3. This is a forbidden condition.
4. Matched in MB "Free" means that the frame matched at least one MB free-to-receive regardless of whether it has matched MBs non-free-to-receive.
5. Matched in FIFO "None" means that the frame has not matched any filter in FIFO. It is as if the FIFO didn't exist (CAN_CTRL2[RFEN]=0).
6. Matched in FIFO "NotFull" means that the frame has matched a FIFO filter and has empty slots to receive it.
7. Matched in FIFO "Full" means that the frame has matched a FIFO filter but couldn't store it because it has no empty slots to receive it.

If a non-safe Mailbox inactivation (see Mailbox inactivation) occurs during matching process and the Mailbox inactivated is the temporary matching winner, then the temporary matching winner is invalidated. The matching elements scan is not stopped nor restarted, it continues normally. The consequence is that the current matching process works as if the matching elements compared before the inactivation did not exist, therefore a message may be lost.

Suppose, for example, that the FIFO is disabled, IRMQ is enabled and there are two MBs with the same ID, and FlexCAN starts receiving messages with that ID. Let us say that these MBs are the second and the fifth in the array. When the first message arrives, the matching algorithm finds the first match in MB number 2. The code of this MB is

EMPTY, so the message is stored there. When the second message arrives, the matching algorithm finds MB number 2 again, but it is not "free-to-receive", so it keeps looking, finds MB number 5 and stores the message there. If yet another message with the same ID arrives, the matching algorithm finds out that there are no matching MBs that are "free-to-receive", so it decides to overwrite the last matched MB, which is number 5. In doing so, it sets the CODE field of the MB to indicate OVERRUN.

The ability to match the same ID in more than one MB can be exploited to implement a reception queue (in addition to the full featured FIFO) to allow more time for the CPU to service the MBs. By programming more than one MB with the same ID, received messages are queued into the MBs. The CPU can examine the Time Stamp field of the MBs to determine the order in which the messages arrived.

Matching to a range of IDs is possible by using ID Acceptance Masks. FlexCAN supports individual masking per MB. See the description of the Rx Individual Mask Registers (CAN_RXIMRx). During the matching algorithm, if a mask bit is asserted, then the corresponding ID bit is compared. If the mask bit is negated, the corresponding ID bit is a "don't care". Note that the Individual Mask Registers are implemented in RAM, so they are not initialized out of reset. Also, they can only be programmed while the module is in Freeze mode; otherwise, they are blocked by hardware.

FlexCAN also supports an alternate masking scheme with only four mask registers (CAN_RXFGMASK, CAN_RXMGMASK, CAN_RX14MASK and CAN_RX15MASK) for backwards compatibility with legacy applications. This alternate masking scheme is enabled when the IRMQ bit in the CAN_MCR Register is negated.

53.5.5 Move process

There are two types of move process: move-in and move-out.

53.5.5.1 Move-in

The move-in process is the copy of a message received by an Rx SMB to a Rx Mailbox or FIFO that has matched it. If the move destination is the Rx FIFO, attributes of the message are also copied to the CAN_RXFIR FIFO. Each Rx SMB has its own move-in process, but only one is performed at a given time as described ahead. The move-in starts only when the message held by the Rx SMB has a corresponding matching winner (see Matching process) and all of the following conditions are true:

- The CAN bus has reached or let past either:

    - The second bit of Intermission field next to the frame that carried the message that is in the Rx SMB
    - The first bit of an overload frame next to the frame that carried the message that is in the Rx SMB
- There is no ongoing matching process
- The destination Mailbox is not locked by the CPU
- There is no ongoing move-in process from another Rx SMB. If more than one move-in processes are to be started at the same time both are performed and the newest substitutes the oldest.

The term *pending move-in* is used throughout the documentation and stands for a move-to-be that still does not satisfy all of the aforementioned conditions.

The move-in is cancelled and the Rx SMB is able to receive another message if any of the following conditions is satisfied:

- The destination Mailbox is inactivated after the CAN bus has reached the first bit of Intermission field next to the frame that carried the message and its matching process has finished
- There is a previous pending move-in to the same destination Mailbox
- The Rx SMB is receiving a frame transmitted by the FlexCAN itself and the self-reception is disabled (CAN_MCR[SRXDIS] bit is asserted)
- Any CAN protocol error is detected

Note that the pending move-in is not cancelled if the module enters Freeze or Low-Power mode. It only stays on hold waiting for exiting Freeze and Low-Power mode and to be unlocked. If an MB is unlocked during Freeze mode, the move-in happens immediately.

The move-in process is the execution by the FlexCAN of the following steps:

1. Push IDHIT into the RXFIR FIFO if the message is destined to the Rx FIFO.
2. Read all data words from the Rx SMB in accordance to the selected payload size for the Rx storage element.
3. Write all data words to the Rx Mailbox in accordance to the selected payload size for the Rx storage element. If the data size of the storage element is smaller than the original payload size described in the message's DLC field, the payload is truncated and the high order bytes that do not fit the destination size are lost.
4. Read the Control/Status and ID words from the Rx SMB.
5. Write Control/Status and ID words to the Rx Mailbox, and update the CODE field.

The move-in process is not atomic, in such a way that it is immediately cancelled by the inactivation of the destination Mailbox (see Mailbox inactivation) and in this case the Mailbox may be left partially updated, thus incoherent. The exception is if the move-in destination is an Rx FIFO Message Buffer, then the process cannot be cancelled.

The BUSY Bit (least significant bit of the CODE field) of the destination Message Buffer is asserted while the move-in is being performed to alert the CPU that the Message Buffer content is temporarily incoherent.

53.5.5.2 Move-out

The move-out process is the copy of the content from a Tx Mailbox to the Tx SMB when a message for transmission is available (see Section "Arbitration process"). The move-out occurs in the following conditions:

- The first bit of Intermission field
- During Bus Off state when TX Error Counter is in the 124 to 128 range
- During Bus Idle state
- During Wait For Bus Idle state

The move-out process is not atomic. Only the CPU has priority to access the memory concurrently out of Bus Idle state. In Bus Idle, the move-out has the lowest priority to the concurrent memory accesses.

53.5.6 Data coherence

In order to maintain data coherency and FlexCAN proper operation, the CPU must obey the rules described in Transmit process and Receive process.

53.5.6.1 Transmission abort mechanism

The abort mechanism provides a safe way to request the abortion of a pending transmission. A feedback mechanism is provided to inform the CPU if the transmission was aborted or if the frame could not be aborted and was transmitted instead.

Two primary conditions must be fulfilled in order to abort a transmission:

- CAN_MCR[AEN] bit must be asserted
- The first CPU action must be the writing of abort code (0b1001) into the CODE field of the Control and Status word.

Active MBs configured for transmission must be aborted first before they can be updated. If the abort code is written to a Mailbox that is currently being transmitted or to a Mailbox that was already loaded into the Tx SMB for transmission, the write operation is blocked and the transmission is not disturbed. However, the abort request is captured and kept pending until one of the following conditions is satisfied:

- The module loses the bus arbitration
- There is an error during the transmission
- The module is put into Freeze mode
- The module enters the BusOff state
- There is an overload frame

If none of the conditions above are reached, the MB is transmitted correctly, the interrupt flag is set in the IFLAG register, and an interrupt to the CPU is generated (if enabled). The abort request is automatically cleared when the interrupt flag is set. On the other hand, if one of the above conditions is reached, the frame is not transmitted; therefore, the abort code is written into the CODE field, the interrupt flag is set in the IFLAG, and an interrupt is (optionally) generated to the CPU.

If the CPU writes the abort code before the transmission begins internally, then the write operation is not blocked; therefore, the MB is updated and the interrupt flag is set. In this way the CPU just needs to read the abort code to make sure the active MB was *safely inactivated*. Although the AEN bit is asserted and the CPU wrote the abort code, in this case the MB is inactivated and not aborted, because the transmission did not start yet. One Mailbox is only aborted when the abort request is captured and kept pending until one of the previous conditions are satisfied.

The abort procedure can be summarized as follows:

- CPU checks the corresponding IFLAG and clears it, if asserted.
- CPU writes 0b1001 into the CODE field of the C/S word.
- CPU waits for the corresponding IFLAG indicating that the frame was either transmitted or aborted.
- CPU reads the CODE field to check if the frame was either transmitted (CODE=0b1000) or aborted (CODE=0b1001).
- It is necessary to clear the corresponding IFLAG in order to allow the MB to be reconfigured.
- It is necessary to reconfigure the EDL, BRS, and ESI bits of the aborted MB before transmitting it again.

53.5.6.2 Mailbox inactivation

Inactivation is a mechanism provided to protect the Mailbox against updates by the FlexCAN internal processes, thus allowing the CPU to rely on Mailbox data coherence after having updated it, even in Normal mode.

Inactivation of transmission Mailboxes must be performed just when MCR[AEN] bit is deasserted.

If a Mailbox is inactivated, it participates in neither the arbitration process nor the matching process until it is reactivated. See Transmit process and Receive process for more detailed instructions on how to inactivate and reactivate a Mailbox.

To inactivate a Mailbox, the CPU must update its CODE field to INACTIVE (either 0b0000 or 0b1000).

Because the user is not able to synchronize the CODE field update with the FlexCAN internal processes, an inactivation can have the following consequences:

- A frame in the bus that matches the filtering of the inactivated Rx Mailbox may be lost without notice, even if there are other Mailboxes with the same filter
- A frame containing the message within the inactivated Tx Mailbox may be transmitted without setting the respective IFLAG

In order to perform a *safe inactivation* and avoid the above consequences for Tx Mailboxes, the CPU must use the Transmission Abort mechanism (see Transmission abort mechanism).

The inactivation automatically unlocks the Mailbox (see Mailbox lock mechanism).

NOTE

Message Buffers that are part of the Rx FIFO cannot be inactivated. There is no write protection on the FIFO region by FlexCAN. CPU must maintain data coherency in the FIFO region when RFEN is asserted.

53.5.6.3 Mailbox lock mechanism

Other than Mailbox inactivation, FlexCAN has another data coherence mechanism for the receive process. When the CPU reads the Control and Status word of an Rx MB with codes FULL or OVERRUN, FlexCAN assumes that the CPU wants to read the whole MB in an atomic operation, and therefore it sets an internal lock flag for that MB. The lock is released when the CPU reads the Free Running Timer (global unlock operation), or when it reads the Control and Status word of another MB regardless of its code. A CPU write into the C/S word also unlocks the MB, but this procedure is not recommended for normal unlock use because it cancels a pending-move and potentially may lose a received message. The MB locking prevents a new frame from being written into the MB while the CPU is reading it.

NOTE

The locking mechanism applies only to Rx MBs that are not part of the FIFO and have a code different than INACTIVE

(0b0000) or EMPTY[1] (0b0100). Also, Tx MBs can not be locked.

Suppose, for example, that the FIFO is disabled and the second and the fifth MBs of the array are programmed with the same ID, and FlexCAN has already received and stored messages into these two MBs. Suppose now that the CPU decides to read MB number 5 and at the same time another message with the same ID is arriving. When the CPU reads the Control and Status word of MB number 5, this MB is locked. The new message arrives and the matching algorithm finds out that there are no "free-to-receive" MBs, so it decides to override MB number 5. However, this MB is locked, so the new message can not be written there. It will remain in the Rx SMB waiting for the MB to be unlocked, and only then will be written to the MB.

If the MB is not unlocked in time and yet another new message with the same ID arrives, then the new message overwrites the one on the Rx SMB and there will be no indication of lost messages either in the CODE field of the MB or in the Error and Status Register.

While the message is being moved-in from the Rx SMB to the MB, the BUSY bit on the CODE field is asserted. If the CPU reads the Control and Status word and finds out that the BUSY bit is set, it should defer accessing the MB until the BUSY bit is negated.

Note

If the BUSY bit is asserted or if the MB is empty, then reading the Control and Status word does not lock the MB.

Inactivation takes precedence over locking. If the CPU inactivates a locked Rx MB, then its lock status is negated and the MB is marked as invalid for the current matching round. Any pending message on the Rx SMB will not be transferred anymore to the MB. An MB is unlocked when the CPU reads the Free Running Timer Register (see Section "Free Running Timer Register (CAN_TIMER)"), or the C/S word of another MB.

Lock and unlock mechanisms have the same functionality in both Normal and Freeze modes.

An unlock during Normal or Freeze mode results in the move-in of the pending message. However, the move-in is postponed if an unlock occurs during a low power mode (see Modes of operation), and it takes place only when the module resumes to Normal or Freeze modes.

1. In previous FlexCAN versions, reading the C/S word locked the MB even if it was EMPTY. This behavior is maintained when the IRMQ bit is negated.

53.5.7 Rx FIFO

The Rx FIFO is receive-only and is enabled by asserting the CAN_MCR[RFEN] bit. The reset value of this bit is zero to maintain software backward compatibility with previous versions of the module that did not have the FIFO feature.

CAUTION

Rx FIFO must not be enabled when CAN FD feature is enabled.

The FIFO is 6-message deep. The memory region occupied by the FIFO structure (both Message Buffers and FIFO engine) is described in Rx FIFO structure. The CPU can read the received messages sequentially, in the order they were received, by repeatedly reading a Message Buffer structure at the output of the FIFO.

The CAN_IFLAG1[BUF5I] (Frames available in Rx FIFO) is asserted when there is at least one frame available to be read from the FIFO. An interrupt is generated if it is enabled by the corresponding mask bit. Upon receiving the interrupt, the CPU can read the message (accessing the output of the FIFO as a Message Buffer) and the CAN_RXFIR register and then clear the interrupt. If there are more messages in the FIFO the act of clearing the interrupt updates the output of the FIFO with the next message and update the CAN_RXFIR with the attributes of that message, reissuing the interrupt to the CPU. Otherwise, the flag remains negated. The output of the FIFO is only valid whilst the CAN_IFLAG1[BUF5I] is asserted.

The CAN_IFLAG1[BUF6I] (Rx FIFO Warning) is asserted when the number of unread messages within the Rx FIFO is increased to 5 from 4 due to the reception of a new one, meaning that the Rx FIFO is almost full. The flag remains asserted until the CPU clears it.

The CAN_IFLAG1[BUF7I] (Rx FIFO Overflow) is asserted when an incoming message was lost because the Rx FIFO is full. Note that the flag will not be asserted when the Rx FIFO is full and the message was captured by a Mailbox. The flag remains asserted until the CPU clears it.

Clearing one of those three flags does not affect the state of the other two.

An interrupt is generated if an IFLAG bit is asserted and the corresponding mask bit is asserted too.

A powerful filtering scheme is provided to accept only frames intended for the target application, reducing the interrupt servicing work load. The filtering criteria is specified by programming a table of up to 128 32-bit registers, according to CAN_CTRL2[RFFN] setting, that can be configured to one of the following formats (see also Rx FIFO structure):

- Format A: 128 IDAFs (extended or standard IDs including IDE and RTR)
- Format B: 256 IDAFs (standard IDs or extended 14-bit ID slices including IDE and RTR)
- Format C: 512 IDAFs (standard or extended 8-bit ID slices)

Note

A chosen format is applied to all entries of the filter table. It is not possible to mix formats within the table.

Every frame available in the FIFO has a corresponding IDHIT (Identifier Acceptance Filter Hit Indicator) that can read in the IDHIT field from C/S word, as shown in the Rx FIFO Structure description. Another way the CPU can obtain this information is by accessing the CAN_RXFIR register. The CAN_RXFIR[IDHIT] field refers to the message at the output of the FIFO and is valid while the CAN_IFLAG1[BUF5I] flag is asserted. The CAN_RXFIR register must be read only before clearing the flag, which guarantees that the information refers to the correct frame within the FIFO.

Up to 32 elements of the filter table are individually affected by the Individual Mask Registers (CAN_RXIMRx), according to the setting of CAN_CTRL2[RFFN], allowing very powerful filtering criteria to be defined. If the CAN_MCR[IRMQ] bit is negated, then the FIFO filter table is affected by CAN_RXFGMASK.

53.5.8 CAN protocol related features

This section describes the CAN protocol related features.

53.5.8.1 CAN FD ISO compliance

The CAN FD protocol has been improved to increase the failure detection capability that was in the original CAN FD protocol, which is also called non-ISO CAN FD by CAN in Automation (CiA). A three-bit stuff counter and a parity bit have been introduced in the improved CAN FD protocol, now called ISO CAN FD. The CRC calculation has also been modified. All these improvements make the ISO CAN FD protocol incompatible with the non-FD CAN FD protocol. The non-ISO CAN FD is still supported by FlexCAN so that it can be used mainly during an intermediate phase, for evaluation and development purposes.

Therefore, it is strongly recommended to configure FlexCAN to the ISO CAN FD protocol by setting the ISOCANFDEN field in the CAN_CTRL2 register.

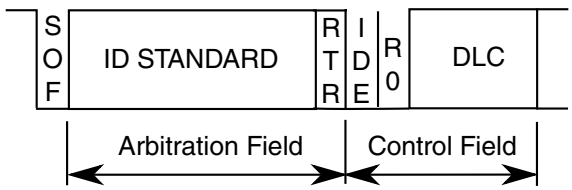
53.5.8.2 CAN FD frames

The ISO 11898-1 standard specifies the Classical Frame format compliant to ISO 11898-1 (2003) and introduces the CAN Flexible Data Rate Frame format. The Classical Frame format allows bit rates up to 1 Mbit/s and payloads up to 8 bytes per frame. The Flexible Data Rate Frame format allows bit rates higher than 1 Mbit/s and payloads longer than 8 bytes per frame. FlexCAN can receive and transmit CAN FD messages interleaved with Classical CAN messages.

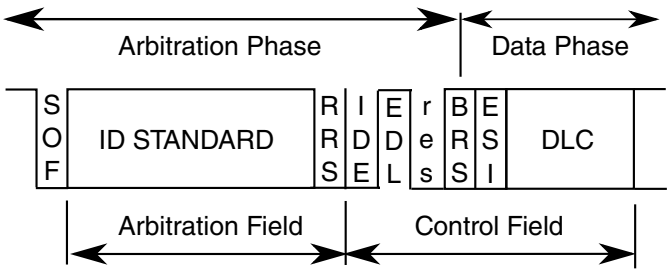
There are three additional control bits in the CAN FD frame. The Extended Data Length (EDL) bit enables a longer data payload with different data length coding. The Bit Rate Switch (BRS) bit decides whether the bit rate is switched inside a CAN FD format frame. The Error State Indicator (ESI) flag is transmitted dominant by error active nodes, and recessive by error passive nodes. There is no Remote Frames (see Remote frames) in the CAN FD format. A message configured to transmit a Remote Frame is always sent out in the Classical CAN format. When a FD frame is received and matches a mailbox, the RTR bit in the receiving message buffer is negated. The RTR bit must be considered in classical frames only.

CAN FD messages may be formatted as long frames where the data field exceeds 8 bytes, and may range from 12 up to 64 bytes. They can also be configured to support bit rate switching, where the control field, the data field, and the CRC field of a CAN frame are transmitted with a higher bit rate than the beginning and the end of the frame. Messages in Classical CAN format are limited to transport a maximum payload of 8 bytes at nominal rate. The following figure illustrates the message formats for Classical and FD frames with either standard or extended ID.

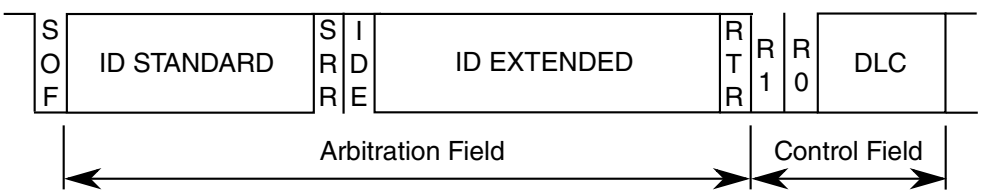
CAN Standard Format



CAN FD Standard Format



CAN Extended Format



CAN FD Extended Format

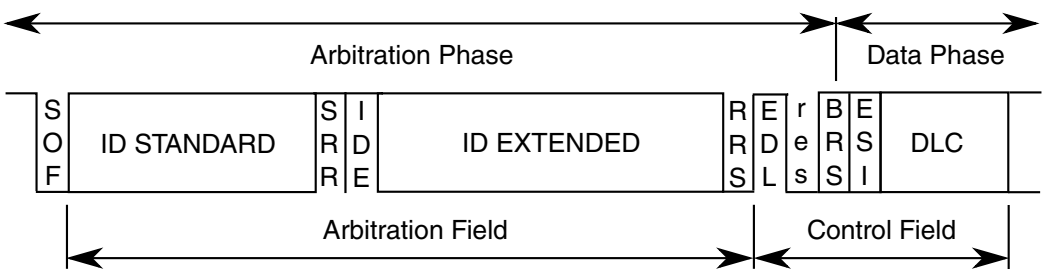


Figure 53-2. CAN message formats

The ability to receive and transmit CAN FD messages is enabled by the CAN_MCR[FDEN] bit. Either a recessive R0 bit in CAN frames with 11-bit identifiers or a recessive R1 bit in CAN frames with 29-bit identifiers are decoded as an EDL bit (not a reserved one). A CAN FD frame is recognized by a recessive EDL bit, while a

Classical CAN frame is recognized by a dominant EDL bit. The BRS bit specifies whether this frame switches the bit rate in its data phase. A long frame is decoded in accordance to the DLC field value (see DLC definition in Message buffer structure).

CAN FD messages can be transmitted with two different bit rates. The first part of a CAN FD frame, from the Start Of Frame (SOF) bit until the Bit Rate Switch (BRS) bit, also called the arbitration phase, is transmitted with the nominal bit rate based on a set of nominal CAN bit timing configuration values. The second part, from the BRS bit until the CRC Delimiter bit, also named the data phase, is transmitted with the data bit rate defined by a second set of CAN data bit timing configuration values. Finally, from the CRC Delimiter until the Intermission bits, the transmission resumes to nominal bit rate. In CAN FD frames with bit rate switching, the bit timing is changed inside the frame at the sample point of the BRS bit if this bit is recessive. Before the BRS bit, in the CAN FD arbitration phase, the nominal CAN bit timing is used as defined by the CAN_CBT register (also by CAN_CTRL1 register for backward compatibility). Upon detecting a recessive BRS bit, the CAN data bit timing is used as defined by the CAN_FDCBT register.

NOTE

If the length of the time quantum in the nominal bit timing and the length of the time quantum in the data bit timing are not identical, a quantization error of up to one time quantum of the arbitration phase may be present as a phase error. This situation can occur after the switch from arbitration to data phase and will last until the next synchronization event. Thus, the length of the time quantum should be the same in nominal and data bit timing in order to minimize the chance of error frames on the CAN bus, and to optimize the clock tolerance in networks that use FD frames.

CAN_FDCTRL[FDRATE] enables the transmission of all frames with bit rate switching if the BRS bit in the selected Tx MB is set. If FDRATE is negated, the transmission is performed at nominal rate regardless of the BRS bit value. The CAN_FDCTRL[FDRATE] bit can be written any time but takes effect only for the next message transmitted or received.

The nominal bit timing is resumed at either the sample point of the CRC Delimiter bit or when an error is detected, whichever occurs first. The following figure describes the mechanism for entering and leaving the data phase when BRS bit is recessive.

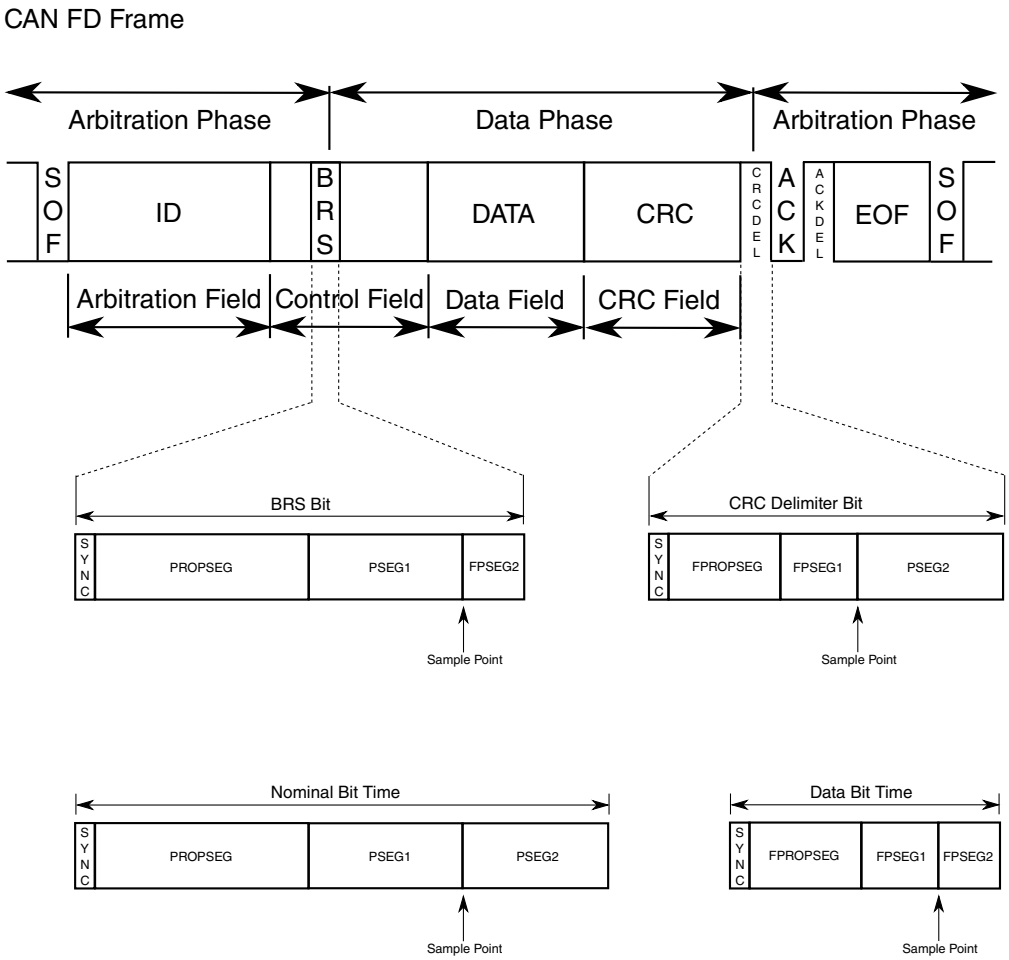

Figure 53-3. Bit rate switching mechanism for CAN FD messages

NOTE

In Classical CAN frames, the CRC delimiter is one single recessive bit. In CAN FD frames, the CRC delimiter may consist of one or two recessive bits. FlexCAN sends only one recessive bit as the CRC delimiter, but it accepts two recessive bits before the edge from recessive to dominant that starts the acknowledge slot. As a receiver, FlexCAN sends its acknowledge bit after the first CRC delimiter bit. In CAN FD frames, FlexCAN accepts a two-bit dominant ACK slot as a valid ACK to compensate for phase shifts between the receivers.

The maximum configurable bit rate in the CAN FD data phase depends on the clock frequency of CAN_PE sub-block. For example, with a CAN_PE clock frequency of 40MHz and the shortest configurable bit time of 8 time quanta, the bit rate in the data phase is 5 Mbit/s.

The value of the ESI bit is determined either by the transmitter's error state at the start of the transmission, if the frame is originated in the FlexCAN node, or by the original transmitting node in case FlexCAN is acting as a gateway for the message. If the transmitter is error passive, ESI is transmitted recessive; otherwise, it is transmitted dominant.

There are different CRC polynomials for different CAN frame formats. The first polynomial, CRC_15, is used for all frames in Classical CAN format. The second, CRC_17, is used for frames in CAN FD format with a data field up to sixteen bytes long. The third, CRC_21, is used for frames in CAN FD format with a data field longer than sixteen bytes. Each polynomial results in a Hamming Distance of 6. At the start of the frame, all three CRC polynomials are calculated concurrently. The CRC sequence to be transmitted is selected by the values of the EDL bit and the DLC bit field. When receiving a message, FlexCAN decodes EDL and DLC to select the adequate CRC polynomial to check for a CRC error.

In CAN FD format frames, stuff bits are included in the bit stream for CRC calculation. In Classical CAN format frames, stuff bits are not included. After the transmission of the last bit relevant to the CRC calculation, the CAN_FDCRC register stores the calculated CRC for the transmitted message, with the adequate length in accordance to the type of message, for both CAN FD and non-FD messages. The CAN_CRCR register reports a valid CRC for Classical CAN messages only.

In CAN FD format frames, the CAN bit stuffing method is changed for the CRC sequence so that the stuff bits are inserted at fixed positions. When FlexCAN is transmitting a CAN FD frame, a fixed stuff bit is inserted just before the first bit of the CRC sequence, even if the last bits of the preceding field do not fulfill the CAN stuff condition. Additional stuff bits are inserted after each fourth bit of the CRC sequence. The value of any fixed stuff bit is the inverse value of its preceding bit. When FlexCAN is receiving a CAN FD frame, it discards the fixed stuff bits from the bit stream for the CRC check. A Stuff Error is detected if the fixed stuff bit has the same value as its preceding bit.

FlexCAN detects errors in CAN FD frames the same way as in Classical CAN frames. The error counters RXERRCNT and TXERRCNT in the CAN_ECR register accumulate the counts of Rx and Tx errors, respectively, for both FD and non-FD frames indistinctly. There are two extra error counters (RXERRCNT_FAST and TXERRCNT_FAST) that accumulate Rx and Tx errors occurring in the data phase of CAN FD frames with the BRS bit set only. The rules for updating the error counters are the same for both CAN FD and non-FD frames (see CAN_ECR register).

Error Flags BITERR1, BITERR0, ACKERR, CRCERR, FRMERR and STFERR in the ESR1 register report errors in both CAN FD and non-FD frames. They also generate the ERRINT interrupt if CAN_CTRL1[ERRMSK] is asserted. The CAN_ESR1 register has

additional error flags (BITERR1_FAST, BITERR0_FAST, CRCERR_FAST, FRMERR_FAST and STFERR_FAST) to individually indicate the occurrence of errors in the data phase of CAN FD frames with the BRS bit set. There is no ACKERR detected in the data phase of a CAN FD frame. Fault confinement status reported in CAN_ESR1[FLTCONF] is the same for both CAN FD and Classical CAN frames, and is based on RXERRCNT and TXERRCNT error counters only. Information contained in RXERRCNT_FAST and TXERRCNT_FAST counters may be considered as status to help detect the error nature related to the bit rate value.

When FlexCAN is in the data phase, either transmitting or receiving a CAN FD message, and detects an error, it immediately switches back to the arbitration phase and to the nominal rate to start an Error Flag.

Resynchronization and Hard Synchronization occur in CAN FD frames in the same way as in Classical CAN ones. Additionally, a Hard Synchronization is also performed at the recessive to dominant edge from EDL to R0 in CAN FD format frames. FlexCAN does not resynchronize while transmitting in the CAN FD data phase.

53.5.8.3 Transceiver Delay Compensation

The CAN FD protocol allows the transmission and reception of data at a higher bit rate than the nominal rate used in the arbitration phase when the message's BRS bit is set. This feature enables the use of rates up to 8 Mbps.

During the data phase of a CAN FD frame, the Transmitter detects a bit error if it cannot receive its own latest transmitted bit at the sample point of that bit. When bit rate switching is enabled (BRS bit is asserted), the length of the CAN bit time in the data phase can become shorter than the transceiver's loop delay, thus impeding the correct comparison between the transmitted bit and the received bit within the current CAN bit time interval.

