module.

52.5.1 General operation

This section gives detailed information on the internal operation of the module. Each timer can be used to generate trigger pulses and interrupts. Each interrupt is available on a separate interrupt line.

52.5.1.1 Timers

The timers generate triggers at periodic intervals, when enabled. The timers load the start values as specified in their LDVAL registers, count down to 0 and then load the respective start value again. Each time a timer reaches 0, it will generate a trigger pulse and set the interrupt flag.

All interrupts can be enabled or masked by setting TCTRLn[TIE]. A new interrupt can be generated only after the previous one is cleared.

If desired, the current counter value of the timer can be read via the CVAL registers.

The counter period can be restarted, by first disabling, and then enabling the timer with TCTRLn[TEN]. See the following figure.

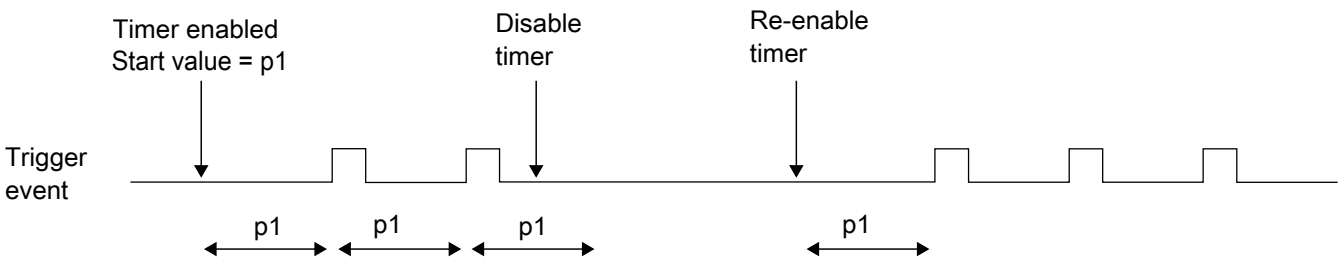

Figure 52-2. Stopping and starting a timer

The counter period of a running timer can be modified, by first disabling the timer, setting a new load value, and then enabling the timer again. See the following figure.

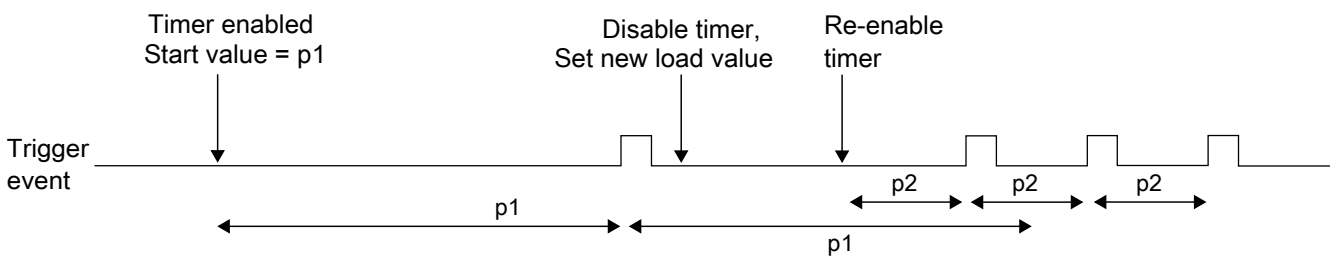

Figure 52-3. Modifying running timer period

It is also possible to change the counter period without restarting the timer by writing LDVAL with the new load value. This value will then be loaded after the next trigger event. See the following figure.

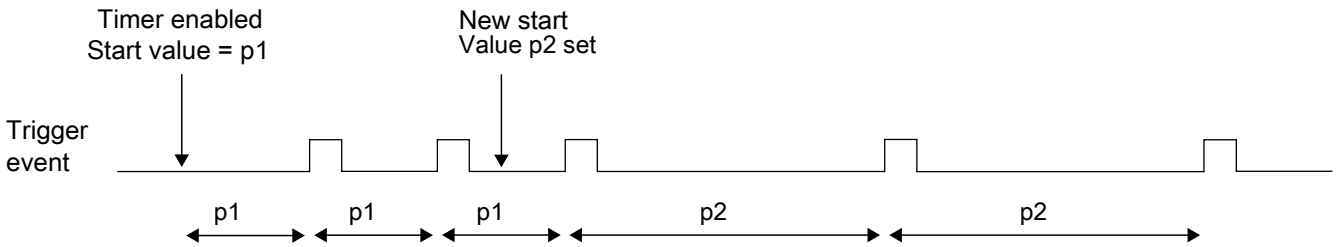

Figure 52-4. Dynamically setting a new load value

52.5.1.2 Debug mode

In Debug mode, the timers will be frozen based on MCR[FRZ]. This is intended to aid software development, allowing the developer to halt the processor, investigate the current state of the system, for example, the timer values, and then continue the operation.

52.5.2 Interrupts

All the timers support interrupt generation. See the MCU specification for related vector addresses and priorities.

Timer interrupts can be enabled by setting TCTRLn[TIE]. TFLGn[TIF] are set to 1 when a timeout occurs on the associated timer, and are cleared to 0 by writing a 1 to the corresponding TFLGn[TIF].

52.5.3 Chained timers

When a timer has chain mode enabled, it will only count after the previous timer has expired. So if timer n-1 has counted down to 0, counter n will decrement the value by one. This allows to chain some of the timers together to form a longer timer. The first timer (timer 0) cannot be chained to any other timer.

52.6 Initialization and application information

In the example configuration:

- The PIT clock has a frequency of 50 MHz.

- Timer 1 creates an interrupt every 5.12 ms.
- Timer 3 creates a trigger event every 30 ms.

The PIT module must be activated by writing a 0 to MCR[MDIS].

The 50 MHz clock frequency equates to a clock period of 20 ns. Timer 1 needs to trigger every 5.12 ms/20 ns = 256,000 cycles and Timer 3 every 30 ms/20 ns = 1,500,000 cycles. The value for the LDVAL register trigger is calculated as:

LDVAL trigger = (period / clock period) -1

This means LDVAL1 and LDVAL3 must be written with 0x0003E7FF and 0x0016E35F respectively.

The interrupt for Timer 1 is enabled by setting TCTRL1[TIE]. The timer is started by writing 1 to TCTRL1[TEN].

Timer 3 shall be used only for triggering. Therefore, Timer 3 is started by writing a 1 to TCTRL3[TEN]. TCTRL3[TIE] stays at 0.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;

// Timer 1
PIT_LDVAL1 = 0x0003E7FF; // setup timer 1 for 256000 cycles
PIT_TCTRL1 = TIE; // enable Timer 1 interrupts
PIT_TCTRL1 |= TEN; // start Timer 1

// Timer 3
PIT_LDVAL3 = 0x0016E35F; // setup timer 3 for 1500000 cycles
PIT_TCTRL3 |= TEN; // start Timer 3
```

52.7 Example configuration for chained timers

In the example configuration:

- The PIT clock has a frequency of 100 MHz.
- Timers 1 and 2 are available.
- An interrupt shall be raised every 1 minute.

The PIT module needs to be activated by writing a 0 to MCR[MDIS].

The 100 MHz clock frequency equates to a clock period of 10 ns, so the PIT needs to count for 6000 million cycles, which is more than a single timer can do. So, Timer 1 is set up to trigger every 6 s (600 million cycles). Timer 2 is chained to Timer 1 and programmed to trigger 10 times.

The value for the LDVAL register trigger is calculated as number of cycles-1, so LDVAL1 receives the value 0x23C345FF and LDVAL2 receives the value 0x00000009.

The interrupt for Timer 2 is enabled by setting TCTRL2[TIE], the Chain mode is activated by setting TCTRL2[CHN], and the timer is started by writing a 1 to TCTRL2[TEN]. TCTRL1[TEN] needs to be set, and TCTRL1[CHN] and TCTRL1[TIE] are cleared.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;

// Timer 2
PIT_LDVAL2 = 0x00000009; // setup Timer 2 for 10 counts
PIT_TCTRL2 = TIE; // enable Timer 2 interrupt
PIT_TCTRL2 |= CHN; // chain Timer 2 to Timer 1
PIT_TCTRL2 |= TEN; // start Timer 2

// Timer 1
PIT_LDVAL1 = 0x23C345FF; // setup Timer 1 for 600 000 000 cycles
PIT_TCTRL1 = TEN; // start Timer 1
```

52.8 Example configuration for the lifetime timer

To configure the lifetimer timer, channels 0 and 1 need to be chained together.

First the PIT module needs to be activated by writing a 0 to the MDIS bit in the CTRL register, then the LDVAL registers need to be set to the maximum value.

The timer is a downcounter.

The following example code matches the described setup:

```
// turn on PIT
PIT_MCR = 0x00;

// Timer 1
PIT_LDVAL1 = 0xFFFFFFFF; // setup timer 1 for maximum counting period
PIT_TCTRL1 = 0x0; // disable timer 1 interrupts
PIT_TCTRL1 |= CHN; // chain timer 1 to timer 0
PIT_TCTRL1 |= TEN; // start timer 1

// Timer 0
```

```
PIT_LDVAL0 = 0xFFFFFFFF; // setup timer 0 for maximum counting period
PIT_TCTRL0 = TEN; // start timer 0
```

To access the lifetime, read first LTMR64H and then LTMR64L.

```
current_uptime = PIT_LTMR64H<<32;
current_uptime = current_uptime + PIT_LTMR64L;
```

Chapter 53
CAN (FlexCAN)

53.1 Chip-specific FlexCAN information

53.1.1 Overview

The chip contains three individual controller area network (FlexCAN3) modules. All these modules implement the CAN protocol according to Bosch Specification version 2.0B. Additionally, two out of the three modules implement the CAN with flexible data rate (CAN-FD) mode of the Bosch Specification and the ISO/DIS11898-1:2015 with the enhanced CRC.

The CAN-FD protocol capable modules are configured for 96 message buffers. The eDMA request for receive transactions and the pretended networking mode are not supported.

Table 53-1. CAN configuration

Module	CAN mode	CAN-FD mode	Number message buffers	Data rate (Mbps)
CAN_0	Yes	Yes	96	8
CAN_1	Yes	No	64	1
CAN_2	Yes	Yes	96	8

The following table shows the high-level memory map differences between FlexCAN and FlexCAN-FD modules.

Register/bit	CAN_0 and CAN_2 (both support FD)	CAN_1
CAN_MCR[FDEN]	Yes	No
CAN_ECR[RXERRCNT_FAST]	Yes	No

Table continues on the next page...

Register/bit	CAN_0 and CAN_2 (both support FD)	CAN_1
CAN_ECR[TXERRCNT_FAST]		
CAN_ESR1[BIT1ERR_FAST]	Yes	No
CAN_ESR1[BIT0ERR_FAST]	Yes	No
CAN_ESR1[CRCERR_FAST]	Yes	No
CAN_ESR1[FRMERR_FAST]	Yes	No
CAN_ESR1[STFERR_FAST]	Yes	No
CAN_ESR1[ERRINT_FAST]	Yes	No
CAN_ESR1[ERROVR]	Yes	No
CAN_ESR1[BOFFDONEINT]	No	No
CAN_CTRL2[ERRMSK_FAST]	Yes	No
CAN_CTRL2[PREXCEN]	Yes	No
CAN_CTRL2[EDFLTDIS]	Yes	No
CAN_CTRL2[ISOCANFDEN]	Yes	No
CAN_IMASK3	Yes	No
CAN_IFLAG3	Yes	No
CAN_RXIMR[64]-CAN_RXIMR[95]	Yes	No
CAN_FDCTRL	Yes	No
CAN_FDCBT	Yes	No
CAN_FDCRC	Yes	No

There are 3 types of reset mentioned in the FlexCAN module chapter:

- "Chip level hard reset" is any SoC level reset. This could be triggered by assertion of an external reset pin, an LVD/HVD event, software interaction with the Reset Generation Module or any other event that places the device in the reset sequence.
- "Chip level soft reset" is not supported by this device.
- "SOFTRST bit in MCR" is the module level reset control and only resets the FlexCAN module.

53.1.1.1 Device Specific reset values

The reset value of all FlexCAN/FlexCAN FD registers that are device specific are shown in the following table. All other register reset values for FlexCAN/FlexCAN FD are shown in the memory map section.

Table 53-2. FlexCAN reset values

Offset (hex)	Register	Reset value (hex)
34	Control 2 register (CAN1_CTRL2)	0x0080_0000

53.1.1.2 CAN_1 Error Injection Address Register (CAN_ERRIAR) - error injection addresses

The following table lists the error injection addresses given in table for CAN_ERRIAR register is valid for CAN_1 (non-FD).

RAM contents	Injection address	Memory map
FlexCAN Registers	Not mapped	-
MBs	0x0000	0x0080
Reserved	-	0x0480
RXIMRs	0x0400	0x0880
Reserved	-	0x0980
RXFIR_0	0x0500	0x0A80
RXFIR_1	0x0504	0x0A84
RXFIR_2	0x0508	0x0A88
RXFIR_3	0x050C	0x0A8C
RXFIR_4	0x0510	0x0A90
RXFIR_5	0x0514	0x0A94

1. If the FlexCAN module supports only classical CAN (CAN 2.0B) i.e. CAN_1, it is not possible to inject errors on TX Serial Message Buffer (TXSMB) address since TXSMB is not implemented on RAM

53.2 Introduction

The FlexCAN module is a communication controller implementing the CAN protocol according to the ISO 11898-1 standard and CAN 2.0 B protocol specifications. A general block diagram is shown in the following figure, which describes the main subblocks implemented in the FlexCAN module, including one associated memory for storing message buffers, Receive Global Mask registers, Receive Individual Mask registers, Receive FIFO filters, and Receive FIFO ID filters. The functions of the submodules are described in subsequent sections.

NOTE

Rx FIFOs cannot be used in FD mode.

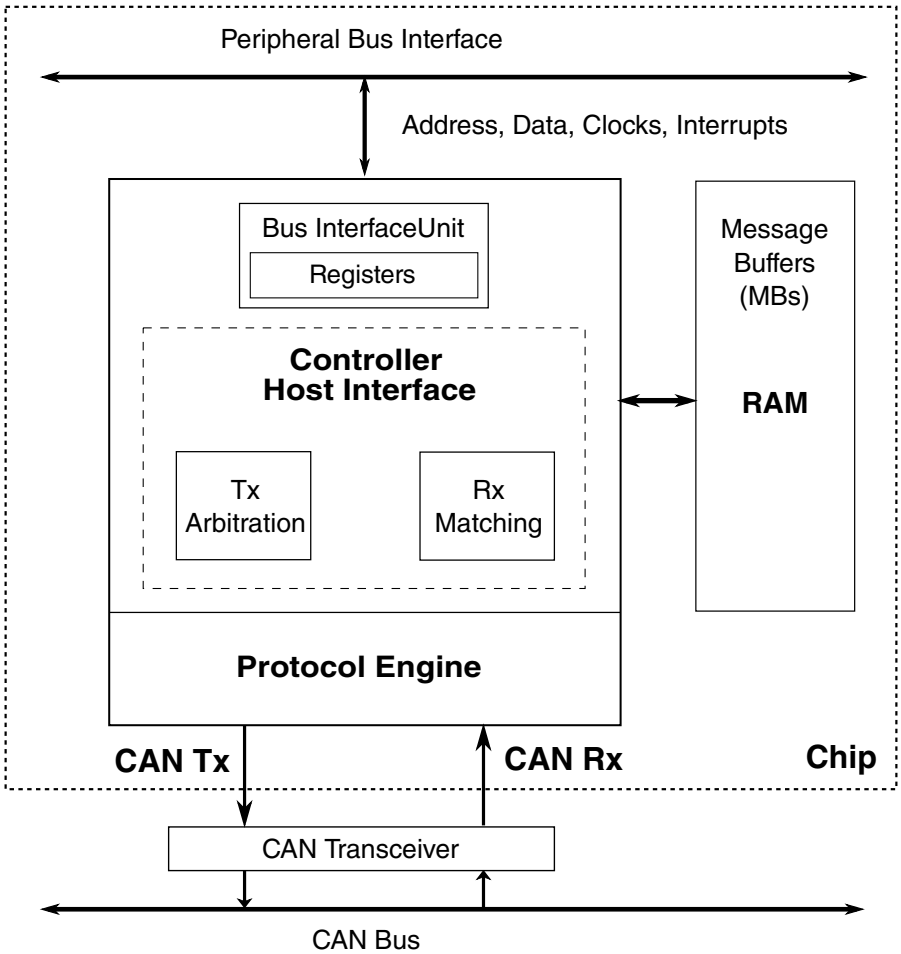

Figure 53-1. FlexCAN block diagram

53.2.1 Overview

The CAN protocol was primarily designed to be used as a vehicle serial data bus, meeting the specific requirements of this field:

- Real-time processing
- Reliable operation in the EMI environment of a vehicle
- Cost-effectiveness
- Required bandwidth

The FlexCAN module is a full implementation of the CAN protocol specification, the CAN with Flexible Data rate (CAN FD) protocol and the CAN 2.0 version B protocol, which supports both standard and extended message frames and long payloads up to 64

bytes transferred at faster rates up to 8 Mbps. The message buffers are stored in an embedded RAM dedicated to the FlexCAN module. See the chip configuration details for the actual number of message buffers configured in the chip.

The Protocol Engine (PE) submodule manages the serial communication on the CAN bus:

- Requesting RAM access for receiving and transmitting message frames
- Validating received messages
- Performing error handling
- Detecting CAN FD messages

The Controller Host Interface (CHI) sub-module handles message buffer selection for reception and transmission, taking care of arbitration and ID matching algorithms for both CAN FD and non-CAN FD message formats.

The Bus Interface Unit (BIU) sub-module controls the access to and from the internal interface bus, in order to establish connection to the CPU and to other blocks. Clocks, address and data buses, interrupt outputs and test signals are accessed through the BIU.

53.2.2 FlexCAN module features

The FlexCAN module includes these distinctive features:

- Full implementation of the CAN with Flexible Data Rate (CAN FD) protocol specification and CAN protocol specification, Version 2.0 B
    - Standard data frames
    - Extended data frames
    - Zero to sixty four bytes data length
    - Programmable bit rate (see the chip-specific FlexCAN information for the specific maximum rate configuration)
    - Content-related addressing
- Compliant with the ISO 11898-1 standard
- Flexible mailboxes configurable to store 0 to 8, 16, 32 or 64 bytes data length
- Each mailbox configurable as receive or transmit, all supporting standard and extended messages
- Individual Rx Mask registers per mailbox

- Full-featured Rx FIFO with storage capacity for up to six frames and automatic internal pointer handling
- Transmission abort capability
- Flexible message buffers (MBs), totaling 96 message buffers of 8 bytes data length each, configurable as Rx or Tx
- Programmable clock source to the CAN Protocol Interface, either peripheral clock or oscillator clock
- RAM not used by reception or transmission structures can be used as general purpose RAM space
- Listen-Only mode capability
- Programmable Loop-Back mode supporting self-test operation
- Programmable transmission priority scheme: lowest ID, lowest buffer number, or highest priority
- Time stamp based on 16-bit free-running timer
- Global network time, synchronized by a specific message
- Maskable interrupts
- Independence from the transmission medium (an external transceiver is assumed)
- Short latency time due to an arbitration scheme for high-priority messages
- Low power modes
- Transceiver Delay Compensation feature when transmitting CAN FD messages at faster data rates
- Remote request frames may be handled automatically or by software
- CAN bit time settings and configuration bits can only be written in Freeze mode
- Tx mailbox status (Lowest priority buffer or empty buffer)
- Identifier Acceptance Filter Hit Indicator (IDHIT) register for received frames
- SYNCH bit available in Error in Status 1 register to inform that the module is synchronous with CAN bus
- CRC status for transmitted message
- Rx FIFO Global Mask register

- Selectable priority between mailboxes and Rx FIFO during matching process
- Powerful Rx FIFO ID filtering, capable of matching incoming IDs against either 128 extended, 256 standard, or 512 partial (8 bit) IDs, with up to 32 individual masking capability
- 100% backward compatibility with previous FlexCAN version
- Supports detection and correction of errors in memory read accesses. Each byte of FlexCAN memory is associated to 5 parity bits and the error correction mechanism ensures that in this 13-bit word, errors in one bit can be corrected (correctable errors) and errors in 2 bits can be detected but not corrected (non-correctable errors)

53.2.3 Modes of operation

The FlexCAN module has these functional modes:

- Normal mode (User or Supervisor):

  In Normal mode, the module operates receiving and/or transmitting message frames, errors are handled normally, and all CAN Protocol functions are enabled. User and Supervisor Modes differ in the access to some restricted control registers.

- Freeze mode:

  Freeze mode is enabled when the FRZ bit in MCR is asserted. If enabled, Freeze mode is entered when MCR[HALT] is set or when Debug mode is requested at chip level and MCR[FRZ_ACK] is asserted by the FlexCAN. In this mode, no transmission or reception of frames is done and synchronicity to the CAN bus is lost. See Freeze mode for more information.

- Loop-Back mode:

  The module enters this mode when the LPB field in the Control 1 Register is asserted. In this mode, FlexCAN performs an internal loop back that can be used for self-test operation. The bit stream output of the transmitter is internally fed back to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic '1'). FlexCAN behaves as it normally does when transmitting and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field to ensure proper reception of its own message. Both transmit and receive interrupts are generated.

- Listen-Only mode:

The module enters this mode when the LOM field in the Control 1 Register is asserted. In this mode, transmission is disabled, all error counters are frozen, and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station will be received. If FlexCAN detects a message that has not been acknowledged, it will flag a BIT0 error (without changing the REC), as if it was trying to acknowledge the message.