FlexCAN supports an optional Transceiver Delay Compensation (TDC) mechanism that defines a secondary sample point where the transmitted bit is correctly compared with the received bit in order to check for bit errors.

The TDC mechanism can be enabled by the CAN_FDCTRL[TDCEN] bit and is effective only during the data phase of FD frames having the BRS bit set. It has no effect either on non-FD frames, or on FD frames transmitted at normal bit rate. The TDC is active from the sample point of the BRS bit until the sample point of the CRC Delimiter bit, provided the respective message under transmission has the BRS bit set. When it is active, a comparison is done between the real received bit and the delayed transmitted bit, where the delay is calculated based on the measured transceiver loop delay.

NOTE

The actual value of the CRC Delimiter bit is disregarded by transmitters using the Transceiver Delay Compensation mechanism. A global error at the end of the CRC Field will cause the receivers to send error frames that the transmitter will detect during Acknowledge or End of Frame.

For every transmitted FD frame having the BRS bit set, the delay measurement is triggered by the transition from the recessive EDL bit to the dominant R0 bit (as shown in the next figure). The loop delay is measured in Protocol Engine (PE) clock periods (CANCLK, see Protocol timing), from the transmitted EDL-R0 edge to the received EDL-R0 edge. The position of the secondary sample point is defined by the measured loop delay time added to an offset value specified in CAN_FDCTRL[TDCOFF]. CAN_FDCTRL[TDCVAL] bit field stores the result of this calculation. The TDCVAL value saturates at its maximum value of 15 CANCLK when the delay measurement is too long.

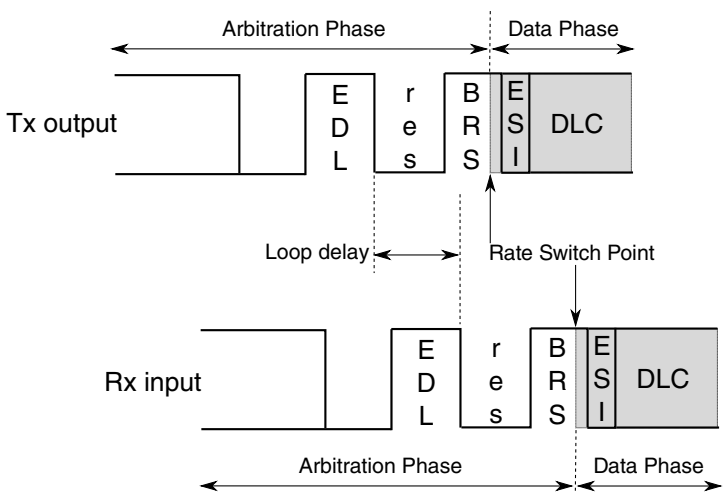

Figure 53-4. Transceiver loop delay measurement

The measured loop delay is not enough to be used to define the secondary sample point because it relates to the CAN bit edges. The transceiver delay compensation offset TDCOFF is used to shift the secondary sample point from the edge to an intermediate point inside the bit time (e.g. half of the bit time in the data phase), far away from its edges. Therefore, the TDCOFF value cannot be larger than the CAN bit duration in the data phase.

During the data phase of CAN FD frames with bit rate switching enabled, at the onset of every Tx CAN bit, the transmitted Tx bit value is temporarily stored in a buffer and a time countdown based on TDCVAL is started which ends with the comparison of the

received Rx bit (delayed by the external loop delay plus the specified offset) with the stored Tx bit. If a bit error is detected at the secondary sample point, the FlexCAN issues an error flag to the CAN bus at the next sample point.

During the arbitration phase the delay compensation is always disabled. The maximum delay which can be compensated by the FlexCAN's transceiver delay compensation during the data phase is 3 CAN bit times - 2 Tq. Beyond this limit, the CAN_FDCTRL[TDCFAIL] flag is set to indicate when the Transceiver Delay Compensation mechanism is out of range, unable to compensate the transceiver loop delay.

53.5.8.4 Remote frames

Remote frame is a special kind of frame. The user can program a mailbox to be a Remote Request Frame by configuring the mailbox as Transmit with the RTR bit set to '1'. After the remote request frame is transmitted successfully, the mailbox becomes a Receive Message Buffer, with the same ID as before.

When a remote request frame is received by FlexCAN, it can be treated in three ways, depending on Remote Request Storing (CTRL2[RRS]) and Rx FIFO Enable (MCR[RFEN]) bits:

- If RRS is negated the frame's ID is compared to the IDs of the Transmit Message Buffers with the CODE field 0b1010. If there is a matching ID, then this mailbox frame will be transmitted. Note that if the matching mailbox has the RTR bit set, then FlexCAN will transmit a remote frame as a response. The received remote request frame is not stored in a receive buffer. It is only used to trigger a transmission of a frame in response. The mask registers are not used in remote frame matching, and all ID bits (except RTR) of the incoming received frame should match. In the case that a remote request frame is received and matches a mailbox, this message buffer immediately enters the internal arbitration process, but is considered as a normal Tx mailbox, with no higher priority. The data length of this frame is independent of the DLC field in the remote frame that initiated its transmission.
- If RRS is asserted the frame's ID is compared to the IDs of the receive mailboxes with the CODE field 0b0100, 0b0010 or 0b0110. If there is a matching ID, then this mailbox will store the remote frame in the same fashion of a data frame. No automatic remote response frame will be generated. The mask registers are used in the matching process.
- If RFEN is asserted FlexCAN will not generate an automatic response for remote request frames that match the FIFO filtering criteria. If the remote frame matches one of the target IDs, it will be stored in the FIFO and presented to the CPU. Note that for

filtering formats A and B, it is possible to select whether remote frames are accepted or not. For format C, remote frames are always accepted (if they match the ID). Remote Request Frames are considered as normal frames, and generate a FIFO overflow when a successful reception occurs and the FIFO is already full.

NOTE

There is no remote frame in the CAN FD format. The RTR bit is replaced by a fixed dominant RRS bit. FlexCAN receives and transmits remote frames in the Classical CAN format.

53.5.8.5 Overload frames

FlexCAN does transmit overload frames due to detection of following conditions on CAN bus:

- Detection of a dominant bit in the first/second bit of Intermission
- Detection of a dominant bit at the 7th bit (last) of End of Frame field (Rx frames)
- Detection of a dominant bit at the 8th bit (last) of Error Frame Delimiter or Overload Frame Delimiter

53.5.8.6 Time stamp

The value of the Free Running Timer is sampled at the beginning of the Identifier field on the CAN bus, and is stored at the end of "move-in" in the TIME STAMP field, providing network behavior with respect to time.

The Free Running Timer is clocked by the FlexCAN bit-clock, which defines the baud rate on the CAN bus. During a message transmission/reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate.

The Free Running Timer is not incremented during Disable, Stop, and Freeze modes. It can be reset upon a specific frame reception, enabling network time synchronization. See the TSYN description in Control 1 Register (CAN_CTRL1).

53.5.8.7 Protocol timing

The following figure shows the structure of the clock generation circuitry that feeds the CAN Protocol Engine (PE) submodule. The clock source bit CLKSRC in the CAN_CTRL1 Register defines whether the internal clock is connected to the output of a crystal oscillator (Oscillator Clock) or to the Peripheral Clock. In order to guarantee reliable operation, the clock source should be selected while the module is in Disable Mode (MDIS bit set in the Module Configuration Register).

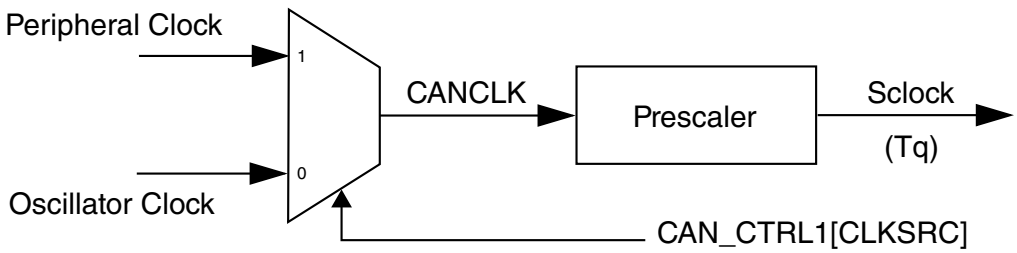

Figure 53-5. CAN engine clocking scheme

The oscillator clock should be selected whenever a tight tolerance (up to 0.1%) is required in the CAN bus timing. The crystal oscillator clock has better jitter performance than the peripheral clock.

The FlexCAN module supports a variety of means to setup bit timing parameters that are required by the CAN protocol. The Control 1 Register (CAN_CTRL1) has various fields used to control bit timing parameters: PRESDIV, PROPSEG, PSEG1, PSEG2 and RJW.

The CAN Bit Timing register (CAN_CBT) extends the range of the CAN bit timing variables in CAN_CTRL1. The CAN FD Bit Timing register (CAN_FDCBT) provides a second set of CAN bit timing variables to be applied at the data phase of CAN FD frames with the Bit Rate Switch (BRS) set.

NOTE

When the CAN FD feature is enabled, always set CAN_CBT[BTF] and configure the CAN bit timing variables in CAN_CBT. See CAN Bit Timing Register (CAN_CBT).

The PRESDIV field (as well as its extended range EPRESDIV and FDPRESDIV for the data phase bits of CAN FD messages) defines the Prescaler Value (see the equation below) that generates the Serial Clock (Sclock), whose period defines the 'time quantum' used to compose the CAN waveform. A time quantum (Tq) is the atomic unit of time handled by the CAN engine.

$$Tq = \frac{(\text{PRESDIV} + 1)}{f_{CANCLK}}$$

The bit rate, which defines the rate the CAN message is either received or transmitted, is given by the formula:

CAN Bit Time = (Number of Time Quanta in 1 bit time) * Tq

$$\text{Bit Rate} = \frac{1}{\text{CAN Bit Time}}$$

A bit time is subdivided into three segments[1] (see Figure 53-6, Figure 53-7 and Table 53-24):

- SYNC_SEG: This segment has a fixed length of one time quantum. Signal edges are expected to happen within this section
- Time Segment 1: This segment includes the Propagation Segment and the Phase Segment 1 of the CAN standard. It can be programmed by setting the PROPSEG and the PSEG1 fields of the CAN_CTRL1 Register so that their sum (plus 2) is in the range of 2 to 16 time quanta. When CAN_CBT[BTF] bit is asserted, FlexCAN uses EPROPSEG and EPSEG1 fields from CAN_CBT register so that their sum (plus 2) is in the range of 2 to 96 time quanta. For messages in CAN FD format with the BRS bit set, FlexCAN uses FDPROPSEG and FDPSEG1 from CAN_FDCBT instead, so that their sum (plus 1) is in the range of 2 to 39 time quanta.
- Time Segment 2: This segment represents the Phase Segment 2 of the CAN standard. It can be programmed by setting the PSEG2 field of the CAN_CTRL1 Register (plus 1) to be 2 to 8 time quanta long. When CAN_CBT[BTF] bit is asserted, FlexCAN uses EPSEG2 fields of CAN_CBT register so that its value (plus 1) is in the range of 2 to 32 time quanta. For messages in CAN FD format with the BRS bit set, FlexCAN uses FDPSEG2 from CAN_FDCBT instead, so that its value (plus 1) is in the range of 2 to 8 time quanta. The Time Segment 2 cannot be smaller than the Information Processing Time (IPT), which value is 2 time quanta in FlexCAN.

NOTE

The bit time defined by the above time segments must not be smaller than 5 time quanta. For bit time calculations, use an

1. For further explanation of the underlying concepts, see ISO 11898-1. See also the CAN 2.0A/B protocol specification for bit timing.

Information Processing Time (IPT) of 2, which is the value implemented in the FlexCAN module.

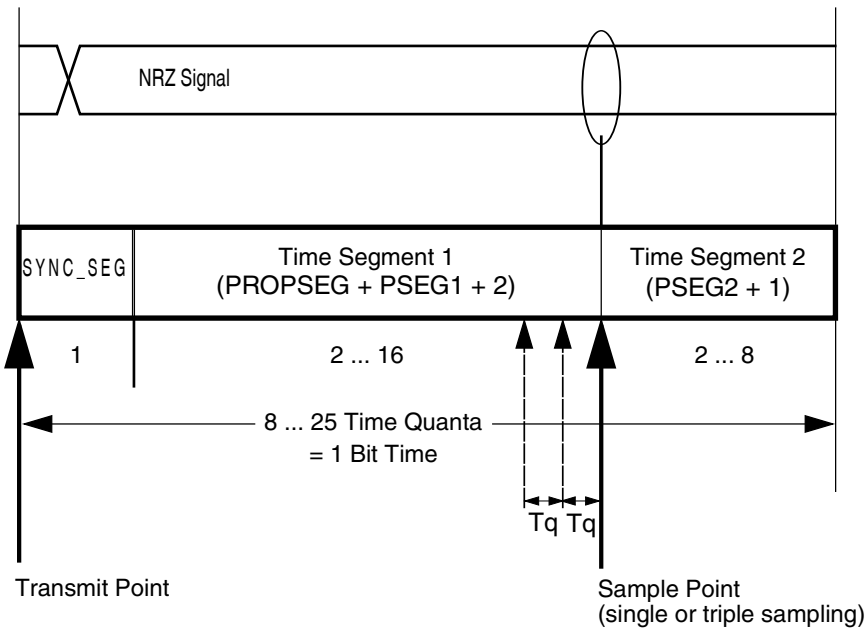

Figure 53-6. Segments within the bit time (example using CAN_CTRL1 bit timing variables for Classical CAN format)

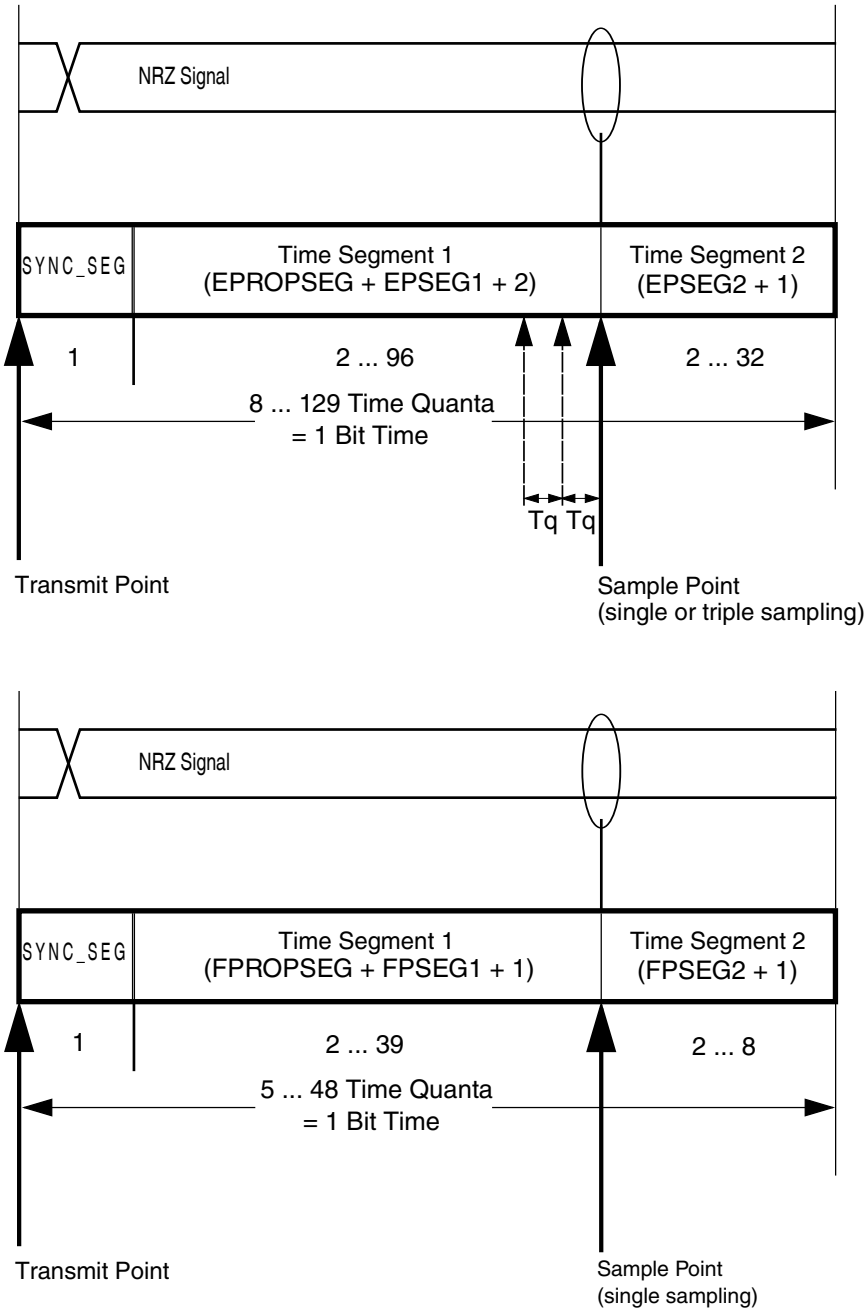

Figure 53-7. Segments within the bit time (example using CAN_CBT and CAN_FDCBT bit timing variables for CAN FD format)

Table 53-24. Time segment syntax

Syntax	Description
SYNC_SEG	System expects transitions to occur on the bus during this period.
TSEG1	Corresponds to the sum of PROPSEG and PSEG1.
TSEG2	Corresponds to the PSEG2 value.

Table continues on the next page...

Table 53-24. Time segment syntax (continued)

Syntax	Description
Transmit Point	A node in transmit mode transfers a new value to the CAN bus at this point.
Sample Point	A node samples the bus at this point. If the three samples per bit option is selected, then this point marks the position of the third sample.

The following table gives some examples of the CAN compliant segment settings for Classical CAN format (Bosch CAN 2.0B) (non-FD) messages.

Table 53-25. Bosch CAN 2.0B standard compliant bit time segment settings

Time segment 1	Time segment 2	Re-synchronization jump width
5 .. 10	2	1 .. 2
4 .. 11	3	1 .. 3
5 .. 12	4	1 .. 4
6 .. 13	5	1 .. 4
7 .. 14	6	1 .. 4
8 .. 15	7	1 .. 4
9 .. 16	8	1 .. 4

Note

The user must ensure the bit time settings are in compliance with the CAN Protocol standard (ISO 11898-1).

Whenever CAN bit is used as a measure of time duration (e.g. estimating the occurrence of a CAN bit event in a message), the number of peripheral clocks in one CAN bit (NumClkBit) can be calculated as:

$$\text{NumClkBit} = \frac{f_{SYS}}{f_{CANCLK}} \text{ X } (\text{PRESDIV} + 1) \text{ X } (\text{PROPSEG} + \text{PSEG1} + \text{PSEG2} + 4)$$

where:

- NumClkBit is the number of peripheral clocks in one CAN bit;
- f_{CANCLK} is the Protocol Engine (PE) Clock (see Figure "CAN Engine Clocking Scheme"), in Hz;
- f_{SYS} is the frequency of operation of the system (CHI) clock, in Hz;
- PSEG1 is the value in CAN_CTRL1[PSEG1] field;
- PSEG2 is the value in CAN_CTRL1[PSEG2] field;
- PROPSEG is the value in CAN_CTRL1[PROPSEG] field;
- PRESDIV is the value in CAN_CTRL1[PRESDIV] field.

The formula above is also applicable to the alternative CAN bit timing variables described in the CAN Bit Timing Register (CAN_CBT) and also to the CAN FD Bit Timing Register (CAN_FDCBT).

For example, 180 CAN bits = (180 x NumClkBit) peripheral clock periods.

53.5.8.8 Arbitration and matching timing

During normal reception and transmission, the matching, arbitration, move-in and move-out processes are executed during certain time windows inside the CAN frame, as shown in the following figures.

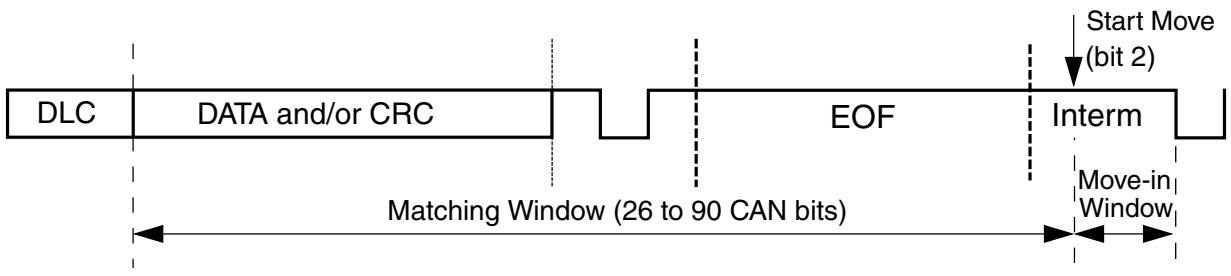

Figure 53-8. Matching and move-in time windows

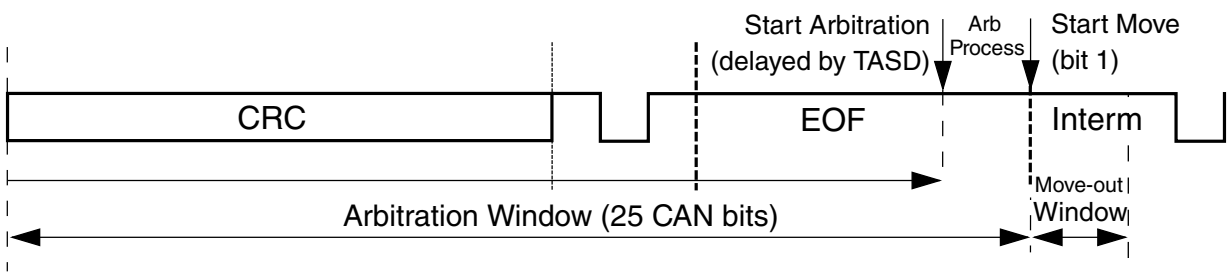

Figure 53-9. Arbitration and move-out time windows

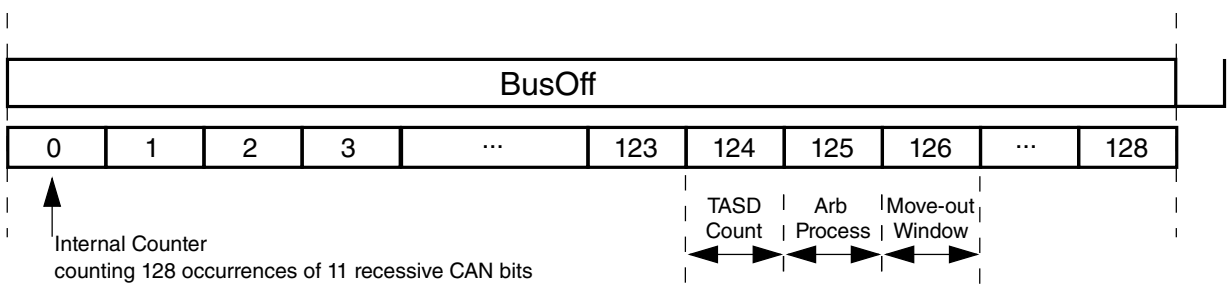

Figure 53-10. Arbitration at the end of bus off and move-out time windows

NOTE

In the preceding figures, the matching and arbitration timing does not take into account the delay caused by the concurrent

memory access due to the CPU or other internal FlexCAN sub-blocks.

53.5.8.9 Tx Arbitration start delay

The Tx Arbitration Start Delay (TASD) bit field in Control 2 register (CAN_CTRL2[TASD]) is a variable that indicates the number of CAN bits used by FlexCAN to delay the Tx Arbitration process start point from the first bit of CRC field of the current frame. This variable can be written only in Freeze mode because it is blocked by hardware in other modes.

The transmission performance is impacted by the ability of the CPU to reconfigure Message Buffers (MBs) for transmission after the end of the internal Arbitration process, where FlexCAN finds the winner MB for transmission (see Arbitration process). If the Arbitration ends too early before the first bit of Intermission field, then there is a chance that the CPU reconfigures some Tx MBs and the winner MB is no longer the best candidate to be transmitted.

TASD is useful to optimize the transmission performance by defining the Arbitration start point, as shown in the next figure, based on factors such as:

- The peripheral-to-oscillator clock ratio
- CAN bit timing variables that determine the CAN bit rate
- The number of Message Buffers (MBs) in use by the Matching and Arbitration processes.

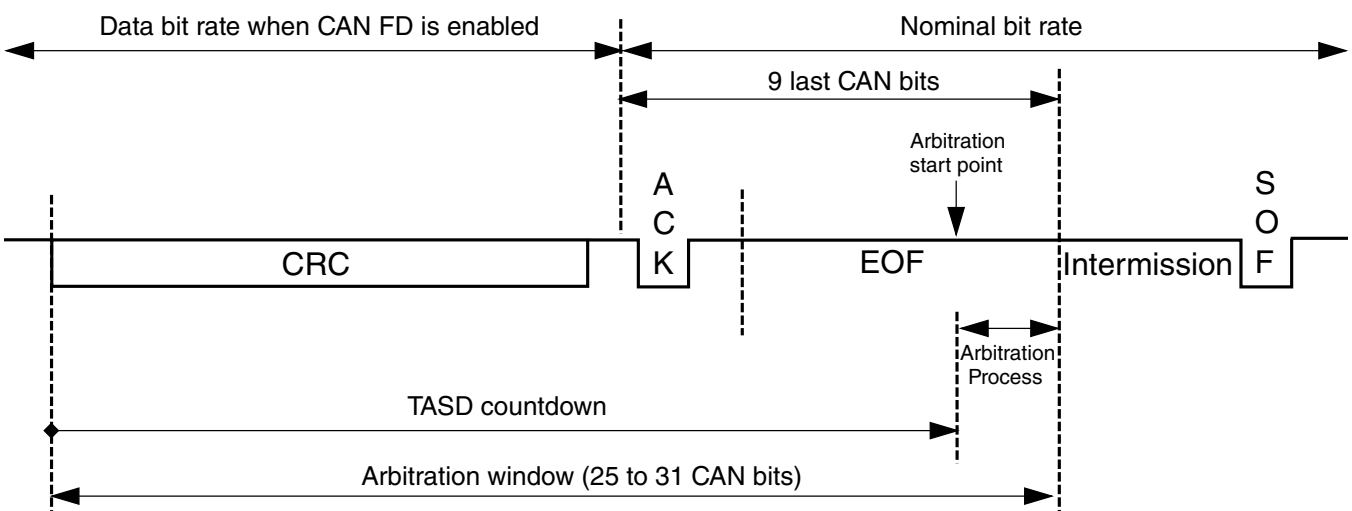

Figure 53-11. Optimal Tx Arbitration start point

The duration of an Arbitration process, in terms of CAN bits, is directly proportional to the number of available MBs and to the CAN bit rate, and inversely proportional to the peripheral clock frequency.

The optimal Arbitration timing is that in which the last MB is scanned right before the first bit of the Intermission field of a CAN frame. For instance, if there are few MBs and the peripheral/oscillator clock ratio is high and the CAN baud rate is low, then the Arbitration can be placed closer to the frame's end, adding more delay to its start point, and vice-versa.

If TASD is set to 0 then the Arbitration start is not delayed and more time is reserved for Arbitration. On the other hand, if TASD is close to 24 then the CPU can configure a Tx MB later and less time is reserved for Arbitration. If too little time is reserved for Arbitration the FlexCAN may be not be able to find a winner MB in time to be transmitted with the best chance to win the bus arbitration against external nodes on the CAN bus.

The optimal TASD value can be calculated as follows:

For CAN FD frames and $(MAXMB + 1) \leqslant NMB_{END}$

$$TASD = 31 - \frac{2 * (MAXMB + 1) + 4}{CPCB_N}$$

For CAN FD frames and $(MAXMB + 1) > NMB_{END}$

$$TASD = 22 - \frac{2 * (MAXMB + 1) - NMB_{END}}{CPCB_F}$$

For non-FD frames

$$TASD = 25 - \frac{2 * (MAXMB + 1) + 4}{CPCB}$$

where:

$$NMB_{END} = \frac{(9 * CPCB_N) - 4}{2}$$

$$BITRATE_N = \left(\frac{f_{CANCLK}}{[1 + (EPSEG1 + 1) + (EPSEG2 + 1) + (EPROPSEG + 1)] \times (EPRESDIV + 1)} \right)$$

$$BITRATE_F = \left(\frac{f_{CANCLK}}{[1 + (FPSEG1 + 1) + (FPSEG2 + 1) + FPROPSEG] \times (FPRESDIV + 1)} \right)$$

$$CPCB_N = \frac{f_{SYS}}{BITRATE_N}$$

$$CPCB_F = \frac{f_{SYS}}{BITRATE_F}$$

$$CPCB = CPCB_N$$

- MAXMB is the value in CAN_CTRL1[MAXMB] field
- NMB_{END} is the number of Message Buffers that can be scanned by the Arbitration process during the 9 last CAN bits at the end of a frame, see the figure above
- $BITRATE_N$ is the CAN bit rate in bits per second calculated by the nominal CAN bit time variables
- $BITRATE_F$ is the CAN bit rate in bits per second calculated by the data CAN bit time variables
- $CPCB_N$ is the number of peripheral clocks per CAN bit in nominal bit rate for CAN FD frames
- $CPCB_F$ is the number of peripheral clocks per CAN bit in data bit rate for CAN FD frames
- CPCB is the number of peripheral clocks per CAN bit for non-FD frames
- f_{CANCLK} is the oscillator clock, in Hz
- f_{SYS} is the peripheral clock, in Hz
- EPSEG1 is the value in CAN_CBT[EPSEG1] field (CAN_CTRL1[PSEG1] can also be used)
- EPSEG2 is the value in CAN_CBT[EPSEG2] field (CAN_CTRL1[PSEG2] can also be used)
- EPROPSEG is the value in CAN_CBT[EPROPSEG] field (CAN_CTRL1[PROPSEG] can also be used)

- EPRESDIV is the value in CAN_CBT[EPRESDIV] field (CAN_CTRL1[PRESDIV] can also be used)
- FPSEG1 is the value in CAN_FDCBT[FPSEG1] field
- FPSEG2 is the value in CAN_FDCBT[FPSEG2] field
- FPROPSEG is the value in CAN_FDCBT[FPROPSEG] field
- FPRESDIV is the value in CAN_FDCBT[FPRESDIV] field

See also Protocol timing for more details.

The following tables give the TASD value calculated for some configuration cases.

Case 1:

- Clock ratio = 2:1 (example: peripheral clock 80 MHz and oscillator clock 40 MHz)
- Bit rate in arbitration phase = 1 Mbaud

Table 53-26. TASD values:

Number of Message Buffers	TASD value	Maximum Bit Rate in Data Phase (Mbaud)
16	24	Invalid
32	24	8.0
64	23	8.0
96	22	8.0

Case 2:

- Clock ratio = 1:1 (example: peripheral clock 40 MHz and oscillator clock 40 MHz)
- Bit rate in arbitration phase = 1 Mbaud

Table 53-27. TASD values:

Number of Message Buffers	TASD value	Maximum Bit Rate in Data Phase (Mbaud)
16	24	Invalid
32	23	6.67
54	22	5.0
64	21	3.33
96	20	1.6

Case 3:

- Clock ratio = 2:1 (example: peripheral clock 40 MHz and oscillator clock 20 MHz)
- Bit rate in arbitration phase = 1 Mbaud

Table 53-28. TASD values:

Number of Message Buffers	TASD value	Maximum Bit Rate in Data Phase (Mbaud)
16	24	Invalid
32	23	4.0
54	22	4.0
64	21	3.33
96	20	1.54

53.5.9 Clock domains and restrictions

The FlexCAN module has two clock domains asynchronous to each other:

- The Bus Domain feeds the Control Host Interface (CHI) submodule and is derived from the peripheral clock.
- The Oscillator Domain feeds the CAN Protocol Engine (PE) submodule and is derived directly from a crystal oscillator clock, so that very low jitter performance can be achieved on the CAN bus.

When the two domains are connected to clocks with different frequencies and/or phases, there are restrictions on the frequency relationship between the two clock domains. In the case of asynchronous operation, the Bus Domain clock frequency must always be greater than the Oscillator Domain clock frequency.

NOTE

Asynchronous operation with a 1:1 ratio between peripheral and oscillator clocks is not allowed.

When doing matching and arbitration, FlexCAN needs to scan the whole Message Buffer memory during the time slot of one CAN frame, comprised of a number of CAN bits. In order to have sufficient time to do that, the following requirements must be observed:

- The peripheral clock frequency can not be smaller than the oscillator clock frequency
- There must be a minimum number of peripheral clocks per CAN bit, as specified in the table shown below

Table 53-29. Minimum number of peripheral clocks per CAN bit for Classical CAN format

Number of Mailboxes	Value of CAN_MCR[RFEN] bit	Minimum number of peripheral clocks per CAN bit
16	0	16

Table continues on the next page...

Table 53-29. Minimum number of peripheral clocks per CAN bit for Classical CAN format (continued)

Number of Mailboxes	Value of CAN_MCR[RFEN] bit	Minimum number of peripheral clocks per CAN bit
32	0	16
64	0	25
96	0	37
16	1	16
32	1	17
64	1	30
96	1	42

For classical frame format, the minimum number of peripheral clocks per CAN bit specified in the preceding table determines the minimum peripheral clock frequency for a given number of Mailboxes and for an expected CAN bit rate. The CAN bit rate depends on the number of time quanta in a CAN bit, that can be defined by adjusting one or more of the bit timing values contained in either the Control 1 Register (CAN_CTRL1) or CAN Bit Time register (CAN_CBT). The time quantum (Tq) is defined in Protocol timing. The minimum number of time quanta per CAN bit must be 8; therefore, the oscillator clock frequency should be at least 8 times the CAN bit rate.

For CAN FD frame format, there are some constraints that need to be satisfied. The number of peripheral clocks per CAN bit in nominal bit rate (NumClkNomBit) can be calculated by the equation below.

$$\text{NumClkNomBit} = \frac{f_{SYS}}{f_{CANCLK}} \text{ X } (\text{PRESDIV} + 1) \text{ X } (\text{PROPSEG} + \text{PSEG1} + \text{PSEG2} + 4)$$

$$= \frac{f_{SYS}}{\text{NomBitRate}}$$

where PRESDIV, PSEG1 and PSEG2 are CAN bit time values in CTRL1 register. Alternatively, EPRESDIV, EPSEG1 and EPSEG2 values in CBT register can be used instead. NumClkNomBit can also be calculated as a function of the expected nominal bit rate used in the Arbitration Phase (NomBitRate) as shown in the equation above.

The number of CAN bits in the Data Phase of a FD Frames with the BRS bit set (fast CAN bits, in short) depends on the number of data bytes in the payload. The number of fast CAN bits (NumOfFastBits) can be determined in the table below. The less the

number of data bytes, the less the number of fast CAN bits, and less time is available for FlexCAN to scan the whole Message Buffer memory during the internal matching and arbitration processes.

Table 53-30. Number of fast CAN bits in a CAN FD frame

Minimum number of data bytes	DLC field	NumOfFastBits
0	0x0	21
1	0x1	29
2	0x2	37
3	0x3	45
4	0x4	53
5	0x5	61
6	0x6	69
7	0x7	77
8	0x8	85
12	0x9	117
16	0xA	149
20	0xB	186
24	0xC	218
32	0xD	282
48	0xE	410
64	0xF	538

The critical part of a CAN FD frame is during the Data Phase, where the CAN bit rate is faster than in the Arbitration Phase. The minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) can be calculated to guarantee that enough time is available for FlexCAN to scan the Message Buffer memory during reception and transmission. The equation below calculates this constraint.

$$MinNumClkFastBit_A = \frac{(8.5 \times MaxNumOfMb) + 64 - (9 \times NumClkNomBit)}{NumOfFastBits}$$

where MaxNumOfMb is the maximum number of available Mailboxes defined in CAN_MCR[MAXMB].

The clock domain crossing circuit between the CHI and PE sub-blocks also imposes a minimum number of peripheral clocks per fast CAN bit for the handshake mechanism to work properly without loosing status information through the interface, as shown in the equation below.

$$MinNumClkFastBit_B = 3 \times \left\langle 1 + \frac{f_{SYS}}{f_{CANCLK}} \right\rangle$$

Therefore, the minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) is determined by the larger of the two values calculated above.

$$MinNumClkFastBit = Maximum\ (\ MinNumClkFastBit_A, MinNumClkFastBit_B)$$

Then, the maximum CAN bit rate in the Data Phase of CAN FD frames (DataBitRateMAX) can be calculated as below.

$$DataBitRate_{MAX} = \frac{f_{CANCLK}}{ROUNDUP\left\langle \frac{MinNumClkFastBit \times f_{CANCLK}}{f_{SYS}} \right\rangle}$$

The peripheral and oscillator clock frequencies, the maximum number of mailboxes and the expected nominal bit rate affect the maximum data bit rate attainable by FlexCAN in CAN FD mode. Besides, the data bit rate depends on the minimum payload size of FD frames used in a given application.

To illustrate how the CAN FD bit rate is affected by the configuration of FlexCAN variables, an application example with the peripheral and oscillator clock frequencies set to 50 MHz and 40 MHz, respectively, is considered.

Step 1 - Considering the nominal bit rate as 1 Mbps, the number of peripheral clocks per CAN bit in nominal bit rate is calculated as below.

$$NumClkNomBit = \frac{50 \times 10^6}{1 \times 10^6} = 50$$

Step 2 - The number of fast CAN bits (NumOfFastBits) is determined in the table presented above. For example, if the minimum payload in FD frames is 8 bytes, then there are 85 CAN bits in the Data Phase.

Step 3 - Assuming the maximum number of mailboxes is 96, the minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) can be calculated.

$$\text{MinNumClkFastBit}_A = \frac{(8.5 \text{ X } 96) + 64 - (9 \text{ X } 50)}{85} = 5.06$$

$$\text{MinNumClkFastBit}_B = 3 \text{ x } \left(1 + \frac{50}{40} \right) = 6.75$$

$$\text{MinNumClkFastBit} = \text{Maximum } (5.06, 6.75) = 6.75$$

Step 4 - The maximum CAN bit rate in the Data Phase can be finally found.

$$\text{DataBitRate}_{MAX} = \frac{40 \text{ x } 10^6}{\text{ROUNDUP} \left(\frac{6.75 \text{ x } 40 \text{ x } 10^6}{50 \text{ x } 10^6} \right)} = 6.667 \text{ Mbps}$$

As demonstrated in this example, even though the oscillator clock frequency (40 MHz) is adequate to generate a data rate of 8 Mbps in CAN FD mode, the specific FlexCAN configuration limits this rate to 6.667 Mbps. This limitation is mainly due to the low peripheral clock frequency that imposes the MinNumClkFastBitB bound.

The table below shows the maximum data rate for CAN FD according to clock frequencies, payload size and number of available mailboxes. See in this table that, for some cases, if the number of available mailboxes is reduced, the FlexCAN can then achieve a data rate up to 8 Mbps.

Table 53-31. Maximum CAN bit rate in Data Phase on CAN FD frames

Peripheral clock frequency (MHz)	Payload size	Number of available mailboxes	Maximum data rate (Mbps)
40	8	94	6.667
40	8	114	5.0
40	12	117	6.667
40	12	128	5.714

Table continues on the next page...

Table 53-31. Maximum CAN bit rate in Data Phase on CAN FD frames (continued)

Peripheral clock frequency (MHz)	Payload size	Number of available mailboxes	Maximum data rate (Mbps)
50	12 to 64	128	6.667
60	8	126	8.0
60	12	128	8.0
67	6	128	8.0
80	3	128	8.0
100	0	128	8.0

53.5.10 Modes of operation details

The FlexCAN module has functional modes and low-power modes. See Modes of operation for an introductory description of all the modes of operation. The following sub-sections contain functional details on Freeze mode and the low-power modes.

CAUTION

"Permanent Dominant" failure on CAN Bus line is not supported by FlexCAN. If a Low-Power request or Freeze mode request is done during a "Permanent Dominant", the corresponding acknowledge can never be asserted.

53.5.10.1 Freeze mode

This mode is requested either by the CPU through the assertion of the HALT bit in the CAN_MCR Register or when the chip is put into Debug mode. In both cases it is also necessary that the FRZ bit is asserted in the CAN_MCR Register and the module is not in a low-power mode. This mode is also requested by FlexCAN through the automatic assertion of both HALT and FRZ bits when CAN_MECR[NCEFAFRZ] bit is set and a non-correctable error is detected in a memory read access performed by FlexCAN internal processes (see Response to Errors).

The acknowledgement is obtained through the assertion by the FlexCAN of FRZ_ACK bit in the same register. The CPU must only consider the FlexCAN in Freeze mode when both request and acknowledgement conditions are satisfied.

When Freeze mode is requested, FlexCAN does the following:

- Waits to be in either Intermission, Passive Error, Bus Off or Idle state

- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. A pending move-in does not prevent going to Freeze mode.
- Ignores the Rx input pin and drives the Tx pin as recessive
- Stops the prescaler, thus halting all CAN protocol activities
- Grants write access to the Error Counters Register, which is read-only in other modes
- Sets the NOT_RDY and FRZ_ACK bits in CAN_MCR

After requesting Freeze mode, the user must wait for the FRZ_ACK bit to be asserted in CAN_MCR before executing any other action, otherwise FlexCAN may operate in an unpredictable way. In Freeze mode, all memory mapped registers are accessible, except for CAN_CTRL1[CLKSRC] bit that can be read but cannot be written.

Exiting Freeze mode is done in one of the following ways:

- CPU negates the FRZ bit in the CAN_MCR Register
- The chip is removed from Debug Mode and/or the HALT bit is negated

The FRZ_ACK bit is negated after the protocol engine recognizes the negation of the freeze request. When out of Freeze mode, FlexCAN tries to re-synchronize to the CAN bus by waiting for 11 consecutive recessive bits.

53.5.10.2 Module Disable mode

This low power mode is normally used to temporarily disable a complete FlexCAN block, with no power consumption. It is requested by the CPU through the assertion of the CAN_MCR[MDIS] bit, and the acknowledgement is obtained through the assertion by the FlexCAN of the CAN_MCR[LPMACK] bit. The CPU must only consider the FlexCAN in Disable mode when both request and acknowledgement conditions are satisfied.

If the module is disabled during Freeze mode, it requests to disable the clocks to the PE and CHI sub-modules, sets the LPMACK bit and negates the FRZACK bit.

If the module is disabled during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and then checks it to be recessive
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. A pending move-in is not taken into account.

- Ignores its Rx input pin and drives its Tx pin as recessive
- Shuts down the clocks to the PE and CHI sub-modules
- Sets the NOTRDY and LPMACK bits in CAN_MCR

The Bus Interface Unit continues to operate, enabling the CPU to access memory mapped registers, except the Rx Mailboxes Global Mask Registers, the Rx Buffer 14 Mask Register, the Rx Buffer 15 Mask Register, the Rx FIFO Global Mask Register. The Rx FIFO Information Register, the Message Buffers, the Rx Individual Mask Registers, and the reserved words within RAM may not be accessed when the module is in Disable Mode. Exiting from this mode is done by negating the MDIS bit by the CPU, which causes the FlexCAN to request to resume the clocks and negate the LPMACK bit after the CAN protocol engine recognizes the negation of disable mode requested by the CPU.

53.5.10.3 Stop mode

This is a system low-power mode in which all chip clocks can be stopped for maximum power savings. The Stop mode is globally requested by the CPU and the acknowledgement is obtained through the assertion by the FlexCAN of a Stop Acknowledgement signal. The CPU must only consider the FlexCAN in Stop mode when both request and acknowledgement conditions are satisfied.

If FlexCAN receives the global Stop mode request during Freeze mode, it sets the LPMACK bit, negates the FRZACK bit and then sends the Stop Acknowledge signal to the CPU, in order to shut down the clocks globally.

If Stop mode is requested during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and checks it to be recessive
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive
- Sets the NOTRDY and LPMACK bits in CAN_MCR
- Sends a Stop Acknowledge signal to the CPU, so that it can shut down the clocks globally

Stop mode is exited when the CPU resumes the clocks and removes the Stop Mode request.

After the CAN protocol engine recognizes the negation of the Stop mode request, the FlexCAN negates the LPMACK bit. FlexCAN will then wait for 11 consecutive recessive bits to synchronize to the CAN bus.

53.5.11 Interrupts

The module has many interrupt sources: interrupts due to message buffers and interrupts due to the ORed interrupts from MBs, Bus Off, Error, Error Fast (errors detected in the data phase of CAN FD format messages with the BRS bit set), Tx Warning, and Rx Warning.

Each one of the message buffers can be an interrupt source, if its corresponding IMASK bit is set. There is no distinction between Tx and Rx interrupts for a particular buffer, under the assumption that the buffer is initialized for either transmission or reception. Each of the buffers has an assigned flag bit in the CAN_IFLAG registers. The bit is set when the corresponding buffer completes a successful transfer and is cleared when the CPU writes it to 1 (unless another interrupt is generated at the same time).

Note

It must be guaranteed that the CPU clears only the bit causing the current interrupt. For this reason, bit manipulation instructions (BSET) must not be used to clear interrupt flags. These instructions may cause accidental clearing of interrupt flags which are set after entering the current interrupt service routine.

If the Rx FIFO is enabled (CAN_MCR[RFEN] = 1), the interrupts corresponding to MBs 0 to 7 have different meanings. Bit 24 of the CAN_IFLAG1 register becomes the "FIFO Overflow" flag; bit 25 becomes the "FIFO Warning" flag, bit 26 becomes the "Frames Available in FIFO" flag and bits 27-30 are unused. See the description of the Interrupt Flags 1 Register (CAN_IFLAG1) for more information.

CAUTION

FIFO cannot be enabled when CAN FD feature is enabled.

For a combined interrupt where multiple MB interrupt sources are OR'd together, the interrupt is generated when any of the associated MBs (or FIFO, if applicable) generates an interrupt. In this case, the CPU must read the CAN_IFLAG registers to determine which MB or FIFO source caused the interrupt.

The interrupt sources for Bus Off, Error, Error Fast, Tx Warning and Rx Warning generate interrupts like the MB interrupt sources, and can be read from CAN_ESR1 register. The Bus Off, Error, Tx Warning, and Rx Warning interrupt mask bits are located in the CAN_CTRL1 Register.

53.5.12 Bus interface

The CPU access to FlexCAN registers are subject to the following rules:

- Unrestricted read and write access to supervisor registers (registers identified with S/U in Table "Module Memory Map" in Supervisor Mode or with S only) results in access error.
- Read and write access to implemented reserved address space results in access error.
- Write access to positions whose bits are all currently read-only results in access error. If at least one of the bits is not read-only then no access error is issued. Write permission to positions or some of their bits can change depending on the mode of operation or transitory state. Refer to register and bit descriptions for details.
- Read and write access to unimplemented address space results in access error.
- Read and write access to RAM located positions during Low Power Mode results in access error.
- It is possible for the RXIMR memory region to be considered as general purpose memory and available for access. There are two ways of doing this:
  a. If CAN_MCR[IRMQ] is cleared, the individual masks (RXIMR) are disabled. In this case the RXIMR memory region is considered as general purpose memory.
  b. If CAN_MCR[MAXMB] is programmed with a value smaller than the available number of MBs, then the unused memory space can be used as general purpose RAM space. Note that reserved words within RAM cannot be used. As an example, suppose FlexCAN's RAM can support up to 16 MBs, CAN_CTRL2[RFFN] is 0x0, and CAN_MCR[MAXMB] is programmed with zero. The maximum number of MBs in this case becomes one. The RAM starts at 0x0080, and the space from 0x0080 to 0x008F is used by the one MB. The memory space from 0x0090 to 0x017F is available. The space between 0x0180 and 0x087F is reserved. The space from 0x0880 to 0x0883 is used by the one Individual Mask and the available memory in the Mask Registers space would be from 0x0884 to 0x08BF. From 0x08C0 through 0x09DF there are reserved words for internal use which cannot be used as general purpose RAM. As a general rule, free memory space for general purpose depends only on MAXMB.

53.5.13 Detection and Correction of Memory Errors

FlexCAN supports detection and correction of errors in memory read accesses. Each byte of FlexCAN memory is associated to 5 parity bits that ensure a Hamming distance of 4. The error correction mechanism ensures that in this 13-bit word, errors in one bit can be corrected (correctable errors) and errors in 2 bits can be detected but not corrected (non-correctable errors). Errors in more than 2 bits may not be detected. In case of non-correctable errors, the corrupted data is not changed by the error correction logic. When a read access is performed, the parity bits are used to calculate a syndrome, which indicates the error in each byte.

FlexCAN detects a non-correctable error in the event either an all-zeros or an all-ones read occurs. See CAN_RERRSYNR register description.

Memory errors are indicated to the Host through status register (Error Status Register (CAN_ERRSR)) and bus transfer errors, and reported through report registers (Error Report Address Register (CAN_RERRAR), Error Report Data Register (CAN_RERRDR) and Error Report Syndrome Register (CAN_RERRSYNR)).

The error detection and correction mechanism can be activated or not, controlled by the ECCDIS bit in Memory Error Control Register (CAN_MECR). When disabled, updates on indications and reporting registers are stopped, but the parity bits are still calculated and written along with data in memory write operations to ensure that memory has consistent parity bits associated to the data.

NOTE

All FlexCAN memory must be initialized before starting its operation in order to have the parity bits in memory properly updated. The WRMFRZ bit in Control 2 Register (CAN_CTRL2) grants write access to all memory positions that require initialization, ranging from 0x080 to 0xADF and from 0xF28 to 0xFFF when the CAN FD feature is enabled. The RXMGMASK, RX14MASK, RX15MASK, and RXFGMASK registers need to be initialized as well. The CAN_MCR[RFEN] bit must not be set during memory initialization.

To avoid accidentally changing the critical error correction configuration, this protocol must be followed to enable the update of the Memory Error Control Register (CAN_MECR):

1. By default, ECRWRE bit in Control 2 Register (CAN_CTRL2) is 0 and ECRWRDIS bit in Memory Error Control Register (CAN_MECR) is 1.
2. Set ECRWRE bit in Control 2 Register (CAN_CTRL2).
3. Clear ECRWRDIS bit in Memory Error Control Register (CAN_MECR).

4. All writes to Memory Error Control Register (CAN_MECR) must keep ECRWRDIS cleared.
5. After configuration is done, lock the Memory Error Control Register (CAN_MECR) by either setting ECRWRDIS or clearing ECRWRE.

53.5.13.1 Sources of the Memory Access

The FlexCAN memory can be accessed by two major sources (or requestors):

- by Host (CPU): the largest word accessed is 32-bit wide
- by FlexCAN internals processes (Rx Matching, Tx Arbitration, Move-in on reception, Move-out on transmission): the largest word accessed is 64-bit wide

The way that non-correctable errors are indicated and reported depends on the source of access.

53.5.13.2 Error Indication

Memory errors are indicated by flags HANCEIF, FANCEIF, CEIF in the Error Status Register (CAN_ERRSR). Non-correctable errors detected in memory reads requested by Host are indicated separately than the ones detected in requests by FlexCAN internal processes. FlexCAN makes no distinction of the source of the access when correctable errors are detected. There are 3 independent flags for these 3 cases. If both non-correctable and correctable errors are found in different bytes in the same read operation, both flags are set.

A non-correctable error detected in Host access is also indicated as a bus transfer error. A bus wait request may be asserted to extend the memory transaction to the moment the report registers are updated. This indication cannot be masked.

Each indication flag has one Overrun flag in Error Status Register (CAN_ERRSR). The Overrun flags do not request interrupts. Overrun flags for non-correctable errors indicate that other errors of the same nature were detected after current error being treated, while overrun flags for correctable errors indicate that other errors of the same nature were detected before the current error being treated. This is the recommended handling sequence for error indication:

1. Get error report information from report registers
2. Use this information to take proper measures in the application
3. Clear the HANCEIF, FANCEIF, CEIF flags
4. If the Overrun flag is active:
    a. Alert application that at least one error could not be handled

b. Clear the Overrun flag

The FlexCAN internal processes can access memory in transactions larger than 32-bits. For the indication, this kind of access is considered a consecutive sequence of 32-bit accesses. If errors are found in 2 or more 32-bit words the Interrupt and Overrun flags are set simultaneously.

53.5.13.3 Error Reporting

The report registers Error Report Address Register (CAN_RERRAR), Error Report Data Register (CAN_RERRDR) and Error Report Syndrome Register (CAN_RERRSYNR) provide detailed information about the address read, raw data and syndrome read with error and indicated by the flags described in Error Indication. The address, data and syndrome registers are updated simultaneously along with the error flags, according to these rules:

1. If any of the 2 non-correctable error flags is currently set, the report registers are not updated (the previous non-correctable error reporting is preserved)
2. Otherwise (either no error flag is currently set or only the correctable error flag is currently set), the report registers are updated according to the new error; or according to the most severe of new errors if non-correctable and correctable errors are simultaneously detected

Reporting of errors detected in accesses larger than 32-bit follows the rules described in Error Indication and in the Error Report Address Register (CAN_RERRAR) description.

The address reported in CAN_RERRAR and defined in CAN_ERRIAR are not the same listed in the module memory map. The relation between the reported addresses and the respective ones in the module memory map is shown in the Error Injection Address Register (CAN_ERRIAR) description.

Addresses reported when reading memory portions organized as FIFOs, such as the Rx FIFO Structure and the Rx FIFO Information Register (CAN_RXFIR), refer to the address of the specific entry accessed in the FIFO, not to the FIFO base address.

To assure coherence of the error report registers it is necessary to turn off the report update by setting the CAN_MECR[RERRDIS] bit before reading the report registers.

53.5.13.4 Response to Errors

Correctable errors have no consequence on FlexCAN operation because affected data is corrected before its use by the host or FlexCAN internal processes.

For host-initiated reads, a non-correctable error may affect the host, but does not affect FlexCAN operation.

Non-correctable errors detected on memory reads requested by the FlexCAN internal processes may result in incorrect operation depending on the state of the NCEFAFRZ bit in CAN_MECR register, as follows:

- During reception (either Matching or Move-in processes), when a non-correctable error occurs, an incorrect destination may be selected to store the incoming frame, a corrupted frame may be stored in the correct destination, or both. In case NCEFAFRZ is set, FlexCAN stops operation automatically and enters in Freeze mode to prevent corrupted data from being treated as valid by FlexCAN internal processes. When NCEFAFRZ is negated, FlexCAN continues working and a corrupted frame is received.
- During Arbitration process, when a non-correctable error occurs, either a non-highest priority Tx Message Buffer may be mistakenly selected for transmission or its data may be corrupted. In case NCEFAFRZ is set, FlexCAN stops operation automatically and enters in Freeze mode before starting the Move-out. When NCEFAFRZ is negated, FlexCAN proceeds to Move-out with a corrupted frame that will be transmitted on the CAN bus.
- During Move-out process, when a non-correctable error occurs, a corrupted frame is copied from the selected Tx MB that won the Arbitration to the Tx SMB for transmission. In case NCEFAFRZ is set, FlexCAN stops operation automatically and enters in Freeze mode before starting the transmission. When NCEFAFRZ is negated, the corrupted frame is transferred from the Tx SMB to the Protocol Engine (PE) sub-block and is transmitted on the CAN bus.
- A non-correctable error can also be detected beyond the Move-out process, when Tx data is read from Tx SMB (buffer located in RAM) to be transferred to the PE sub-block for transmission. In this case, a frame with corrupted ID and/or data is transmitted on the CAN bus. To prevent the frame from being successfully received by the external nodes, FlexCAN inverts all bits in the CRC field (CRC sequence plus CRC Delimiter), and transmits an Error Flag just after CRC Delimiter as a result of self-detecting a Bit1 Error and a Form Error due to the CRC field inversion. When NCEFAFRZ is set, FlexCAN stops operation automatically and enters in Freeze mode just after the Error Frame. When NCEFAFRZ is negated, FlexCAN may attempt to re-transmit the same frame, as long as no other higher priority Tx MB is subsequently configured for transmission. In the event the non-correctable error persists, FlexCAN eventually reaches the Bus Off state because of consecutive error detections. The CAN_ECR[TXERRCNT] is updated every time the FlexCAN inverts the CRC field causing errors as described above.

When NCEFAFRZ is set and FlexCAN enters in Freeze Mode, only the CPU can cause FlexCAN to exit Freeze mode and resume Normal Mode. The assertion of the CAN_MECR[NCEFAFRZ] bit is the only way to prevent corrupted frames from being transmitted on the CAN bus up to the Move-out internal process.

The error report registers can provide information to the application for a customized handling of these situations.

53.5.13.5 Error Injection

The error injection registers CAN_ERRIAR, CAN_ERRIDPR, and CAN_ERRIPPR are used to inject errors in memory reads in order to force errors and consequently update the indication and reporting registers. The relation between the error injection addresses and the respective ones in the module memory map is shown in the CAN_ERRIAR description.

The injection is done by flipping the data and parity bits correspondent to the bits in 1 in CAN_ERRIDPR and CAN_ERRIPPR. Injection can be selected specifically for memory accesses requested by Host or by FlexCAN internal processes.

In case of accesses larger than 32-bits, the EXTERRIE bit in Memory Error Control Register (CAN_MECR) extends the injection pattern, replicating it in 32-bit words to fill the width of the access.

NOTE

It is very unlikely, but error injection may correct a bit with error. This will not raise the error flags and reports as expected.

To ensure coherence among error injection registers and avoid spurious error injections, the HAERRIE and FAERRIE bits in Memory Error Control Register (CAN_MECR) must be cleared while configuring the memory injection registers.

53.6 Initialization/application information

This section provide instructions for initializing the FlexCAN module.

53.6.1 FlexCAN initialization sequence

The FlexCAN module may be reset in three ways:

- Chip level hard reset, which resets all memory mapped registers asynchronously

- SOFTRST bit in MCR, which resets some of the memory mapped registers synchronously. See Table 53-4 to see what registers are affected by soft reset.
- Chip level soft reset, which has the same effect as the SOFTRST bit in MCR

Soft reset is synchronous and has to follow an internal request/acknowledge procedure across clock domains. Therefore, it may take some time to fully propagate its effects. The CAN_MCR[SOFTRST] bit remains asserted while soft reset is pending, so software can poll this bit to know when the reset has completed. Also, soft reset can not be applied while clocks are shut down in a low power mode. The low power mode should be exited and the clocks resumed before applying soft reset.

The clock source should be selected while the module is in Disable mode (see CAN_CTRL1[CLKSRC] bit). After the clock source is selected and the module is enabled (CAN_MCR[MDIS] bit negated), FlexCAN automatically goes to Freeze mode. In Freeze mode, FlexCAN is un-synchronized to the CAN bus, the HALT and FRZ bits in CAN_MCR Register are set, the internal state machines are disabled and the FRZACK and NOTRDY bits in the CAN_MCR Register are set. The Tx pin is in recessive state and FlexCAN does not initiate any transmission or reception of CAN frames. Note that the Message Buffers and the Rx Individual Mask Registers are not affected by reset, so they are not automatically initialized.

For any configuration change/initialization it is required that FlexCAN is put into Freeze mode (see Freeze mode). The following is a generic initialization sequence applicable to the FlexCAN module:

- Initialize the Module Configuration Register (CAN_MCR)
  - Enable the individual filtering per MB and reception queue features by setting the IRMQ bit
  - Enable the warning interrupts by setting the WRNEN bit
  - If required, disable frame self reception by setting the SRXDIS bit
  - Enable the Rx FIFO by setting the RFEN bit
  - Enable the abort mechanism by setting the AEN bit
  - Enable the local priority feature by setting the LPRIOEN bit
- Initialize the Control 1 Register (CAN_CTRL1) and optionally the CAN Bit Timing Register (CAN_CBT). Initialize also the CAN FD CAN Bit Timing Register (CAN_FDCBT).
  - Determine the bit timing parameters: PROPSEG, PSEG1, PSEG2, RJW

    - Optionally determine the bit timing parameters: EPROPSEG, EPSEG1, EPSEG2, ERJW
    - Determine the CAN FD bit timing parameters: FPROPSEG, FPSEG1, FPSEG2, FRJW
    - Determine the bit rate by programming the PRESDIV field and optionally the EPRESDIV field
    - Determine the CAN FD bit rate by programming the FPRESDIV field
    - Determine the internal arbitration mode (LBUF bit)
- Initialize the Message Buffers
    - The Control and Status word of all Message Buffers must be initialized
    - If Rx FIFO was enabled, the ID filter table must be initialized
    - Other entries in each Message Buffer should be initialized as required
- Initialize the Rx Individual Mask Registers (CAN_RXIMRn)
- Set required interrupt mask bits in the CAN_IMASK Registers (for all MB interrupts) and in CAN_CTRL1 / CAN_CTRL2 Registers (for Bus Off and Error interrupts)
- Negate the HALT bit in CAN_MCR

After the last step listed above, FlexCAN attempts to synchronize to the CAN bus.

Chapter 54
Zipwire

54.1 Chip-specific Zipwire information

This section summarizes the module configuration in the controller. For a comprehensive description of SIPI and LFAST, please refer the specific dedicated chapters for SIPI and LFAST.

The SIPI and LFAST are connected to one another and appear as a single unit. The LFAST portion of the two modules allows for high speed inter-device communications. The SIPI allows memory to be shared between devices which have SIPI and LFAST communication modules (see Figure 54-1). Zipwire is official brand for the combination of LFAST and SIPI.