- CAN FD Active mode:

  In this mode, FlexCAN is capable of transmitting and receiving all messages formatted according to the CAN FD Protocol and CAN 2.0 Protocol 2.0 in a interleaved fashion. The CPU can set the FlexCAN into CAN FD Active mode by configuring the MCR[FDEN] bit field in Freeze Mode.

For low-power operation, the FlexCAN module has:

- Module Disable mode:

  This low-power mode is entered when the MDIS bit in the MCR Register is asserted by the CPU and the LPM_ACK is asserted by the FlexCAN. When disabled, the module requests to disable the clocks to the CAN Protocol Engine and Controller Host Interface submodules. Exit from this mode is done by negating the MDIS bit in the MCR register. See Module Disable mode for more information.

- Stop mode:

  This low power mode is entered when Stop mode is requested at chip level and the LPM_ACK bit in the MCR Register is asserted by the FlexCAN. When in Stop Mode, the module puts itself in an inactive state and then informs the CPU that the clocks can be shut down globally. Exit from this mode happens when the Stop mode request is removed. See Stop mode for more information.

53.3 FlexCAN signal descriptions

The FlexCAN module has two I/O signals connected to the external chip pins. These signals are summarized in the following table and described in more detail in the next subsections.

Table 53-3. FlexCAN signal descriptions

Signal	Description	I/O
CAN Rx	CAN Receive Pin	Input
CAN Tx	CAN Transmit Pin	Output

53.3.1 CAN Rx

This pin is the receive pin from the CAN bus transceiver. Dominant state is represented by logic level 0. Recessive state is represented by logic level 1.

53.3.2 CAN Tx

This pin is the transmit pin to the CAN bus transceiver. Dominant state is represented by logic level 0. Recessive state is represented by logic level 1.

53.4 Memory map/register definition

This section describes the registers and data structures in the FlexCAN module. The base address of the module depends on the particular memory map of the chip.

53.4.1 FlexCAN memory mapping

The memory map for the FlexCAN module is shown in the following table.

The address space occupied by FlexCAN has 128 bytes for registers starting at the module base address, followed by embedded RAM starting at address offset 0x0080.

Each individual register is identified by its complete name and the corresponding mnemonic. The access type can be Supervisor (S) or Unrestricted (U). Most of the registers can be configured to have either Supervisor or Unrestricted access by programming the SUPV field in the MCR register. These registers are identified as S/U in the Access column of Table 53-4.

Table 53-4. Register access and reset information

Register	Access type	Affected by hard reset	Affected by soft reset
Module Configuration Register (CAN_MCR)	S	Yes	Yes
Control 1 register (CAN_CTRL1)	S/U	Yes	No
Free Running Timer register (CAN_TIMER)	S/U	Yes	Yes
Rx Mailboxes Global Mask register (CAN_RXMGMASK)	S/U	No	No
Rx Buffer 14 Mask register (CAN_RX14MASK)	S/U	No	No
Rx Buffer 15 Mask register (CAN_RX15MASK)	S/U	No	No

Table continues on the next page...

Table 53-4. Register access and reset information (continued)

Register	Access type	Affected by hard reset	Affected by soft reset
Error Counter Register (CAN_ECR)	S/U	Yes	Yes
Error and Status 1 Register (CAN_ESR1)	S/U	Yes	Yes
Interrupt Masks 2 register (CAN_IMASK2)	S/U	Yes	Yes
Interrupt Masks 1 register (CAN_IMASK1)	S/U	Yes	Yes
Interrupt Flags 2 register (CAN_IFLAG2)	S/U	Yes	Yes
Interrupt Flags 1 register (CAN_IFLAG1)	S/U	Yes	Yes
Control 2 Register (CAN_CTRL2)	S/U	Yes	No
Error and Status 2 Register (CAN_ESR2)	S/U	Yes	Yes
CRC Register (CAN_CRCR)	S/U	Yes	Yes
Rx FIFO Global Mask register (CAN_RXFGMASK)	S/U	No	No
Rx FIFO Information Register (CAN_RXFIR)	S/U	No	No
CAN Bit Timing Register (CAN_CBT)	S/U	Yes	No
Interrupt Masks 3 register (CAN_IMASK3)	S/U	Yes	Yes
Interrupt Flags 3 register (CAN_IFLAG3)	S/U	Yes	Yes
Message buffers	S/U	No	No
Rx Individual Mask Registers	S/U	No	No
Memory Error Control register (CAN_MECR)	S/U	Yes	Yes
Error Injection Address register (CAN_ERRIAR)	S/U	Yes	Yes
Error Injection Data Pattern register (CAN_ERRIDPR)	S/U	Yes	Yes
Error Injection Parity Pattern register (CAN_ERRIPPR)	S/U	Yes	Yes
Error Report Address register (CAN_RERRAR)	S/U	Yes	Yes
Error Report Data register (CAN_RERRDR)	S/U	Yes	Yes
Error Report Syndrome register (CAN_RERRSYNR)	S/U	Yes	Yes
Error Status register (CAN_ERRSR)	S/U	Yes	Yes
CAN FD Control register (CAN_FDCTRL)	S/U	Yes	No
CAN FD Bit Timing register (CAN_FDCBT)	S/U	Yes	No
CAN FD CRC register (CAN_FDCRC)	S/U	Yes	Yes

The FlexCAN module can store CAN messages for transmission and reception using mailboxes and Rx FIFO structures.

The table below shows the FlexCAN memory map.

The address range from offset 0x80 to 0x67F allocates the ninety-six 128-bit Message Buffers (MBs).

The memory maps for the message buffers are in FlexCAN message buffer memory map.

CAN memory map

CAN_MCR field descriptions

Field	Description
0 MDIS	Module Disable This bit controls whether FlexCAN is enabled or not. When disabled, FlexCAN disables the clocks to the CAN Protocol Engine and Controller Host Interface sub-modules. This bit is not affected by soft reset. 0 Enable the FlexCAN module. 1 Disable the FlexCAN module.
1 FRZ	Freeze Enable The FRZ bit specifies the FlexCAN behavior when the HALT bit in the CAN_MCR Register is set or when Debug mode is requested at chip level. When FRZ is asserted, FlexCAN is enabled to enter Freeze mode. Negation of this bit field causes FlexCAN to exit from Freeze mode. This bit is set by hardware when a non-correctable error is detected and NCEFAFRZ bit in CAN_MECR register is asserted.

Table continues on the next page...

CAN_MCR field descriptions (continued)

Field	Description
	0 Not enabled to enter Freeze mode. 1 Enabled to enter Freeze mode.
2 RFEN	Rx FIFO Enable This bit controls whether the Rx FIFO feature is enabled or not. When RFEN is set, MBs 0 to 5 cannot be used for normal reception and transmission because the corresponding memory region (0x80-0xDC) is used by the FIFO engine as well as additional MBs (up to 32, depending on CAN_CTRL2[RFFN] setting) which are used as Rx FIFO ID Filter Table elements. RFEN also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in the table "Minimum Ratio Between Peripheral Clock Frequency and CAN Bit Rate" (see Arbitration and matching timing). This bit can be written in Freeze mode only because it is blocked by hardware in other modes. **NOTE:** This bit cannot be set when CAN FD operation is enabled (see FDEN bit). 0 Rx FIFO not enabled. 1 Rx FIFO enabled.
3 HALT	Halt FlexCAN Assertion of this bit puts the FlexCAN module into Freeze mode. The CPU should clear it after initializing the Message Buffers and the Control Registers CAN_CTRL1 and CAN_CTRL2. No reception or transmission is performed by FlexCAN before this bit is cleared. Freeze mode cannot be entered while FlexCAN is in a low power mode. The HALT bit is set by hardware when a non-correctable error is detected and NCEFAFRZ bit in CAN_MECR register is asserted. 0 No Freeze mode request. 1 Enters Freeze mode if the FRZ bit is asserted.
4 NOTRDY	FlexCAN Not Ready This read-only bit indicates that FlexCAN is either in Disable mode, Stop mode or Freeze mode. It is negated once FlexCAN has exited these modes. This bit is not affected by soft reset. 0 FlexCAN module is either in Normal mode, Listen-Only mode or Loop-Back mode. 1 FlexCAN module is either in Disable mode, Stop mode or Freeze mode.
5 Reserved	This field is reserved. When writing to this field, always write the reset value.
6 SOFTRST	Soft Reset When this bit is asserted, FlexCAN resets its internal state machines and some of the memory mapped registers. The SOFTRST bit can be asserted directly by the CPU when it writes to the MCR Register, but it is also asserted when global soft reset is requested at chip level. Because soft reset is synchronous and has to follow a request/acknowledge procedure across clock domains, it may take some time to fully propagate its effect. The SOFTRST bit remains asserted while reset is pending, and is automatically negated when reset completes. Therefore, software can poll this bit to know when the soft reset has completed. Soft reset cannot be applied while clocks are shut down in a low power mode. The module should be first removed from low power mode, and then soft reset can be applied. This bit is not affected by soft reset. 0 No reset request. 1 Resets the registers affected by soft reset.
7 FRZACK	Freeze Mode Acknowledge

Table continues on the next page...

CAN_MCR field descriptions (continued)

Field	Description
	This read-only bit indicates that FlexCAN is in Freeze mode and its prescaler is stopped. The Freeze mode request cannot be granted until current transmission or reception processes have finished. Therefore the software can poll the FRZACK bit to know when FlexCAN has actually entered Freeze mode. If Freeze Mode request is negated, then this bit is negated after the FlexCAN prescaler is running again. If Freeze mode is requested while FlexCAN is in a low power mode, then the FRZACK bit will be set only when the low-power mode is exited. See Section "Freeze Mode". This bit is not affected by soft reset. **NOTE:** FRZACK will be asserted within 178 CAN bits from the freeze mode request by the CPU, and negated within 2 CAN bits after the freeze mode request removal (see Section "Protocol Timing"). 0 FlexCAN not in Freeze mode, prescaler running. 1 FlexCAN in Freeze mode, prescaler stopped.
8 SUPV	Supervisor Mode This bit configures the FlexCAN to be either in Supervisor or User mode. The registers affected by this bit are marked as S/U in the Access Type column of the module memory map. Reset value of this bit is 1, so the affected registers start with Supervisor access allowance only. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 FlexCAN is in User mode. Affected registers allow both Supervisor and Unrestricted accesses. 1 FlexCAN is in Supervisor mode. Affected registers allow only Supervisor access. Unrestricted access behaves as though the access was done to an unimplemented register location.
9 Reserved	This field is reserved. When writing to this field, always write the reset value.
10 WRNEN	Warning Interrupt Enable When asserted, this bit enables the generation of the TWRNINT and RWRNINT flags in the Error and Status Register 1 (ESR1). If WRNEN is negated, the TWRNINT and RWRNINT flags will always be zero, independent of the values of the error counters, and no warning interrupt will ever be generated. This bit can be written in Freeze mode only because it is blocked by hardware in other modes. 0 TWRNINT and RWRNINT bits are zero, independent of the values in the error counters. 1 TWRNINT and RWRNINT bits are set when the respective error counter transitions from less than 96 to greater than or equal to 96.
11 LPMACK	Low-Power Mode Acknowledge This read-only bit indicates that FlexCAN is in a low-power mode (Disable mode, Stop mode). A low-power mode cannot be entered until all current transmission or reception processes have finished, so the CPU can poll the LPMACK bit to know when FlexCAN has actually entered low power mode. This bit is not affected by soft reset. **NOTE:** LPMACK will be asserted within 180 CAN bits from the low-power mode request by the CPU, and negated within 2 CAN bits after the low-power mode request removal (see Section "Protocol Timing"). 0 FlexCAN is not in a low-power mode. 1 FlexCAN is in a low-power mode.
12 Reserved	This field is reserved. When writing to this field, always write the reset value.
13 Reserved	This field is reserved. When writing to this field, always write the reset value.

Table continues on the next page...

CAN_MCR field descriptions (continued)

Field	Description
14 SRXDIS	Self Reception Disable This bit defines whether FlexCAN is allowed to receive frames transmitted by itself. If this bit is asserted, frames transmitted by the module will not be stored in any MB, regardless if the MB is programmed with an ID that matches the transmitted frame, and no interrupt flag or interrupt signal will be generated due to the frame reception. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 Self reception enabled. 1 Self reception disabled.
15 IRMQ	Individual Rx Masking And Queue Enable This bit indicates whether Rx matching process will be based either on individual masking and queue or on masking scheme with CAN_RXMGMASK, CAN_RX14MASK, CAN_RX15MASK and CAN_RXFGMASK. This bit can be written in Freeze mode only because it is blocked by hardware in other modes. 0 Individual Rx masking and queue feature are disabled. For backward compatibility with legacy applications, the reading of C/S word locks the MB even if it is EMPTY. 1 Individual Rx masking and queue feature are enabled.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 LPRIOEN	Local Priority Enable This bit is provided for backwards compatibility with legacy applications. It controls whether the local priority feature is enabled or not. It is used to expand the ID used during the arbitration process. With this expanded ID concept, the arbitration process is done based on the full 32-bit word, but the actual transmitted ID still has 11-bit for standard frames and 29-bit for extended frames. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. 0 Local Priority disabled. 1 Local Priority enabled.
19 AEN	Abort Enable When asserted, this bit enables the Tx abort mechanism. This mechanism guarantees a safe procedure for aborting a pending transmission, so that no frame is sent in the CAN bus without notification. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. **NOTE:** When CAN_MCR[AEN] is asserted, only the abort mechanism (see Transmission abort mechanism) must be used for updating Mailboxes configured for transmission. **CAUTION:** Writing the Abort code into Rx Mailboxes can cause unpredictable results when the CAN_MCR[AEN] is asserted. 0 Abort disabled. 1 Abort enabled.
20 FDEN	CAN FD operation enable This bit enables the CAN with Flexible Data rate (CAN FD) operation. This bit can be written in Freeze mode only. **NOTE:** The Rx FIFO Enable (RFEN) bit cannot be set if FDEN is asserted.

Table continues on the next page...

CAN_MCR field descriptions (continued)

Field	Description
	1 CAN FD is enabled. FlexCAN is able to receive and transmit messages in both CAN FD and CAN 2.0 formats. 0 CAN FD is disabled. FlexCAN is able to receive and transmit messages in CAN 2.0 format.
21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–23 IDAM	ID Acceptance Mode This 2-bit field identifies the format of the Rx FIFO ID Filter Table elements. Note that all elements of the table are configured at the same time by this field (they are all the same format). See Section "Rx FIFO Structure". This field can be written only in Freeze mode because it is blocked by hardware in other modes. 00 Format A: One full ID (standard and extended) per ID Filter Table element. 01 Format B: Two full standard IDs or two partial 14-bit (standard and extended) IDs per ID Filter Table element. 10 Format C: Four partial 8-bit Standard IDs per ID Filter Table element. 11 Format D: All frames rejected.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–31 MAXMB	Number Of The Last Message Buffer This 7-bit field defines the number of the last Message Buffers that will take part in the matching and arbitration processes. The reset value (0x0F) is equivalent to a 16 MB configuration. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Number of the last MB = MAXMB **NOTE:** MAXMB must be programmed with a value smaller than or equal to the number of available Message Buffers, as described in FlexCAN Memory Partition for CAN FD. Additionally, the definition of MAXMB value must take into account the region of MBs occupied by Rx FIFO and its ID filters table space defined by RFFN bit in CAN_CTRL2 register. MAXMB also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in Table "Minimum Ratio Between Peripheral Clock Frequency and CAN Bit Rate" (see Arbitration and matching timing).

53.4.3 Control 1 register (CAN_CTRL1)

This register is defined for specific FlexCAN control features related to the CAN bus, such as bit-rate, programmable sampling point within an Rx bit, Loop Back mode, Listen-Only mode, Bus Off recovery behavior and interrupt enabling (Bus-Off, Error, Warning). It also determines the Division Factor for the clock prescaler.

The CAN bit timing variables (PRESDIV, PROPSEG, PSEG1, PSEG2 and RJW) can also be configured in CAN_CBT register, which extends the range of all these variables. If CAN_CBT[BTF] is set, PRESDIV, PROPSEG, PSEG1, PSEG2 and RJW fields of CAN_CTRL1 become read only.

NOTE

When the CAN FD feature is enabled, do not use the PRESDIV, RJW, PSEG1, PSEG2, and PROPSEG fields of the CAN_CTRL1 register for CAN bit timing. Instead use the the CAN_CBT register's EPRESDIV, ERJW, EPSEG1, EPSEG2, and EPROPSEG fields.

The contents of this register are not affected by soft reset.

NOTE

The CAN bit variables in CAN_CTRL1 and in CAN_CBT are stored in the same register.

Address: 0h base + 4h offset = 4h

CAN_CTRL1 field descriptions

Field	Description
0–7 PRESDIV	Prescaler Division Factor This 8-bit field defines the ratio between the PE clock frequency and the Serial Clock (Sclock) frequency. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency. The Maximum value of this field is 0xFF, that gives a minimum Sclock frequency equal to the PE clock frequency divided by 256. See Section "Protocol Timing". This field can be written only in Freeze mode because it is blocked by hardware in other modes. Sclock frequency = PE clock frequency / (PRESDIV + 1)

Table continues on the next page...

CAN_CTRL1 field descriptions (continued)

Field	Description
8–9 RJW	Resync Jump Width This 2-bit field defines the maximum number of time quanta that a bit time can be changed by one re-synchronization. One time quantum is equal to the Sclock period. The valid programmable values are 0–3. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Resync Jump Width = RJW + 1.
10–12 PSEG1	Phase Segment 1 This 3-bit field defines the length of Phase Segment 1 in the bit time. The valid programmable values are 0–7. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Buffer Segment 1 = (PSEG1 + 1) × Time-Quanta.
13–15 PSEG2	Phase Segment 2 This 3-bit field defines the length of Phase Segment 2 in the bit time. The valid programmable values are 1–7. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Buffer Segment 2 = (PSEG2 + 1) × Time-Quanta.
16 BOFFMSK	Bus Off Interrupt Mask This bit provides a mask for the Bus Off Interrupt BOFFINT in CAN_ESR1 register. 0 Bus Off interrupt disabled. 1 Bus Off interrupt enabled.
17 ERRMSK	Error Interrupt Mask This bit provides a mask for the Error Interrupt ERRINT in the CAN_ESR1 register. 0 Error interrupt disabled. 1 Error interrupt enabled.
18 CLKSRC	CAN Engine Clock Source This bit selects the clock source to the CAN Protocol Engine (PE) to be either the peripheral clock or the oscillator clock. The selected clock is the one fed to the prescaler to generate the Serial Clock (Sclock). In order to guarantee reliable operation, this bit can be written only in Disable mode because it is blocked by hardware in other modes. See Protocol timing". 0 The CAN engine clock source is the oscillator clock. Under this condition, the oscillator clock frequency must be lower than the bus clock. 1 The CAN engine clock source is the peripheral clock.
19 LPB	Loop Back Mode This bit configures FlexCAN to operate in Loop-Back mode. In this mode, FlexCAN performs an internal loop back that can be used for self test operation. The bit stream output of the transmitter is fed back internally to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic 1). FlexCAN behaves as it normally does when transmitting, and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field, generating an internal acknowledge bit to ensure proper reception of its own message. Both transmit and receive interrupts are generated. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. **NOTE:** In this mode, the CAN_MCR[SRXDIS] cannot be asserted because this will impede the self reception of a transmitted message.

Table continues on the next page...

CAN_CTRL1 field descriptions (continued)

Field	Description
	NOTE: The TDCEN bit in CAN_FDCTRL register must be disabled when LPB is asserted. 0 Loop Back disabled. 1 Loop Back enabled.
20 TWRNMSK	Tx Warning Interrupt Mask This bit provides a mask for the Tx Warning Interrupt associated with the TWRNINT flag in the Error and Status Register 1 (ESR1). This bit is read as zero when CAN_MCR[WRNEN] bit is negated. This bit can be written only if CAN_MCR[WRNEN] bit is asserted. 0 Tx Warning Interrupt disabled. 1 Tx Warning Interrupt enabled.
21 RWRNMSK	Rx Warning Interrupt Mask This bit provides a mask for the Rx Warning Interrupt associated with the RWRNINT flag in the Error and Status Register 1 (ESR1). This bit is read as zero when CAN_MCR[WRNEN] bit is negated. This bit can be written only if CAN_MCR[WRNEN] bit is asserted. 0 Rx Warning Interrupt disabled. 1 Rx Warning Interrupt enabled.
22 Reserved	This field is reserved.
23 Reserved	This field is reserved.
24 SMP	CAN Bit Sampling This bit defines the sampling mode of CAN bits at the Rx input. It can be written in Freeze mode only because it is blocked by hardware in other modes. **NOTE:** For proper operation, to assert SMP it is necessary to guarantee a minimum value of 2 TQs in CAN_CTRL1[PSEG1] (or CAN_CBT[EPSEG1]).This bit cannot be asserted when CAN FD is enabled (CAN_MCR[FDEN] = 1). 0 Just one sample is used to determine the bit value. 1 Three samples are used to determine the value of the received bit: the regular one (sample point) and 2 preceding samples; a majority rule is used.
25 BOFFREC	Bus Off Recovery This bit defines how FlexCAN recovers from Bus Off state. If this bit is negated, automatic recovering from Bus Off state occurs according to the CAN Specification 2.0B. If the bit is asserted, automatic recovering from Bus Off is disabled and the module remains in Bus Off state until the bit is negated by the user. If the negation occurs before 128 sequences of 11 recessive bits are detected on the CAN bus, then Bus Off recovery happens as if the BOFFREC bit had never been asserted. If the negation occurs after 128 sequences of 11 recessive bits occurred, then FlexCAN will re-synchronize to the bus by waiting for 11 recessive bits before joining the bus. After negation, the BOFFREC bit can be re-asserted again during Bus Off, but it will be effective only the next time the module enters Bus Off. If BOFFREC was negated when the module entered Bus Off, asserting it during Bus Off will not be effective for the current Bus Off recovery. 0 Automatic recovering from Bus Off state enabled. 1 Automatic recovering from Bus Off state disabled.
26 TSYN	Timer Sync

Table continues on the next page...