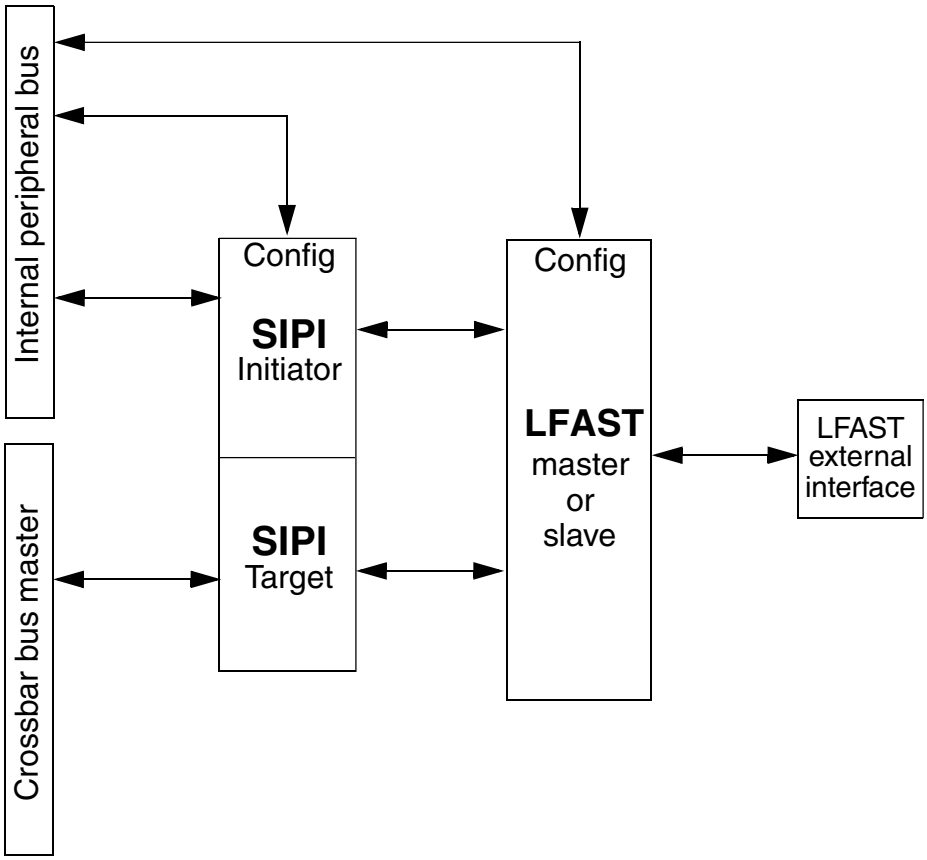

Figure 54-1. LFAST and SIPI block diagram

The LFAST can operate in either slave or master mode configurations. The node running in master mode controls the serial link, but SIPI, in both master and slave modes, can act as both initiator and target for SIPI commands simultaneously. Please see the SIPI and LFAST chapters for detailed information on module configuration and functionality. The SIPI CHIP ID = 098D801D.

54.2 Overview

The SIPI and LFAST modules work together as a single unit called Zipwire. The LFAST portion of the two modules allows for high speed inter-device communications. The SIPI allows memory to be shared between devices which have SIPI and LFAST communication modules.

The LFAST can operate in either slave or master mode configurations. The node running in master mode controls the serial link, but SIPI, in both master and slave modes, can act as both initiator and target for SIPI commands simultaneously. Please see the SIPI and LFAST chapters for detailed information on module configuration and functionality.

54.3 Introduction

Zipwire is a group of modules that allow one MCU to have a fast, low pin count, serial communication link directly into the memory mapped peripherals and/or memories of another MCU or smart ASIC. Zipwire is implemented in hardware so there is no CPU load for the intitiator or target node. Zipwire supports 8-bit, 16-bit or 32-bit reads and writes to any 32-bit address at the target node.

Zipwire architecture is fully pipelined and support multiple outstanding commands to allow maximum use of the serial link bandwidth.

The serial link runs at a high speed using LVDS physical layer. One LVDS pair for Tx and another pair for Rx, with a separate LFAST reference clock for a total of five pins.

Zipwire also supports a streaming mode for the transfer of large blocks of data.

In streaming mode Zipwire has a high transfer rate.

54.4 Zipwire Block Diagram

Figure 54-2 shows two MCUs with Zipwire connected using a five wire interface. Both MCUs support Target and Initiator modes of Zipwire. The SIPI Bus Master Interface is used for all Target mode transactions. The SIPI Register Interface is used for all Initiator Transactions and initial setup. The LFAST Register Interface is used for Initial Setup.

The diagram shows the LFAST reference clock coming from MCU B clock system. The Ref_Clock can come from either MCU. It is user configurable, but it must be the same clock that drives both LFAST modules.

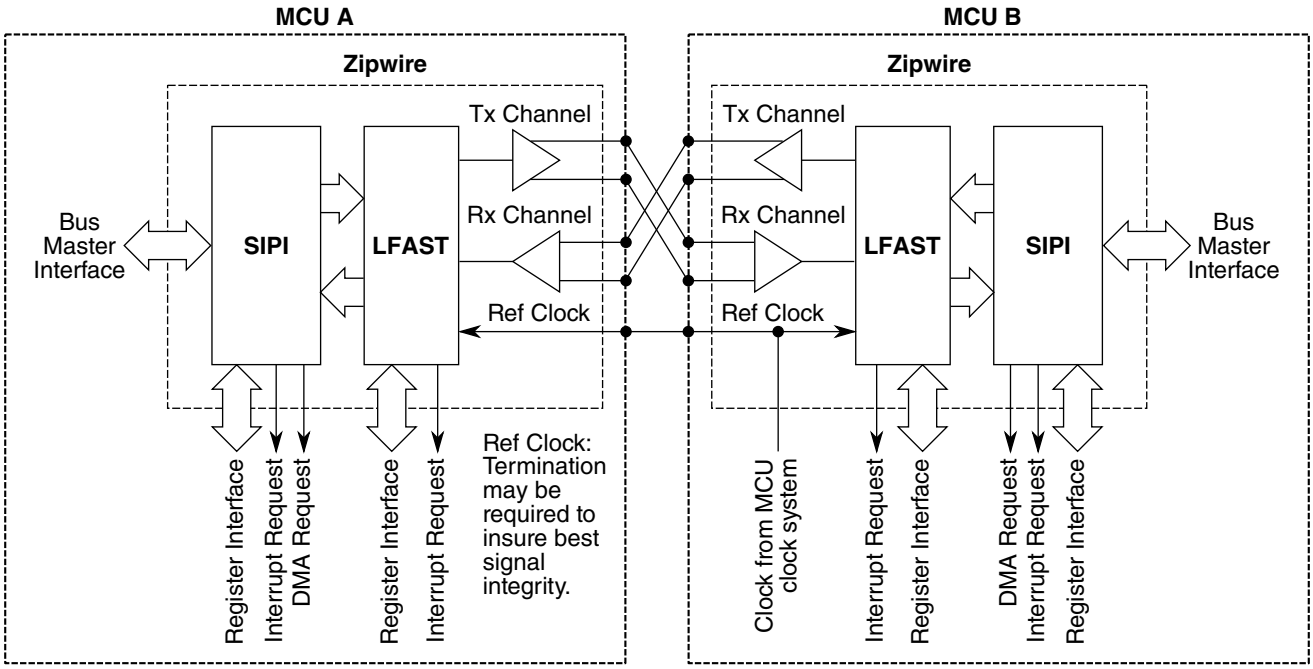

Figure 54-2. Zipwire connection diagram

54.5 Architecture

Zipwire is composed of several modules and system resources. The physical layer is LVDS with common mode voltage and defined swing.

The transport layer is a protocol called LFAST. LFAST is an asynchronous prototcol, using non-return to zero encoding. The LFAST protocol is composed of the following:

- A fixed 16-bit sync frame to allow the receiver to detect the optimal point to sample the incoming data.
- Followed by an 8-bit LFAST header, that defines the channel number and the size of the LFAST payload.
- Finally the payload, which can be between 8 and 288 bits.

The application layer protocol is called Serial Inter Processor Interface (SIPI). SIPI runs on top of LFAST and is fully encapsulated within the LFAST payload. SIPI uses four fixed sizes of LFAST payload in Zipwire:

- 32-bit
- 64-bit

- 96-bit
- 288-bit

The SIPI protocol implements a suite of commands initiated by one MCU, for reading and writing any 32-bit address location in another connected MCU. The SIPI protocol allows either or both MCUs to initiate commands. The protocol also supports interrupt requests from one MCU to the other.

The SIPI module implements both the initiator part of the protocol and the recipient part of the protocol. The module implements four SIPI Initiator channels that can run independently of each other and can run simultaneously. The SIPI module is a bus master on the low speed XBAR. As the target MCU for a command from the inititating MCU, SIPI can perform read and write accesses to any address location within the target MCU. The software running on the local MCU, should configure the system MPU to allow/deny memory accesses to MCU memory and resources as required.

The initiator part of the module is connected to the DMA controller and is able to generate DMA requests as a command is completed. This allows a series of read or write commands to be queued in the Inititator MCU and executed by DMA and SIPI without CPU intervention at either Initiator or Target MCU.

54.6 Zipwire interconnections

LFAST has the following connections:

- Tx and Rx configuration is controlled by LFAST Control registers .
- Peripheral Bridge interface (PBRIDGE) — Allows software to read and write configuration registers.
- Tx Data Port/Rx Data Port — Directly connected to the SIPI module. Allows received data to be efficiently transferred to SIPI and transmit data to be transferred from SIPI.
- Interrupt Request connections — Allows the module to flag to the CPU when it requires servicing.

SIPI has the following connections:

- Peripheral Bridge interface (PBRIDGE) — Allows software to read and write configuration registers and SIPI Interface Registers.

- DMA connections — Allows SIPI command sequences to be queues and initiated without CPU intervention.
- Crossbar master port — Allows SIPI to execute requested commands to read and write MCU address space.
- Tx Data Port/Rx Data Port — Directly connected to the LFAST module. Allows received data to be efficiently transferred from LFAST and transmit data to be transferred to LFAST.
- Interrupt Request connections — Allows the module to flag to the CPU when it requires servicing.

54.7 Zipwire performance

Two aspects of performance are considered:

- Bandwidth — The rate at which data can be read or written between two nodes. It assumes that read or write commands from the Inititator node, can be sent continuously at the highest speed the Target node can consume those commands.
- Latency — The time from the Initiator node sending a read or write command to the Initiator node receiving back the read data or write acknowledge.

54.7.1 Read performance

A Zipwire read operation consists of three stages:

- Inititator sends SIPI Read command to Target.
- Target parses the received command and runs a master bus cycle to read the data.
- Target sends the SIPI Read response back to the Initiator.

A SIPI Read command consists of:

- 16-bit header
- 32-bit read address
- 16-bit CRC
- 64 bits total

A SIPI Read response consists of:

- 16-bit header
- 32-bit read data
- 16-bit CRC
- 64 bits total

The SIPI message is encapsulated in a LFAST frame where the LFAST payload is the size of the SIPI message.

The LFAST frame consists of:

- 16-bit synchronisation header
- 8-bit header
- 64-bit payload
- 1-bit stop bit
- 89 bits total

LFAST Baud rate is *c* Mbaud which yields a bit time of *d* ns

Therefore, an 89-bit LFAST transmission of a SIPI 64-bit Read command or 64-bit Read response takes 89*d* ns.

The SIPI module takes thirteen system clock cycles to parse a command and create a Read response, plus the time to run the master bus cycle. The time to run the master bus cycle will vary depending on the memory being read.

Assumptions:

- Average of $n \times$ XBAR cycles to read different memories.
- XBAR clocked at *x* MHz
- SIPI clocked at *y* MHz

Therefore, time for SIPI to read an address location is:

$(13 \times y \text{ MHz clocks}) + (n \times x \text{ MHz clocks}) = z \text{ ns}$

54.7.1.1 Read bandwidth

The Zipwire target node has a three message deep receive FIFO and a three message deep transmit FIFO. So, the Target node can simulataneously be receiving a command, processing a command, and sending the Read response.

The time to transmit a command or response is less than the time to process the command. Therefore, the bandwidth is limited by the time to process the message.

Read Bandwidth = 4 bytes in z ns = 4 × z MB/second

54.7.1.2 Read latency

The latency is the time taken to send a Read command, process the command, and send a Read response.

Read Latency = 89d ns + z ns + 89d ns = z + 178d ns

54.7.2 Write performance

A Zipwire write operation consists of three stages:

- Initiator sends SIPI Write command to Target.
- Target parses the received command and runs a master bus cycle to write the data.
- Target sends the SIPI Write response back to the Initiator.

A SIPI Write command consists of:

- 16-bit header
- 32-bit write address
- 32-bit write data
- 16-bit CRC
- 96 bits total

A SIPI Write acknowledge consists of:

- 16-bit header

- 16-bit CRC
- 32 bits total

The SIPI message is encapsulated in an LFAST frame where the LFAST payload is the size of the SIPI message.

The LFAST frame consists of:

- 16-bit synchronisation header
- 8-bit header
- 96-bit payload (command) or 32-bit (acknowledge)
- 1-bit stop bit
- 121 bits total (command) or 57 bits (acknowledge)

LFAST Baud rate is *c* Mbaud which yields a bit time of *d* ns

Therefore, the time for an LFAST transmission is:

- 121-bit LFAST transmission of a SIPI 96-bit Write Command takes 121*d* ns
- 57-bit LFAST transmission of a SIPI 32-bit Write Acknowledge takes 57*d* ns

The SIPI module takes thirteen system clock cycles to parse a command and create a Write response, plus the time to run the master bus cycle. The time to run the master bus cycle will vary depending on the memory being written.

Assumptions:

- Average of $m \times$ XBAR cycles to write different memories.
- XBAR clocked at *x* MHz
- SIPI clocked at *y* MHz

Therefore, the time for SIPI to write an address location is:

$(13 \times y \text{ MHz clocks}) + (m \times x \text{ MHz clocks}) = v \text{ ns}$

54.7.2.1 Write bandwidth

The Zipwire target node has a three message deep receive FIFO and a three message deep transmit FIFO. So, the Target node can simulataneously be receiving a command, processing a command, and sending the Write Acknowledge response.

The time to transmit the command is longer than the time to process the command, or the time to transmit the Write Acknowledge. Therefore, the bandwidth is limited by the time to transmit the command.

Write Bandwidth = 4 bytes in v ns = 4 × v MB/second

54.7.2.2 Write latency

The latency is the time taken to send a Write command, process the command, and send a Write Acknowledge.

Write Latency = 121d ns + v ns + 57d ns = v + 178d ns

Chapter 55
Serial Interprocessor Interface (SIPI)

55.1 Introduction

The Serial Interprocessor Interface (SIPI) is an application layer protocol which runs on top of the LFAST (LVDS Fast Asynchronous Serial Transmission) module. It is used by the local device to access the shared memory of a remote device. SIPI defines point-to-point full duplex communication between two devices, where LFAST works as a physical medium of communication between both the devices.

55.1.1 Scalability

The SIPI protocol is designed to provide a sophisticated, high bandwidth, multimaster, multi-channel memory interface between 2 devices using few interconnecting signals. But the protocol is designed in such a way that a subset of the protocol can be implemented, where die area is more important than features.

Main scalable features:

- Number of concurrent channels:
  - Full Implementation = 4
  - Minimum Implementation = 1
- Full implementation has a node both as Initiator and Target of commands. Minimum implementation either Initiator or Target.
- Full Implementation includes a block transfer feature, but this feature is optional.

The rest of this section describes a full implementation of SIPI which includes:

- Advanced High-Performance Bus (AHB-Lite) master interface

- Direct Memory Access (DMA) interface
- LFAST Tx/Rx (transmit/receive) interfaces along with Peripheral Bus Interface (IPS)

55.2 Overview

An instance of SIPI can act as initiator, or target or both. SIPI can access the shared memory directly through its AHB master interface or through its DMA interface. DMA interface is used when the node acts as an initiator while the AHB Master interface will be used when the node acts as target. SIPI has four channels, with one channel (Channel 2) having data streaming capability. Payload width for channel 0, 1 and 3 is 32 bits, and for channel 2 data widths can be 32 bits, or 256 bits when streaming. Any of these channels can be used for DMA access or bus interface access depending on the setting of the SIPI_CCR*n*. CRC encoder calculates the CRC on the command frame. Then the SIPI initiator appends the CRC to the end of the frame before transmission.

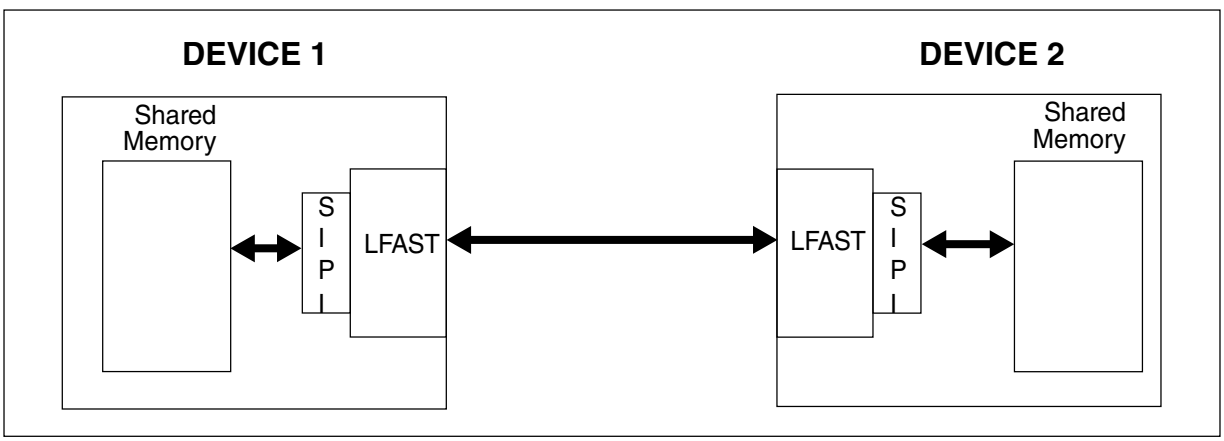

Figure 55-1. Interprocessor communication diagram

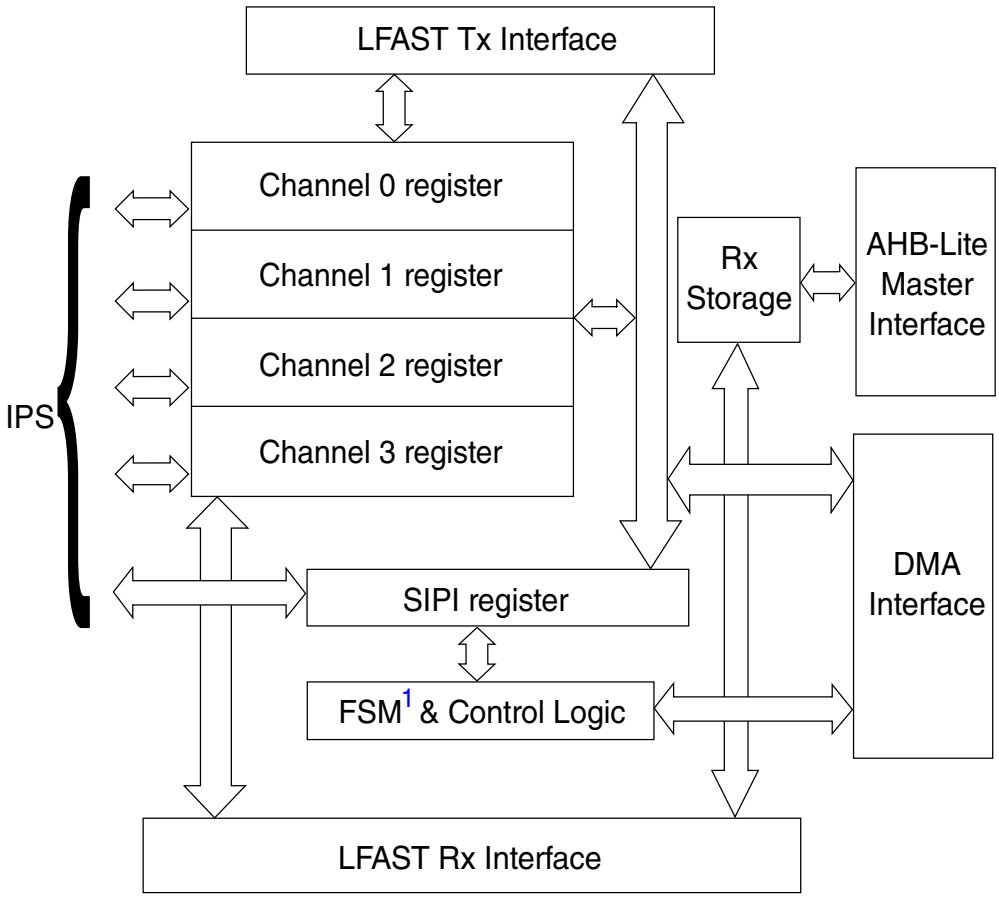
55.3 SIPI block diagram



[1] Finite State Machine

Figure 55-3. SIPI block diagram

55.4 Feature description

This section describes the features of the SIPI module.

55.4.1 Main features

- Point-to-point communication between two devices
- Full duplex communication
- Four channels, including one channel with data streaming capability

- Configurable DMA access for each channel
- CRC protection mechanism
- Timeout protection mechanism
- Fixed priority channel selection
- Data size up to 256 bits on streaming channel
- Common tag pool for assigning sequential transfer IDs to every new transfer
- AHB master interface which is used by target node to access shared memory
- Target node contains a set of nine 32-bit internal registers to store commands
- Up to two outstanding requests are supported at initiator

55.4.2 Standard features

- IPS bus interface (PBRIDGE)
- SPP DMA2x bus interface
- AHB Master Interface
- LFAST Tx/Rx interfaces
- Cyclic Redundancy Check error detection (CRC16)

55.5 SIPI operation from reset

When the SIPI module exits reset, it is operational and target mode is enabled without the need to configure the control registers.

55.6 Functional description

55.6.1 External signals

The SIPI has no chip external signals.

55.6.2 Frame format

All frames have the same general format:

- 16 bit header
- Address, Address and Data, or nothing
- 16-bit CRC

There are 2 main groups of command; read and write. Within those 2 groups are three read/write formats:

- 32-bit
- 16-bit
- 8-bit

Each command generates one of three different responses:

- Read data
- Write acknowledge
- Error

There is one additional command that requests the module ID from the Target node. The ID is a unique 32-bit ID that is specific to a particular device. It is normally the same as the JTAG ID. The sections below illustrate the four different frame formats that are used to implement all the commands and responses.

The number of frames depends on the data buffers (associated with every channel), the frame data is stored in data buffers at the initiator. Address and data are both transmitted in the same order in which they are stored.

55.6.2.1 Register read request

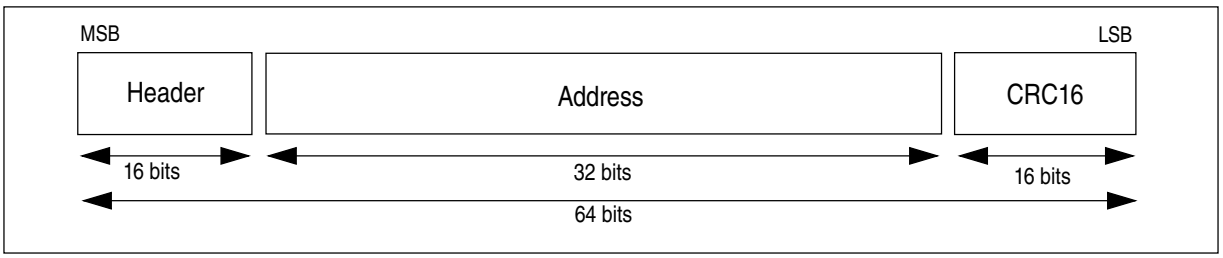


Figure 55-4. SIPI register read request

55.6.2.2 Register read response, ID request response

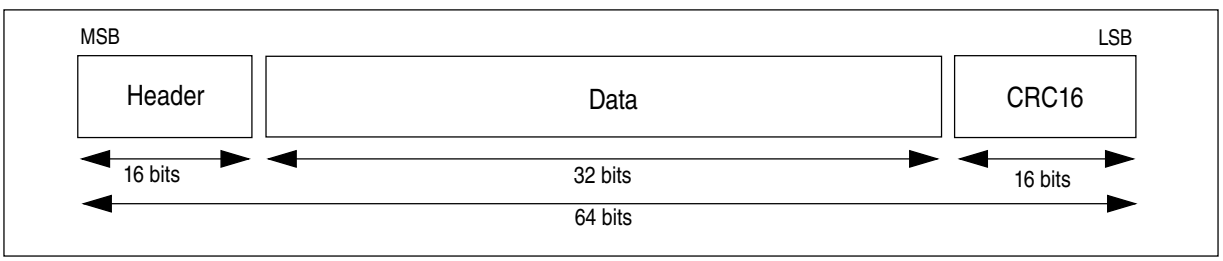

Figure 55-5. SIPI read response

55.6.2.3 Register write request

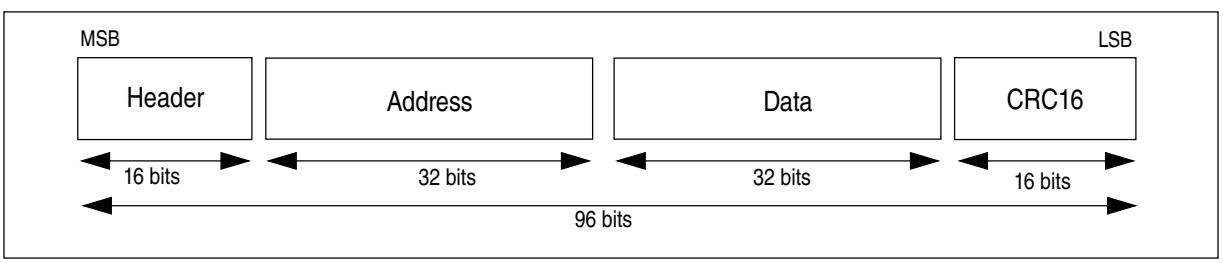

Figure 55-6. SIPI register write request

55.6.2.4 Trigger transfer, ID transfer, write acknowledge and streaming write acknowledge

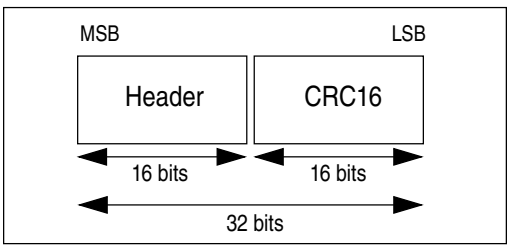

Figure 55-7. SIPI write acknowledge

55.6.2.5 Streaming write request

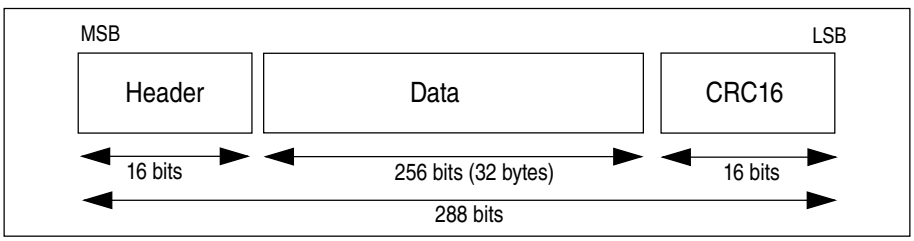

Figure 55-8. Streaming write request format

NOTE

Direct write operations are used to set the streaming address.

Streaming data write is performed using the format shown in Figure 55-8.

55.6.2.6 Header field

Header field contains 16 bits of configuration information. MSB will be transmitted first.

55.6.2.6.1 SIPI header coding

Figure 55-9, Table 55-1, Figure 55-10, and Table 55-2 show how the SIPI header bits are coded.

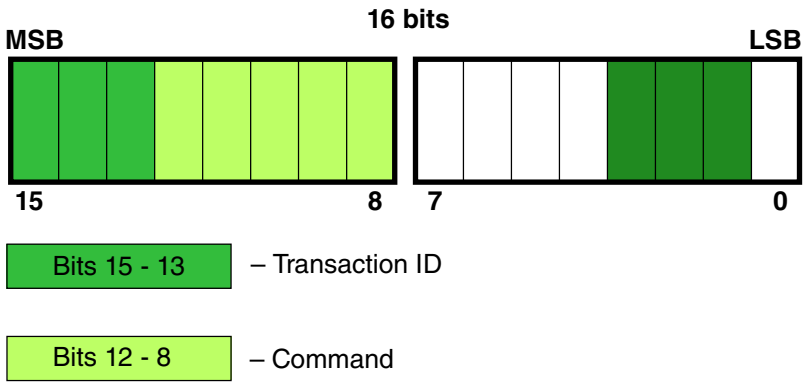

Figure 55-9. SIPI header coding

Table 55-1 shows the command coding for the bits[12:8] of the header.

Table 55-1. SIPI header command coding

b[12:8] (hex)	Command	Payload Size
00	Read 8 bits	64
01	Read 16 bits	64
02	Read 32 Bits	64
03	Reserved	—
04	Write 8 bits with ACK	96
05	Write 16 bits with ACK	96
06	Write 32 bits with ACK	96
07	Reserved	—
08	ACK – OK	32
09	ACK – Fault	32
0A	Read Answer – OK	64
0B	Reserved	—
0C	Trigger comm and with ACK	32
0D	Reserved	—
…	…	…
11	Reserved	—
12	ID Register Read Request	32
13	Reserved	—
…	…	…
16	Reserved	—
17	Stream Data with ACK (32 bytes)	288
18	Reserved	—
…	…	…
1F	Reserved	—

Figure 55-10 shows the channel number field in the header and Table 55-2 shows the channel number coding.

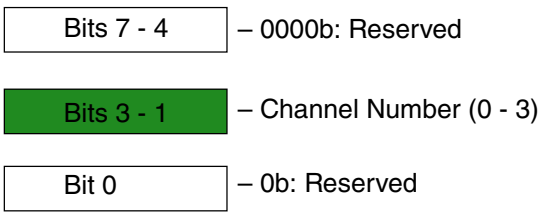

Figure 55-10. SIPI header channel field

Table 55-2. SIPI header channel number coding

SIPI channel name	Channel number coding in header(s)		Comment
	SIPI channel coding select field (SIPI_MCR[CHNSB])		
	Code table I (SIPI_MCR[CHNSB] = 1)	Code table II (SIPI_MCR[CHNSB] = 0)	
0 (Channel A)	000b	100b	In use
1 (Channel B)	001b	101b	In use
2 (Channel C)	010b	110b	In use
3 (Channel D)	011b	111b	In use
4 (Channel E)	100b	000b	Reserved
5 (Channel F)	101b	001b	Reserved
6 (Channel G)	110b	010b	Reserved
7 (Channel H)	111b	011b	Reserved

55.6.2.7 Address field

The address field is 32 bits wide with the MSB transmitted first.

55.6.2.8 Payload field

Table 55-3 shows the payload sizes of LFAST frames.

Table 55-3. Payload size of LFAST channel frame

LFAST Code	SIPI Code	LFAST Payload Size (bits)	LFAST Payload Size (bytes)
000b	—	8	1
001b	—	32	4
010b	010b	64	8
011b	011b	96	12
100b	100b	128	16

Table continues on the next page...

Table 55-3. Payload size of LFAST channel frame (continued)

LFAST Code	SIPI Code	LFAST Payload Size (bits)	LFAST Payload Size (bytes)
101b	101b	256	32
110b	110b	512	64
111b	111b	288	36

Table 55-4 shows the converted coding of LFAST for a given SIPI code.

Table 55-4. Converted coding of LFAST channel code for SIPI headers

LFAST Code	SIPI Code	Channel (hex)[1]
0100b	100b	A
0101b	101b	B
0110b	110b	C
0111b	111b	D
1000b	000b	E (not used by SIPI)
1001b	001b	F (not used by SIPI)
1010b	010b	G (not used by SIPI)
1011b	011b	H (not used by SIPI)

1. SIPI channel 0 sends all commands on LFAST channel A, commands received on LFAST channel A, are processed and the response sent back on LFAST channel A.
SIPI channel 1 sends all commands on LFAST channel B, commands received on LFAST channel B, are processed and the response sent back on LFAST channel B.
SIPI channel 2 sends all commands on LFAST channel C, commands received on LFAST channel C, are processed and the response sent back on LFAST channel C.
SIPI channel 3 sends all commands on LFAST channel D, commands received on LFAST channel D, are processed and the response sent back on LFAST channel D.

55.6.2.9 CRC field

CRC field is 16 bits wide with calculation always enabled using CRC-16-CCITT syndrome (x16 + x12 + x5 + 1). MSB is sent first in the data stream.

55.6.2.9.1 CRC field examples

55.6.2.9.1.1 Example 1 – 32 bit write on channel 1 with ID1

- Header = 260Ah
- Address = 1122_3344h
- Data = CCDD_EEFFh
- CRC = BF7Dh

55.6.2.9.1.2 Example 2 – 32 bit read on channel 2 with ID2

- Header = 420Ch
- Address = 89AB_CDEFh
- CRC = 6B80h

55.6.2.9.1.3 Example 3 – Event command on channel 3 with ID3

- Header = 6C0Eh
- CRC = B286h

55.7 Transfer types

This section describes the available transfer types of the SIPI module. The SIPI frame is inserted inside the payload of the LFAST frame as shown in the figures of the following examples.

55.7.1 Read transfer

A Read transfer can be of two types:

- Read Request Transfer (at initiator node)
- Read Response Transfer (at target node)

55.7.1.1 Register read request transfer

If there is a read request transfer, the initiator node will send header, address and CRC bits as shown in Figure 55-11.

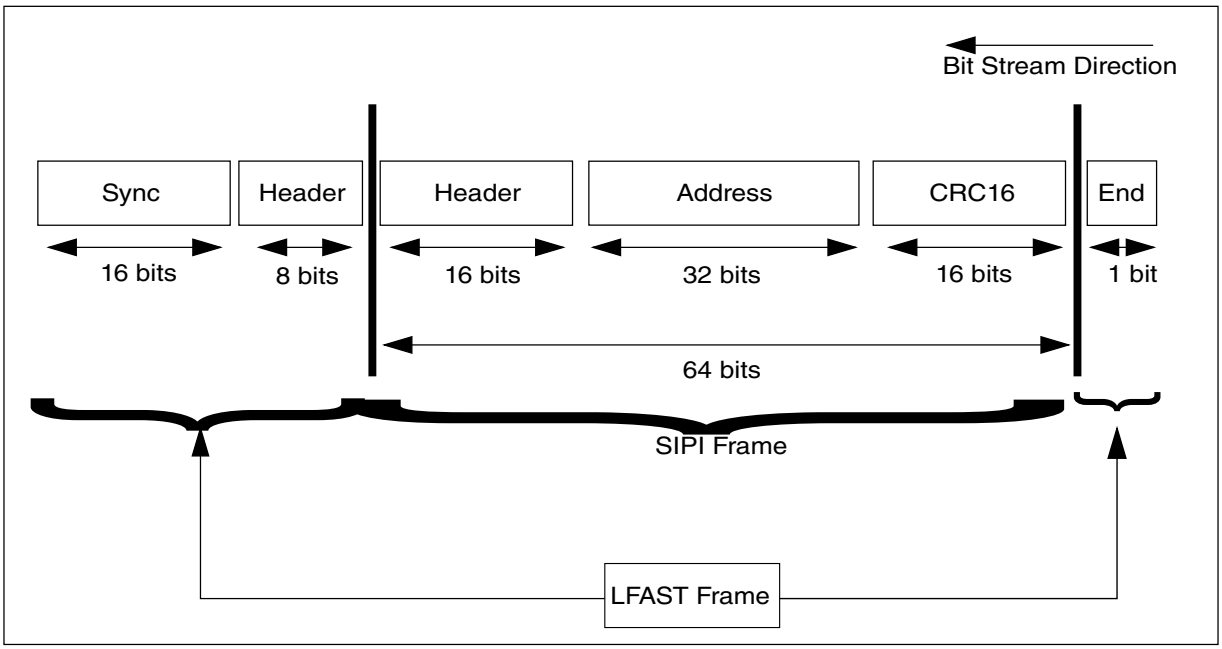

Figure 55-11. Read request transfer

55.7.2 Register read answer transfer

In response to a read request by the initiator node, the target node will send header, payload and CRC16. Data transfer could be in 8-bit, 16-bit or 32-bit modes (see Figure 55-12). In the case of 8-bit or 16-bit modes, copies of the SIPI data is sent in the payload (see Figure 55-13).

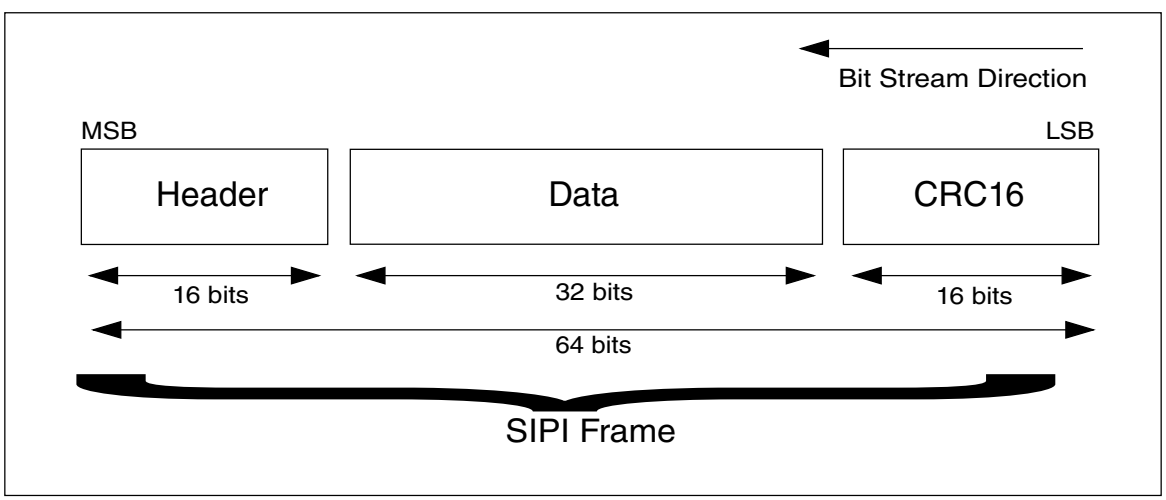

Figure 55-12. Read answer transfer

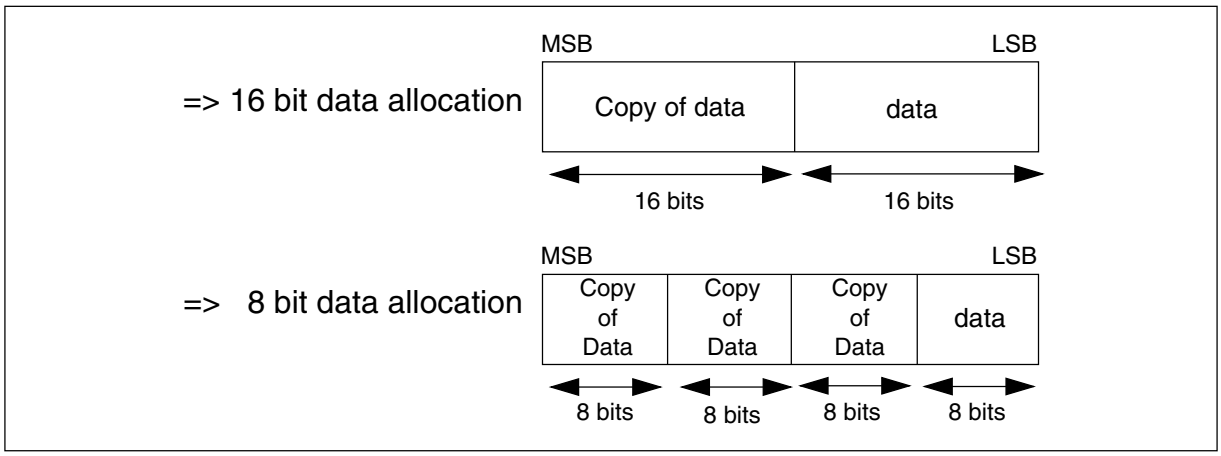

Figure 55-13. Data allocation

Note

- For an 8-bit transfer, address bits [31:2] are used as address and bits [1:0] are used as byte enables.
  - Bits[1:0]:
    - 00 - byte 3 enabled (MSB)
    - 01 - byte 2 enabled
    - 10 - byte 1 enabled
    - 11 - byte 0 enabled (LSB)
- For a 16-bit transfer, address bits [31:1] are used as address and bit [0] is used as halfword enable.
  - Bit[0]:
    - 0 - halfword 1 enabled (MSB)
    - 1 - halfword 0 enabled (LSB)

55.7.3 Register Write transfer

Register Write transfer can be of two types:

- Normal write transfer - channels 0, 1, 2 and 3
- Streaming data transfer - channel 2 only

A Register Write transfer can be done through Normal Write transfer on channels 0, 1, 2 and 3 (see Normal write transfer) as shown in Figure 55-14.

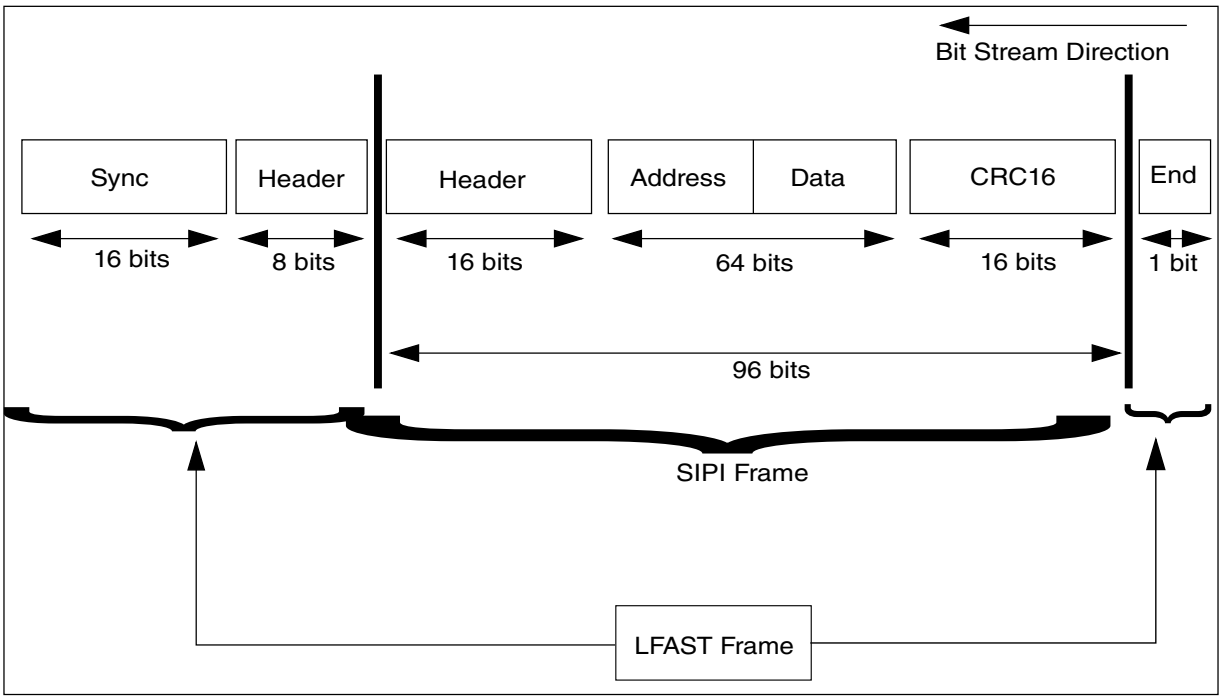

Figure 55-14. Register write transfer (showing LFAST frame encapsulation)

55.7.3.1 Normal write transfer

A normal write transfer contains header, address, data (32-bit) and CRC as shown in Figure 55-15.

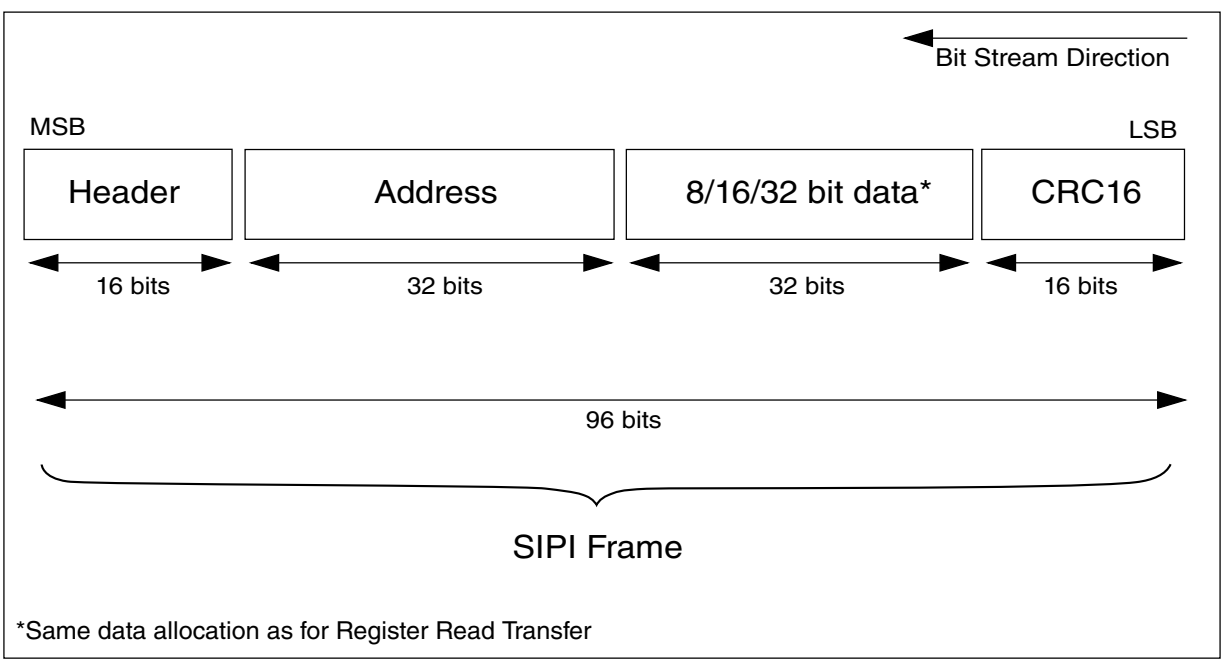

Figure 55-15. Write transfer (LFAST frame encapsulation is not shown)

Note

- For an 8-bit transfer, address bits [31:2] are used as address and bits [1:0] are used as byte enables.
  - Bits[1:0]:
    - 00 - byte 3 enabled (MSB)
    - 01 - byte 2 enabled
    - 10 - byte 1 enabled
    - 11 - byte 0 enabled (LSB)
- For a 16-bit transfer, address bits [31:1] are used as address and bit [0] is used as half word enable.
  - Bit[0]:
    - 0 - half-word 1 enabled (MSB)
    - 1 - half-word 0 enabled (LSB)

55.7.3.2 Streaming write transfer

Streaming write transfer has 256 bits of payload.

55.7.3.2.1 Streaming write transfer with address

Setting the address is performed using a direct write transfer. The SIPI Maximum Count Register (SIPI_MAXCR) and SIPI Address Reload Register (SIPI_ARR) are written before the SIPI Address Count Register (SIPI_ACR). This is to avoid unwanted behavior of the SIPI attempting to access non-shared memory. This is only true for the very first streaming command, subsequent streaming command(s) may not need to write the SIPI_MAXCR and SIPI_ARR (see SIPI Max Count Register (SIPI_MAXCR), SIPI Address Count Register (SIPI_ACR) and SIPI Address Reload Register (SIPI_ARR)).

55.7.3.2.2 Streaming transfer with data

Figure 55-16 shows the packet structure of the streaming transfer containing data.

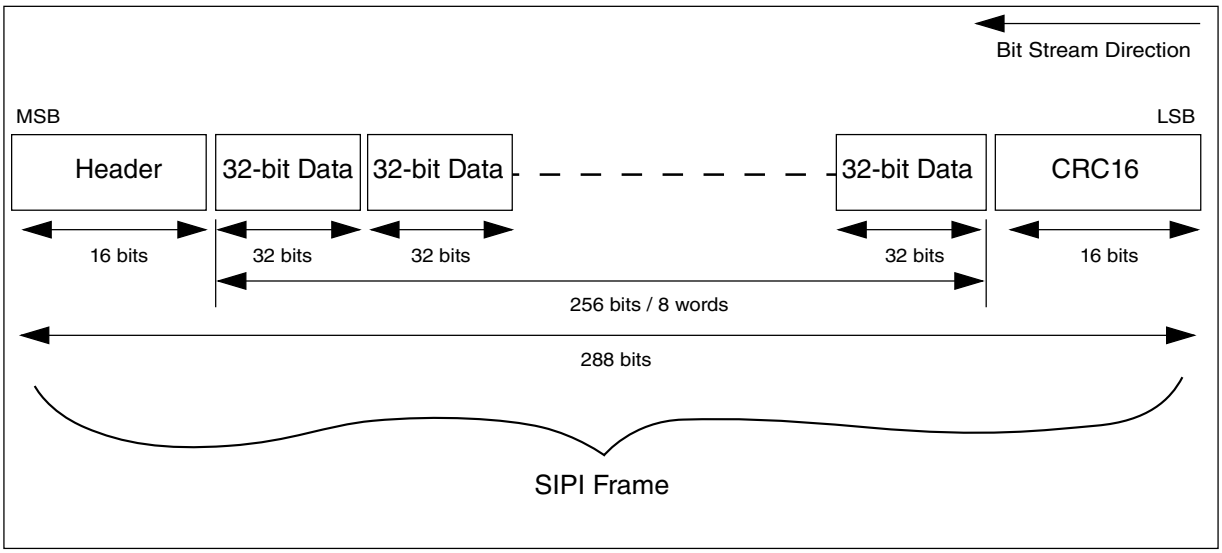

Figure 55-16. Streaming transfer with data

55.7.4 Write Acknowledge transfer

A Write Acknowledge transfer contains only header and CRC bits (see Write Aknowledge transfer. The CRC bits are calculated on the header field.

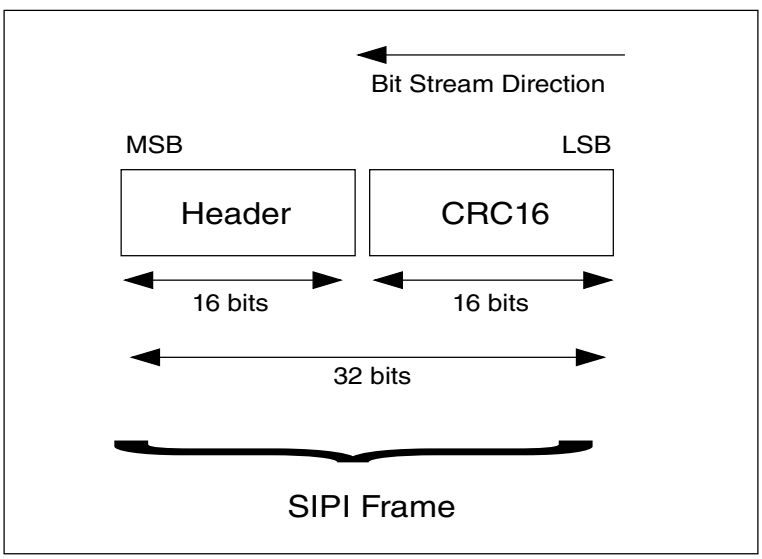

Figure 55-17. Write Aknowledge transfer (LFAST encapsulation is not shown)

55.7.5 ID request response

55.7.5.1 ID request transfer

An ID request is transmitted by the initiator node as shown in Figure 55-18.

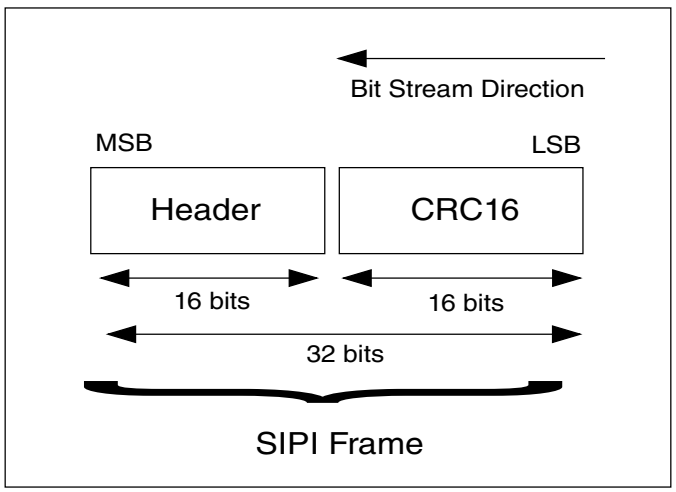

Figure 55-18. ID request transfer (LFAST encapsulation is not shown)

55.7.5.2 ID request response transfer

An ID request response is transmitted by the target node as shown in Figure 55-19.

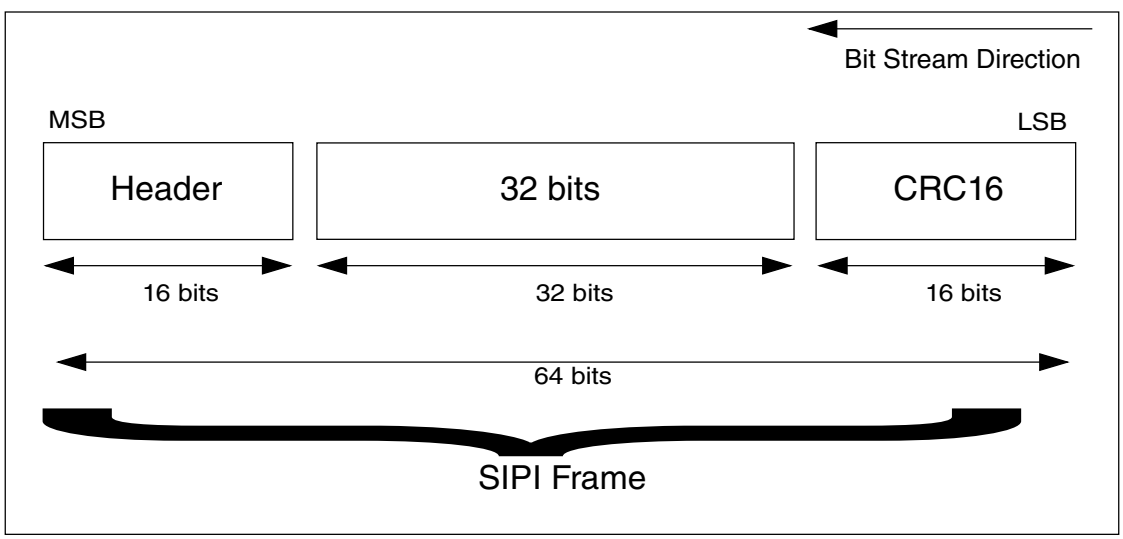

Figure 55-19. ID request response transfer

Note

The ID request response contains the value of the CHIP ID in place of data.

55.8 Transfer API and flow charts

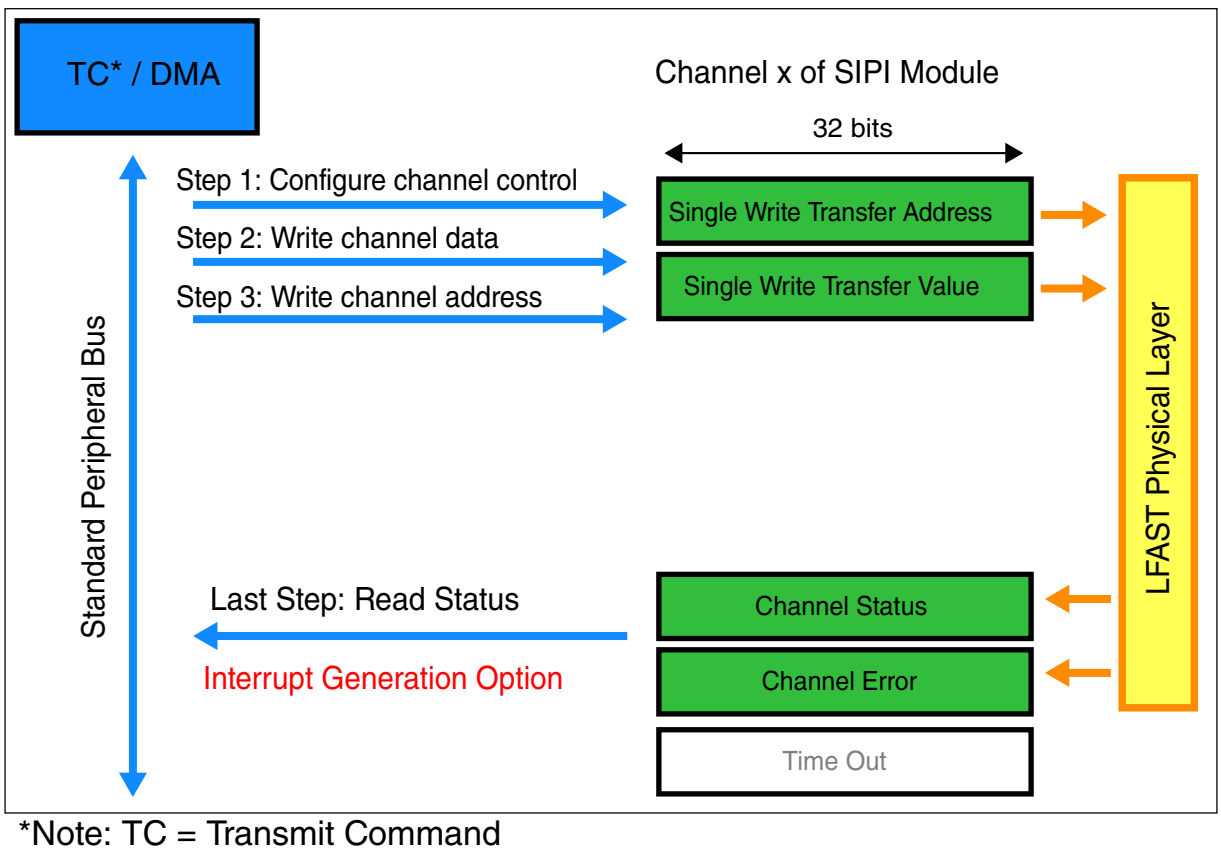

Figure 55-20. SIPI single register write API

Implement the following steps to generate a single Write Transfer Request (Figure 55-20):

1. Configure data and SIPI_CCR*n* at the initiator node.
2. Configure SIPI_CAR*n* at the initiator node.

   As soon as the channel address register (SIPI_CAR*n*) is written and if CCR*n*[CHEN] = 1, the initiator SIPI will calculate the CRC on header, address and data field and will start transmitting data to LFAST.
3. Software polls the status register bits (SIPI_CSR*n*) to determine when the request completes, SIPI_CSR*n*[ACKR] = 1. An interrupt will be generated if the corresponding SIPI_CIR*n*[ACKIE] = 1.

On a single Write transfer request reception (Figure 55-21):

1. Target node will place the address, data and control information on its AHB master interface.
2. When the process in completed, the target node will generate an acknowledge frame and send it back to the LFAST.

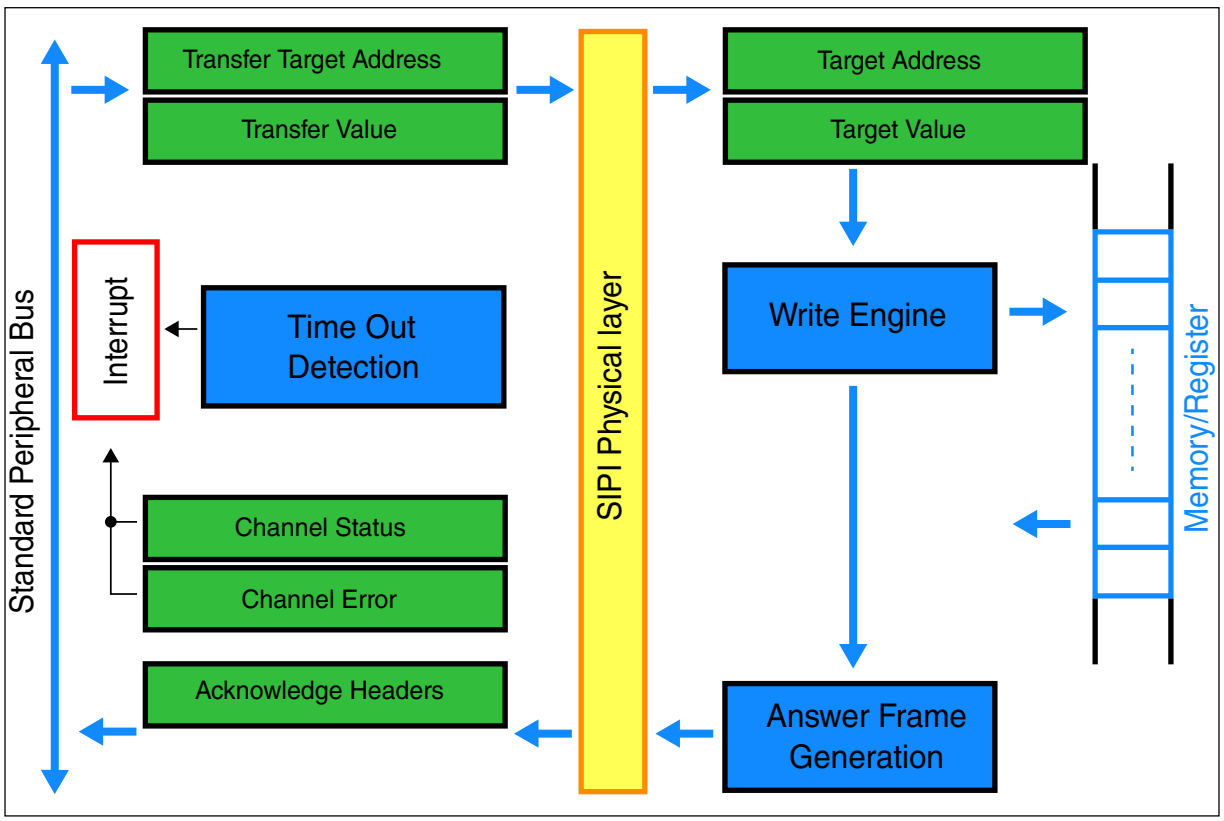

Figure 55-21. SIPI Single Register Write API – Flow Chart

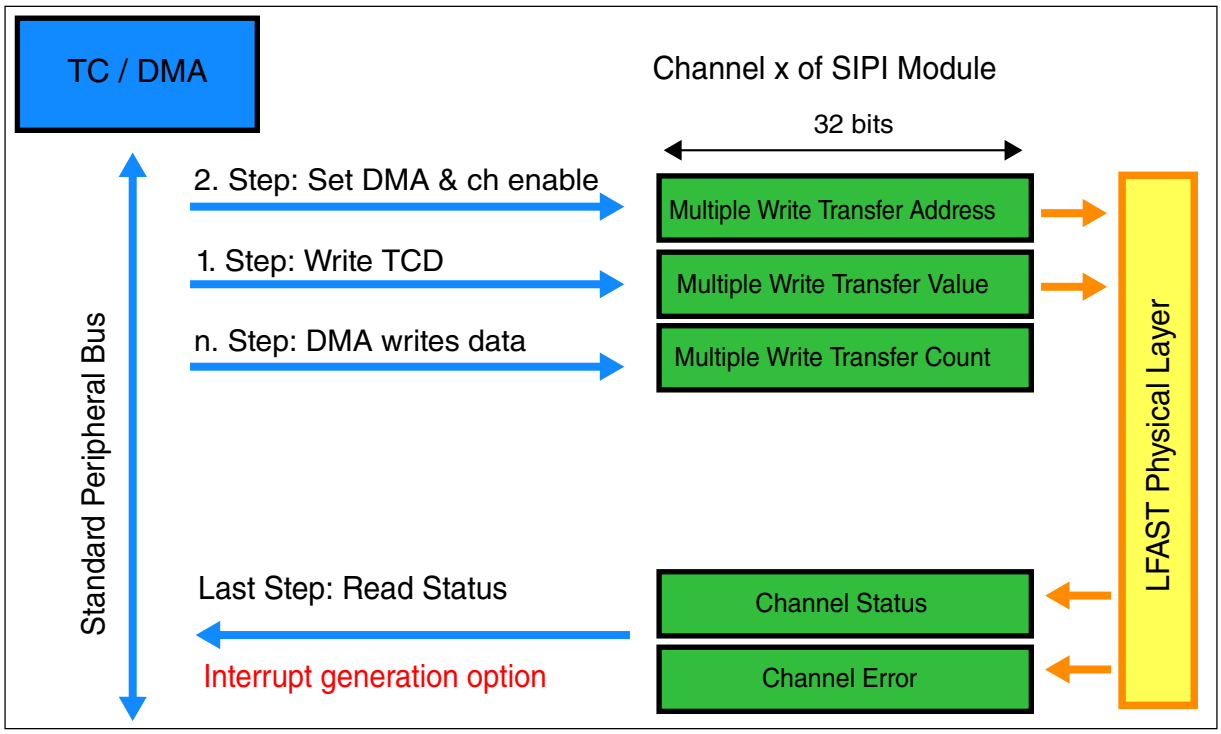

Figure 55-22. SIPI Multiple Register Write API

For multiple write transfer request generation (Figure 55-22):

1. Software will configure the Transfer Control Descriptor (TCD) of the DMA.
2. Software will write SIPI_CCR*n*[CHEN] = 1 and SIPI_CCR*n*[DAN] = 1.
3. SIPI will start copying data into the SIPI_CDR*n* through its DMA interface, depending on the transfer count and data registers size. SIPI_CDR2_0 should be written with the MSB.
4. When the copying process is completer, initiator SIPI will calculate CRC on header, address and data field and start transmitting data to LFAST.
5. Software should poll the SIPI_CSR*n* status register bits to determine if the request has completed. If SIPI_CSR*n*[ACKR] = 1, an interrupt will be generated (if the corresponding SIPI_CIR*n*[ACKIE] = 1).
6. If SIPI_CCR*n*[DEN] = 1, the SIPI request will transfer to the DMA controller. If not, the state machine go idle.
7. Steps 4–7 will be repeated.