CAN_CTRL1 field descriptions (continued)

Field	Description
	This bit enables a mechanism that resets the free-running timer each time a message is received in Message Buffer 0. This feature provides means to synchronize multiple FlexCAN stations with a special "SYNC" message, that is, global network time. If the RFEN bit in CAN_MCR is set (Rx FIFO enabled), the first available Mailbox, according to CAN_CTRL2[RFFN] setting, is used for timer synchronization instead of MB0. This bit can be written in Freeze mode only because it is blocked by hardware in other modes. 0 Timer Sync feature disabled 1 Timer Sync feature enabled
27 LBUF	Lowest Buffer Transmitted First This bit defines the ordering mechanism for Message Buffer transmission. When asserted, the CAN_MCR[LPRIOEN] bit does not affect the priority arbitration. This bit can be written in Freeze mode only because it is blocked by hardware in other modes. 0 Buffer with highest priority is transmitted first. 1 Lowest number buffer is transmitted first.
28 LOM	Listen-Only Mode This bit configures FlexCAN to operate in Listen-Only mode. In this mode, transmission is disabled, all error counters described in CAN_ECR register are frozen and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station will be received. If FlexCAN detects a message that has not been acknowledged, it will flag a BIT0 error without changing the receive error counter (RXERRCNT) in CAN_ECR register, as if it was trying to acknowledge the message. Listen-Only mode is acknowledged by the state of CAN_ESR1[FLTCONF] field indicating Passive Error. There can be some delay between the Listen-Only mode request and acknowledge. This bit can be written in Freeze mode only because it is blocked by hardware in other modes. 0 Listen-Only mode is deactivated. 1 FlexCAN module operates in Listen-Only mode.
29–31 PROPSEG	Propagation Segment This 3-bit field defines the length of the Propagation Segment in the bit time. The valid programmable values are 0–7. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Propagation Segment Time = (PROPSEG + 1) × Time-Quanta. Time-Quantum = one Sclock period.

53.4.4 Free Running Timer (CAN_TIMER)

This register represents a 16-bit free running counter that can be read and written by the CPU. The timer starts from 0x0 after Reset, counts linearly to 0xFFFF, and wraps around.

The timer is incremented by the CAN bit clock, which defines the baud rate on the CAN bus. During a message transmission/reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate. The timer is not incremented during Disable, Stop and Freeze modes.

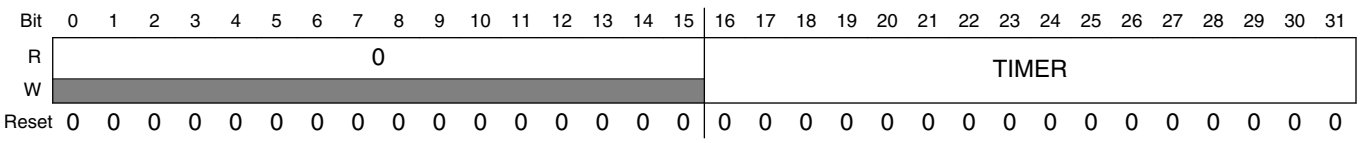
The timer value is captured when the second bit of the identifier field of any frame is on the CAN bus. This captured value is written into the Time Stamp entry in a message buffer after a successful reception or transmission of a message.

If bit CAN_CTRL1[TSYN] is asserted, the Timer is reset whenever a message is received in the first available Mailbox, according to CAN_CTRL2[RFFN] setting.

The CPU can write to this register anytime. However, if the write occurs at the same time that the Timer is being reset by a reception in the first Mailbox, then the write value is discarded.

Reading this register affects the Mailbox Unlocking procedure, see Section "Mailbox Lock Mechanism".

Address: 0h base + 8h offset = 8h



CAN_TIMER field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 TIMER	Timer Value Contains the free-running counter value.

53.4.5 Rx Mailboxes Global Mask Register (CAN_RXMGMASK)

This register is located in RAM.

RXMGMASK is provided for legacy application support.

- When the CAN_MCR[IRMQ] bit is negated, RXMGMASK is always in effect (the bits in the MG field will mask the Mailbox filter bits).
- When the CAN_MCR[IRMQ] bit is asserted, RXMGMASK has no effect (the bits in the MG field will not mask the Mailbox filter bits).

RXMGMASK is used to mask the filter fields of all Rx MBs, excluding MBs 14-15, which have individual mask registers.

This register can only be written in Freeze mode as it is blocked by hardware in other modes.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

* Notes:
- x = Undefined at reset.

CAN_RXMGMASK field descriptions

Field	Description
0–31 MG	Rx Mailboxes Global Mask Bits These bits mask the Mailbox filter bits. Note that the alignment with the ID word of the Mailbox is not perfect as the two most significant MG bits affect the fields RTR and IDE, which are located in the Control and Status word of the Mailbox. The following table shows in detail which MG bits mask each Mailbox filter field.

SMB[RTR] [1]	CAN_CTRL2[RRS]	CAN_CTRL2[EACEN]	Mailbox filter fields			
			MB[RTR]	MB[IDE]	MB[ID]	Reserved
0	-	0	note [2]	note [3]	MG[28:0]	MG[31:29]
0	-	1	MG[31]	MG[30]	MG[28:0]	MG[29]
1	0	-	-	-	-	MG[31:0]
1	1	0	-	-	MG[28:0]	MG[31:29]
1	1	1	MG[31]	MG[30]	MG[28:0]	MG[29]

1. RTR bit of the Incoming Frame. It is saved into an auxiliary MB called Rx Serial Message Buffer (Rx SMB).
2. If the CTRL2[EACEN] bit is negated, the RTR bit of Mailbox is never compared with the RTR bit of the incoming frame.
3. If the CAN_CTRL2[EACEN] bit is negated, the IDE bit of Mailbox is always compared with the IDE bit of the incoming frame.

0 The corresponding bit in the filter is "don't care."
1 The corresponding bit in the filter is checked.

1. RTR bit of the Incoming Frame. It is saved into an auxiliary MB called Rx Serial Message Buffer (Rx SMB).
2. If the CTRL2[EACEN] bit is negated, the RTR bit of Mailbox is never compared with the RTR bit of the incoming frame.
3. If the CAN_CTRL2[EACEN] bit is negated, the IDE bit of Mailbox is always compared with the IDE bit of the incoming frame.

53.4.6 Rx 14 Mask register (CAN_RX14MASK)

This register is located in RAM.

RX14MASK is provided for legacy application support. When the CAN_MCR[IRMQ] bit is asserted, RX14MASK has no effect.

RX14MASK is used to mask the filter fields of Message Buffer 14.

This register can only be programmed while the module is in Freeze mode as it is blocked by hardware in other modes.

Address: 0h base + 14h offset = 14h

CAN_RX14MASK field descriptions

Field	Description
0–31 RX14M	Rx Buffer 14 Mask Bits Each mask bit masks the corresponding Mailbox 14 filter field in the same way that RXMGMASK masks other Mailboxes' filters. See the description of the CAN_RXMGMASK register. 0 The corresponding bit in the filter is "don't care." 1 The corresponding bit in the filter is checked.

53.4.7 Rx 15 Mask register (CAN_RX15MASK)

This register is located in RAM.

RX15MASK is provided for legacy application support. When the CAN_MCR[IRMQ] bit is asserted, RX15MASK has no effect.

RX15MASK is used to mask the filter fields of Message Buffer 15.

This register can be programmed only while the module is in Freeze mode because it is blocked by hardware in other modes.

Address: 0h base + 18h offset = 18h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

CAN_RX15MASK field descriptions

Field	Description
0–31 RX15M	Rx Buffer 15 Mask Bits

CAN_RX15MASK field descriptions (continued)

Field	Description
	Each mask bit masks the corresponding Mailbox 15 filter field in the same way that RXMGMASK masks other Mailboxes' filters. See the description of the CAN_RXMGMASK register. 0 The corresponding bit in the filter is "don't care." 1 The corresponding bit in the filter is checked.

53.4.8 Error Counter (CAN_ECR)

This register has four 8-bit fields reflecting the value of the FlexCAN error counters:

- Transmit Error Counter (TXERRCNT field)
- Receive Error Counter (RXERRCNT field)
- Transmit Error Counter for errors detected in the Data Phase of CAN FD messages with the BRS bit set (TXERRCNT_FAST field)
- Receive Error Counter for errors detected in the Data Phase of CAN FD messages with the BRS bit set (RXERRCNT_FAST field)

The TXERRCNT and RXERRCNT counters take into account all errors in both CAN FD and non-FD message formats. TXERRCNT_FAST and RXERRCNT_FAST are dedicated to count only the errors occurred in the Data Phase of CAN FD frames with the BRS bit set.

The Fault Confinement State (FLTCONF field in Error and Status Register 1 - CAN_ESR1) is updated based on TXERRCNT and RXERRCNT counters only. TXERRCNT and RXERRCNT counters can be written in Freeze mode only. TXERRCNT_FAST and RXERRCNT_FAST counters are read-only except in Freeze mode where the CPU can write value zero. The rules for increasing and decreasing these counters are described in the CAN protocol and are completely implemented in the FlexCAN module.

The following are the basic rules for FlexCAN bus state transitions:

- If the value of TXERRCNT or RXERRCNT increases to be greater than or equal to 128, the FLTCONF field in the Error and Status Register is updated to reflect "Error Passive" state.
- If the FlexCAN state is "Error Passive", and either TXERRCNT or RXERRCNT decrements to a value less than or equal to 127 while the other already satisfies this condition, the FLTCONF field in the Error and Status Register is updated to reflect "Error Active" state.

- If the value of TXERRCNT increases to be greater than 255, the FLTCONF field in the Error and Status Register is updated to reflect "Bus Off" state, and an interrupt may be issued. The value of TXERRCNT is then reset to zero.
- If FlexCAN is in "Bus Off' state, then TXERRCNT is cascaded together with another internal counter to count the 128th occurrences of 11 consecutive recessive bits on the bus. Hence, TXERRCNT is reset to zero and counts in a manner where the internal counter counts 11 such bits and then wraps around while incrementing the TXERRCNT. When TXERRCNT reaches the value of 128, the FLTCONF field in the Error and Status Register is updated to be "Error Active" and both error counters are reset to zero. At any instance of dominant bit following a stream of less than 11 consecutive recessive bits, the internal counter resets itself to zero without affecting the TXERRCNT value. The TXERRCNT_FAST counter is frozen during busoff.
- If during system start-up, only one node is operating, then its TXERRCNT increases in each message it is trying to transmit, as a result of acknowledge errors (indicated by the ACKERR bit in the Error and Status Register). After the transition to "Error Passive" state, the TXERRCNT does not increment anymore by acknowledge errors. Therefore the device never goes to the "Bus Off" state.
- If the RXERRCNT increases to a value greater than 127, it is not incremented further, even if more errors are detected while being a receiver. At the next successful message reception, the counter is set to a value between 119 and 127 to resume to "Error Active" state.
- TXERRCNT_FAST and RXERRCNT_FAST error counters values increment and decrement based on errors detected only in the Data Phase of CAN FD frames with the BRS bit set, following the same increment and decrement rules as TXERRCNT and RXERRCNT counters. These counters do not wrap around and get stuck at their maximum value (255). They stop counting and keep their values frozen while FlexCAN is in "Bus Off" state. They are reset when FlexCAN leaves "Bus Off" state and restart counting once FlexCAN resumes to "Error Active" state.

Address: 0h base + 1Ch offset = 1Ch

CAN_ECR field descriptions

Field	Description
0–7 RXERRCNT_ FAST	Receive Error Counter for fast bits Receive Error Counter for errors detected in the Data Phase of received CAN FD messages with the BRS bit set. The RXERRCNT_FAST counter is read-only except in Freeze mode, where the CPU can write a 8-bit zero value only.

Table continues on the next page...

CAN_ECR field descriptions (continued)

Field	Description
8–15 TXERRCNT_ FAST	Transmit Error Counter for fast bits Transmit Error Counter for errors detected in the Data Phase of transmitted CAN FD messages with the BRS bit set. The TXERRCNT_FAST counter is read-only except in Freeze mode, where the CPU can write a 8-bit zero value only.
16–23 RXERRCNT	Receive Error Counter Receive Error Counter for all errors detected in received messages. The RXERRCNT counter is read-only except in Freeze mode, where it can be written by the CPU.
24–31 TXERRCNT	Transmit Error Counter Transmit Error Counter for all errors detected in transmitted messages. The TXERRCNT counter is read-only except in Freeze mode, where it can be written by the CPU.

53.4.9 Error and Status 1 register (CAN_ESR1)

This register reports various error conditions detected in the reception and transmission of a CAN frame, some general status of the device and it is the source of some interrupts to the CPU.

The reported error conditions are BIT1ERR, BIT0ERR, ACKKERR, CRCERR, FRMERR and STFERR, for errors detected in CAN frames of any format, and BIT1ERR_FAST, BIT0ERR_FAST, CRCERR_FAST, FRMERR_FAST and STFERR_FAST for errors detected in the Data Phase of CAN FD frames with the BRS bit set only.

An error detected in a single CAN frame may be reported by one or more error flags. Also, error reporting is cummulative in case more error events happen in the next frames while the CPU does not attempt to read this register.

TXWRN, RXWRN, IDLE, TX, FLTCONF, RX and SYNCH are status bits.

BOFFINT, BOFFDONEINT, ERRINT, ERRINT_FAST, TWRNINT and RWRNINT are interrupt bits. It is recommended the CPU to use the following procedure when servicing interrupt requests generated by these bits:

- Read this register to capture all error condition and status bits. This action clear the respective bits that were set since the last read access.
- Write 1 to clear the interrupt bit that has triggered the interrupt request.
- Write 1 to clear the ERR_OVR bit if it is set.

Starting from all error flags cleared, a first error event sets either the ERRINT or the ERRINT_FAST (provided the corresponding mask bit is asserted). If other error events in subsequent frames happen before the CPU to serve the interrupt request, the ERR_OVR bit is set to indicate that errors from different frames had accumulated.

CAN_ESR1 field descriptions

Field	Description
0 BIT1ERR_FAST	Bit1 Error in the Data Phase of CAN FD frames with the BRS bit set This bit indicates when an inconsistency occurs between the transmitted and the received bit in the Data Phase of CAN FD frames with the BRS bit set. 0 No such occurrence. 1 At least one bit sent as recessive is received as dominant.
1 BIT0ERR_FAST	Bit0 Error in the Data Phase of CAN FD frames with the BRS bit set This bit indicates when an inconsistency occurs between the transmitted and the received bit in the Data Phase of CAN FD frames with the BRS bit set. 0 No such occurrence. 1 At least one bit sent as dominant is received as recessive.
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 CRCERR_FAST	Cyclic Redundancy Check Error in the CRC field of CAN FD frames with the BRS bit set This bit indicates that a CRC Error has been detected by the receiver node in the CRC field of CAN FD frames with the BRS bit set, that is, the calculated CRC is different from the received. 0 No such occurrence. 1 A CRC error occurred since last read of this register.
4 FRMERR_FAST	Form Error in the Data Phase of CAN FD frames with the BRS bit set This bit indicates that a Form Error has been detected by the receiver node in the Data Phase of CAN FD frames with the BRS bit set, that is, a fixed-form bit field contains at least one illegal bit.

Table continues on the next page...

CAN_ESR1 field descriptions (continued)

Field	Description
	0 No such occurrence. 1 A Form Error occurred since last read of this register.
5 STFERR_FAST	Stuffing Error in the Data Phase of CAN FD frames with the BRS bit set This bit indicates that a Stuffing Error has been detected in the Data Phase of CAN FD frames with the BRS bit set. 0 No such occurrence. 1 A Stuffing Error occurred since last read of this register.
6–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 ERROVR	Error Overrun bit This bit indicates that an error condition occurred when any error flag is already set. This bit is cleared by writing it to 1. 0 Overrun has not occurred. 1 Overrun has occurred.
11 ERRINT_FAST	Error Interrupt for errors detected in the Data Phase of CAN FD frames with the BRS bit set This bit indicates that at least one of the Error Bits detected in the Data Phase of CAN FD frames with the BRS bit set (BIT1ERR_FAST, BIT0ERR_FAST, CRCERR_FAST, FRMERR_FAST or STFERR_FAST) is set. If the corresponding mask bit CAN_CTRL2[ERRMSK_FAST] is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect. 0 No such occurrence. 1 Indicates setting of any Error Bit detected in the Data Phase of CAN FD frames with the BRS bit set.
12 Reserved	This field is reserved.
13 SYNCH	CAN Synchronization Status This read-only flag indicates whether the FlexCAN is synchronized to the CAN bus and able to participate in the communication process. It is set and cleared by the FlexCAN. See the table in the overall CAN_ESR1 register description. 0 FlexCAN is not synchronized to the CAN bus. 1 FlexCAN is synchronized to the CAN bus.
14 TWRNINT	Tx Warning Interrupt Flag If the WRNEN bit in CAN_MCR is asserted, the TWRNINT bit is set when the TXWRN flag transitions from 0 to 1, meaning that the Tx error counter reached 96. If the corresponding mask bit in the Control 1 Register (CAN_CTRL1[TWRNMSK]) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. When WRNEN is negated, this flag is masked. CPU must clear this flag before disabling the bit. Otherwise it will be set when the WRNEN is set again. Writing 0 has no effect. This flag is not generated during Bus Off state. This bit is not updated during Freeze mode. 0 No such occurrence. 1 The Tx error counter transitioned from less than 96 to greater than or equal to 96.
15 RWRNINT	Rx Warning Interrupt Flag If the WRNEN bit in CAN_MCR is asserted, the RWRNINT bit is set when the RXWRN flag transitions from 0 to 1, meaning that the Rx error counters reached 96. If the corresponding mask bit in the Control 1

Table continues on the next page...

CAN_ESR1 field descriptions (continued)

Field	Description
	Register (CAN_CTRL1[RWRNMSK]) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. When WRNEN is negated, this flag is masked. CPU must clear this flag before disabling the bit. Otherwise it will be set when the WRNEN is set again. Writing 0 has no effect. This bit is not updated during Freeze mode. 0 No such occurrence. 1 The Rx error counter transitioned from less than 96 to greater than or equal to 96.
16 BIT1ERR	Bit1 Error This bit indicates when an inconsistency occurs between the transmitted and the received bit in a non-CAN FD message or in the arbitration or data phase of a CAN FD message. **NOTE:** This bit is not set by a transmitter in case of arbitration field or ACK slot, or in case of a node sending a passive error flag that detects dominant bits. 0 No such occurrence. 1 At least one bit sent as recessive is received as dominant.
17 BIT0ERR	Bit0 Error This bit indicates when an inconsistency occurs between the transmitted and the received bit in a non-CAN FD message or in the arbitration or data phase of a CAN FD message. 0 No such occurrence. 1 At least one bit sent as dominant is received as recessive.
18 ACKERR	Acknowledge Error This bit indicates that an Acknowledge Error has been detected by the transmitter node, that is, a dominant bit has not been detected during the ACK SLOT. 0 No such occurrence. 1 An ACK error occurred since last read of this register.
19 CRCERR	Cyclic Redundancy Check Error This bit indicates that a CRC Error has been detected by the receiver node either in a non-FD message or in the arbitration or data phase of a frame in CAN FD format, that is, the calculated CRC is different from the received. 0 No such occurrence. 1 A CRC error occurred since last read of this register.
20 FRMERR	Form Error This bit indicates that a Form Error has been detected in a non-FD message or else in an FD message's arbitration or data phase by the receiver node, that is, a fixed-form bit field contains at least one illegal bit. 0 No such occurrence. 1 A Form Error occurred since last read of this register.
21 STFERR	Stuffing Error This bit indicates that a Stuffing Error has been detected in a non-FD message or else in an FD message's arbitration or data phase by the receiver node. 0 No such occurrence. 1 A Stuffing Error occurred since last read of this register.

Table continues on the next page...

CAN_ESR1 field descriptions (continued)

Field	Description
22 TXWRN	TX Error Warning This bit indicates when repetitive errors are occurring during message transmission and is affected by the value of TXERRCNT in CAN_ECR register only. This bit is not updated during Freeze mode. 0 No such occurrence. 1 TXERRCNT is greater than or equal to 96.
23 RXWRN	Rx Error Warning This bit indicates when repetitive errors are occurring during message reception and is affected by the value of RXERRCNT in CAN_ECR register only. This bit is not updated during Freeze mode. 0 No such occurrence. 1 RXERRCNT is greater than or equal to 96.
24 IDLE	This bit indicates when CAN bus is in IDLE state. See the table in the overall CAN_ESR1 register description. 0 No such occurrence. 1 CAN bus is now IDLE.
25 TX	FlexCAN In Transmission This bit indicates if FlexCAN is transmitting a message. See the table in the overall CAN_ESR1 register description. 0 FlexCAN is not transmitting a message. 1 FlexCAN is transmitting a message.
26–27 FLTCONF	Fault Confinement State This 2-bit field indicates the Confinement State of the FlexCAN module. If the LOM bit in the Control Register 1 is asserted, after some delay that depends on the CAN bit timing the FLTCONF field will indicate “Error Passive”. The very same delay affects the way how FLTCONF reflects an update to CAN_ECR register by the CPU. It may be necessary up to one CAN bit time to get them coherent again. This bit field is affected by soft reset, but if the LOM bit is asserted, its reset value lasts just one CAN bit. After this time, FLTCONF reports "Error Passive". 00 Error Active 01 Error Passive 1x Bus Off
28 RX	FlexCAN In Reception This bit indicates if FlexCAN is receiving a message. See the table in the overall CAN_ESR1 register description. 0 FlexCAN is not receiving a message. 1 FlexCAN is receiving a message.
29 BOFFINT	Bus Off Interrupt This bit is set when FlexCAN enters ‘Bus Off’ state. If the corresponding mask bit in the Control Register 1 (CAN_CTRL1[BOFFMSK]) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect.