On Multiple Write transfer request reception (Figure 55-22):

1. Target node will place the address, data and control information on its AHB Master Interface.
2. When the process in completed, target node will generate an acknowledge frame and send it back to the LFAST.

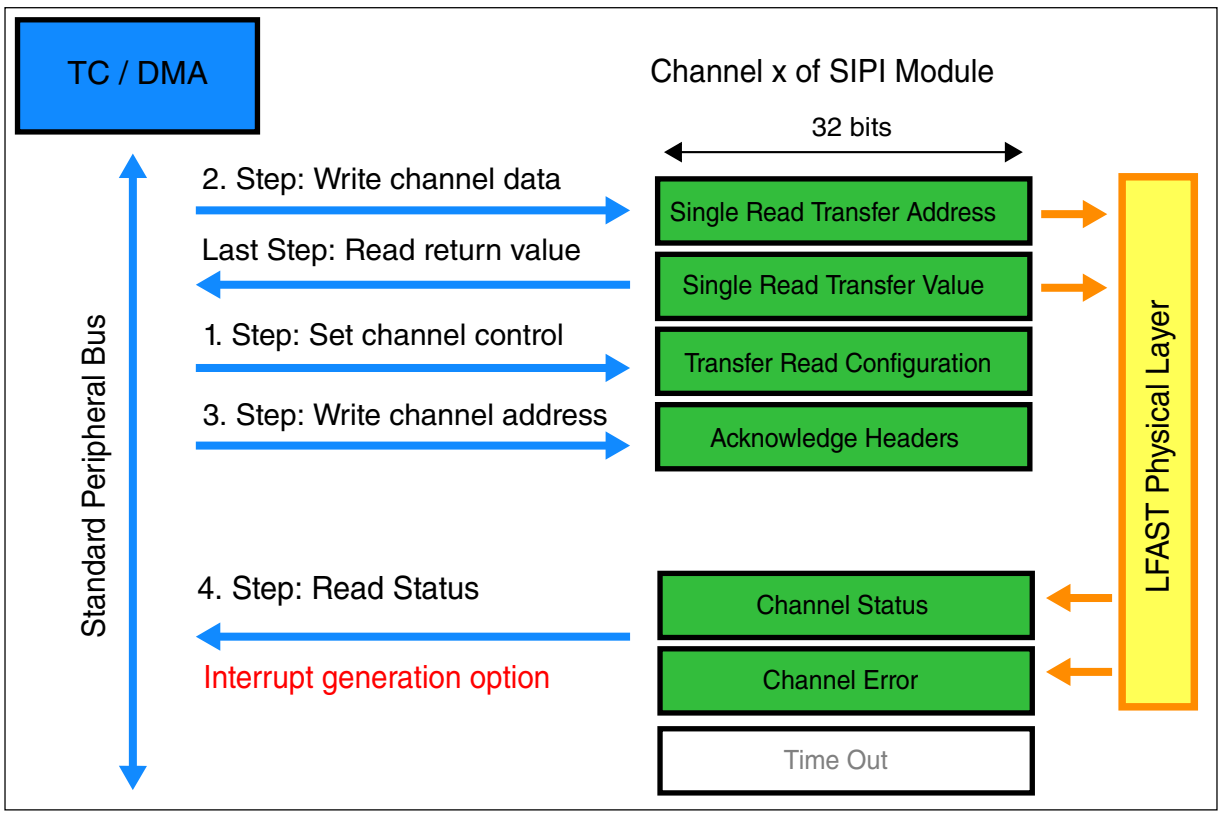

Figure 55-23. SIPI Single Register Read API

For Single Read Transfer Request generation (Figure 55-23):

1. Software/DMA will configure SIPI_CCR*n* and SIPI_CDR*n*, with the last step by writing CAR*n*.
2. As soon as SIPI_CAR is written, the initiator SIPI will calculate CRC of the header and address fields and start transmitting data to the LFAST.
3. Software should poll CSR*n* to determine when the request has completed. If SIPI_CSR*n*[RAR] = 1, an interrupt will be generated (if SIPI_CIR*n*[RAIE] = 1). If SIPI_CSR*n*[RAR] does not set then SIPI_ERR[TOE*n*] = 1 which indicates a timeout has occured.
4. If SIPI_CSR*n*[RAR] = 1 then software can read the data register, or can other necessary action if SIPI_CSR*n*[RAR] = 0.

On Single Read transfer request reception (Figure 55-23):

1. Target node will place the address and control information on its AHB Master Interface.
2. When the process in completed, target node will send read response back to LFAST.

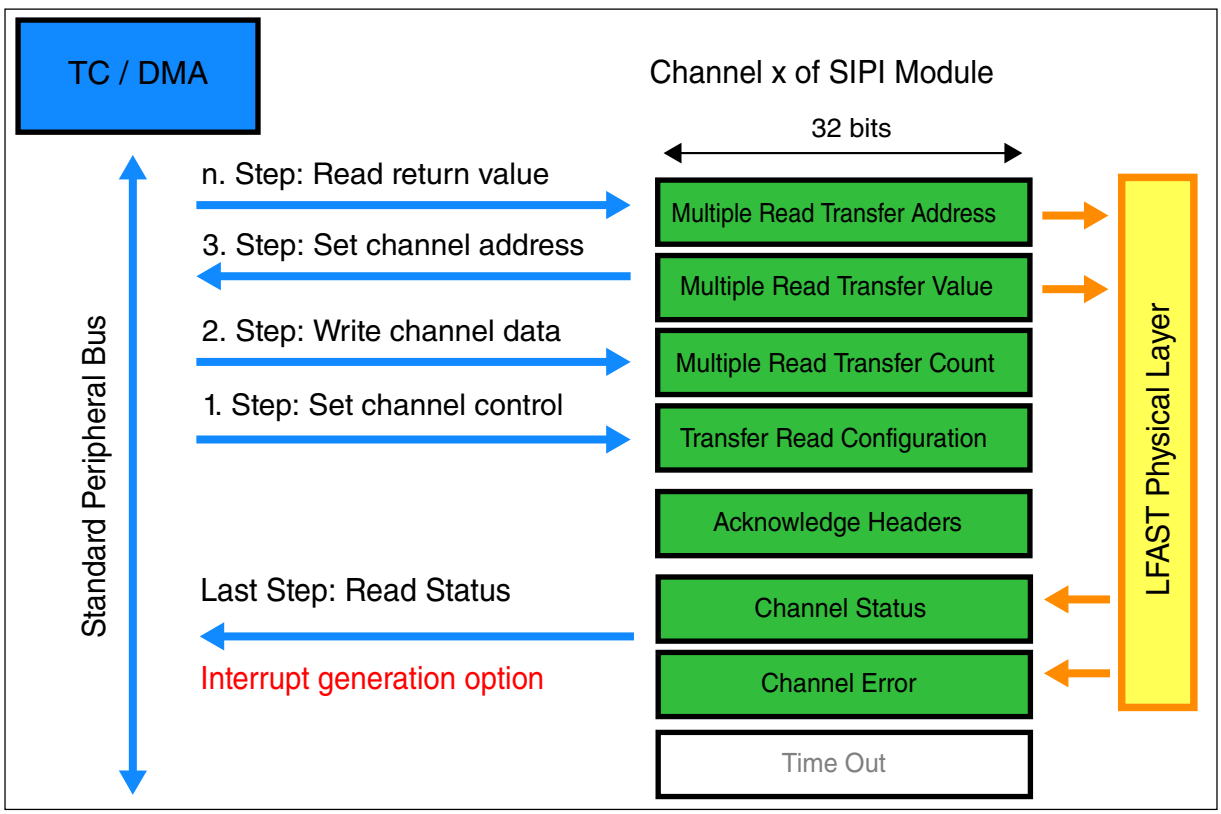

Figure 55-24. SIPI multiple register read API

For multiple read transfer request generation (Figure 55-24):

1. Software/DMA will configure SIPI_CCR*n* and SIPI_CDR*n*, with the last step by writing SIPI_CAR*n*.
2. As soon as channel address register is written, initiator SIPI will calculate CRC on the header and address fields, then starts transmitting data to the LFAST.
3. Software should poll SIPI_CSR*n* to determine when the request has completed. If SIPI_CSR*n*[RAR] = 1 and SIPI_CIR*n*[RAIE] = 1 an interrupt will be generated. If SIPI_CSR*n*[RAR] does not set, then SIPI_ERR[TOE*n*] = 1 which indicates a timeout.
4. Steps 2–3 will be repeated for multiple requests.

On Multiple Read transfer request reception (Figure 55-24):

1. Target node then will start reading data through its AHB interface.
2. When the transfer is completed/all data registers are full, it will calculate CRC and send the response frame back to LFAST.

NOTE

Read answer interrupt pins are also cleared by hardware in DMA transfers. This can lead the software in trouble where it tracks the requests by keep counting the number of times the interrupt was received and cleared.

Figure 55-25, Figure 55-26, Figure 55-27 and Figure 55-28 show the SIPI data streaming of data.

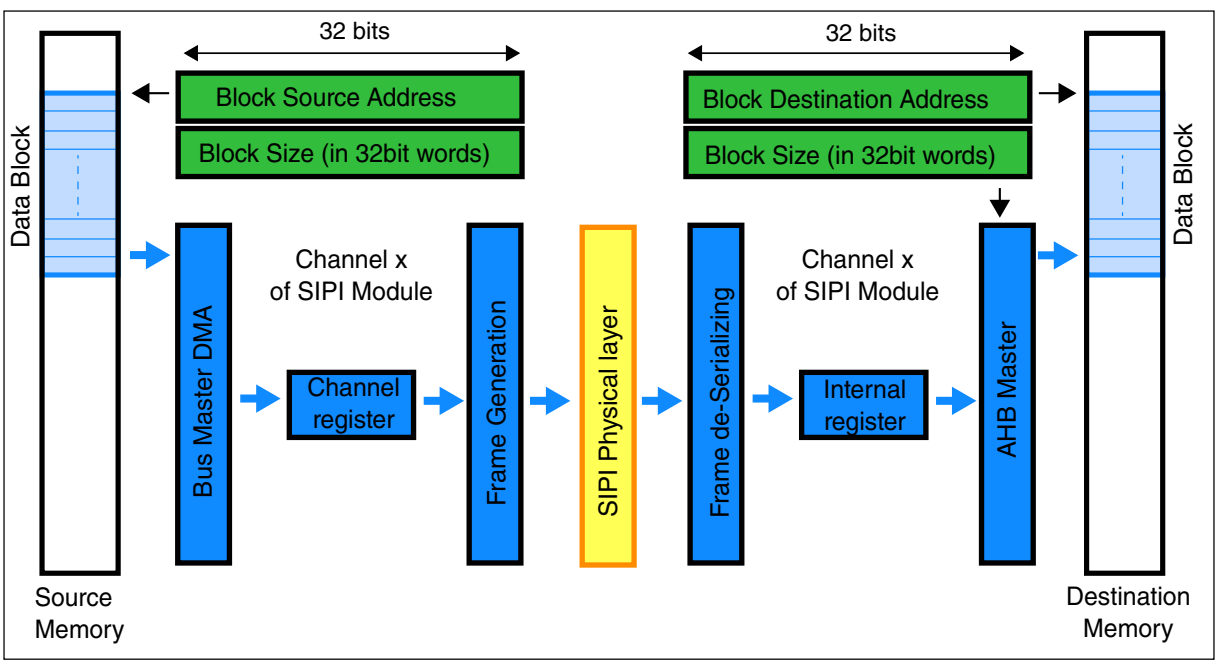

Figure 55-25. SIPI data stream model

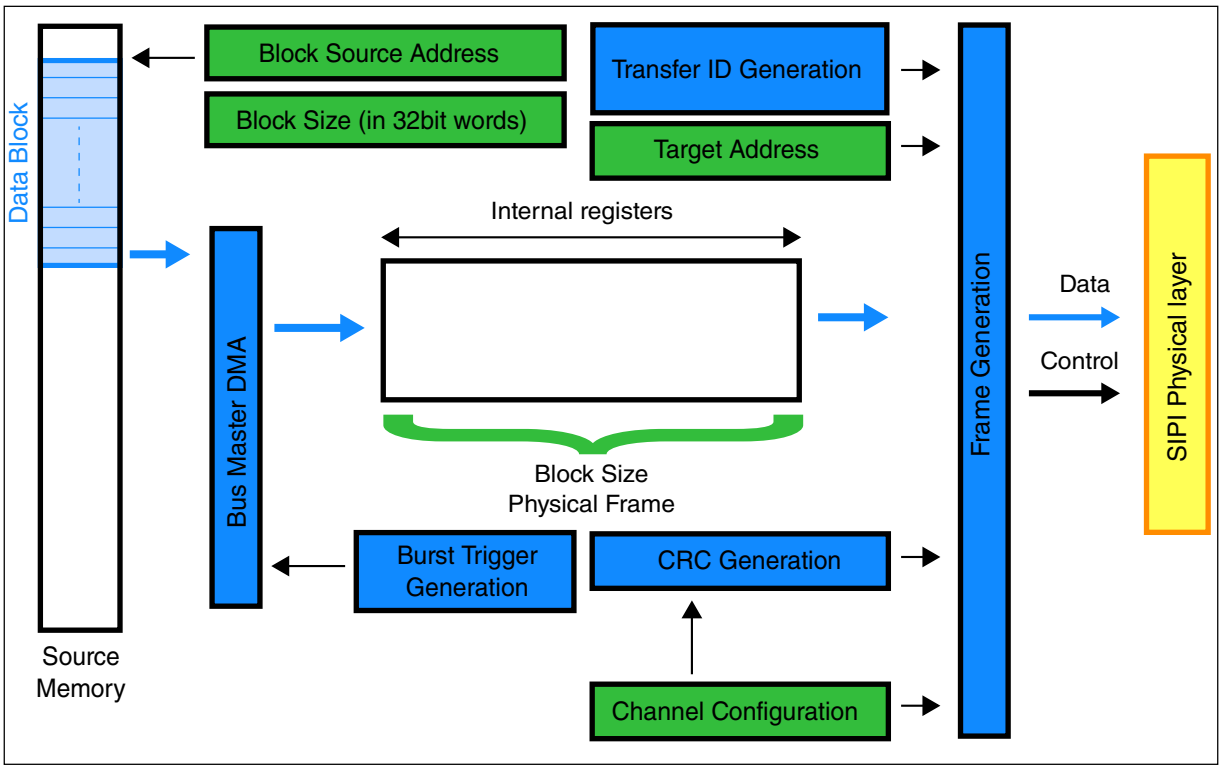

Figure 55-26. SIPI data stream model - Initiator

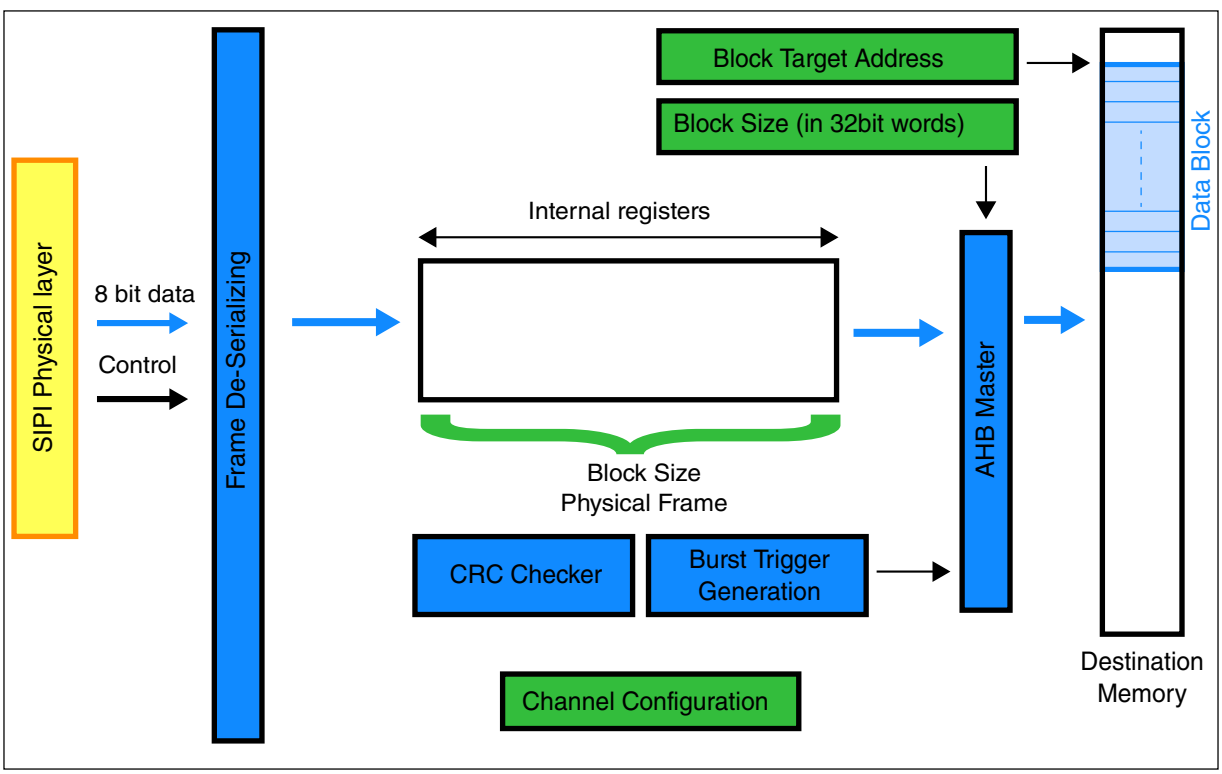

Figure 55-27. SIPI data stream model - Target

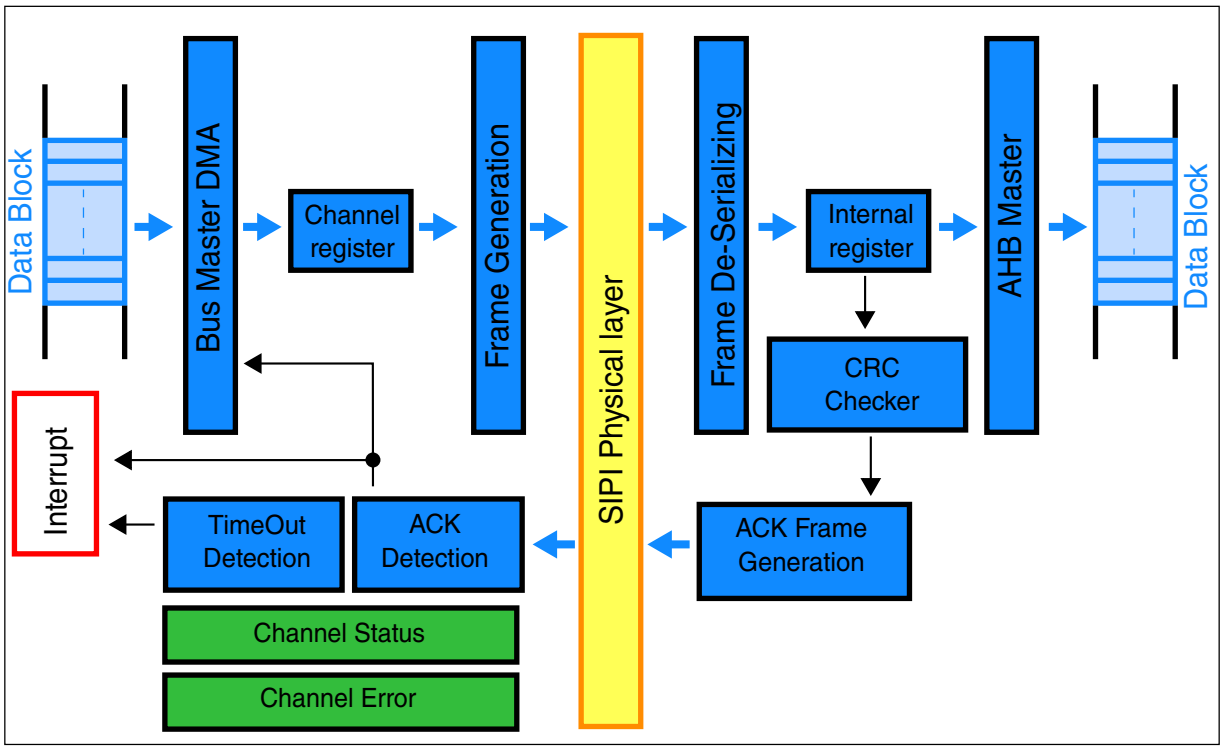

Figure 55-28. SIPI data stream with acknowledge trigger

55.9 DMA programming sequence

The DMA programming sequence is as follows:

1. Software configures TCD (DMA data).
2. DMA transfers from RAM to SIPI registers.
3. SIPI starts transferring the data through LFAST Tx ports.
4. If an acknowledge or fault response is received, SIPI will repeat the process. If any error response is received, SIPI will move to an idle state. An interrupt will be flagged by SIPI, and software will take control of the SIPI.
5. When SIPI receives read response and LFAST's error flags are not asserted, it initiates a DMA request. In case the LFAST asserts error flag, SIPI moves to step 8.
6. When SIPI initiates DMA request, the DMA transfers data between SIPI and RAM.
7. If DMA transfer minor loop/major loop is complete, and the request is negated, ipd_request is negated.
8. If an error occurs:

- The SIPI generates an interrupt
- Software takes control of the SIPI

9. Steps 5 – 8 are repeated until the transfer is finished.

55.10 Modes of operation

SIPI has three operating modes:

- Initialization
- Normal
- Module Disable

After hardware reset the SIPI is in module disable mode, which helps reduce power consumption.

55.10.1 Initialization mode

To enter Initialization mode software writes SIPI_MCR[INIT]=1 SIPI_MCR[MOEN] must be set before attempting to write SIPI_MCR[INIT]). To exit Initialization mode software writes SIPI_MCR[INIT]=0 (see SIPI Module Configuration Register (SIPI_MCR)).

Note

It is recommended that software checks the state of SIPI (SIPI_MCR[MOEN]) before setting SIPI_MCR[INIT].

55.10.2 Normal mode

Once software has completed initialization of SIPI (SIPI_MCR[INIT]=1), it can enter Normal mode by writing SIPI_MCR[INIT]=0. SIPI needs to be in Normal mode for all data transfers (see SIPI Module Configuration Register (SIPI_MCR)).

Note

SIPI must be enabled before a attempting to write SIPI_MCR[INIT] (SIPI_MCR[MOEN]=1).

55.10.3 Module Disable (MD)

MD mode in the SIPI is used to help reduce power consumption. By default, SIPI is in Disable mode, SIPI_MCR[MOEN]=0, and is exited by writing SIPI_MCR[MOEN]=1 (see SIPI Module Configuration Register (SIPI_MCR)). Future SIPI Tx transfers are disabled in Module Disable mode. To disable Rx functionality, the Target Enable (TEN) bit field has to be deasserted, then the internal Rx state machine resets to initial state.

55.11 Errors

This section describes the potential errors that can occur during SIPI operation.

55.11.1 Timeout error

A timeout error is generated at the initiator node when the acknowledge/response is not received within the time configured in the corresponding CTOR*n*[TOR] field setting (see SIPI Channel Timeout Register 0 (SIPI_CTOR0), SIPI Channel Timeout Register 1 (SIPI_CTOR1), SIPI Channel Timeout Register 2 (SIPI_CTOR2) and SIPI Channel Timeout Register 3 (SIPI_CTOR3)). A timeout error is indicated when ERR[TOE*n*]=1 (see SIPI Error Register (SIPI_ERR)).

Note

SIPI should not drop the response even after a timeout occurs. Software will poll both error and status flags after the transfer to see if there was a timeout error. If there was a timeout error the response received may then be discarded.

55.11.2 CRC error

A CRC error is generated at the target nodes when the CRC received with the frame does not match the calculated CRC, and the SR[GCRCE] is set (see SIPI Status Register (SIPI_SR)). An interrupt will be asserted if MCR[CRCIE]=1 (see SIPI Module Configuration Register (SIPI_MCR)).

Note

The target node will not send an acknowledge to the initiator node when a CRC error is generated. An interrupt will be generated on the target side if the corresponding interrupt

enable bit is set. The initiator node will detect a timeout and take necessary action.

55.11.3 Maximum count reached error

The maximum count reached error is only generated at the target node. It is generated when the value of the SIPI_ACR is equal to the SIPI_MAXCR (see SIPI Max Count Register (SIPI_MAXCR) and SIPI Address Count Register (SIPI_ACR)). When the maximum count is reached, SIPI_SR[MCR] = 1 (see SIPI Status Register (SIPI_SR)). An interrupt will be generated if SIPI_MCR[MCRIE] = 1 (see SIPI Module Configuration Register (SIPI_MCR)).

55.11.4 Transaction ID error

The Transaction ID (TID) error is always generated at the initiator node only. It is generated when header bits 15–13 do not match SIPI_CSR*n*[TID] (transaction ID bits, see SIPI Channel Status Register 0 (SIPI_CSR0), SIPI Channel Status Register 1 (SIPI_CSR1), SIPI Channel Status Register 2 (SIPI_CSR2), and SIPI Channel Status Register 3 (SIPI_CSR3)). SIPI_CSR*n*[TIDE] = 1 when a TID error is detected, and an interrupt will be generated if SIPI_CIR*n*[TIDIE] = 1 (see SIPI Channel Interrupt Register 0 (SIPI_CIR0), SIPI Channel Interrupt Register 1 (SIPI_CIR1), SIPI Channel Interrupt Register 2 (SIPI_CIR2), and SIPI Channel Interrupt Register 3 (SIPI_CIR3)).

55.11.5 Acknowledge error

An incorrect acknowledge is received only from the initiator. When the acknowledge received is incorrect, SIPI_ERR[ACKR*n*] will be set (see SIPI Error Register (SIPI_ERR)). An interrupt will be generated if SIPI_CIR*n*[WAIE]=1 (see SIPI Channel Interrupt Register 0 (SIPI_CIR0), SIPI Channel Interrupt Register 1 (SIPI_CIR1), SIPI Channel Interrupt Register 2 (SIPI_CIR2), and SIPI Channel Interrupt Register 3 (SIPI_CIR3)).

55.12 CRC calculation

Example: If header is AABBh, address is 1122_3344h and data is CCDD_EEFFh. Then CRC calculation will take place as follows:

1) The CRC seed is initialized by FFFF_FFFFh.

2) All the data will be mirrored before sending to CRC engine (for example, MSB will be sent as LSB).

3) So the header will be sent as DD55_0000h.

4) Address will be sent as 22CC_4488h.

5) Data will be sent as FF77_BB33h.

55.13 Interrupt logic

A description of the interrupt logic can be found in the following figure.

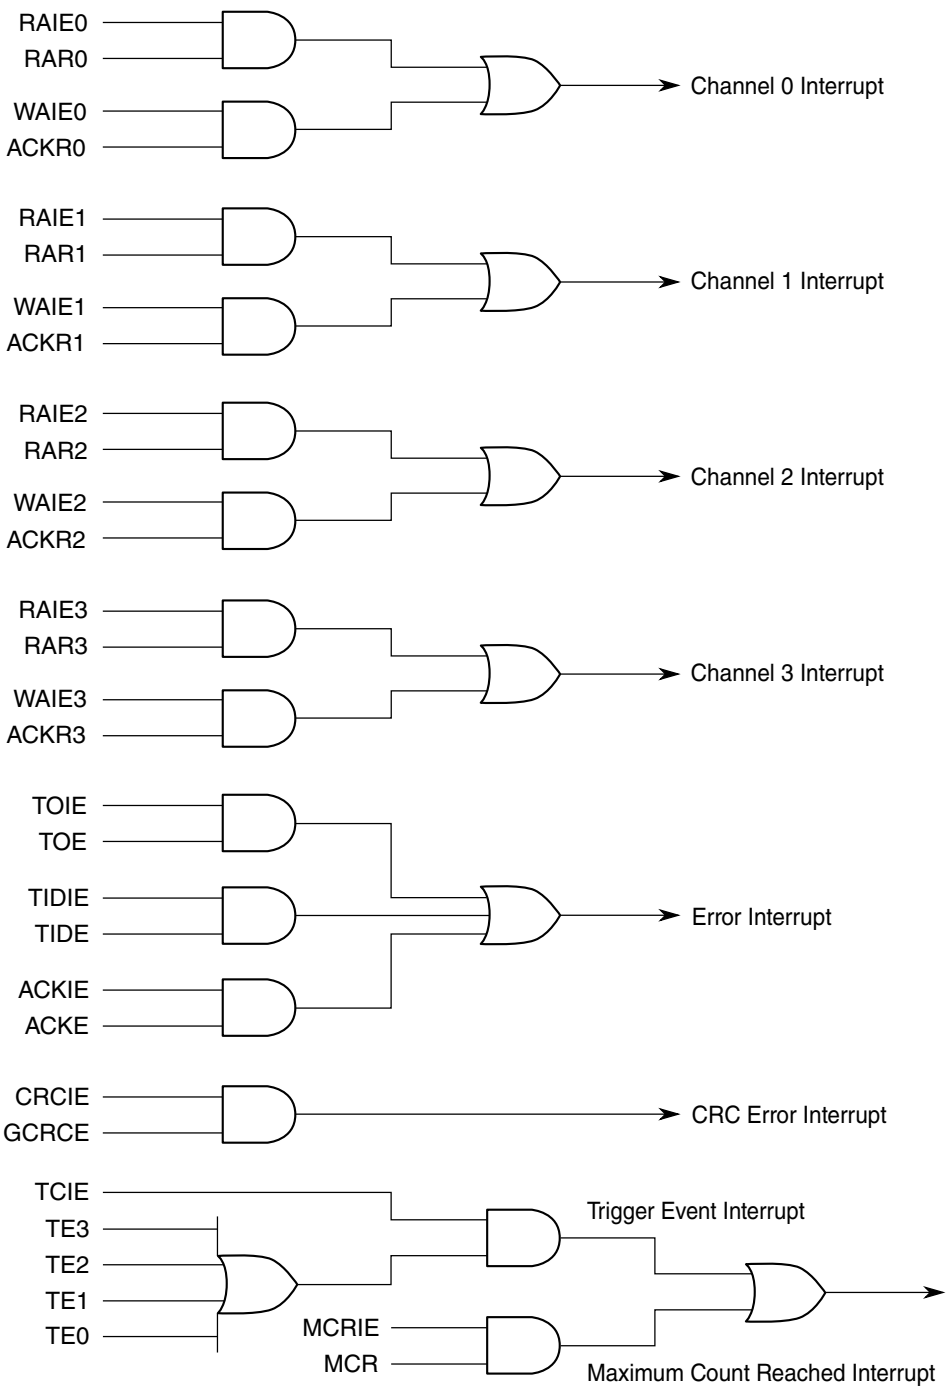

Figure 55-29. Interrupt description

55.14 SIPI control and status overview

The diagram below shows the relationship between transfers and the SIPI control and status registers.

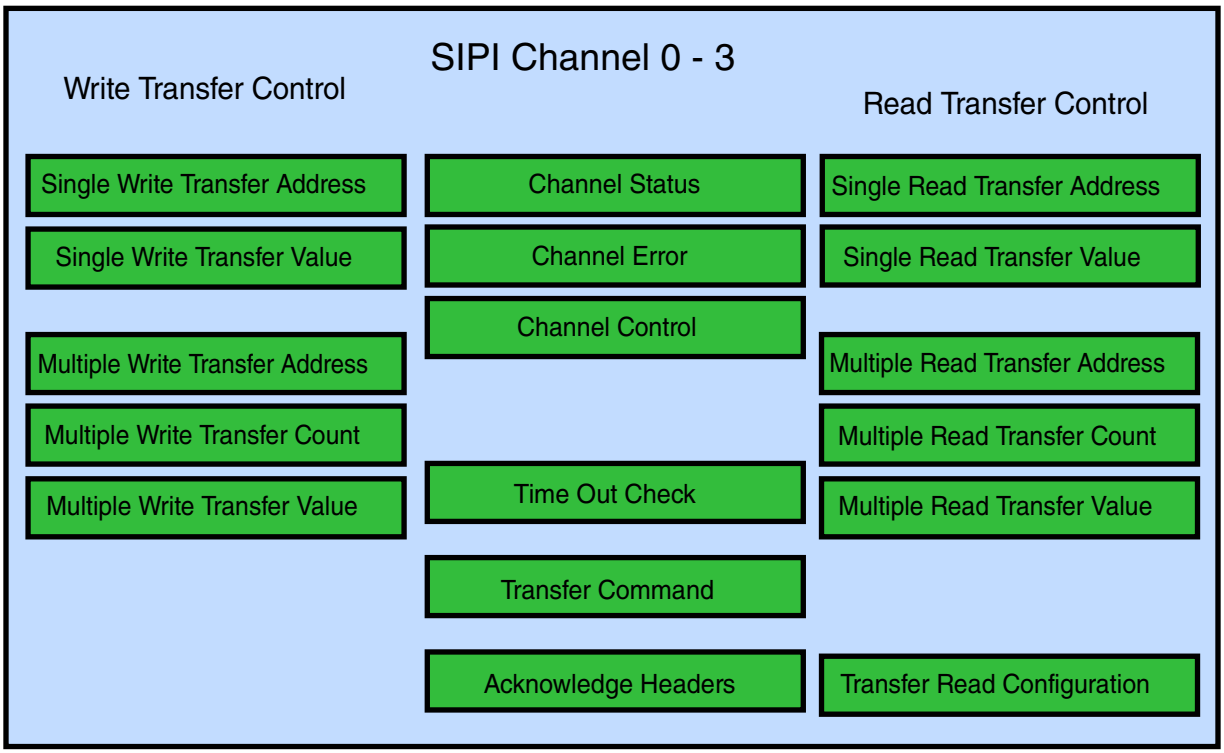

Figure 55-30. SIPI control and status overview – Register transfer

55.15 Memory map and register definition

SIPI memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	SIPI Channel Control Register 0 (SIPI_CCR0)	32	R/W	0000_0000h	55.15.1/ 2543

55.15.1 SIPI Channel Control Register 0 (SIPI_CCR0)

NOTE

Back to back transactions are not supported on a single channel (for example, if the channel busy bit, SIPI_CSR0[CB] = 1, is configured for a channel, it cannot be triggered for another transfer until the data buffers are empty and the channel is free, SIPI_CSR0[CB] = 0).

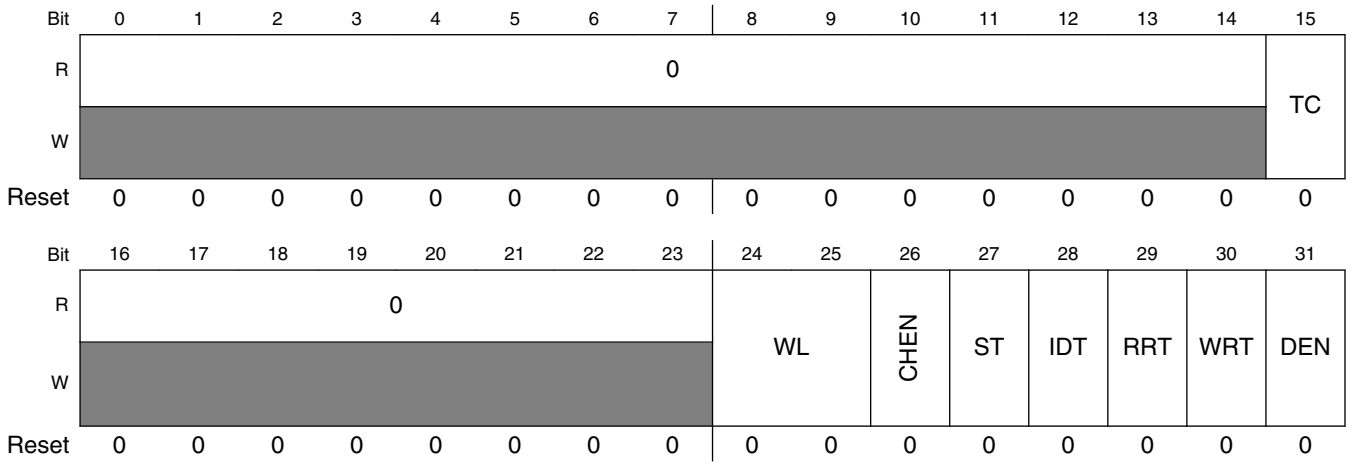
PRIORITY SCHEDULING: The channel whose SIPI_CAR*n* is written first will gain access first irrespective of its priority at the start of the transfer. As more transfers are requested, priority will be resolved as per the priority scheme (for example, channel 0 – channel 1 – channel 2 – channel 3). Scheduling will occur each time the LFAST is not ready to receive data and no channel is pending for data transmission. The reason for the scheduling is that a common CRC module is shared by all channels. If the LFAST is ready to receive data during the entire process, it will happen only in the beginning and later on priority will be resolved as per the priority scheme.

NOTE

This register is only writable in Initialization mode (SIPI_MCR[INIT] = 1), except for command bits (for example, TC, WL, ST, IDT, RRT and WRT). Also, the command bits can be written only when the corresponding Channel busy bit is not asserted (SIPI_CSR*n*[CB] = 1 (see SIPI Channel Status Register 0 (SIPI_CSR0)). Software will need to poll the respective channel busy bits before attempting to change the command type.

Only one channel at a time can transmit. Therefore, only one channel can remain busy. Maximum time allowed to transmit a full command is nine clock cycles. The Command type of a channel can only be changed when it is no longer busy. Also, to send a command, we need to write to the corresponding SIPI_CAR*n* (see SIPI Channel Address Register 0 (SIPI_CAR0)).

Address: 0h base + 0h offset = 0h



SIPI_CCR0 field descriptions

Field	Description
0–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 TC	Send Trigger Command. A Trigger Command requires that only this bit to be set by software, the trigger does not depend on settings in SIPI_CAR0. 0 Trigger command not sent 1 Trigger command sent
16–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–25 WL	Word Length Transfer. For Streaming write, WL bits should be written 10. 00 8-bit 01 16-bit 10 32-bit 11 not used
26 CHEN	Channel Enable. If all channel enables are simultaneously written to enable the channels, channel 0 will be given the highest priority for transmission. For channels, the lowest channel number is given highest priority. 0 Channel is disabled 1 Channel is enabled
27 ST	Streaming Transfer. This bit is hard-coded to 0. It can only be written for channel 2 (SIPI_CCR2). This bit can only be written when the corresponding SIPI_CCR*n*[WRT] = 1. **NOTE:** Only transfers with channel 2 can write 1 to this bit. All other channels force SIPI_CCR*n*[ST] = 0. The SIPI_CCR2[WRT] and SIPI_CCR2[ST] bits must be set for streaming.

Table continues on the next page...

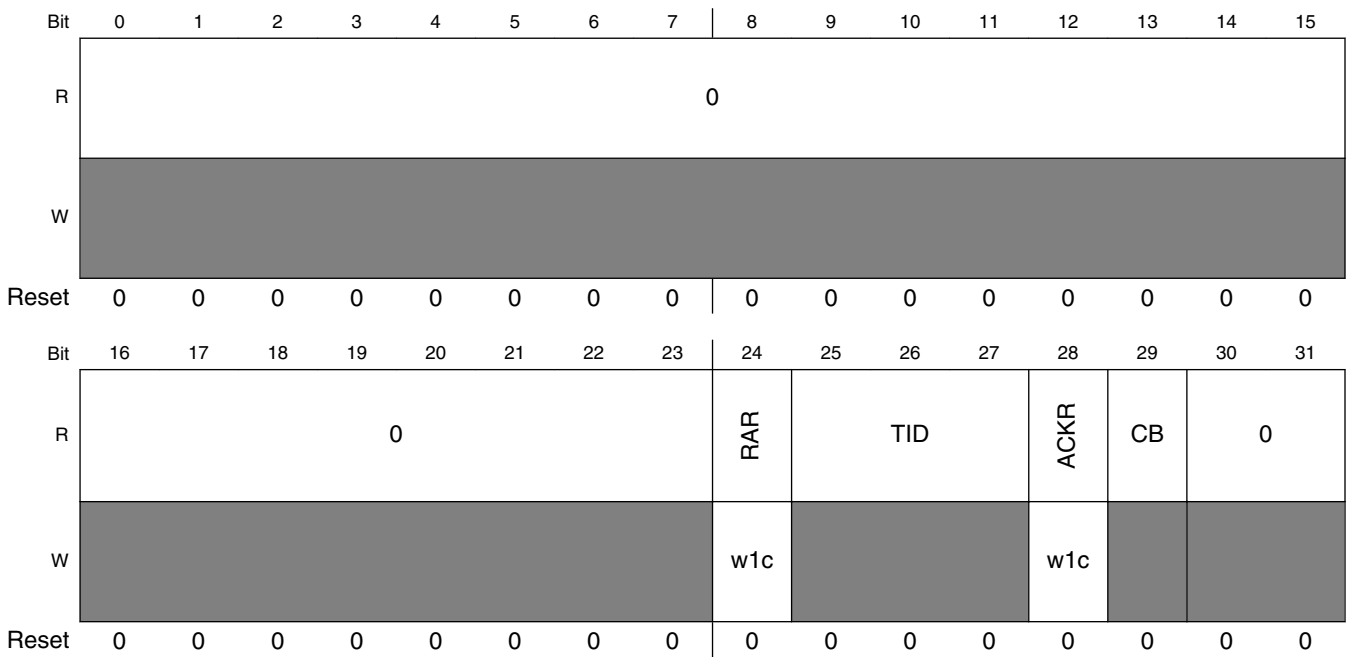
SIPI_CCR0 field descriptions (continued)

Field	Description
	0 Streaming transfer is disabled 1 Streaming transfer is enabled
28 IDT	ID Read Request Transfer. This request returns the value of the CHIP ID. **NOTE:** The order of priority for writing to IDT, WRT and RRT must be in this order: 1. IDT 2. RRT 3. WRT 0 ID read request not sent 1 ID read request sent
29 RRT	Read Request Transfer. **NOTE:** The order of priority for writing to IDT, WRT and RRT must be in this order: 1. IDT 2. RRT 3. WRT 0 Read request will not be sent 1 Read request transfer by the initiator. This bit can not be written if SIPI_CCR0[IDT] = 1.
30 WRT	Write Request Transfer. **NOTE:** The order of priority for writing to IDT, WRT and RRT must be in this order: 1. IDT 2. RRT 3. WRT 0 No write request will be sent 1 Write request transfer by the initiator. This bit can not be written if SIPI_CCR0[IDT] = 1 or SIPI_CCR0[RRT] = 1.
31 DEN	DMA Enable. When enabling DMA mode, this bit should be set by software. It will then be cleared by hardware after one major loop has completed. 0 Channel will be used for bus interface access. 1 Channel will be used for DMA access

55.15.2 SIPI Channel Status Register 0 (SIPI_CSR0)

CSR0 contains the status bits for the current transfer.

Address: 0h base + 4h offset = 4h



SIPI_CSR0 field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 RAR	Read Answer Reception. 0 Read answer not received 1 Read answer received
25–27 TID	Transaction ID of transmitted frame. Transaction ID is a random number associated with every Tx frame to match the received response/ack with the command.
28 ACKR	Acknowledge Received. 0 Acknowledge not received 1 Acknowledge received
29 CB	Channel Busy. Indicates channel 0 status. 0 Channel 0 free 1 Channel 0 busy

Table continues on the next page...

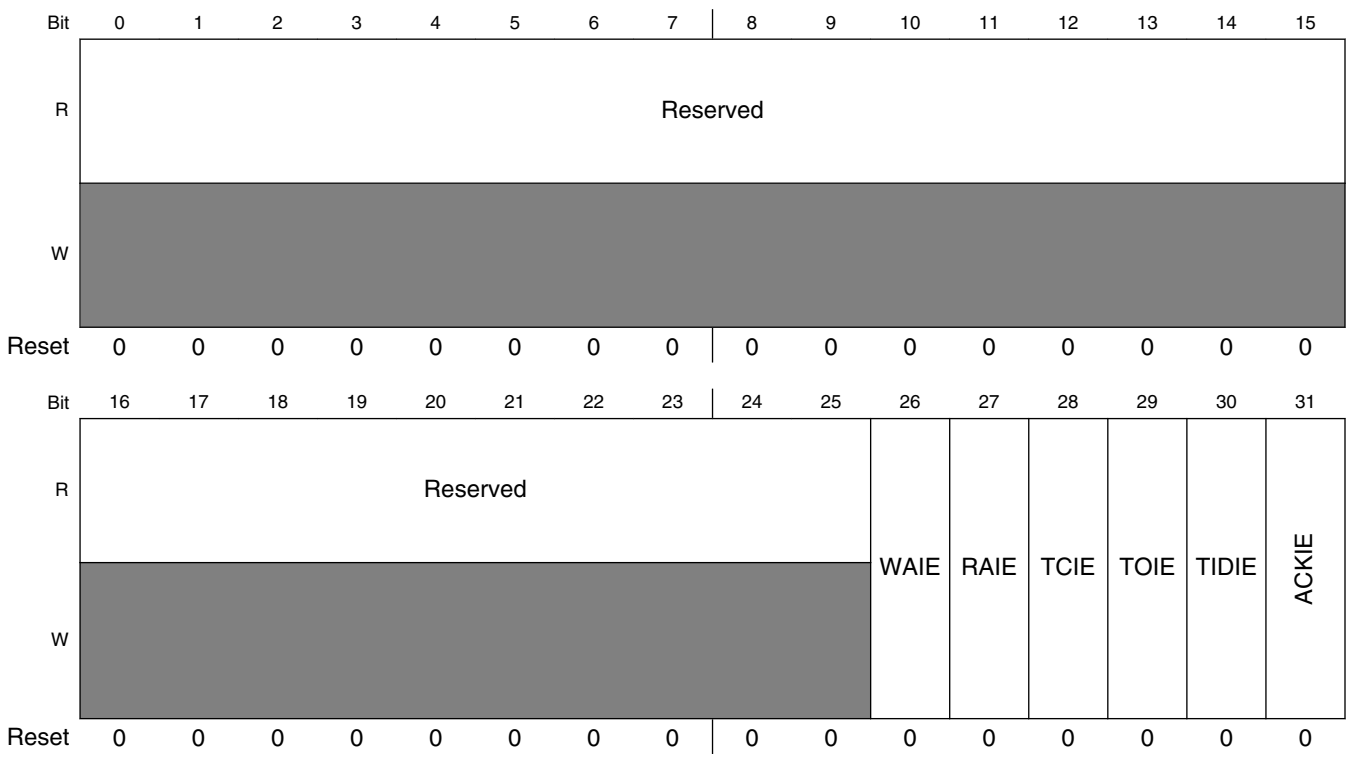
SIPI_CSR0 field descriptions (continued)

Field	Description
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

55.15.3 SIPI Channel Interrupt Register 0 (SIPI_CIR0)

SIPI_CIR0 contains the interrupt enable bits for channel 0.

Address: 0h base + Ch offset = Ch



SIPI_CIR0 field descriptions

Field	Description
0–25 Reserved	This field is reserved.
26 WAIE	Write Acknowledge Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled
27 RAIE	Read Answer Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled

Table continues on the next page...

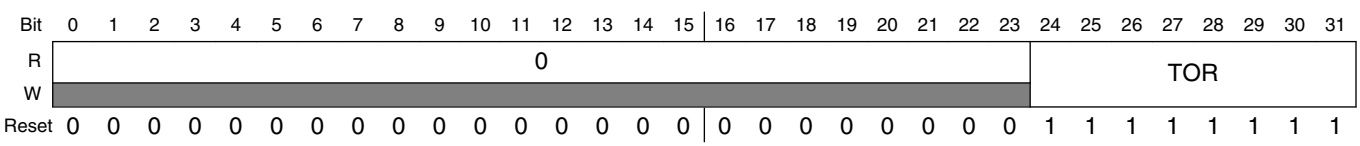
SIPI_CIR0 field descriptions (continued)

Field	Description
28 TCIE	Trigger Command Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled
29 TOIE	Timeout Error Interrupt Enabled. 0 Interrupt is disabled 1 Interrupt is enabled
30 TIDIE	Transaction ID Error Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled
31 ACKIE	Acknowledge Error Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled

55.15.4 SIPI Channel Timeout Register 0 (SIPI_CTOR0)

SIPI_CTOR0 contains the timeout value for Tx requests.

Address: 0h base + 10h offset = 10h



SIPI_CTOR0 field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 TOR	Timeout value for transmitted requests. Timeout counter runs on the prescaled peripheral clock. Prescaler is defined by SIPI_MCR[PRSCLR]. **NOTE:** Field can only be written during Initialization mode (SIPI_MCR[INIT] = 1).

55.15.5 SIPI Channel CRC Register 0 (SIPI_CCRC0)

SIPI_CCRC*n* is a read only which returns the CRC calculated value on the header, address and data bits.

Address: 0h base + 14h offset = 14h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	CRCI																CRCT															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SIPI_CCRC0 field descriptions

Field	Description
0–15 CRCI	Reflects received CRC value at initiator
16–31 CRCT	Reflects received CRC value at target

55.15.6 SIPI Channel Address Register 0 (SIPI_CAR0)

SIPI_CAR0 is the address target for data transmission.

Address: 0h base + 18h offset = 18h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	CAR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SIPI_CAR0 field descriptions

Field	Description
0–31 CAR	These bits contain the address of the target node.

55.15.7 SIPI Channel Data Register 0 (SIPI_CDR0)

SIPI_CDR0 contains the data to be transmitted, and can be written anytime by software or the DMA. The data can be written in 8, 16 or 32 bit formats.

Address: 0h base + 1Ch offset = 1Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	CDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SIPI_CDR0 field descriptions

Field	Description
0–31 CDR	Data register bits. Contains the data that will be transmitted, or received.

55.15.8 SIPI Channel Control Register 1 (SIPI_CCR1)

NOTE

Back to back transactions are not supported on a single channel (for example, if the channel busy bit, SIPI_CSR1[CB] = 1, is configured for a channel, it cannot be triggered for another transfer until the data buffers are empty and the channel is free, SIPI_CSR1[CB] = 0).

PRIORITY SCHEDULING: The channel whose SIPI_CAR*n* is written first will gain access first irrespective of its priority at the start of the transfer. As more transfers are requested, priority will be resolved as per the priority scheme (for example, channel 0 – channel 1 – channel 2 – channel 3). Scheduling will occur each time the LFAST is not ready to receive data and no channel is pending for data transmission. The reason for the scheduling is that a common CRC module is shared by all channels. If the LFAST is ready to receive data during the entire process, it will happen only in the beginning and later on priority will be resolved as per the priority scheme.

NOTE

This register is only writable in Initialization mode (SIPI_MCR[INIT] = 1), except for command bits (for example, TC, WL, ST, IDT, RRT and WRT). Also, the command bits can be written only when the corresponding Channel busy bit is not asserted (SIPI_CSR*n*[CB] = 1 (see SIPI Channel Status Register 1 (SIPI_CSR1)). Software will need to poll the respective channel busy bits before attempting to change the command type.

Only one channel at a time can transmit. Therefore, only one channel can remain busy. Maximum time allowed to transmit a full command is nine clock cycles. The Command type of a channel can only be changed when it is no longer busy. Also, to send a command, we need to write to the corresponding SIPI_CAR*n* (see SIPI Channel Address Register 1 (SIPI_CAR1)).

15 TC	Send Trigger Command. A Trigger Command requires that only this bit to be set by software, the trigger does not depend on settings in SIPI_CAR1. 0 Trigger command not sent 1 Trigger command sent

Table continues on the next page...

SIPI_CCR1 field descriptions (continued)

Field	Description
16–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–25 WL	Word Length Transfer. For Streaming write WL bits should be written 10. 00 8-bit 01 16-bit 10 32-bit 11 not used
26 CHEN	Channel Enable. If all channel enables are simultaneously written to enable the channels, channel 0 will be given the highest priority for transmission. For channels, the lowest channel number is given highest priority. 0 Channel is disabled 1 Channel is enabled
27 ST	This bit is hard-coded to 0. It can only be written for channel 2 (SIPI_CCR2). This bit can only be written when the corresponding SIPI_CCR*n*[WRT] = 1. **NOTE:** Only transfers with channel 2 can write 1 to this bit. All other channels force SIPI_CCR*n*[ST] = 0. The SIPI_CCR2[WRT] and SIPI_CCR2[ST] bits must be set for streaming. 0 Streaming transfer is disabled 1 Streaming transfer is enabled
28 IDT	ID Read Request Transfer. This request returns the value of the CHIP ID. **NOTE:** The order of priority for writing to IDT, WRT and RRT must be in this order: 1. IDT 2. RRT 3. WRT 0 ID read request not sent 1 ID read request sent
29 RRT	Read Request Transfer. **NOTE:** The order of priority for writing to IDT, WRT and RRT must be in this order: 1. IDT 2. RRT 3. WRT 0 Read request will not be sent 1 Read request transfer by the initiator. This bit can not be written if SIPI_CCR1[IDT] = 1.
30 WRT	Write Request Transfer. **NOTE:** The order of priority for writing to IDT, WRT and RRT must be in this order: 1. IDT 2. RRT 3. WRT

Table continues on the next page...

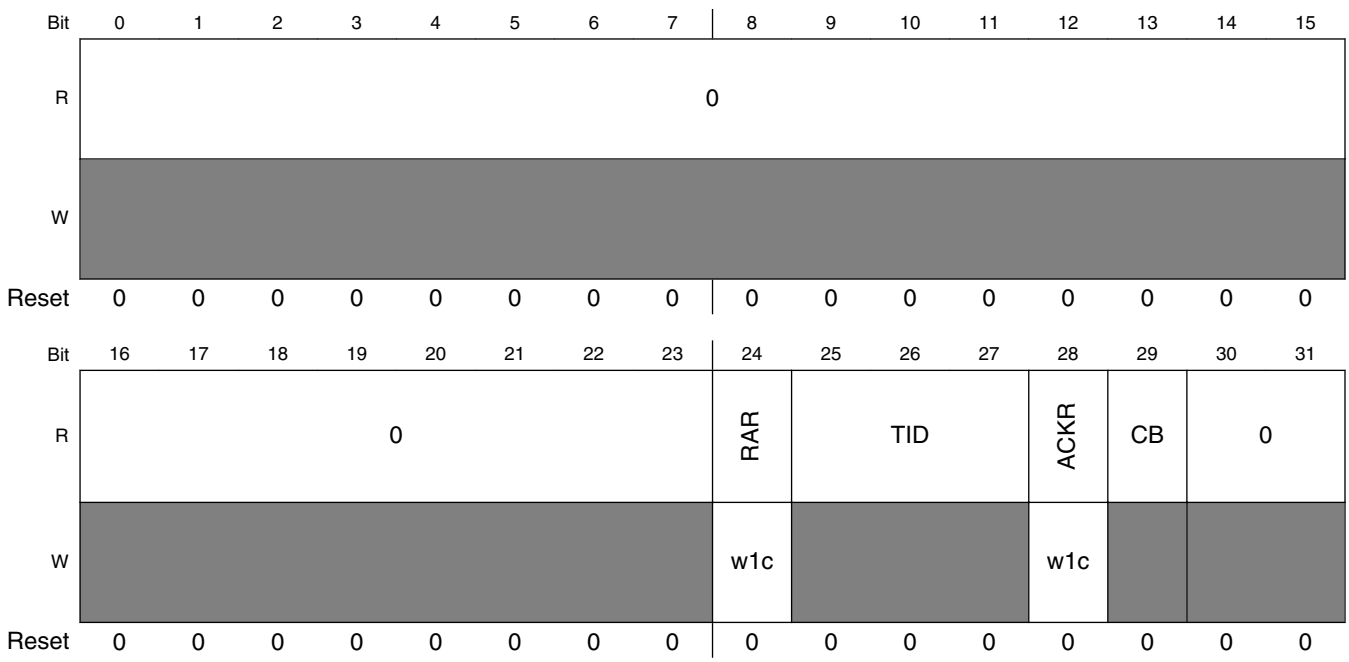
SIPI_CCR1 field descriptions (continued)

Field	Description
	0 No write request will be sent 1 Write request transfer by the initiator. This bit can not be written if SIPI_CCR1[IDT] = 1 or SIPI_CCR1[RRT] = 1.
31 DEN	DMA Enable. When enabling DMA mode, this bit should be set by software. It will then be cleared by hardware after one major loop has completed. 0 Channel will be used for bus interface access. 1 Channel will be used for DMA access

55.15.9 SIPI Channel Status Register 1 (SIPI_CSR1)

CSR1 contains the status bits for the current transfer.

Address: 0h base + 24h offset = 24h



SIPI_CSR1 field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 RAR	Read Answer Reception.

Table continues on the next page...

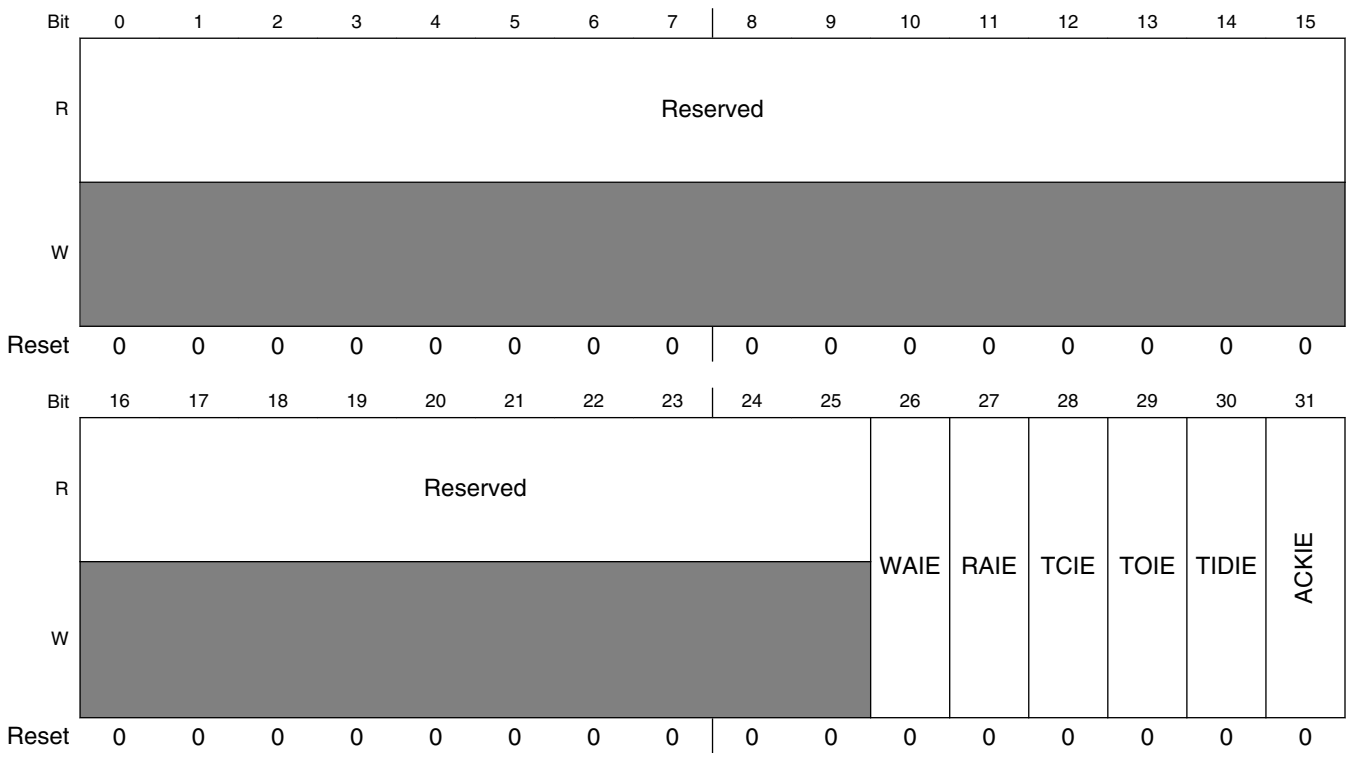
SIPI_CSR1 field descriptions (continued)

Field	Description
	0 Read answer not received 1 Read answer received
25–27 TID	Transaction ID of transmitted frame. Transaction ID is a random number associated with every Tx frame to match the received response/ack with the command.
28 ACKR	Acknowledge Received. 0 Acknowledge not received 1 Acknowledge received
29 CB	Channel Busy. Indicates channel 1 status. 0 Channel 1 free 1 Channel 1 busy
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

55.15.10 SIPI Channel Interrupt Register 1 (SIPI_CIR1)

The CIR1 contains the interrupt enable bits for channel 1.