Table continues on the next page...

CAN_ESR1 field descriptions (continued)

Field	Description
	0 No such occurrence. 1 FlexCAN module entered Bus Off state.
30 ERRINT	Error Interrupt This bit indicates that at least one of the Error Bits (BIT1ERR, BIT0ERR, ACKERR. CRCERR, FRMERR or STFERR) is set. If the corresponding mask bit CAN_CTRL1[ERRMSK] is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect. 0 No such occurrence. 1 Indicates setting of any Error Bit in the Error and Status Register.
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

53.4.10 Interrupt Masks 2 register (CAN_IMASK2)

This register allows any number of a range of the 32 Message Buffer Interrupts to be enabled or disabled for MB63 to MB32. It contains one interrupt mask bit per buffer, enabling the CPU to determine which buffer generates an interrupt after a successful transmission or reception, that is, when the corresponding CAN_IFLAG2 bit is set.

Address: 0h base + 24h offset = 24h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

CAN_IMASK2 field descriptions

Field	Description
0–31 BUF63TO32M	Buffer MB $_i$ Mask Each bit enables or disables the corresponding FlexCAN Message Buffer Interrupt for MB63 to MB32. **NOTE:** Setting or clearing a bit in the CAN_IMASK2 Register can assert or negate an interrupt request, if the corresponding IFLAG2 bit is set. 0 The corresponding buffer Interrupt is disabled. 1 The corresponding buffer Interrupt is enabled.

53.4.11 Interrupt Masks 1 register (CAN_IMASK1)

This register allows any number of a range of the 32 Message Buffer Interrupts to be enabled or disabled for MB31 to MB0. It contains one interrupt mask bit per buffer, enabling the CPU to determine which buffer generates an interrupt after a successful transmission or reception, that is, when the corresponding CAN_IFLAG1 bit is set.

Address: 0h base + 28h offset = 28h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	BUF31TO0M

CAN_IMASK1 field descriptions

Field	Description
0–31 BUF31TO0M	Buffer MB $_i$ Mask Each bit enables or disables the corresponding FlexCAN Message Buffer Interrupt for MB31 to MB0. **NOTE:** Setting or clearing a bit in the CAN_IMASK1 Register can assert or negate an interrupt request, if the corresponding IFLAG1 bit is set. 0 The corresponding buffer Interrupt is disabled. 1 The corresponding buffer Interrupt is enabled.

53.4.12 Interrupt Flags 2 register (CAN_IFLAG2)

This register defines the flags for the 32 Message Buffer interrupts for MB63 to MB32. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the respective CAN_IFLAG2 bit. If the corresponding CAN_IMASK2 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect.

Before updating CAN_MCR[MAXMB] field, CPU must service the CAN_IFLAG2 bits whose MB value is greater than the MAXMB to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

Address: 0h base + 2Ch offset = 2Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	BUF63TO32I																															
W	w1c																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CAN_IFLAG2 field descriptions

Field	Description
0–31 BUF63TO32I	Buffer MB $_i$ Interrupt Each bit flags the corresponding FlexCAN Message Buffer interrupt for MB63 to MB32. 0 The corresponding buffer has no occurrence of successfully completed transmission or reception. 1 The corresponding buffer has successfully completed transmission or reception.

53.4.13 Interrupt Flags 1 register (CAN_IFLAG1)

This register defines the flags for the 32 Message Buffer interrupts for MB31 to MB0. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding CAN_IFLAG1 bit. If the corresponding CAN_IMASK1 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect.

The BUF7I to BUF5I flags are also used to represent FIFO interrupts when the Rx FIFO is enabled. When the bit CAN_MCR[RFEN] is set, the function of the 8 least significant interrupt flags changes: BUF7I, BUF6I and BUF5I indicate operating conditions of the FIFO and the BUF4I to BUF0I field is reserved.

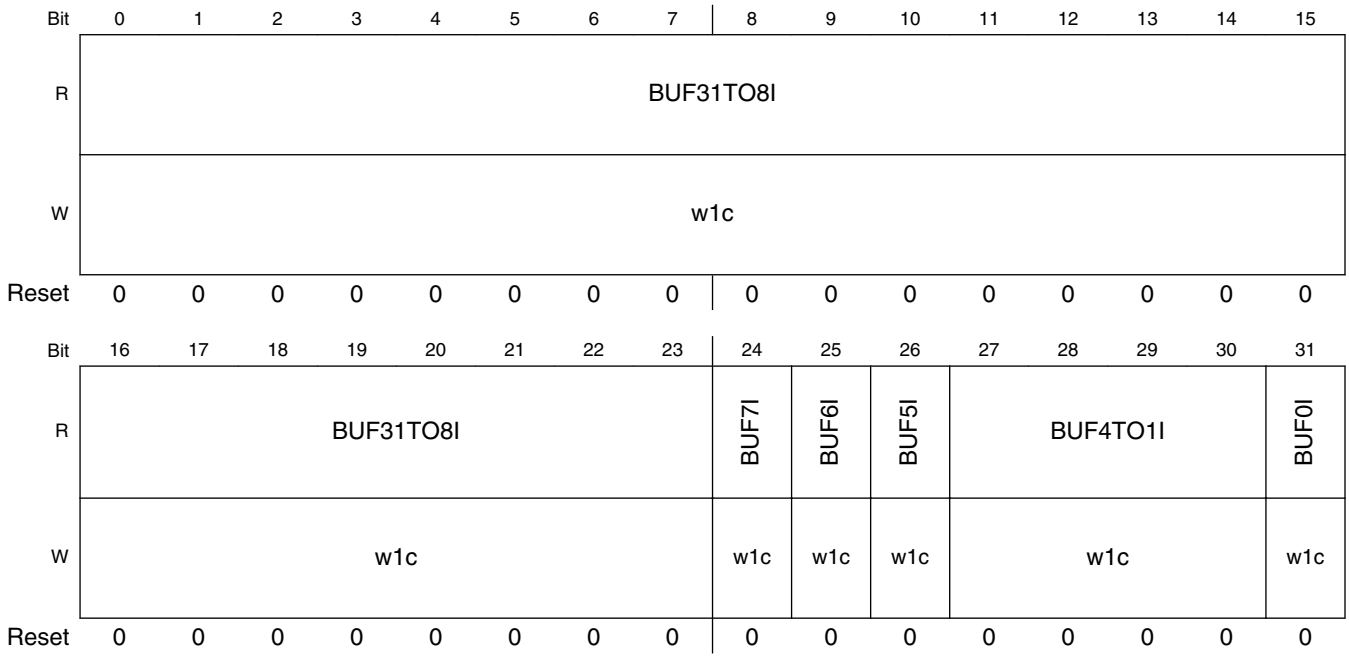
Before enabling the CAN_MCR[RFEN], the CPU must service the IFLAG bits asserted in the Rx FIFO region; see Section "Rx FIFO". Otherwise, these IFLAG bits will mistakenly show the related MBs now belonging to FIFO as having contents to be serviced. When the CAN_MCR[RFEN] bit is negated, the FIFO flags must be cleared. The same care must be taken when an CAN_CTRL2[RFFN] value is selected extending Rx FIFO filters beyond MB7. For example, when RFFN is 0x8, the MB0-23 range is occupied by Rx FIFO filters and related IFLAG bits must be cleared.

FIFO must be disabled when FDEN bit in CAN_MCR register is enabled.

Before updating CAN_MCR[MAXMB] field, CPU must service the CAN_IFLAG1 bits whose MB value is greater than the CAN_MCR[MAXMB] to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

Memory map/register definition

Address: 0h base + 30h offset = 30h



CAN_IFLAG1 field descriptions

Field	Description
0–23 BUF31TO8I	Buffer MB_i Interrupt Each bit flags the corresponding FlexCAN Message Buffer interrupt for MB31 to MB8. 0 The corresponding buffer has no occurrence of successfully completed transmission or reception. 1 The corresponding buffer has successfully completed transmission or reception.
24 BUF7I	Buffer MB7 Interrupt Or "Rx FIFO Overflow" When the RFEN bit in the CAN_MCR register is cleared (Rx FIFO disabled), this bit flags the interrupt for MB7. **NOTE:** This flag is cleared by the FlexCAN whenever the bit CAN_MCR[RFEN] is changed by CPU writes. The BUF7I flag represents "Rx FIFO Overflow" when CAN_MCR[RFEN] is set. In this case, the flag indicates that a message was lost because the Rx FIFO is full. Note that the flag will not be asserted when the Rx FIFO is full and the message was captured by a Mailbox. 0 No occurrence of MB7 completing transmission/reception when MCR[RFEN]=0, or of Rx FIFO overflow when MCR[RFEN]=1 1 MB7 completed transmission/reception when MCR[RFEN]=0, or Rx FIFO overflow when MCR[RFEN]=1
25 BUF6I	Buffer MB6 Interrupt Or "Rx FIFO Warning" When the RFEN bit in the CAN_MCR register is cleared (Rx FIFO disabled), this bit flags the interrupt for MB6. **NOTE:** This flag is cleared by the FlexCAN whenever the bit CAN_MCR[RFEN] is changed by CPU writes.

Table continues on the next page...

CAN_IFLAG1 field descriptions (continued)

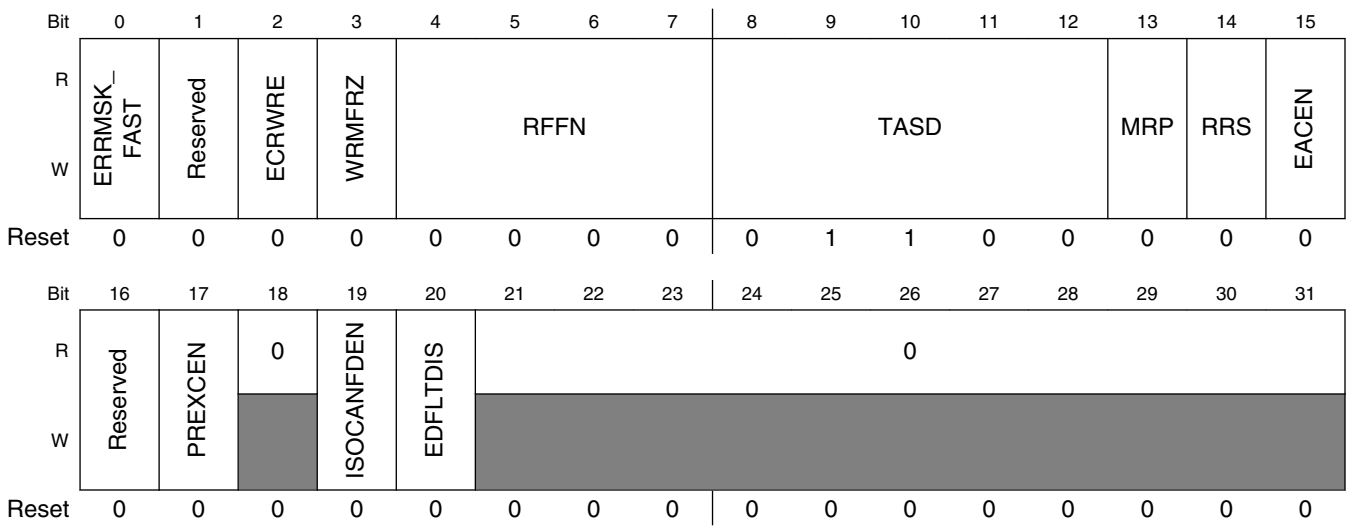
Field	Description
	The BUF6I flag represents "Rx FIFO Warning" when CAN_MCR[RFEN] is set. In this case, the flag indicates when the number of unread messages within the Rx FIFO is increased to 5 from 4 due to the reception of a new one, meaning that the Rx FIFO is almost full. Note that if the flag is cleared while the number of unread messages is greater than 4, it does not assert again until the number of unread messages within the Rx FIFO is decreased to be equal to or less than 4. 0 No occurrence of MB6 completing transmission/reception when MCR[RFEN]=0, or of Rx FIFO almost full when MCR[RFEN]=1 1 MB6 completed transmission/reception when MCR[RFEN]=0, or Rx FIFO almost full when MCR[RFEN]=1
26 BUF5I	Buffer MB5 Interrupt Or "Frames available in Rx FIFO" When the RFEN bit in the CAN_MCR register is cleared (Rx FIFO disabled), this bit flags the interrupt for MB5. **NOTE:** This flag is cleared by the FlexCAN whenever the bit CAN_MCR[RFEN] is changed by CPU writes. The BUF5I flag represents "Frames available in Rx FIFO" when CAN_MCR[RFEN] is set. In this case, the flag indicates that at least one frame is available to be read from the Rx FIFO. 0 No occurrence of MB5 completing transmission/reception when MCR[RFEN]=0, or of frame(s) available in the FIFO, when MCR[RFEN]=1 1 MB5 completed transmission/reception when MCR[RFEN]=0, or frame(s) available in the Rx FIFO when MCR[RFEN]=1
27–30 BUF4TO1I	Buffer MB $_i$ Interrupt Or "reserved" When the RFEN bit in the CAN_MCR register is cleared (Rx FIFO disabled), these bits flag the interrupts for MB4 to MB1. **NOTE:** These flags are cleared by the FlexCAN whenever the bit CAN_MCR[RFEN] is changed by CPU writes. The BUF4TO1I flags are reserved when CAN_MCR[RFEN] is set. 0 The corresponding buffer has no occurrence of successfully completed transmission or reception when MCR[RFEN]=0. 1 The corresponding buffer has successfully completed transmission or reception when MCR[RFEN]=0.
31 BUF0I	Buffer MB0 Interrupt Or "reserved" When the RFEN bit in the CAN_MCR register is cleared (Rx FIFO disabled), this bit flags the interrupt for MB0. **NOTE:** This flag is cleared by the FlexCAN whenever the bit CAN_MCR[RFEN] is changed by CPU writes. The BUF0I flag is reserved when CAN_MCR[RFEN] is set. 0 The corresponding buffer has no occurrence of successfully completed transmission or reception when MCR[RFEN]=0. 1 The corresponding buffer has successfully completed transmission or reception when MCR[RFEN]=0.

53.4.14 Control 2 register (CAN_CTRL2)

This register complements Control1 Register providing control bits for memory write access in Freeze Mode, for extending FIFO filter quantity, and for adjust the operation of internal FlexCAN processes like matching and arbitration.

The contents of this register are not affected by soft reset.

Address: 0h base + 34h offset = 34h



CAN_CTRL2 field descriptions

Field	Description
0 ERRMSK_FAST	Error Interrupt Mask for errors detected in the Data Phase of fast CAN FD frames This bit provides a mask for the ERRINT_FAST Interrupt in CAN_ESR1 register. 0 ERRINT_FAST Error interrupt disabled. 1 ERRINT_FAST Error interrupt enabled.
1 Reserved	This field is reserved. When writing to this field, always write the reset value.
2 ECRWRE	Error-correction Configuration Register Write Enable This bit enables the CAN_MECR register to be updated. This bit is automatically set to 0 if the protocol described in section Detection and Correction of Memory Errors is not followed. 0 Disable update. 1 Enable update.
3 WRMFRZ	Write-Access To Memory In Freeze Mode Enable unrestricted write access to FlexCAN memory in Freeze mode. This bit can only be written in Freeze mode and has no effect out of Freeze mode. CAN_MCR[RFEN] bit must not be set during FlexCAN memory initialization.

Table continues on the next page...

CAN_CTRL2 field descriptions (continued)

Field	Description
	0 Maintain the write access restrictions. 1 Enable unrestricted write access to FlexCAN memory.
4–7 RFFN	Number Of Rx FIFO Filters This 4-bit field defines the number of Rx FIFO filters, as shown in the following table. The maximum selectable number of filters is determined by the chip. This field can only be written in Freeze mode as it is blocked by hardware in other modes. This field must not be programmed with values that make the number of Message Buffers occupied by Rx FIFO and ID Filter exceed the number of Mailboxes present, defined by CAN_MCR[MAXMB]. **NOTE:** Each group of eight filters occupies a memory space equivalent to two Message Buffers which means that the more filters are implemented the less Mailboxes will be available. Considering that the Rx FIFO occupies the memory space originally reserved for MB0-5, RFFN should be programmed with a value corresponding to a number of filters not greater than the number of available memory words which can be calculated as follows: (SETUP_MB - 6) × 4 where SETUP_MB is the least between the parameter NUMBER_OF_MB and CAN_MCR[MAXMB]. The number of remaining Mailboxes available will be: (SETUP_MB - 8) - (RFFN × 2) If the Number of Rx FIFO Filters programmed through RFFN exceeds the SETUP_MB value (memory space available) the exceeding ones will not be functional. **NOTE:** • The number of the last remaining available mailboxes is defined by the least value between the NUMBER_OF_MB minus 1 and the CAN_MCR[MAXMB] field. • If Rx Individual Mask Registers are not enabled then all Rx FIFO filters are affected by the Rx FIFO Global Mask.

RFFN[3:0]	Number of Rx FIFO filter elements	Message Buffers occupied by Rx FIFO and ID Filter Table	Remaining Available Mailboxes	Rx FIFO ID Filter Table Elements Affected by Rx Individual Masks	Rx FIFO ID Filter Table Elements Affected by Rx FIFO Global Mask
0x0	8	MB 0-7	MB 8-95	Elements 0-7	none
0x1	16	MB 0-9	MB 10-95	Elements 0-9	Elements 10-15

PREXCEN</td><td>Protocol Exception Enable

This bit enables the Protocol Exception feature.

This field is writable only in Freeze mode.</td></tr>
</table>

Table continues on the next page...

CAN_CTRL2 field descriptions (continued)

Field	Description
	0 Protocol Exception is disabled. 1 Protocol Exception is enabled.
18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 ISOCANFDEN	ISO CAN FD Enable This field enables the CAN FD protocol according to ISO specification (ISO 11898-1) (see CAN FD ISO compliance). This field is writable only in Freeze mode. 0 FlexCAN operates using the non-ISO CAN FD protocol. 1 FlexCAN operates using the ISO CAN FD protocol (ISO 11898-1).
20 EDFLTDIS	Edge Filter Disable This bit disables the Edge Filter used during the bus integration state. When the Edge Filter is enabled, two consecutive nominal time quanta with dominant bus state are required to detect an edge that causes synchronization. When synchronization occurs, the counting of the sequence of eleven consecutive recessive bits is restarted. The Edge Filter prevents the dominant pulses that are shorter than a nominal bit time (present during the data phase of an FD Frame) from being mistaken for an idle condition. This field is writable only in Freeze mode. 0 Edge Filter is enabled. 1 Edge Filter is disabled.
21–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

53.4.15 Error and Status 2 register (CAN_ESR2)

This register reports some general status information.

Address: 0h base + 38h offset = 38h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0									LPTM						
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	VPS	IMB	0												
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

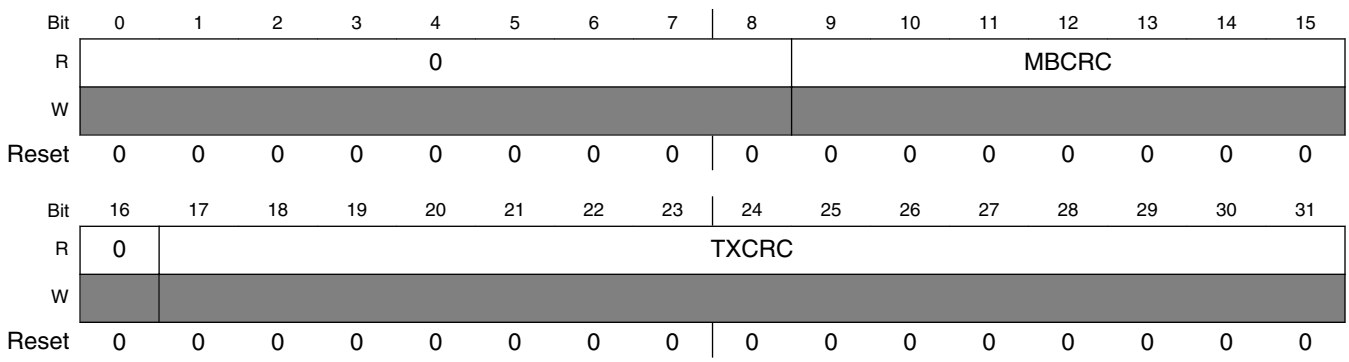
CAN_ESR2 field descriptions

Field	Description
0–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–15 LPTM	Lowest Priority Tx Mailbox If CAN_ESR2[VPS] is asserted, this field indicates the lowest number inactive Mailbox (see the CAN_ESR2[IMB] bit description). If there is no inactive Mailbox then the Mailbox indicated depends on CAN_CTRL1[LBUF] bit value. If CAN_CTRL1[LBUF] bit is negated then the Mailbox indicated is the one that has the greatest arbitration value (see the "Highest priority Mailbox first" section). If CAN_CTRL1[LBUF] bit is asserted then the Mailbox indicated is the highest number active Tx Mailbox. If a Tx Mailbox is being transmitted it is not considered in LPTM calculation. If CAN_ESR2[IMB] is not asserted and a frame is transmitted successfully, LPTM is updated with its Mailbox number.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 VPS	Valid Priority Status This bit indicates whether CAN_ESR2[IMB] and CAN_ESR2[LPTM] contents are currently valid or not. It is asserted upon every complete Tx arbitration process unless the CPU writes to Control and Status word of a Mailbox that has already been scanned, that is, it is behind Tx Arbitration Pointer, during the Tx arbitration process. If there is no inactive Mailbox and only one Tx Mailbox that is being transmitted then VPS is not asserted. This bit is negated upon the start of every Tx arbitration process or upon a write to Control and Status word of any Mailbox. **NOTE:** CAN_ESR2[VPS] is not affected by any CPU write into Control Status (C/S) of a MB that is blocked by abort mechanism. When CAN_MCR[AEN] is asserted, the abort code write in C/S of a MB that is being transmitted (pending abort), or any write attempt into a Tx MB with CAN_IFLAG set is blocked. 0 Contents of IMB and LPTM are invalid. 1 Contents of IMB and LPTM are valid.
18 IMB	Inactive Mailbox If ESR2[VPS] is asserted, this bit indicates whether there is any inactive Mailbox (CODE field is either 0b1000 or 0b0000). This bit is asserted in the following cases: • During arbitration, if an CAN_ESR2[LPTM] is found and it is inactive. • If CAN_ESR2[IMB] is not asserted and a frame is transmitted successfully. This bit is cleared in all start of arbitration (see Section "Arbitration process"). **NOTE:** CAN_ESR2[LPTM] mechanism have the following behavior: if an MB is successfully transmitted and CAN_ESR2[IMB]=0 (no inactive Mailbox), then CAN_ESR2[VPS] and CAN_ESR2[IMB] are asserted and the index related to the MB just transmitted is loaded into CAN_ESR2[LPTM]. 0 If ESR2[VPS] is asserted, the ESR2[LPTM] is not an inactive Mailbox. 1 If ESR2[VPS] is asserted, there is at least one inactive Mailbox. LPTM content is the number of the first one.
19–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

53.4.16 CRC Register (CAN_CRCR)

This register provides information about the CRC of transmitted messages for non FD messages. This register only reports the 15 low order bits of CRC calculations for messages in CAN FD format that require either 17 or 21 bits. For CAN FD format frames, the CAN_FDCRC register must be used. This register is updated at the same time the Tx Interrupt Flag is asserted.

Address: 0h base + 44h offset = 44h



CAN_CRCR field descriptions

Field	Description
0–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–15 MBCRC	CRC Mailbox This field indicates the number of the Mailbox corresponding to the value in CAN_CRCR[TXCRC] field.
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–31 TXCRC	Transmitted CRC value This field indicates the CRC value of the last transmitted message for non-FD frames. For FD frames, CRC value is reported in CAN_FDCRC register.

53.4.17 Rx FIFO Global Mask register (CAN_RXFGMASK)

This register is located in RAM.

If Rx FIFO is enabled, RXFGMASK is used to mask the Rx FIFO ID Filter Table elements that do not have a corresponding RXIMR according to CAN_CTRL2[RFFN] field setting.

This register can only be written in Freeze mode as it is blocked by hardware in other modes.

Address: 0h base + 48h offset = 48h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	FGM

* Notes:
- x = Undefined at reset.

CAN_RXFGMASK field descriptions

Field	Description
0–31 FGM	Rx FIFO Global Mask Bits These bits mask the ID Filter Table elements bits in a perfect alignment. The following table shows how the FGM bits correspond to each IDAF field.

Rx FIFO ID Filter Table Elements Format (CAN_MCR[IDAM])	Identifier Acceptance Filter Fields					
	RTR	IDE	RXIDA	RXIDB [1]	RXIDC [2]	Reserved
A	FGM[31]	FGM[30]	FGM[29:1]	-	-	FGM[0]
B	FGM[31], FGM[15]	FGM[30], FGM[14]	-	FGM[29:16], FGM[13:0]		-
C	-	-		-	FGM[31:24], FGM[23:16], FGM[15:8], FGM[7:0]	

1. If CAN_MCR[IDAM] field is equivalent to the format B only the fourteen most significant bits of the Identifier of the incoming frame are compared with the Rx FIFO filter.
2. If CAN_MCR[IDAM] field is equivalent to the format C only the eight most significant bits of the Identifier of the incoming frame are compared with the Rx FIFO filter.

0 The corresponding bit in the filter is "don't care."
1 The corresponding bit in the filter is checked.

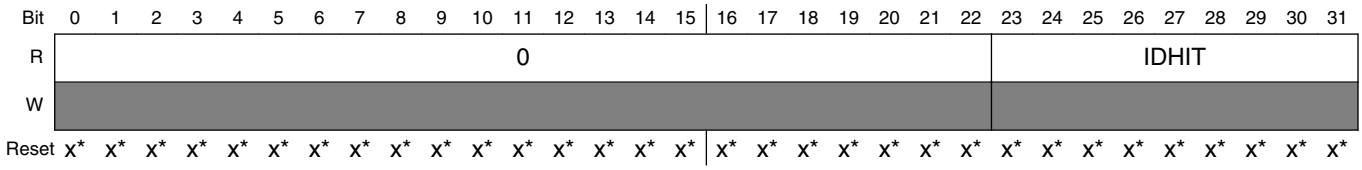
1. If CAN_MCR[IDAM] field is equivalent to the format B only the fourteen most significant bits of the Identifier of the incoming frame are compared with the Rx FIFO filter.
2. If CAN_MCR[IDAM] field is equivalent to the format C only the eight most significant bits of the Identifier of the incoming frame are compared with the Rx FIFO filter.

53.4.18 Rx FIFO Information Register (CAN_RXFIR)

RXFIR provides information on Rx FIFO.

This register is the port through which the CPU accesses the output of the RXFIR FIFO located in RAM. The RXFIR FIFO is written by the FlexCAN whenever a new message is moved into the Rx FIFO as well as its output is updated whenever the output of the Rx FIFO is updated with the next message. See Section "Rx FIFO" for instructions on reading this register.

Address: 0h base + 4Ch offset = 4Ch



* Notes:
- x = Undefined at reset.

CAN_RXFIR field descriptions

Field	Description
0–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–31 IDHIT	Identifier Acceptance Filter Hit Indicator This field indicates which Identifier Acceptance Filter was hit by the received message that is in the output of the Rx FIFO. If multiple filters match the incoming message ID then the first matching IDAF found (lowest number) by the matching process is indicated. This field is valid only while the CAN_IFLAG1[BUF5I] is asserted.

53.4.19 CAN Bit Timing Register (CAN_CBT)

This register is an alternative way to store the CAN bit timing variables described in CAN_CTRL1 register. EPRESDIV, EPROPSEG, EPSEG1, EPSEG2 and ERJW are extended versions of PRESDIV, PROPSEG, PSEG1, PSEG2 and RJW bit fields respectively.

The BTF bit selects the use of the timing variables defined in this register.

The contents of this register are not affected by soft reset.

NOTE

The CAN bit variables in CAN_CTRL1 and in CAN_CBT are stored in the same register.

NOTE

When the CAN FD feature is enabled (CAN_MCR[FDEN] is set), always set CAN_CBT[BTF].

Memory map/register definition

Address: 0h base + 50h offset = 50h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	EPROPSEG						EPSEG1					EPSEG2				
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CAN_CBT field descriptions

Field	Description
0 BTF	Bit Timing Format Enable Enables the use of extended CAN bit timing fields EPRESDIV, EPROPSEG, EPSEG1, EPSEG2 and ERJW replacing the CAN bit timing variables defined in CAN_CTRL1 register. This field can be written in Freeze mode only. 0 Extended bit time definitions disabled. 1 Extended bit time definitions enabled.
1–10 EPRESDIV	Extended Prescaler Division Factor This 10-bit field defines the ratio between the PE clock frequency and the Serial Clock (Sclock) frequency when CAN_CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CAN_CTRL1[PRESDIV] value range. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency (see Protocol timing). This field can be written only in Freeze mode because it is blocked by hardware in other modes. Sclock frequency = PE clock frequency / (EPRESDIV + 1)
11–15 ERJW	Extended Resync Jump Width This 5-bit field defines the maximum number of time quanta that a bit time can be changed by one re-synchronization when CAN_CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CAN_CTRL1[RJW] value range. One time quantum is equal to the Sclock period. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Resync Jump Width = ERJW + 1.
16–21 EPROPSEG	Extended Propagation Segment This 6-bit field defines the length of the Propagation Segment in the bit time when CAN_CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CAN_CTRL1[PROPSEG] value range. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Propagation Segment Time = (EPROPSEG + 1) × Time-Quanta. Time-Quantum = one Sclock period.
22–26 EPSEG1	Extended Phase Segment 1 This 5-bit field defines the length of Phase Segment 1 in the bit time when CAN_CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CAN_CTRL1[PSEG1] value range. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Buffer Segment 1 = (EPSEG1 + 1) × Time-Quanta. Time-Quantum = one Sclock period.

Table continues on the next page...

CAN_CBT field descriptions (continued)

Field	Description
27–31 EPSEG2	Extended Phase Segment 2 This 5-bit field defines the length of Phase Segment 2 in the bit time when CAN_CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CAN_CTRL1[PSEG2] value range. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Buffer Segment 1 = (EPSEG2 + 1) × Time-Quanta. Time-Quantum = one Sclock period.

53.4.20 Interrupt Masks 3 Register (CAN_IMASK3)

This register allows any number of a range of the 32 Message Buffer Interrupts to be enabled or disabled for MB95 to MB64. It contains one interrupt mask bit per buffer, enabling the CPU to determine which buffer generates an interrupt after a successful transmission or reception, that is, when the corresponding CAN_IFLAG3 bit is set.

Address: 0h base + 6Ch offset = 6Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	BUF95TO64M																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CAN_IMASK3 field descriptions

Field	Description
0–31 BUF95TO64M	Buffer MB $_i$ Mask Each bit enables or disables the corresponding FlexCAN Message Buffer Interrupt for MB95 to MB64. When CAN FD is enabled, the MB range is defined in accordance to the MBDSRs bit fields of CAN_FDCTRL register. **NOTE:** Setting or clearing a bit in the CAN_IMASK3 Register can assert or negate an interrupt request, if the corresponding CAN_IFLAG3 bit is set. 0 The corresponding buffer Interrupt is disabled. 1 The corresponding buffer Interrupt is enabled.

53.4.21 Interrupt Flags 3 Register (CAN_IFLAG3)

This register defines the flags for the 32 Message Buffer interrupts for MB95 to MB64. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding CAN_IFLAG3 bit. If the corresponding CAN_IMASK3 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect.

Before updating CAN_MCR[MAXMB] field, CPU must service the CAN_IFLAG3 bits whose MB value is greater than the MAXMB to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

Address: 0h base + 74h offset = 74h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

CAN_IFLAG3 field descriptions

Field	Description
0–31 BUF95TO64	Buffer MB $_i$ Interrupt Each bit flags the corresponding FlexCAN Message Buffer interrupt for MB95 to MB64.When CAN FD is enabled, the MB range is defined in accordance to the MBDSRs bit fields of CAN_FDCTRL register. 0 The corresponding buffer has no occurrence of successfully completed transmission or reception 1 The corresponding buffer has successfully completed transmission or reception

53.4.22 Rx Individual Mask Registers (CAN_RXIMR*n*)

The RX Individual Mask Registers are used to store the acceptance masks for ID filtering in Rx MBs and the Rx FIFO.

When the Rx FIFO is disabled (CAN_MCR[RFEN] bit is negated), an individual mask is provided for each available Rx Mailbox on a one-to-one correspondence. When the Rx FIFO is enabled (CAN_MCR[RFEN] bit is asserted), an individual mask is provided for each Rx FIFO ID Filter Table Element on a one-to-one correspondence depending on the setting of CAN_CTRL2[RFFN] (see Rx FIFO).

CAN_RXIMR0 stores the individual mask associated to either MB0 or ID Filter Table Element 0, CAN_RXIMR1 stores the individual mask associated to either MB1 or ID Filter Table Element 1 and so on.

CAN_RXIMR registers can only be accessed by the CPU while the module is in Freeze mode, otherwise, they are blocked by hardware. These registers are not affected by reset. They are located in RAM and must be explicitly initialized prior to any reception.

It is possible for the RXIMR memory region to be accessed as general purpose memory. See Bus interface for more information.

Address: 0h base + 880h offset + (4d × i), where i=0d to 95d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

CAN_RXIMR*n* field descriptions

Field	Description
0–31 MI	Individual Mask Bits Each Individual Mask Bit masks the corresponding bit in both the Mailbox filter and Rx FIFO ID Filter Table element in distinct ways. For Mailbox filters, see the RXMGMASK register description. For Rx FIFO ID Filter Table elements, see the RXFGMASK register description. 0 The corresponding bit in the filter is "don't care." 1 The corresponding bit in the filter is checked.

53.4.23 Memory Error Control Register (CAN_MECR)

This register contains control bits for memory error detection and correction (ECC).

NOTE

When bit CTRL2[ECRWRE] is 0, writes in this register are blocked, except in the ECRWRDIS bit.

Address: 0h base + AE0h offset = AE0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

CAN_MECR field descriptions

Field	Description
0 ECRWRDIS	Error Configuration Register Write Disable Disables writes on this register. This bit is automatically set to 1 (disabled) when CTRL2[ECRWRE] is enabled. The protocol described in section Detection and Correction of Memory Errors must be followed. 0 Write is enabled. 1 Write is disabled.
1–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 Reserved	This field is reserved. When writing to this field, always write the reset value.
13 Reserved	This field is reserved. When writing to this field, always write the reset value.
14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 Reserved	This field is reserved. When writing to this field, always write the reset value.
16 HAERRIE	Host Access Error Injection Enable Enables the injection of errors only in memory reads issued by the host (CPU). 0 Injection is disabled. 1 Injection is enabled.
17 FAERRIE	FlexCAN Access Error Injection Enable Enables the injection of errors only in memory reads issued by the FlexCAN internal processes. 0 Injection is disabled. 1 Injection is enabled.
18 EXTERRIE	Extended Error Injection Enable Memory accesses performed by internal FlexCAN processes are 64-bit. This bit extends the error injection on 32-bit memory accesses to the complementary 32-bit word using the same 32-bit error injection data and parity words. See Error Injection Data Pattern Register (CAN_FCERRIDPR) and Error Injection Parity Pattern Register (CAN_FCERRIPPR) 0 Error injection is applied only to the 32-bit word. 1 Error injection is applied to the 64-bit word.
19–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

CAN_MECR field descriptions (continued)

Field	Description
22 RERRDIS	Error Report Disable Disables the update of the error report registers. The update of error-related flags and the generation of bus transfer errors are still active. **NOTE:** When reading the report registers, this bit must be set to assure coherence on the consecutive register reads. 0 Enable updates of the error report registers. 1 Disable updates of the error report registers.
23 ECCDIS	Error Correction Disable Disables completely the memory detection and correction mechanism. Besides disabling the error report mechanism, it also stops the update of the error-related flags and generation of bus transfer errors. The parity bits continue being calculated and written into memory on write transactions. 0 Enable memory error correction. 1 Disable memory error correction.
24 NCEFAFRZ	Non-Correctable Errors In FlexCAN Access Put Device In Freeze Mode Determines the response when a non-correctable error is detected in a memory read performed by FlexCAN internal processes. In this case, entering Freeze mode prevents corrupted data from being treated as valid by FlexCAN internal processes. 0 Keep normal operation. 1 Put FlexCAN in Freeze mode (according to the "Freeze mode" section).
25–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

53.4.24 Error Injection Address Register (CAN_ERRIAR)

This register holds the address where error is to be injected.

Use the following table to convert from the memory map address to the location in the physical FlexCAN RAM (where pairs of values are provided, the first is the address for CAN_MCR[FDEN] negated, the second is for CAN_MCR[FDEN] asserted):

RAM contents	Injection address	Memory map
FlexCAN Registers	Not mapped	-
MBs	0x0000	0x0080
Reserved	-	0x0480
RXIMRs	0x0600	0x0880
Reserved	-	0x0980
RXFIR_0	0x0780	0x0A80

CAN_ERRIDPR field descriptions

Field	Description
0–31 DFLIP	Data flip pattern Bits set to 1 in the flip pattern cause the corresponding data bit in the word read from memory to invert.

53.4.26 Error Injection Parity Pattern Register (CAN_ERRIPPR)

Holds the error pattern to be injected in parity bits read from memory along with data word.

Bits set to 1 in the flip pattern cause the corresponding parity bit in the word read from memory to invert.

Address: 0h base + AECh offset = AECh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

CAN_ERRIPPR field descriptions

Field	Description
0–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–7 PFLIP3	Parity Flip Pattern For Byte 3 (most significant)
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–15 PFLIP2	Parity Flip Pattern For Byte 2
16–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–23 PFLIP1	Parity Flip Pattern For Byte 1
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 PFLIP0	Parity Flip Pattern For Byte 0 (Least Significant)

53.4.27 Error Report Address Register (CAN_RERRAR)

Reports the address used for an access in which an error (correctable or non-correctable) was detected, and also reports the identification of the source of that access.

This address is always reported using a 32-bit alignment. Non-aligned accesses (ERRADDR[1:0] non-0) are reported with the address aligned and data is reported in RERRDR accordingly shifted. In case of errors detected in accesses larger than 32-bit (as performed by FlexCAN internal processes), the address of the 32-bit word which the error was detected is reported. In case of errors detected in more than one 32-bit word, only the least significant address is reported.

Address: 0h base + AF0h offset = AF0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

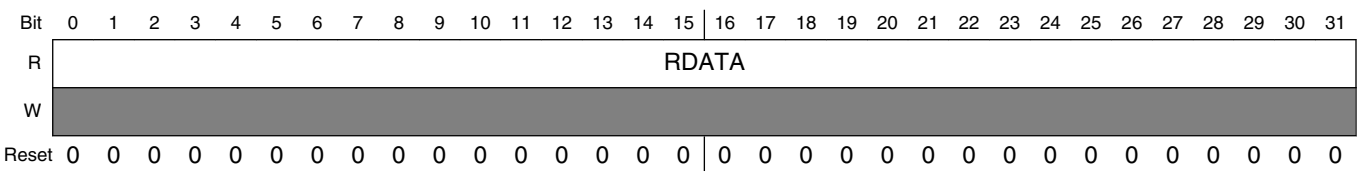
16–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–31 ERRADDR	Address Where The Error Was Detected See the description of the Error Injection Address Register (ERRIAR).

53.4.28 Error Report Data Register (CAN_RERRDR)

Reports the raw data (unmodified by the correction performed by ECC logic) read from memory with error. The value reported does not represent the transient values of the BUSY bit (see the “Message Buffer Code for Rx buffers” table) when reading a Message Buffer.

Address: 0h base + AF4h offset = AF4h



CAN_RERRDR field descriptions

Field	Description
0–31 RDATA	Raw data word read from memory with error

53.4.29 Error Report Syndrome Register (CAN_RERRSYNR)

Holds the syndrome detected in a memory read with error. It also reports the bytes which were read in this 32-bit read transaction.

Each SYNDn field indicates the type of error and which bit in byte (n) is affected by the error. (SYND3 corresponds to the most significant byte in the data word read from memory; SYND0 corresponds to the least significant.)

Table 53-6. Syndrome Definition

SYNDn (hex)	Type	Bit affected
00	-	none (no error)
01	Code	0
02	Code	1
04	Code	2
07	Data	5
08	Code	3
0E	Data	7
10	Code	4
13	Data	2
15	Data	6
16	Data	1
19	Data	3
1A	Data	4
1C	Data	0
06	-	All-zeros non-correctable error
1F	-	All-ones non-correctable error
All others	-	Non-correctable error

Each BEn field indicates which byte in the 32-bit word reported was effectively read. The syndrome bits are calculated for all bytes, even for the non-read ones. Errors detected in non-read bytes are indicated (see the "Error Indication" section) and reported (see the "Error Reporting" section).

Address: 0h base + AF8h offset = AF8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

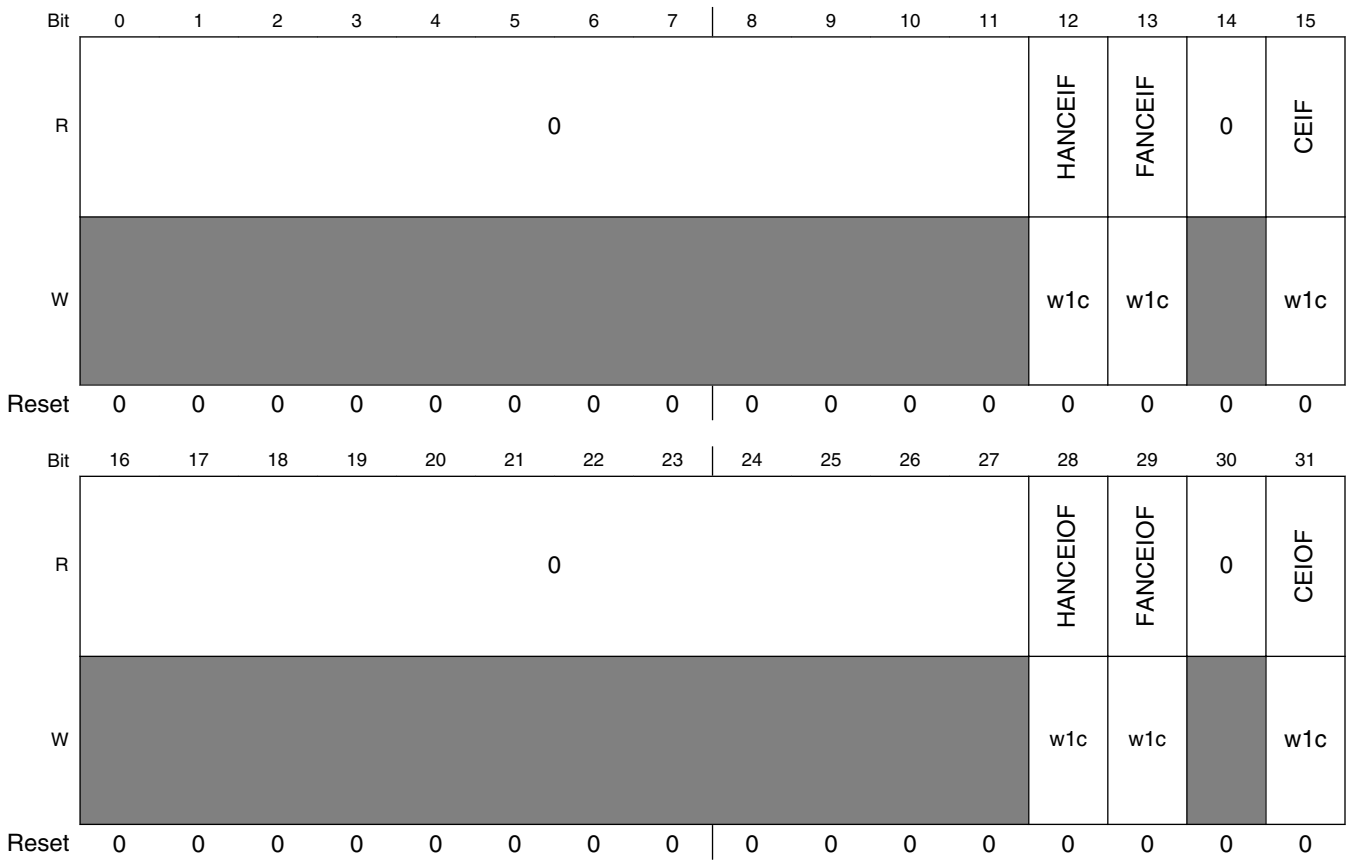
CAN_RERRSYNR field descriptions

Field	Description
0 BE3	Byte Enabled For Byte 3 (Most Significant) 0 The byte was not read. 1 The byte was read.
1–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–7 SYND3	Error Syndrome For Byte 3 (Most Significant) See the "Syndrome Definition" table.
8 BE2	Byte Enabled For Byte 2 0 The byte was not read. 1 The byte was read.
9–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–15 SYND2	Error Syndrome For Byte 2 See the "Syndrome Definition" table.
16 BE1	Byte Enabled For Byte 1 0 The byte was not read. 1 The byte was read.
17–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–23 SYND1	Error Syndrome for Byte 1 See the "Syndrome Definition" table.
24 BE0	Byte Enabled For Byte 0 (least significant) 0 The byte was not read. 1 The byte was read.
25–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 SYND0	Error Syndrome For Byte 0 (least significant) See the "Syndrome Definition" table.

53.4.30 Error Status Register (CAN_ERRSR)

Holds the status bits of the error correction and detection operations. These flags can be cleared by writing 1 to them. Writing 0 has no effect.

Address: 0h base + AFCh offset = AFCh



CAN_ERRSR field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 HANCEIF	Host Access With Non-Correctable Error Interrupt Flag Indicates that a non-correctable error was detected in a memory read initiated by Host. A bus transfer error is asserted for that access. No interrupt is associated to this flag. 0 No non-correctable errors were detected in Host accesses so far. 1 A non-correctable error was detected in a Host access.
13 FANCEIF	FlexCAN Access With Non-Correctable Error Interrupt Flag

Table continues on the next page...

CAN_ERRSR field descriptions (continued)

Field	Description
	Indicates that a non-correctable error was detected in a memory read initiated by FlexCAN internal processes. No interrupt is associated to this flag. 0 No non-correctable errors were detected in FlexCAN accesses so far. 1 A non-correctable error was detected in a FlexCAN access.
14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 CEIF	Correctable Error Interrupt Flag Indicates that a correctable error was detected in a memory read. 0 No correctable errors were detected so far. 1 A correctable error was detected.
16–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 HANCEIOF	Host Access With Non-Correctable Error Interrupt Overrun Flag Indicates that a non-correctable error was detected in a memory read initiated by Host when HANCEIF was set. No interrupt is associated to this flag. See Error Indication. 0 No overrun on non-correctable errors in Host access 1 Overrun on non-correctable errors in Host access
29 FANCEIOF	FlexCAN Access With Non-Correctable Error Interrupt Overrun Flag Indicates that a non-correctable error was detected in a memory read initiated by FlexCAN internal processes when FANCEIF was set. No interrupt is associated to this flag. See Error Indication. 0 No overrun on non-correctable errors in FlexCAN access 1 Overrun on non-correctable errors in FlexCAN access
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 CEIOF	Correctable Error Interrupt Overrun Flag Indicates that a correctable error was detected in a memory read when CEIF was set. No interrupt is associated to this flag. See Error Indication. 0 No overrun on correctable errors 1 Overrun on correctable errors

53.4.31 CAN FD Control Register (CAN_FDCTRL)

This register contains control bits for the CAN FD operation. It also defines the data size of Message Buffers allocated in different partitions of RAM (memory blocks) as described in the table below.

When 8 bytes payload is selected:

- Block R0 allocates MB0 to MB31.

- Block R1 allocates MB32 to MB63.
- Block R2 allocates MB64 to MB95.

When more than 8 bytes payload is selected, the maximum number of MBs in a block is limited as described below:

Table 53-7. Number of Message Buffers

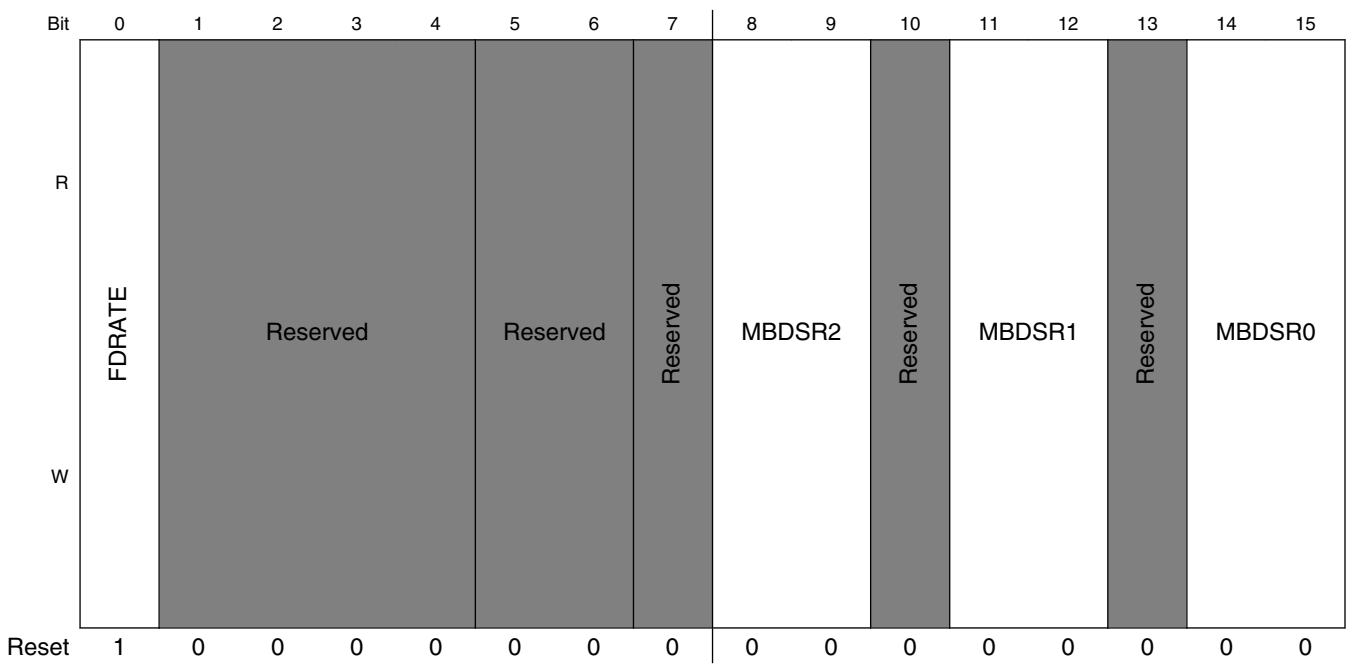
Payload Size	Maximum number of Message Buffers per RAM block
8 bytes	32
16 bytes	21
32 bytes	12
64 bytes	7

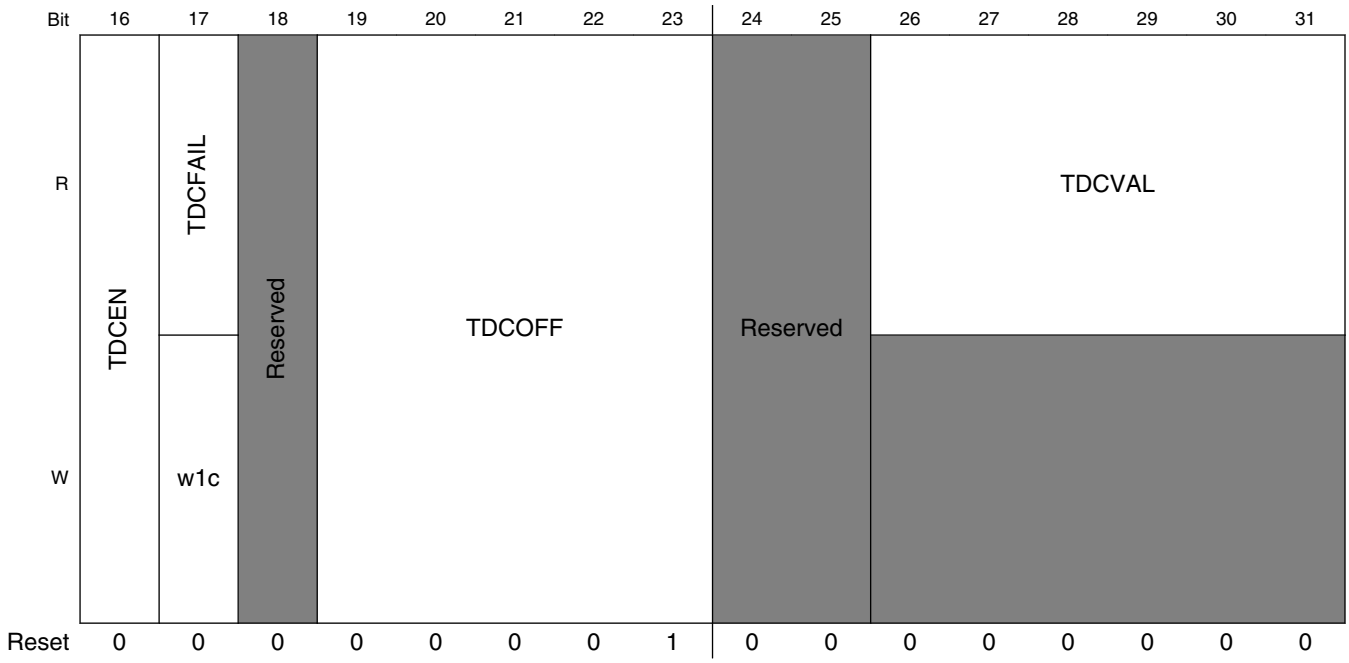
NOTE

One memory block fits exactly 32 MBs with 8 bytes payload. For the other options of payload sizes, empty memory may exist between last MB in a block and the beginning of the next block. This empty memory corresponds to less than one MB, and must not be used.

The contents of this register are not affected by soft reset.

Address: 0h base + C00h offset = C00h





CAN_FDCTRL field descriptions

Field	Description
0 FDRATE	Bit Rate Switch Enable This bit enables the effect of the Bit Rate Switch (BRS bit) during the data phase of Tx messages. The CPU can write this bit any time. However, its effect turns active only when the CAN bus is in Wait for Bus Idle, Bus Idle or Bus Off state, or when the current frame under reception or transmission reaches the interframe space. By negating the CAN_FDCTRL[FDRATE] bit, the CPU can force all bits in CAN FD messages to be transmitted in nominal bit rate, despite of the value in the BRS bit of the Tx MBs. 0 Transmit a frame in nominal rate. The BRS bit in the Tx MB has no effect. 1 Transmit a frame with bit rate switching if the BRS bit in the Tx MB is recessive.
1–4 Reserved	This field is reserved.
5–6 Reserved	This field is reserved.
7 Reserved	This field is reserved.
8–9 MBDSR2	Message Buffer Data Size for Region 2 This two bit field selects the data size (8, 16, 32 or 64 bytes) for the region R2 of Message Buffers allocated in RAM. It can be written in Freeze Mode only. 00 Selects 8 bytes per Message Buffer. 01 Selects 16 bytes per Message Buffer. 10 Selects 32 bytes per Message Buffer. 11 Selects 64 bytes per Message Buffer.

Table continues on the next page...

CAN_FDCTRL field descriptions (continued)

Field	Description
10 Reserved	This field is reserved.
11–12 MBDSR1	Message Buffer Data Size for Region 1 This two bit field selects the data size (8, 16, 32 or 64 bytes) for the region R1 of Message Buffers allocated in RAM. It can be written in Freeze Mode only. 00 Selects 8 bytes per Message Buffer. 01 Selects 16 bytes per Message Buffer. 10 Selects 32 bytes per Message Buffer. 11 Selects 64 bytes per Message Buffer.
13 Reserved	This field is reserved.
14–15 MBDSR0	Message Buffer Data Size for Region 0 This two bit field selects the data size (8, 16, 32 or 64 bytes) for the region R0 of Message Buffers allocated in RAM. It can be written in Freeze Mode only. 00 Selects 8 bytes per Message Buffer. 01 Selects 16 bytes per Message Buffer. 10 Selects 32 bytes per Message Buffer. 11 Selects 64 bytes per Message Buffer.
16 TDCEN	Transceiver Delay Compensation Enable This bit can be used to enable and disable the TDC feature. It can be written in Freeze mode only. **NOTE:** TDC must be disabled when the Loop Back Mode is enabled (see CAN_CTRL1[LPB] register). 0 TDC is disabled 1 TDC is enabled
17 TDCFAIL	Transceiver Delay Compensation Fail This bit indicates when the Transceiver Delay Compensation (TDC) mechanism is out of range, unable to compensate the transceiver's loop delay and successfully compare the delayed received bits to the transmitted ones (see Transceiver Delay Compensation. TDCFAIL sets in the first time FlexCAN detects the out of range condition. The CPU needs to write 1 to clear it. 0 Measured loop delay is in range. 1 Measured loop delay is out of range.
18 Reserved	This field is reserved.
19–23 TDCOFF	Transceiver Delay Compensation Offset This bit field contains the offset value to be added to the measured transceiver's loop delay in order to define the position of the delayed comparison point when bit rate switching is active. See Transceiver Delay Compensation for more details on how the loop delay measurement is performed. TDCOFF can be written in Freeze mode only. Its value can be defined in Protocol Engine (PE) Clock periods (CANCLK, see Protocol timing for more details), and must be selected to be smaller than the CAN bit duration in the data bit rate for proper operation.

Table continues on the next page...

CAN_FDCTRL field descriptions (continued)

Field	Description
	NOTE: It is not recommended to use TDCOFF equal to zero.
24–25 Reserved	This field is reserved.
26–31 TDCVAL	Transceiver Delay Compensation Value This register contains the value of the transceiver loop delay measured from the transmitted EDL to R0 transition edge to the respective received one added to the TDCOFF value specified in the CAN_FDCTRL register. This value is an integer multiple of the Protocol Engine (PE) Clock period (CANCLK). See Protocol timing for more details on how the loop delay measurement is performed.

53.4.32 CAN FD Bit Timing Register (CAN_FDCBT)

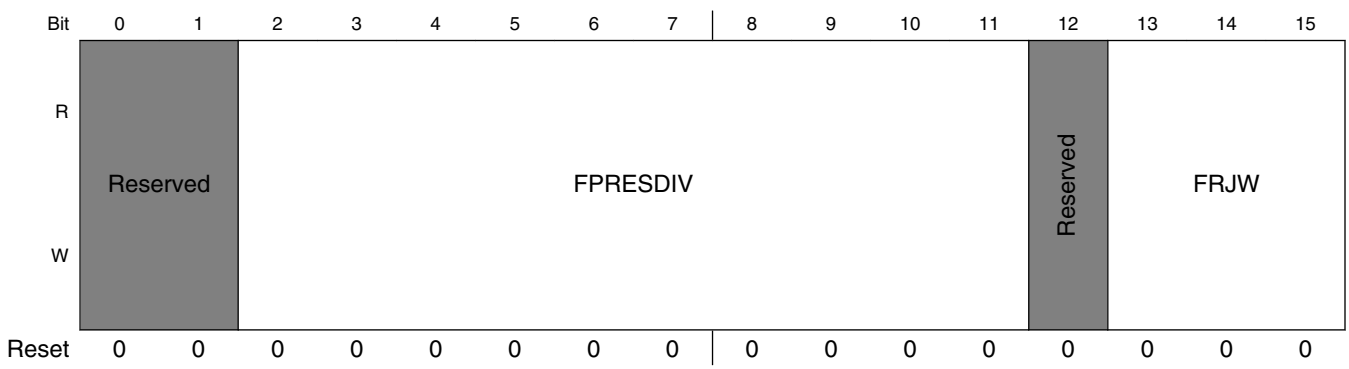
This register stores the CAN bit timing variables used in the data phase of CAN FD messages when the CAN_FDCTRL[FDRATE] is set, compatible with CAN FD specification. FPRESDIV, FPROPSEG, FPSEG1, FPSEG2 and FRJW are used to define the time quantum duration, the number of time quanta per CAN bit and the sample point position for the data bit rate portion of a CAN FD message with the BRS bit set.

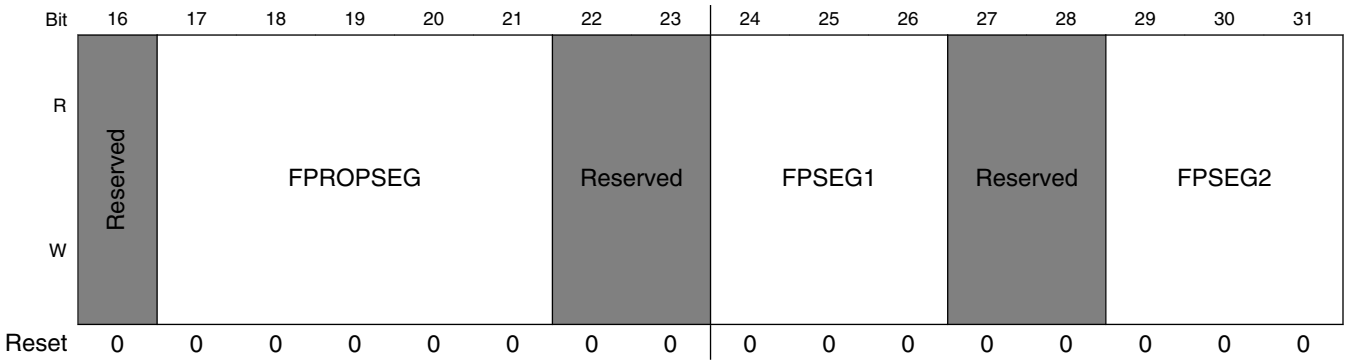
The contents of this register are not affected by soft reset.

NOTE

The sum of the Fast Propagation Segment (FPROPSEG) and Fast Phase Segment 1 (FPSEG1) must be at least two time quanta.

Address: 0h base + C04h offset = C04h





CAN_FDCBT field descriptions

Field	Description
0–1 Reserved	This field is reserved.
2–11 FPRESDIV	Fast Prescaler Division Factor This 10-bit field defines the ratio between the PE clock frequency and the Serial Clock (Sclock) frequency in the data bit rate portion of a CAN FD message with the BRS bit set. The Sclock period defines the time quantum of the CAN FD protocol for the data bit rate. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Sclock frequency = PE clock frequency / (FPRESDIV + 1). **NOTE:** To minimize errors when processing FD frames, use the same value for FPRESDIV and PRESDIV (in CAN_CBT or CAN_CTRL1). For more details refer to the first NOTE in section CAN FD frames.
12 Reserved	This field is reserved.
13–15 FRJW	Fast Resync Jump Width This 3-bit field defines the maximum number of time quanta that a bit time can be changed by one re-synchronization in the data bit rate portion of a CAN FD message with the BRS bit set. One time quantum is equal to the Sclock period. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Resync Jump Width = FSJW + 1.
16 Reserved	This field is reserved.
17–21 FPROPSEG	Fast Propagation Segment This 5-bit field defines the length of the Propagation Segment in the bit time in the data bit rate portion of a CAN FD message with the BRS bit set. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Propagation Segment Time = FPROPSEG × Time-Quanta. Time-Quantum = one Sclock period.
22–23 Reserved	This field is reserved.
24–26 FPSEG1	Fast Phase Segment 1

Table continues on the next page...

CAN_FDCBT field descriptions (continued)

Field	Description
	This 3-bit field defines the length of Phase Segment 1 in the bit time in the data bit rate portion of a CAN FD message with the BRS bit set. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Segment 1 = (FPSEG1 + 1) × Time-Quanta. Time-Quantum = one Sclock period.
27–28 Reserved	This field is reserved.
29–31 FPSEG2	Fast Phase Segment 2 This 3-bit field defines the length of Phase Segment 2 in the data bit rate portion of a CAN FD message with the BRS bit set. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Segment 2 = (FPSEG2 + 1) × Time-Quanta. Time-Quantum = one Sclock period.

53.4.33 CAN FD CRC Register (CAN_FDCRC)

This register provides information about the CRC of transmitted messages.

FlexCAN uses different CRC polynomials for different frame formats, as shown below.

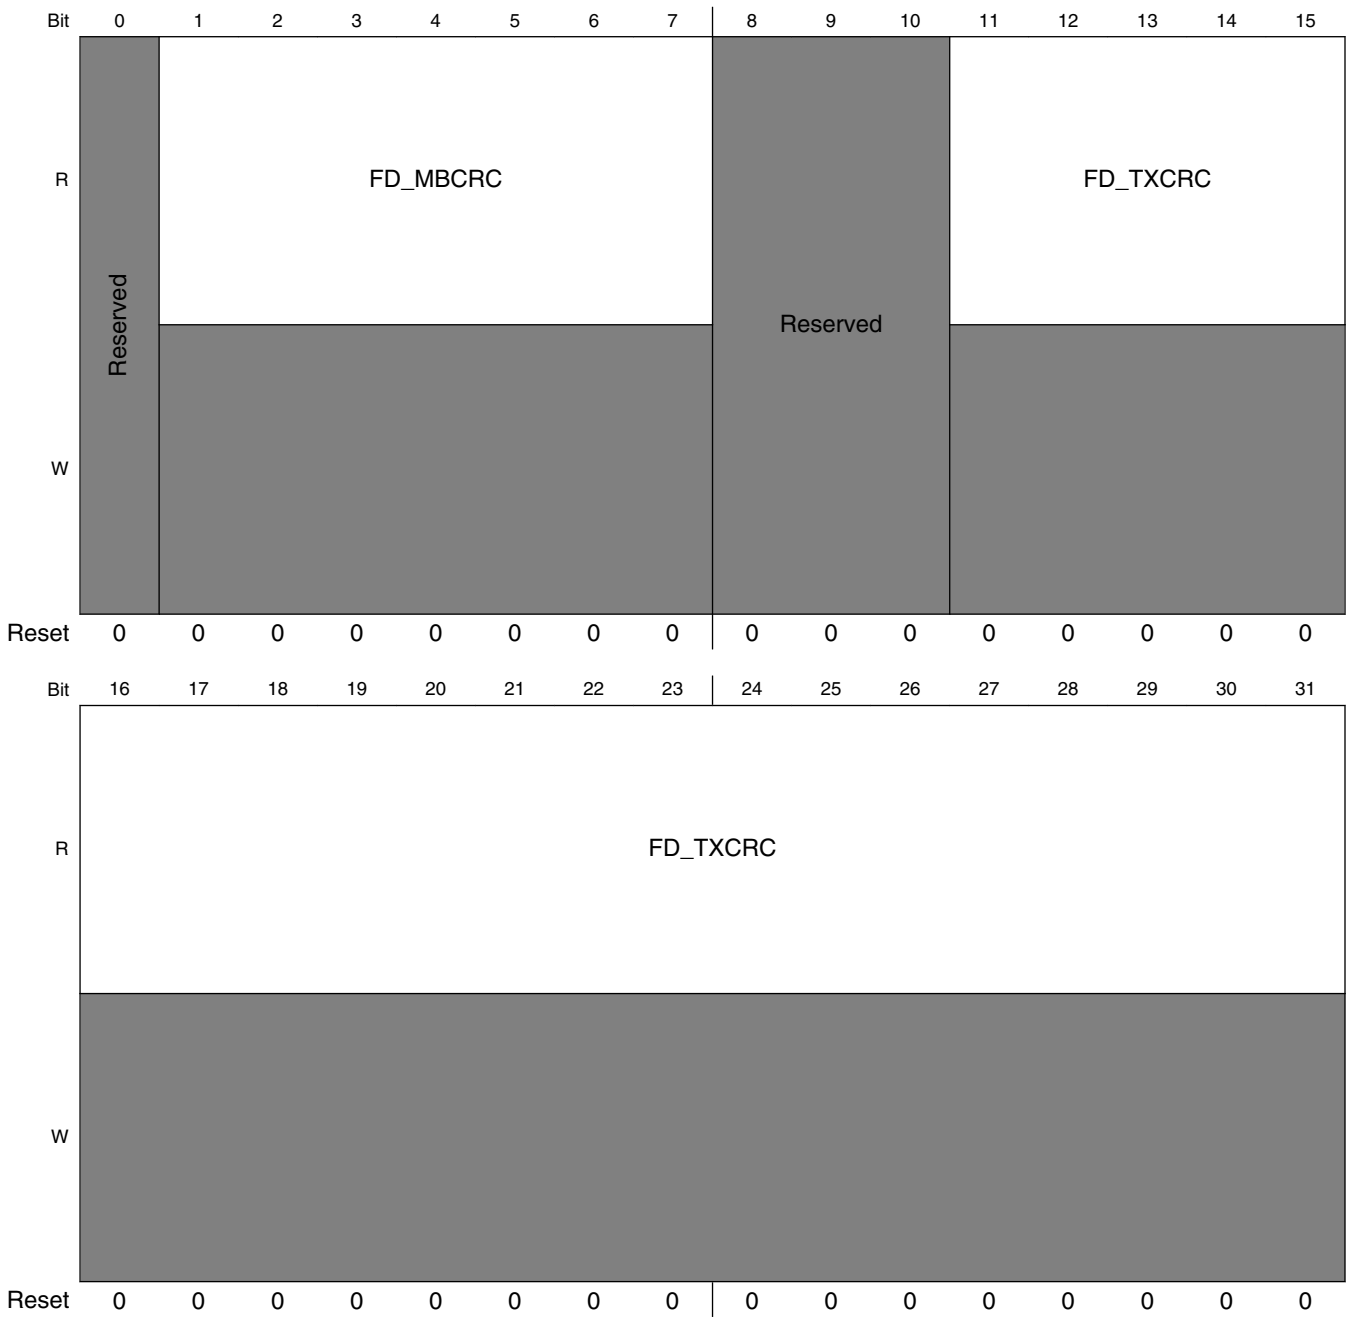
The CRC_15 polynomial is used for all frames in CAN format. The CRC_17 polynomial is used for frames in CAN FD format with a DATA FIELD up to sixteen bytes. The CRC_21 polynomial is used for frames in CAN FD format with a DATA FIELD longer than sixteen bytes. Each polynomial shown below results in a Hamming Distance of 6. This register is updated at the same time the Tx Interrupt Flag is asserted.

CRC_15 = 0xC599: $(x^{15} + x^{14} + x^{10} + x^8 + x^7 + x^4 + x^3 + 1)$

CRC_17 = 0x3685B: $(x^{17} + x^{16} + x^{14} + x^{13} + x^{11} + x^6 + x^4 + x^3 + x^1 + 1)$

CRC_21 = 0x302899: $(x^{21} + x^{20} + x^{13} + x^{11} + x^7 + x^4 + x^3 + 1)$

Address: 0h base + C08h offset = C08h



CAN_FDCRC field descriptions

Field	Description
0 Reserved	This field is reserved.
1–7 FD_MBCRC	CRC Mailbox Number for FD_TXCRC This field indicates the number of the Mailbox corresponding to the value in FD_TXCRC field, for both FD and non-FD frames. It reports the same information as in MBCRC bit field in CAN_CRCR register.

Table continues on the next page...

CAN_FDCRC field descriptions (continued)

Field	Description
8–10 Reserved	This field is reserved.
11–31 FD_TXCRC	Extended Transmitted CRC value This 21-bit field contains the CRC value calculated over the most recent transmitted message. Different CRC polynomials are used for different frame formats. A 15-bit polynomial, CRC_15, is used for all frames in CAN format. The second 17-bit polynomial, CRC_17, is used for frames in CAN FD format with a data field up to sixteen bytes long. The third 21-bit polynomial, CRC_21, is used for frames in CAN FD format with a data field longer than sixteen bytes. For CRC_15 and CRC_17, the 6 most significant bits and the 4 most significant bits are reported as zeros, respectively. For CRC_15, this register has the same content as CRC Register.

53.4.34 Message buffer structure

The message buffer structure used by the FlexCAN module is represented in the following figure. Both Extended (29-bit identifier) and Standard (11-bit identifier) frames used in the CAN specification (Version 2.0 Part B) are represented. Each individual MB is formed by 16, 24, 40 or 72 bytes, depending on the quantity of data bytes allocated for the message payload: 8, 16, 32 or 64 data bytes, respectively.

The memory area from 0x80 to 0x67F is used by the mailboxes. When CAN FD is enabled, the exact address for each MB depends on the size of its payload. See FlexCAN Memory Partition for CAN FD for more detailed information.

Table 53-8. Message buffer structure - example with 64 bytes payload

	0	1	2	3	4 7	8	9	10	11	12 13 14 15	16 23	24 31

= Unimplemented or Reserved

EDL - Extended Data Length

This bit distinguishes between CAN format and CAN FD format frames. The EDL bit must not be set for Message Buffers configured to RANSWER with code field 0b1010 (see Table below).

BRS - Bit Rate Switch

This bit defines whether the bit rate is switched inside a CAN FD format frame.

ESI - Error State Indicator

This bit indicates if the transmitting node is error active or error passive.

CODE - Message Buffer Code

This 4-bit field can be accessed (read or write) by the CPU and by the FlexCAN module itself, as part of the message buffer matching and arbitration process. The encoding is shown in Table 53-9 and Table 53-10. See Functional description for additional information.

Table 53-9. Message buffer code for Rx buffers

CODE description	Rx code BEFORE receive new frame	SRV[1]	Rx code AFTER successful reception[2]	RRS[3]	Comment
0b0000: INACTIVE - MB is not active.	INACTIVE	-	-	-	MB does not participate in the matching process.
0b0100: EMPTY - MB is active and empty.	EMPTY	-	FULL	-	When a frame is received successfully (after the Move-in) process), the CODE field is automatically updated to FULL.

Table continues on the next page...

Table 53-9. Message buffer code for Rx buffers (continued)

CODE description	Rx code BEFORE receive new frame	SRV[1]	Rx code AFTER successful reception[2]	RRS[3]	Comment
0b0010: FULL - MB is full.	FULL	Yes	FULL	-	The act of reading the C/S word followed by unlocking the MB (SRV) does not make the code return to EMPTY. It remains FULL. If a new frame is moved to the MB after the MB was serviced, the code still remains FULL. See Matching process for matching details related to FULL code.
		No	OVERRUN	-	If the MB is FULL and a new frame is moved to this MB before the CPU services it, the CODE field is automatically updated to OVERRUN. See Matching process for details about overrun behavior.
0b0110: OVERRUN - MB is being overwritten into a full buffer.	OVERRUN	Yes	FULL	-	If the CODE field indicates OVERRUN and CPU has serviced the MB, when a new frame is moved to the MB then the code returns to FULL.
		No	OVERRUN	-	If the CODE field already indicates OVERRUN, and another new frame must be moved, the MB will be overwritten again, and the code will remain OVERRUN. See Matching process for details about overrun behavior.

Table continues on the next page...

Table 53-9. Message buffer code for Rx buffers (continued)

CODE description	Rx code BEFORE receive new frame	SRV[1]	Rx code AFTER successful reception[2]	RRS[3]	Comment
0b1010: RANSWER[4] - A frame was configured to recognize a Remote Request Frame and transmit a Response Frame in return.[5]	RANSWER	-	TANSWER(0b1110)	0	A Remote Answer was configured to recognize a remote request frame received. After that an MB is set to transmit a response frame. The code is automatically changed to TANSWER (0b1110). See Matching process for details. If CAN_CTRL2[RRS] is negated, transmit a response frame whenever a remote request frame with the same ID is received.
		-	-	1	This code is ignored during matching and arbitration process. See Matching process for details.
CODE[0]=1: BUSY - FlexCAN is updating the contents of the MB. The CPU must not access the MB.	BUSY[6]	-	FULL	-	Indicates that the MB is being updated. It will be negated automatically and does not interfere with the next CODE.
		-	OVERRUN	-	

1. SRV: Serviced MB. MB was read and unlocked by reading TIMER or other MB.
2. A frame is considered a successful reception after the frame to be moved to MB (move-in process). See Move-in for details.
3. Remote Request Stored bit, see "Control 2 Register (CAN_CTRL2)" for details.
4. Code 0b1010 is not considered Tx and an MB with this code should not be aborted.
5. Code 0b1010 must be used in Message Buffers configured in CAN FD format, having the EDL bit set.
6. Note that for Tx MBs, the BUSY bit should be ignored upon read, except when AEN bit is set in the MCR register. If this bit is asserted, the corresponding MB does not participate in the matching process.

Table 53-10. Message buffer code for Tx buffers

CODE Description	Tx Code BEFORE tx frame	MB RTR	Tx Code AFTER successful transmission	Comment
0b1000: INACTIVE - MB is not active	INACTIVE	-	-	MB does not participate in arbitration process.
0b1001: ABORT - MB is aborted	ABORT	-	-	MB does not participate in arbitration process.
0b1100: DATA - MB is a Tx Data Frame (MB RTR must be 0)	DATA	0	INACTIVE	Transmit data frame unconditionally once. After transmission, the MB automatically returns to the INACTIVE state.
0b1100: REMOTE - MB is a Tx Remote Request Frame (MB RTR must be 1)	REMOTE	1	EMPTY	Transmit remote request frame unconditionally once. After transmission, the MB automatically becomes an Rx Empty MB with the same ID.
0b1110: TANSWER - MB is a Tx Response Frame from an incoming Remote Request Frame	TANSWER	-	RANSWER	This is an intermediate code that is automatically written to the MB by the CHI as a result of a match to a remote request frame. The remote response frame will be transmitted unconditionally once, and then the code will automatically return to RANSWER (0b1010). The CPU can also write this code with the same effect. The remote response frame can be either a data frame or another remote request frame depending on the RTR bit value. See Matching process and Arbitration process for details.

SRR - Substitute Remote Request

Fixed recessive bit, used only in extended format. It must be set to one by the user for transmission (Tx Buffers) and will be stored with the value received on the CAN bus for Rx receiving buffers. It can be received as either recessive or dominant. If FlexCAN receives this bit as dominant, then it is interpreted as an arbitration loss.

1 = Recessive value is compulsory for transmission in extended format frames

0 = Dominant is not a valid value for transmission in extended format frames

IDE - ID Extended Bit

This field identifies whether the frame format is standard or extended.

1 = Frame format is extended

0 = Frame format is standard

RTR - Remote Transmission Request

This bit affects the behavior of remote frames and is part of the reception filter. See Table 53-9, Table 53-10, and the description of the RRS bit in Control 2 Register (CAN_CTRL2) for additional details.

If FlexCAN transmits this bit as '1' (recessive) and receives it as '0' (dominant), it is interpreted as an arbitration loss. If this bit is transmitted as '0' (dominant), then if it is received as '1' (recessive), the FlexCAN module treats it as a bit error. If the value received matches the value transmitted, it is considered a successful bit transmission.

1 = Indicates the current MB may have a remote request frame to be transmitted if MB is Tx. If the MB is Rx then incoming remote request frames may be stored.

0 = Indicates the current MB has a data frame to be transmitted. In Rx MB it may be considered in matching processes.

NOTE

When configuring CAN FD frames, the RTR bit must be negated.

DLC - Length of Data in Bytes

This 4-bit field is the length (in bytes) of the Rx or Tx data, which is located in offset 0x8 through 0xF of the MB space (see Table 53-8) . In reception, this field is written by the FlexCAN module, copied from the DLC (Data Length Code) field of the received frame. In transmission, this field is written by the CPU and corresponds to the DLC field value of the frame to be transmitted. When RTR = 1, the frame to be transmitted is a remote frame and does not include the data field, regardless of the DLC field (see Table 53-11).

TIME STAMP - Free-Running Counter Time Stamp

This 16-bit field is a copy of the Free-Running Timer, captured for Tx and Rx frames at the time when the beginning of the Identifier field appears on the CAN bus.

PRIO - Local priority

This 3-bit field is used only when LPRIO_EN bit is set in CAN_MCR, and it only makes sense for Tx mailboxes. These bits are not transmitted. They are appended to the regular ID to define the transmission priority. See Arbitration process.

ID - Frame Identifier

In standard frame format, only the 11 most significant bits (3 to 13) are used for frame identification in both receive and transmit cases. The 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification in both receive and transmit cases.

DATA BYTE 0 to 63 - Data Field

Up to sixty four bytes can be used for a data frame, depending on the size of payload selected for the Message Buffers.

For Rx frames, the data is stored as it is received from the CAN bus. DATA BYTE (*n*) is valid only if *n* is less than DLC as shown in the table below.

Table 53-11. DATA BYTEs validity

DLC	Valid DATA BYTEs
0	none
1	DATA BYTE 0
2	DATA BYTE 0 to 1
3	DATA BYTE 0 to 2
4	DATA BYTE 0 to 3
5	DATA BYTE 0 to 4
6	DATA BYTE 0 to 5
7	DATA BYTE 0 to 6
8	DATA BYTE 0 to 7
9	DATA BYTE 0 to 11
10	DATA BYTE 0 to 15
11	DATA BYTE 0 to 19
12	DATA BYTE 0 to 23
13	DATA BYTE 0 to 31
14	DATA BYTE 0 to 47
15	DATA BYTE 0 to 63

53.4.35 FlexCAN Memory Partition for CAN FD

When CAN FD is enabled, the FlexCAN RAM can be partitioned in blocks of 512 bytes. Each block can accommodate a number of Message Buffers which depends on the configuration provided by CAN_FDCTRL[MBDSRn] bit fields as shown in table below.

Table 53-12. RAM partition

RAM block	Number of MBs with 8 bytes (default range)	Size control bit field in CAN_FDCTRL register	Number of MBs of different sizes, per block
0	0 to 31	MBDSR0	MBDSR0=00, 32 MBs with 8 bytes payload MBDSR0=01, 21 MBs with 16 bytes payload MBDSR0=10, 12 MBs with 32 bytes payload MBDSR0=11, 7 MBs with 64 bytes payload
1	32 to 63	MBDSR1	MBDSR1=00, 32 MBs with 8 bytes payload MBDSR1=01, 21 MBs with 16 bytes payload MBDSR1=10, 12 MBs with 32 bytes payload MBDSR1=11, 7 MBs with 64 bytes payload
2	64 to 95	MBDSR2	MBDSR2=00, 32 MBs with 8 bytes payload MBDSR2=01, 21 MBs with 16 bytes payload MBDSR2=10, 12 MBs with 32 bytes payload MBDSR2=11, 7 MBs with 64 bytes payload

When payload sizes of 16, 32 or 64 bytes are configured in some or all RAM blocks, the total number of MBs and its respective number order may differ from the default configuration of 8 bytes. For example, suppose Block0 is configured to 8 bytes payload, Block1 to 16 bytes, Block2 to 32 bytes, than the following table indicates how the Message Buffers will be arranged into RAM.

Table 53-13. RAM partition example

RAM block	Payload size	Number of MBs in the RAM block	Message Buffer range
0	CAN_FDCTRL[MBDSR0]=00, 8 bytes payload	32	0 to 31

Table continues on the next page...

Table 53-13. RAM partition example (continued)

RAM block	Payload size	Number of MBs in the RAM block	Message Buffer range
1	CAN_FDCTRL[MBDSR1]=01, 16 bytes payload	21	32 to 52
2	CAN_FDCTRL[MBDSR2]=10, 32 bytes payload	12	53 to 64

53.4.36 FlexCAN message buffer memory map

The FlexCAN memory buffers are allocated in memory according to the tables below.

53.4.37 Rx FIFO structure

When the CAN_MCR[RFEN] bit is set, the memory area from 0x80 to 0xDC (which is normally occupied by MBs 0–5) is used by the reception FIFO engine.

The region 0x80-0x8C contains the output of the FIFO which must be read by the CPU as a message buffer. This output contains the oldest message that has been received but not yet read. The region 0x90-0xDC is reserved for internal use of the FIFO engine.

An additional memory area, which starts at 0xE0 and may extend up to 0x2DC (normally occupied by MBs 6–37) depending on the CAN_CTRL2[RFFN] field setting, contains the ID filter table (configurable from 8 to 128 table elements) that specifies filtering criteria for accepting frames into the FIFO.

Out of reset, the ID filter table flexible memory area defaults to 0xE0 and extends only to 0xFC, which corresponds to MBs 6 to 7 for RFFN = 0, for backward compatibility with previous versions of FlexCAN.

The following shows the Rx FIFO data structure.

Table 53-18. Rx FIFO structure

	0 3 7 8	9	10	11	12 13 14 15	16 23	24 31
0x80		SRR	IDE	RTR	DLC	TIME STAMP	
0x84		ID standard				ID extended	
0x88	Data byte 0	Data byte 1				Data byte 2	Data byte 3
0x8C	Data byte 4	Data byte 5				Data byte 6	Data byte 7
0x90 to 0xDC	Reserved						
0xE0	ID filter table element 0						
0xE4	ID filter table element 1						
0xE8 to 0x2D4	ID filter table elements 2 to 125						
0x2D8	ID filter table element 126						
0x2DC	ID filter table element 127						

= Unimplemented or reserved

Each ID filter table element occupies an entire 32-bit word and can be compounded by one, two, or four Identifier Acceptance Filters (IDAF) depending on the CAN_MCR[IDAM] field setting. The following figures show the IDAF indexation.

The following table shows the three different formats of the ID table elements. Note that all elements of the table must have the same format. See Rx FIFO for more information.

Table 53-19. ID table structure

	0	1	2 7	8 15	16	17	18 23	24 30	31
A	RTR	IDE	RXIDA (standard = 2–12, extended = 2–30)						
B	RTR	IDE	RXIDB_0 (standard = 2–12, extended = 2–15)		RTR	IDE	RXIDB_1 (standard = 18–28, extended = 18–31)		
C	RXIDC_0 (std/ext = 0–7)			RXIDC_1 (std/ext = 8–15)	RXIDC_2 (std/ext = 16–23)			RXIDC_3 (std/ext = 24–31)	

= Unimplemented or Reserved

RTR — Remote Frame

This bit specifies if Remote Frames are accepted into the FIFO if they match the target ID.

1 = Remote Frames can be accepted and data frames are rejected

0 = Remote Frames are rejected and data frames can be accepted

IDE — Extended Frame

Specifies whether extended or standard frames are accepted into the FIFO if they match the target ID.

1 = Extended frames can be accepted and standard frames are rejected

0 = Extended frames are rejected and standard frames can be accepted

RXIDA — Rx Frame Identifier (Format A)

Specifies an ID to be used as acceptance criteria for the FIFO. In the standard frame format, only the 11 most significant bits (2 to 12) are used for frame identification. In the extended frame format, all bits are used.

RXIDB_0, RXIDB_1 — Rx Frame Identifier (Format B)

Specifies an ID to be used as acceptance criteria for the FIFO. In the standard frame format, the 11 most significant bits (a full standard ID) (2 to 12 and 18 to 28) are used for frame identification. In the extended frame format, all 14 bits of the field are compared to the 14 most significant bits of the received ID.

RXIDC_0, RXIDC_1, RXIDC_2, RXIDC_3 — Rx Frame Identifier (Format C)

Specifies an ID to be used as acceptance criteria for the FIFO. In both standard and extended frame formats, all 8 bits of the field are compared to the 8 most significant bits of the received ID.

53.5 Functional description

The FlexCAN module is a CAN protocol engine with a very flexible mailbox system for transmitting and receiving CAN frames. The mailbox system is composed by a set of Message Buffers (MB) that store configuration and control data, time stamp, message ID and data (see Message buffer structure). The memory corresponding to the first 38 MBs can be configured to support a FIFO reception scheme with a powerful ID filtering mechanism, capable of checking incoming frames against a table of IDs (up to 128 extended IDs or 256 standard IDs or 512 8-bit ID slices), with individual mask register for up to 32 ID Filter Table elements.

For Classical CAN frames, simultaneous reception through FIFO and mailbox is supported. For CAN FD frames, reception is supported through mailboxes only. For mailbox reception, a matching algorithm makes it possible to store received frames only into MBs that have the same ID programmed on its ID field. A masking scheme makes it

possible to match the ID programmed on the MB with a range of IDs on received CAN frames. For transmission, an arbitration algorithm decides the prioritization of MBs to be transmitted based on the message ID (optionally augmented by 3 local priority bits) or the MB ordering.

Before proceeding with the functional description, an important concept must be explained. A Message Buffer is said to be "active" at a given time if it can participate in both the Matching and Arbitration processes. An Rx MB with a 0b0000 code is inactive (refer to Table 53-9). Similarly, a Tx MB with a 0b1000 or 0b1001 code is also inactive (refer to Table 53-10).

The FlexCAN module is also able to receive and transmit messages in CAN FD format. The Message Buffers are sized to adequately store the quantity of data bytes selected by the MBDSRn bit fields in CAN_FDCTRL register. The quantity of FD MBs available for a given quantity of data bytes is described CAN_FDCTRL register. See also FlexCAN Memory Partition for CAN FD.

53.5.1 Transmit process

To transmit a CAN frame, the CPU must prepare a Message Buffer for transmission by executing the following procedure:

1. Check whether the respective interrupt bit is set and clear it.
2. If the MB is active (transmission pending), write the ABORT code (0b1001) to the CODE field of the Control and Status word to request an abortion of the transmission. Wait for the corresponding IFLAG bit to be asserted by polling the CAN_IFLAG register or by the interrupt request if enabled by the respective IMASK bit. Then read back the CODE field to check if the transmission was aborted or transmitted (see Transmission abort mechanism). If backwards compatibility is desired (CAN_MCR[AEN] bit is negated), just write the INACTIVE code (0b1000) to the CODE field to inactivate the MB but then the pending frame may be transmitted without notification (see Mailbox inactivation).
3. Write the ID word.
4. Write the data bytes.
5. Write the DLC, Control, and CODE fields of the Control and Status word to activate the MB. When CAN_MCR[FDEN] is set, write also the EDL, BRS and ESI bits.

When the MB is activated, it participates in the arbitration process and is eventually transmitted according to its priority. When the DLC value stored in the MB selected for transmission is larger than the respective MB payload size, FlexCAN adds the necessary number of bytes with constant 0xCC pattern to complete the expected DLC.

At the end of the successful transmission, the value of the Free Running Timer is written into the Time Stamp field, the CODE field in the Control and Status word is updated, both CAN_CRC and CAN_FDCRC Registers are updated, a status flag is set in the Interrupt Flag Register and an interrupt is generated if allowed by the corresponding Interrupt Mask Register bit. The new CODE field after transmission depends on the code that was used to activate the MB (see Table 53-9 and Table 53-10 in Message buffer structure).

When the Abort feature is enabled (CAN_MCR[AEN] is asserted), after the Interrupt Flag is asserted for a Mailbox configured as transmit buffer, the Mailbox is blocked. Therefore the CPU is not able to update it until the Interrupt Flag is negated by CPU. This means that the CPU must clear the corresponding IFLAG bit before starting to prepare this MB for a new transmission or reception.

53.5.2 Arbitration process

The arbitration process scans the Mailboxes searching the Tx one that holds the message to be sent in the next opportunity. This Mailbox is called the *arbitration winner*.

The scan starts from the lowest number Mailbox and runs toward the higher ones.

The arbitration process is triggered in the following events:

- From the CRC field of the CAN frame. The start point depends on the CAN_CTRL2[TASD] field value.
- During the Error Delimiter field of a CAN frame.
- During the Overload Delimiter field of a CAN frame.
- When the winner is inactivated and the CAN bus has still not reached the first bit of the Intermission field.
- When there is CPU write to the C/S word of a winner MB and the CAN bus has still not reached the first bit of the Intermission field.
- When CHI is in Idle state and the CPU writes to the C/S word of any MB.
- When FlexCAN exits Bus Off state.
- Upon leaving Freeze mode or Low Power mode.

If the arbitration process does not manage to evaluate all Mailboxes before the CAN bus has reached the first bit of the Intermission field the temporary arbitration winner is invalidated and the FlexCAN will not compete for the CAN bus in the next opportunity.

The arbitration process selects the winner among the active Tx Mailboxes at the end of the scan according to both CAN_CTRL1[LBUF] and CAN_MCR[LPRIOEN] bits settings.

53.5.2.1 Lowest-number Mailbox first

If CAN_CTRL1[LBUF] bit is asserted the first (lowest number) active Tx Mailbox found is the arbitration winner. CAN_MCR[LPRIOEN] bit has no effect when CAN_CTRL1[LBUF] is asserted.

53.5.2.2 Highest-priority Mailbox first

If CAN_CTRL1[LBUF] bit is negated, then the arbitration process searches the active Tx Mailbox with the highest priority, which means that this Mailbox's frame would have a higher probability to win the arbitration on CAN bus when multiple external nodes compete for the bus at the same time.

The sequence of bits considered for this arbitration is called the *arbitration value* of the Mailbox. The highest-priority Tx Mailbox is the one that has the lowest arbitration value among all Tx Mailboxes.

If two or more Mailboxes have equivalent arbitration values, the Mailbox with the lowest number is the arbitration winner.

The composition of the arbitration value depends on CAN_MCR[LPRIOEN] bit setting.

53.5.2.2.1 Local Priority disabled

If CAN_MCR[LPRIOEN] bit is negated the arbitration value is built in the exact sequence of bits as they would be transmitted in a CAN frame (see the following table) in such a way that the Local Priority is disabled.

Table 53-20. Composition of the arbitration value when Local Priority is disabled

Format	Mailbox Arbitration Value (32 bits)				
Standard (IDE = 0)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	- (18 bits)	- (1 bit)
Extended (IDE = 1)	Extended ID[28:18] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

53.5.2.2.2 Local Priority enabled

If Local Priority is desired CAN_MCR[LPRIOEN] must be asserted. In this case the Mailbox PRIO field is included at the very left of the arbitration value (see the following table).

Table 53-21. Composition of the arbitration value when Local Priority is enabled

Format	Mailbox Arbitration Value (35 bits)					
Standard (IDE = 0)	PRIO (3 bits)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	- (18 bits)	- (1 bit)
Extended (IDE = 1)	PRIO (3 bits)	Extended ID[28:18] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

As the PRIO field is the most significant part of the arbitration value Mailboxes with low PRIO values have higher priority than Mailboxes with high PRIO values regardless the rest of their arbitration values.

Note that the PRIO field is not part of the frame on the CAN bus. Its purpose is only to affect the internal arbitration process.

53.5.2.3 Arbitration process (continued)

After the arbitration winner is found, its content is copied to a hidden auxiliary MB called Tx Serial Message Buffer (Tx SMB), which has the same structure as a normal MB but is not user accessible. This operation is called move-out and after it is done, write access to the C/S word of the corresponding MB is blocked (if the AEN bit in CAN_MCR register is asserted). Write access is restored in the following events:

- After the MB is transmitted and the corresponding IFLAG bit is cleared by the CPU
- FlexCAN enters in Freeze mode or Bus Off
- FlexCAN loses the bus arbitration or there is an error during the transmission

At the first opportunity window on the CAN bus, the message on the Tx SMB is transmitted according to the CAN protocol rules.

Arbitration process can be triggered in the following situations:

- During Rx and Tx frames from CAN CRC field to end of frame. CAN_CTRL2[TASD] bit value may be changed to optimize the arbitration start point.

- During CAN BusOff state from TX_ERR_CNT=124 to 128. CAN_CTRL2[TASD] bit value may be changed to optimize the arbitration start point.
- During C/S write by CPU in BusIdle. First C/S write starts arbitration process and a second C/S write during this same arbitration restarts the process. If other C/S writes are performed, Tx arbitration process is pending. If there is no arbitration winner after the arbitration process has finished, then the TX arbitration machine begins a new arbitration process. If there is a pending arbitration and BusIdle state starts then an arbitration process is triggered. In this case the first and second C/S write in BusIdle will not restart the arbitration process. It is possible that there is not enough time to finish arbitration in WaitForBusIdle state and the next state is Idle. In this case the scan is not interrupted, and it is completed during BusIdle state. During this arbitration C/S write does not cause arbitration restart.
- Arbitration winner deactivation during a valid arbitration window.
- Upon exiting Freeze mode (first bit of the WaitForBusIdle state). If there is a re-synchronization during WaitForBusIdle, the arbitration process is restarted.

Arbitration process stops in the following situations:

- All Mailboxes were scanned
- A Tx active Mailbox is found in case of Lowest Buffer feature enabled
- Arbitration winner inactivation or abort during any arbitration process
- There was not enough time to finish Tx arbitration process (for instance, when a deactivation was performed near the end of frame). In this case arbitration process is pending.
- Error or Overload flag in the bus
- Low Power or Freeze mode request in Idle state

Arbitration is considered pending as described below:

- It was not possible to finish arbitration process in time
- C/S write during arbitration if write is performed in a MB whose number is lower than the Tx arbitration pointer
- Any C/S write if there is no Tx Arbitration process in progress
- Rx Match has just updated a Rx Code to Tx Code
- Entering Busoff state

C/S write during arbitration has the following effect:

- If C/S write is performed in the arbitration winner, a new process is restarted immediately.
- If C/S write is performed in a MB whose number is higher than the Tx arbitration pointer, the ongoing arbitration process will scan this MB as normal.

53.5.3 Receive process

To be able to receive CAN frames into a Mailbox, the CPU must prepare it for reception by executing the following steps:

1. If the Mailbox is active (either Tx or Rx) inactivate the Mailbox (see Mailbox inactivation), preferably with a safe inactivation (see Transmission abort mechanism).
2. Write the ID word
3. Write the EMPTY code (0b0100) to the CODE field of the Control and Status word to activate the Mailbox. No setup is required for EDL, BRS and ESI bits, they are overwritten by the respective bit fields in the received message.

After the MB is activated, it will be able to receive frames that match the programmed filter. At the end of a successful reception, the Mailbox is updated by the *move-in* process (see Move-in) as follows:

1. The received Data field (8 bytes at most for Classical CAN message format and up to 64 bytes for CAN FD message format) is stored.
2. The received Identifier field is stored.
3. The value of the Free Running Timer at the time of the second bit of frame's Identifier field is written into the Mailbox's Time Stamp field.
4. The received SRR, IDE, RTR, EDL, BRS, ESI and DLC fields are stored.
5. The CODE field in the Control and Status word is updated (see Table 53-9 and Table 53-10 in Section Message buffer structure).
6. A status flag is set in the Interrupt Flag Register and an interrupt is generated if allowed by the corresponding Interrupt Mask Register bit.

The recommended way for CPU servicing (read) the frame received in an Mailbox is using the following procedure:

1. Read the Control and Status word of that Mailbox.
2. Check if the BUSY bit is deasserted, indicating that the Mailbox is locked. Repeat step 1) while it is asserted. See Mailbox lock mechanism.
3. Read the contents of the Mailbox. Once Mailbox is locked now, its contents won't be modified by FlexCAN Move-in processes. See Move-in.

4. Acknowledge the proper flag at IFLAG registers.
5. Read the Free Running Timer. It is optional but recommended to unlock Mailbox as soon as possible and make it available for reception.

The CPU should poll for frame reception by the status flag bit for the specific Mailbox in one of the IFLAG Registers and not by the CODE field of that Mailbox. Polling the CODE field does not work because once a frame was received and the CPU services the Mailbox (by reading the C/S word followed by unlocking the Mailbox), the CODE field will not return to EMPTY. It will remain FULL, as explained in Table 53-9 . If the CPU tries to workaround this behavior by writing to the C/S word to force an EMPTY code after reading the Mailbox without a prior *safe inactivation*, a newly received frame matching the filter of that Mailbox may be lost.

CAUTION

In summary: *never do polling by reading directly the C/S word of the Mailboxes. Instead, read the IFLAG registers.*

Note that the received frame's Identifier field is always stored in the matching Mailbox, thus the contents of the ID field in an Mailbox may change if the match was due to masking. When CAN_MCR[SRXDIS] bit is asserted, FlexCAN will not store frames transmitted by itself in any MB, even if it contains a matching Rx Mailbox, and no interrupt flag or interrupt signal will be generated. Otherwise, when CAN_MCR[SRXDIS] bit is deasserted, FlexCAN can receive frames transmitted by itself if there exists a matching Rx Mailbox.

To be able to receive CAN frames through the Rx FIFO, the CPU must enable and configure the Rx FIFO during Freeze mode (see Rx FIFO). Upon receiving the Frames Available in Rx FIFO interrupt (see the description of the BUF5I bit "Frames available in Rx FIFO" bit in the CAN_IFLAG1 register), the CPU should service the received frame using the following procedure:

1. Read the Control and Status word (optional: needed only if a mask was used for IDE and RTR bits)
2. Read the ID field (optional: needed only if a mask was used)
3. Read the Data field
4. Read the CAN_RXFIR register (optional)
5. Clear the Frames Available in Rx FIFO interrupt by writing 1 to CAN_IFLAG1[BUF5I] bit (mandatory: releases the MB and allows the CPU to read the next Rx FIFO entry)

53.5.4 Matching process

The matching process scans the MB memory looking for Rx MBs programmed with the same ID as the one received from the CAN bus. If the FIFO is enabled, the priority of scanning can be selected between Mailboxes and FIFO filters. The matching starts from the lowest number Message Buffer toward the higher ones. If no match is found within the first structure then the other is scanned subsequently. In the event that the FIFO is full, the matching algorithm always looks for a matching MB outside the FIFO region.

As the frame is being received, it is stored in a hidden auxiliary MB called Rx Serial Message Buffer (Rx SMB).

The matching process start point depends on the following conditions:

- If the received frame is a remote frame, the start point is the CRC field of the frame
- If the received frame is a data frame with DLC field equal to zero, the start point is the CRC field of the frame
- If the received frame is a data frame with DLC field different than zero, the start point is the DATA field of the frame

If a matching ID is found in the FIFO table or in one of the Mailboxes, the contents of the Rx SMB are transferred to the FIFO or to the matched Mailbox by the move-in process. If any CAN protocol error is detected then no match results are transferred to the FIFO or to the matched Mailbox at the end of reception.

The matching process scans all matching elements of both Rx FIFO (if enabled) and the active Rx Mailboxes (CODE is EMPTY, FULL, OVERRUN or RANSWER) in search of a successful comparison with the matching elements of the Rx SMB that is receiving the frame on the CAN bus. The Rx SMB has the same structure of a Mailbox. The reception structures (Rx FIFO or Mailboxes) associated with the matching elements that had a successful comparison are the *matched structures*. The *matching winner* is selected at the end of the scan among those matched structures and depends on conditions described ahead. See the following table.

Table 53-22. Matching architecture

Structure	SMB[RTR]	CTRL2[RRS]	CTRL2[EACEN]	MB[IDE]	MB[RTR]	MB[ID[1]]	MB[CODE]
Mailbox	0	-	0	cmp[2]	no_cmp[3]	cmp_msk[4]	EMPTY or FULL or OVERRUN

Table continues on the next page...

Table 53-22. Matching architecture (continued)

Structure	SMB[RTR]	CTRL2[RRS]	CTRL2[EACEN]	MB[IDE]	MB[RTR]	MB[ID[1]]	MB[CODE]
Mailbox	0	-	1	cmp_msk	cmp_msk	cmp_msk	EMPTY or FULL or OVERRUN
Mailbox	1	0	-	cmp	no_cmp	cmp	RANSWER
Mailbox	1	1	0	cmp	no_cmp	cmp_msk	EMPTY or FULL or OVERRUN
Mailbox	1	1	1	cmp_msk	cmp_msk	cmp_msk	EMPTY or FULL or OVERRUN
FIFO[5]	-	-	-	cmp_msk	cmp_msk	cmp_msk	-

1. For Mailbox structure, If SMB[IDE] is asserted, the ID is 29 bits (ID Standard + ID Extended). If SMB[IDE] is negated, the ID is only 11 bits (ID Standard). For FIFO structure, the ID depends on IDAM.
2. cmp: Compares the Rx SMB contents with the MB contents regardless the masks.
3. no_cmp: The Rx SMB contents are not compared with the MB contents.
4. cmp_msk: Compares the Rx SMB contents with MB contents taking into account the masks.
5. SMB[IDE] and SMB[RTR] are not taken into account when IDAM is type C.

A reception structure is *free-to-receive* when any of the following conditions is satisfied:

- The CODE field of the Mailbox is EMPTY
- The CODE field of the Mailbox is either FULL or OVERRUN and it has already been serviced (the C/S word was read by the CPU and unlocked as described in Mailbox lock mechanism)
- The CODE field of the Mailbox is either FULL or OVERRUN and an inactivation (see Mailbox inactivation) is performed
- The Rx FIFO is not full

The scan order for Mailboxes and Rx FIFO is from the matching element with lowest number to the higher ones.

The matching winner search for Mailboxes is affected by the CAN_MCR[IRMQ] bit. If it is negated, the matching winner is the first matched Mailbox regardless if it is free-to-receive or not. If it is asserted, the matching winner is selected according to the priority below:

1. the first free-to-receive matched Mailbox;
2. the last non free-to-receive matched Mailbox.

It is possible to select the priority of scan between Mailboxes and Rx FIFO by the CAN_CTRL2[MRP] bit.

If the selected priority is Rx FIFO first:

- If the Rx FIFO is a matched structure and is free-to-receive, then the Rx FIFO is the matching winner regardless of the scan for Mailboxes
- Otherwise (the Rx FIFO is not a matched structure or is not free-to-receive), then the matching winner is searched among Mailboxes as described above

If the selected priority is Mailboxes first:

- If a free-to-receive matched Mailbox is found, it is the matching winner regardless of the scan for Rx FIFO
- If no matched Mailbox is found, then the matching winner is searched in the scan for the Rx FIFO
- If both conditions above are not satisfied and a non free-to-receive matched Mailbox is found, then the matching winner determination is conditioned by the CAN_MCR[IRMQ] bit:
- - If CAN_MCR[IRMQ] bit is negated, the matching winner is the first matched Mailbox
  - If CAN_MCR[IRMQ] bit is asserted, the matching winner is the Rx FIFO if it is a free-to-receive matched structure; otherwise, the matching winner is the last non free-to-receive matched Mailbox

See the following table for a summary of matching possibilities.

Table 53-23. Matching possibilities and resulting reception structures

RFEN	IRMQ	MRP	Matched in MB	Matched in FIFO	Reception structure	Description
No FIFO, only MB, match is always MB first						
0	0	X[1]	None[2]	-[3]	None	Frame lost by no match
0	0	X	Free[4]	-	FirstMB	
0	1	X	None	-	None	Frame lost by no match
0	1	X	Free	-	FirstMb	
0	1	X	NotFree	-	LastMB	Overrun
FIFO enabled, no match in FIFO is as if FIFO does not exist						
1	0	X	None	None[5]	None	Frame lost by no match
1	0	X	Free	None	FirstMB	
1	1	X	None	None	None	Frame lost by no match
1	1	X	Free	None	FirstMb	
1	1	X	NotFree	None	LastMB	Overrun
FIFO enabled, Queue disabled						
1	0	0	X	NotFull[6]	FIFO	

Table continues on the next page...

Table 53-23. Matching possibilities and resulting reception structures (continued)

RFEN	IRMQ	MRP	Matched in MB	Matched in FIFO	Reception structure	Description
1	0	0	None	Full[7]	None	Frame lost by FIFO full (FIFO Overflow)
1	0	0	Free	Full	FirstMB	
1	0	0	NotFree	Full	FirstMB	
1	0	1	None	NotFull	FIFO	
1	0	1	None	Full	None	Frame lost by FIFO full (FIFO Overflow)
1	0	1	Free	X	FirstMB	
1	0	1	NotFree	X	FirtsMb	Overrun
FIFO enabled, Queue enabled						
1	1	0	X	NotFull	FIFO	
1	1	0	None	Full	None	Frame lost by FIFO full (FIFO Overflow)
1	1	0	Free	Full	FirstMB	
1	1	0	NotFree	Full	LastMb	Overrun
1	1	1	None	NotFull	FIFO	
1	1	1	Free	X	FirstMB	
1	1	1	NotFree	NotFull	FIFO	
1	1	1	NotFree	Full	LastMb	Overrun

1. This is a don't care condition.
2. Matched in MB "None" means that the frame has not matched any MB (free-to-receive or non-free-to-receive).