Address: 0h base + 2Ch offset = 2Ch



SIPI_CIR1 field descriptions

Field	Description
0–25 Reserved	This field is reserved.
26 WAIE	Write Acknowledge Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled
27 RAIE	Read Answer Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled

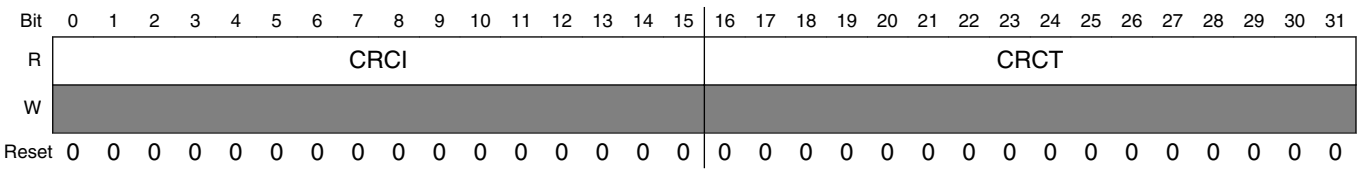
SIPI_CTOR1 field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 TOR	Timeout value for transmitted requests. Timeout counter runs on the prescaled peripheral clock. Prescaler is defined by SIPI_MCR[PRSCLR]. **NOTE:** Field can only be written during Initialization mode (SIPI_MCR[INIT] = 1).

55.15.12 SIPI Channel CRC Register 1 (SIPI_CCRC1)

SIPI_CCRC*n* is a read only which returns the CRC calculated value on the header, address and data bits.

Address: 0h base + 34h offset = 34h



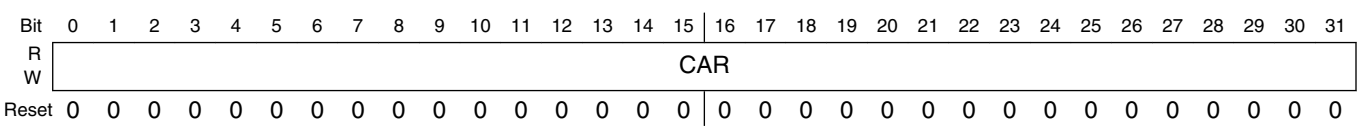
SIPI_CCRC1 field descriptions

Field	Description
0–15 CRCI	Reflects received CRC value at initiator
16–31 CRCT	Reflects received CRC value at target

55.15.13 SIPI Channel Address Register 1 (SIPI_CAR1)

SIPI_CAR1 is the address target for data transmission.

Address: 0h base + 38h offset = 38h



SIPI_CAR1 field descriptions

Field	Description
0–31 CAR	These bits contain the address of the target node.

55.15.14 SIPI Channel Data Register 1 (SIPI_CDR1)

SIPI_CDR1 contains the data to be transmitted, and can be written anytime by software or the DMA. The data can be written in 8, 16 or 32 bit formats.

Address: 0h base + 3Ch offset = 3Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

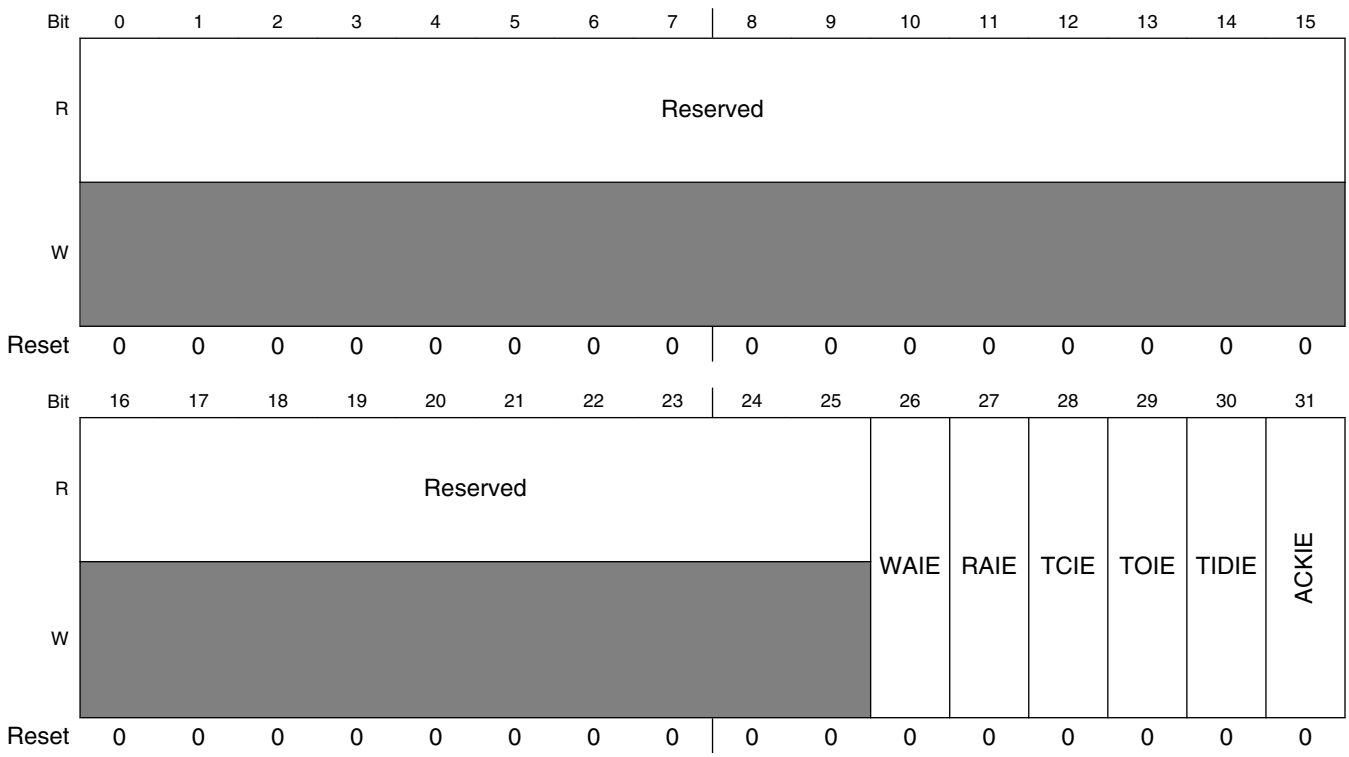
25–27 TID	Transaction ID of transmitted frame. Transaction ID is a random number associated with every Tx frame to match the received response/ack with the command.
28 ACKR	Acknowledge Received. 0 Acknowledge not received 1 Acknowledge received
29 CB	Channel Busy. Indicates channel 2 status. 0 Channel 2 free 1 Channel 2 busy
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

55.15.17 SIPI Channel Interrupt Register 2 (SIPI_CIR2)

The SIPI_CIR2 contains the interrupt enable bits for channel 2.

Address: 0h base + 4Ch offset = 4Ch



SIPI_CIR2 field descriptions

Field	Description
0–25 Reserved	This field is reserved.
26 WAIE	Write Acknowledge Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled
27 RAIE	Read Answer Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled
28 TCIE	Trigger Command Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled
29 TOIE	Timeout Error Interrupt Enabled.

Table continues on the next page...

SIPI_CIR2 field descriptions (continued)

Field	Description
	0 Interrupt is disabled 1 Interrupt is enabled
30 TIDIE	Transaction ID Error Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled
31 ACKIE	Acknowledge Error Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled

55.15.18 SIPI Channel Timeout Register 2 (SIPI_CTOR2)

SIPI_CTOR2 contains the timeout value for Tx requests.

Address: 0h base + 50h offset = 50h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1

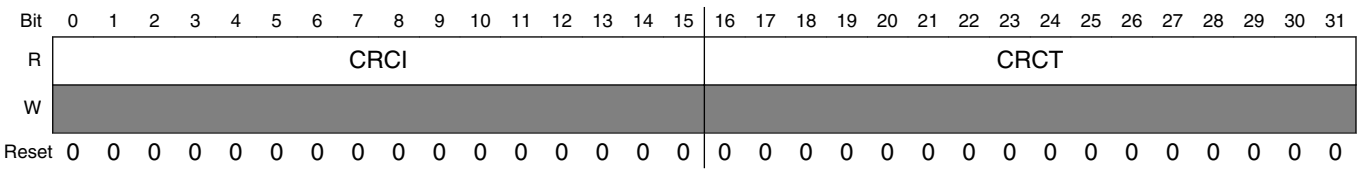
SIPI_CTOR2 field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 TOR	Timeout counter runs on the prescaled peripheral clock. Prescaler is defined by SIPI_MCR[PRSCLR]. **NOTE:** Field can only be written during Initialization mode (SIPI_MCR[INIT] = 1).

55.15.19 SIPI Channel CRC Register 2 (SIPI_CCRC2)

SIPI_CCRC*n* is a read only which returns the CRC calculated value on the header, address and data bits.

Address: 0h base + 54h offset = 54h



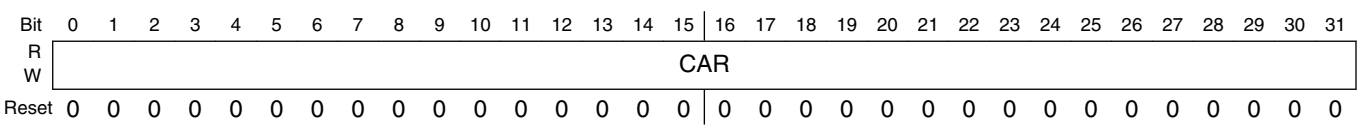
SIPI_CCRC2 field descriptions

Field	Description
0–15 CRCI	Reflects received CRC value at initiator
16–31 CRCT	Reflects received CRC value at target

55.15.20 SIPI Channel Address Register 2 (SIPI_CAR2)

SIPI_CAR2 is the address target for data transmission. For streaming operations this register is the start address.

Address: 0h base + 58h offset = 58h



SIPI_CAR2 field descriptions

Field	Description
0–31 CAR	These bits contain the address of the target node.

55.15.21 SIPI Channel Data Register 2 (SIPI_CDR2_*n*)

SIPI_CDR2_*n*contains the data to be transmitted, and can be written anytime by software or the DMA. The data can be written in 8, 16 or 32 bit formats.

Address: 0h base + 5Ch offset + (4d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	CDR2																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SIPI_CDR2_*n* field descriptions

Field	Description
0–31 CDR2	Data register bits. Contains the data that will be transmitted, or received.

55.15.22 SIPI Channel Control Register 3 (SIPI_CCR3)

NOTE

Back to back transactions are not supported on a single channel (for example, if the channel busy bit, SIPI_CSR3[CB] = 1, is configured for a channel, it cannot be triggered for another transfer until the data buffers are empty and the channel is free, SIPI_CSR3[CB] = 0).

PRIORITY SCHEDULING: The channel whose SIPI_CAR*n* is written first will gain access first irrespective of its priority at the start of the transfer. As more transfers are requested, priority will be resolved as per the priority scheme (for example, channel 0 – channel 1 – channel 2 – channel 3). Scheduling will occur each time the LFAST is not ready to receive data and no channel is pending for data transmission. The reason for the scheduling is that a common CRC module is shared by all channels. If the LFAST is ready to receive data during the entire process, it will happen only in the beginning and later on priority will be resolved as per the priority scheme.

NOTE

This register is only writable in Initialization mode (SIPI_MCR[INIT] = 1), except for command bits (for example, TC, WL, ST, IDT, RRT and WRT). Also, the command bits can be written only when the corresponding Channel busy bit is not asserted (SIPI_CSR*n*[CB] = 1 (see SIPI Channel Status Register 3 (SIPI_CSR3)). Software will need to poll the respective channel busy bits before attempting to change the command type.

Only one channel at a time can transmit. Therefore, only one channel can remain busy. Maximum time allowed to transmit a full command is nine clock cycles. The Command type of a channel can only be changed when it is no longer busy. Also, to send a command, we need to write to the corresponding SIPI_CAR*n* (see SIPI Channel Address Register 3 (SIPI_CAR3)).

Address: 0h base + 7Ch offset = 7Ch

SIPI_CCR3 field descriptions

Field	Description
0–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 TC	Send Trigger Command. A Trigger Command requires that only this bit to be set by software, the trigger does not depend on settings in SIPI_CAR3. 0 Trigger command not sent 1 Trigger command sent

Table continues on the next page...

SIPI_CCR3 field descriptions (continued)

Field	Description
16–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–25 WL	Word Length Transfer. For Streaming write WL bits should be written 10. 00 8-bit 01 16-bit 10 32-bit 11 not used
26 CHEN	Channel Enable. If all channel enables are simultaneously written to enable the channels, channel 0 will be given the highest priority for transmission. For channels, the lowest channel number is given highest priority. 0 Channel is disabled 1 Channel is enabled
27 ST	Streaming Transfer. This bit is hard-coded to 0. It can only be written for channel 2 (SIPI_CCR2). This bit can only be written when the corresponding SIPI_CCR*n*[WRT] = 1. **NOTE:** Only transfers with channel 2 can write 1 to this bit. All other channels force SIPI_CCR*n*[ST] = 0. The SIPI_CCR2[WRT] and SIPI_CCR2[ST] bits must be set for streaming. 0 Streaming transfer is disabled 1 Streaming transfer is enabled
28 IDT	ID Read Request Transfer. This request returns the value of the CHIP ID. **NOTE:** The order of priority for writing to IDT, WRT and RRT must be in this order: 1. IDT 2. RRT 3. WRT 0 ID read request not sent 1 ID read request sent
29 RRT	Read Request Transfer. **NOTE:** The order of priority for writing to IDT, WRT and RRT must be in this order: 1. IDT 2. RRT 3. WRT 0 Read request will not be sent 1 Read request transfer by the initiator. This bit can not be written if SIPI_CCR3[IDT] = 1.
30 WRT	Write Request Transfer. **NOTE:** The order of priority for writing to IDT, WRT and RRT must be in this order: 1. IDT 2. RRT

Table continues on the next page...

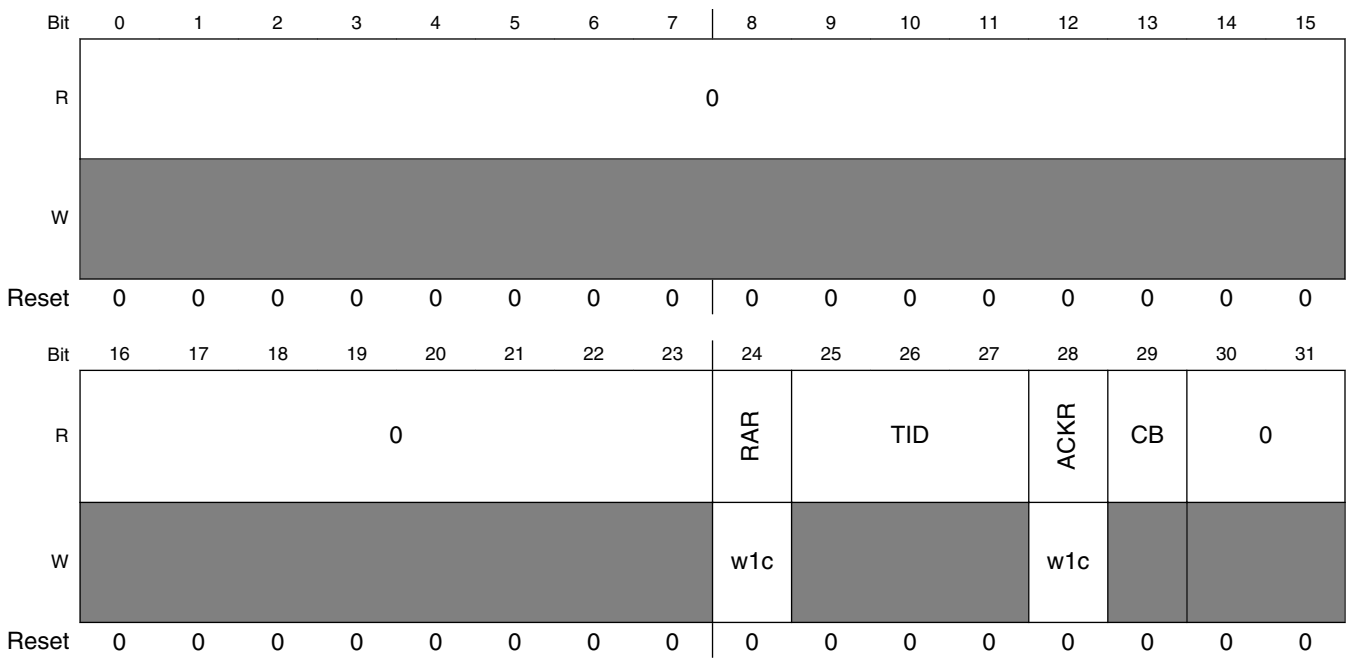
SIPI_CCR3 field descriptions (continued)

Field	Description
	3. WRT 0 No write request will be sent 1 Write request transfer by the initiator. This bit can not be written if SIPI_CCR3[IDT] = 1 or SIPI_CCR3[RRT] = 1.
31 DEN	DMA Enable. When enabling DMA mode, this bit should be set by software. It will then be cleared by hardware after one major loop has completed. 0 Channel will be used for bus interface access. 1 Channel will be used for DMA access

55.15.23 SIPI Channel Status Register 3 (SIPI_CSR3)

SIPI_CSR3 contains the status bits for the current transfer.

Address: 0h base + 80h offset = 80h



SIPI_CSR3 field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

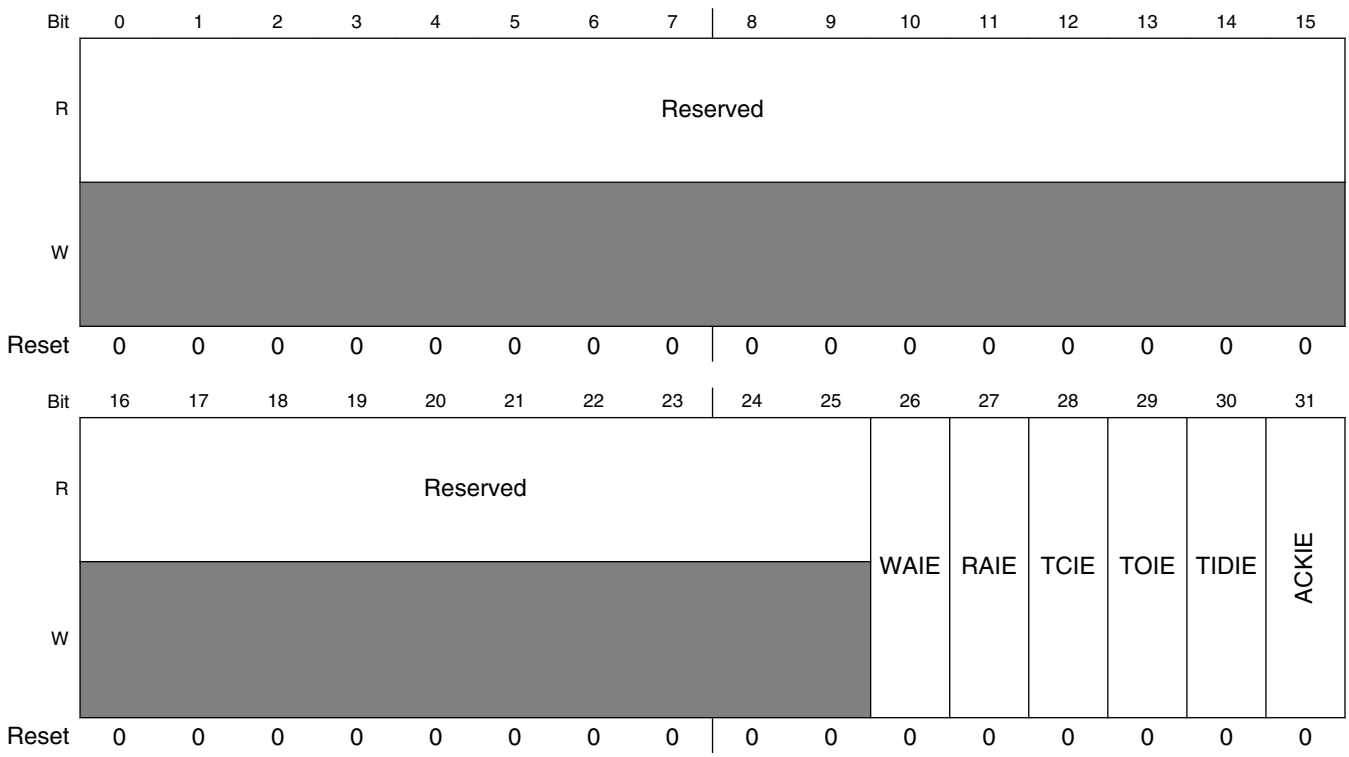
SIPI_CSR3 field descriptions (continued)

Field	Description
24 RAR	Read Answer Reception. 0 Read answer not received 1 Read answer received
25–27 TID	Transaction ID of transmitted frame. Transaction ID is a random number associated with every Tx frame to match the received response/ack with the command.
28 ACKR	Acknowledge Received. 0 Acknowledge not received 1 Acknowledge received
29 CB	Channel Busy. Indicates channel 3 status. 0 Channel 3 free 1 Channel 3 busy
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

55.15.24 SIPI Channel Interrupt Register 3 (SIPI_CIR3)

SIPI_CIR3 contains the interrupt enable bits for channel 3.

Address: 0h base + 88h offset = 88h



SIPI_CIR3 field descriptions

Field	Description
0–25 Reserved	This field is reserved.
26 WAIE	Write Acknowledge Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled
27 RAIE	Read Answer Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled
28 TCIE	Trigger Command Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled
29 TOIE	Timeout Error Interrupt Enabled.

Table continues on the next page...

SIPI_CIR3 field descriptions (continued)

Field	Description
	0 Interrupt is disabled 1 Interrupt is enabled
30 TIDIE	Transaction ID Error Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled
31 ACKIE	Acknowledge Error Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled

55.15.25 SIPI Channel Timeout Register 3 (SIPI_CTOR3)

SIPI_CTOR3 contains the timeout value for Tx requests.

Address: 0h base + 8Ch offset = 8Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Reset	0*	0*	0	0	0	0*	0*	0	0	0	0	0*	0*	0*	0	0

* Notes:

- INIT field: Can only be written when SIPI_MCR[MOEN] = 1.
- TEN field: Can only be written when SIPI_MCR[MOEN] = 1.
- CHNSB field: Can be written only once after reset.
- MCRIE field: Can only be written when SIPI_MCR[MOEN] = 1.
- CRCIE field: Can only be written when SIPI_MCR[MOEN] = 1.
- AID field: Can be written in initialization mode only (SIPI_MCR[INIT] = 1).

SIPI_MCR field descriptions

Field	Description
0 FRZ	Freeze Enable The FRZ bit specifies the SIPI behavior when Debug mode is requested at the MCU level. When FRZ is asserted, the SIPI is enabled to enter Freeze mode. Negation of this bit field causes SIPI to exit Freeze mode. **NOTE:** Can only be written when SIPI_MCR[MOEN] = 1. 0 Not enabled to enter Freeze mode 1 Enabled to enter Freeze mode
1 Reserved	This field is reserved. **Important:** Always write the default value to this field.
2 HALT	Halt Mode Enable Assertion of this bit puts SIPI into Freeze mode. No Rx or Tx is performed in the SIPI until this bit is cleared. If this bit is enabled in during Tx or Rx communications, the current activity will finish, then the SIPI will enter Freeze mode. **NOTE:** Can only be written when SIPI_MCR[MOEN] = 1. 0 No Freeze mode request 1 Enters Freeze mode if FRZ bit is asserted.
3–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–15 PRSCLR	Timeout counter prescaler The timeout counter runs on the prescaled system clock. Default value is 64 (040h). The allowed programmable values are (all other values are ignored): 040h 64 (default) 080h 128 100h 256 200h 512 400h 1024 **NOTE:** This field should be programmed by software during initialization mode, SIPI_MCR[INIT] = 1. Writes during other times are ignored. **NOTE:** Writes to SIPI_MCR[PRSCLR] can only be accomplished with 16-bit or 32-bit writes.
16–17 AID	Address Increment/Decrement These bits define the type of address change at the target node. **NOTE:** This bits should be programmed by software in initialization mode, SIPI_MCR[INIT] = 1. Writes during other times are ignored. 00 no change. address stays same 01 address increments by 4 10 address decrements by 4 11 not used
18–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

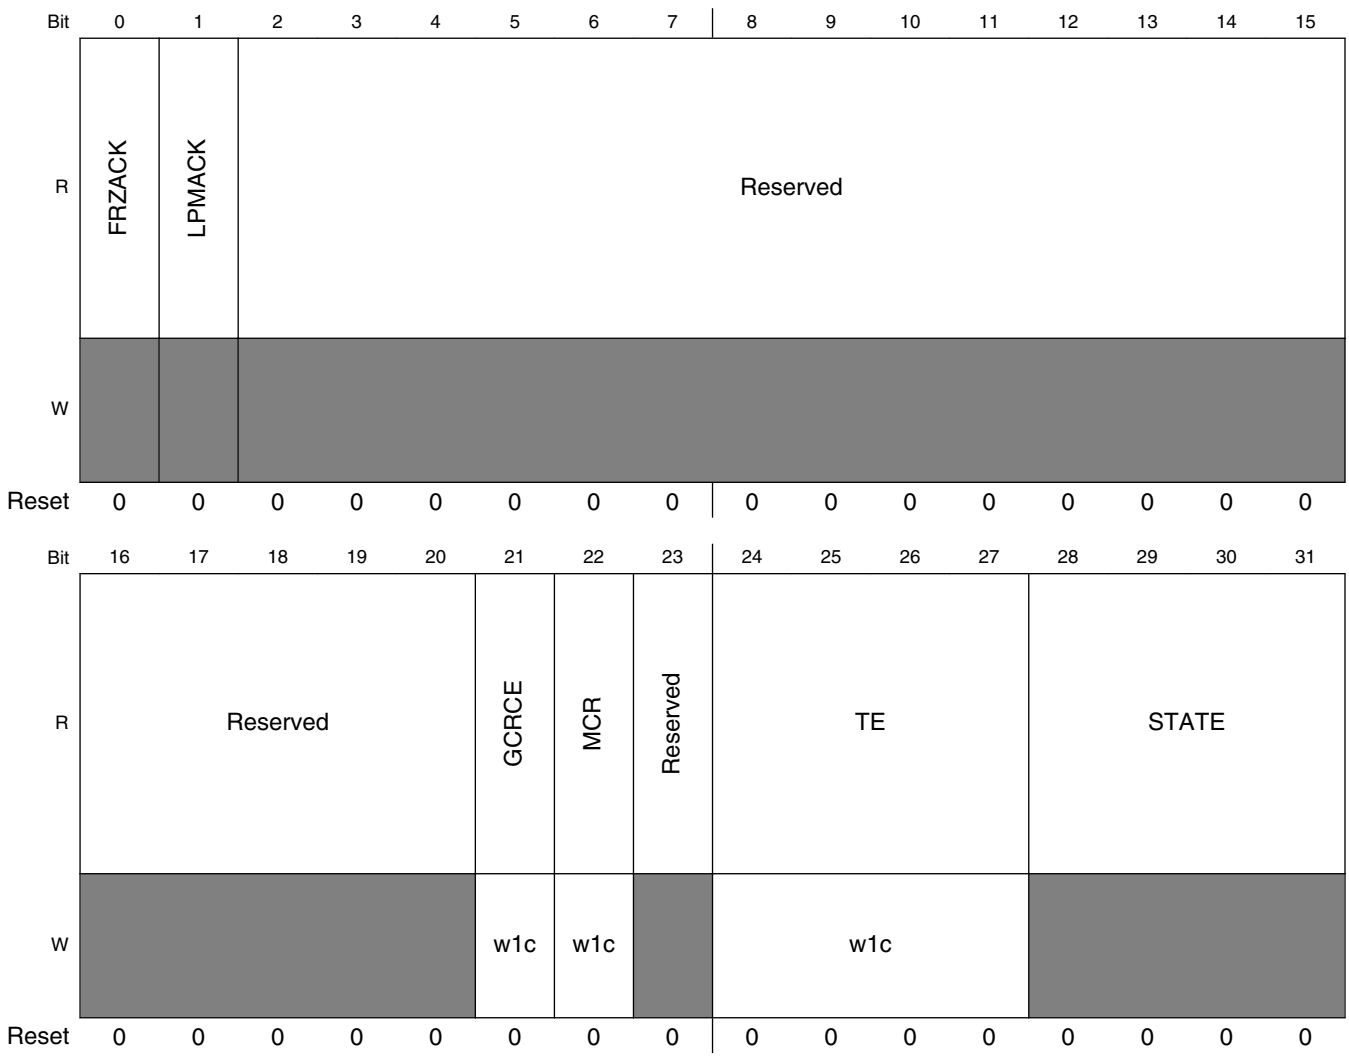
SIPI_MCR field descriptions (continued)

Field	Description
21 CRCIE	CRC Error Interrupt Enable 0 Interrupt is disabled 1 Interrupt is enabled
22 MCRIE	Max Count Reached Interrupt Enable 0 Interrupt is disabled 1 Interrupt is enabled
23–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 CHNSB	Channel coding select bit. 0 Code Table II (see Table 55-2) 1 Code Table I (see Table 55-2)
28 TEN	Target Enable Setting this bit enables the target functionality at SIPI. This bit can be read or written anytime. This bit is automatically negated by hardware when target detects an error in "streaming without ACK" mode. This bit has to be enabled for the transmission operations also.
29 INIT	Initialization Mode Setting this bit puts the module in initialization mode. This bit should be cleared by software. Most register bits are configured using this bit. The SIPI_MCR[MOEN] bit needs to be set first, and then the INIT bit can be set and both bits can't be enabled together. 0 Normal Mode 1 Initialization Mode
30 MOEN	Module Enable This bit should be set or cleared by software. When this bit is negated, future SIPI Tx transfers are disabled.
31 SR	Soft Reset Setting this bit clears all status and error registers, and FSMs are moved to idle state. This bit is automatically cleared by hardware once the reset operation is complete.

55.15.30 SIPI Status Register (SIPI_SR)

The SIPI_SR is the global status register of SIPI.

Address: 0h base + A0h offset = A0h



SIPI_SR field descriptions

Field	Description
0 FRZACK	Freeze Mode Acknowledge. This read-only bit indicates that SIPI is in Freeze mode. The Freeze mode request cannot be granted until current transmission or reception processes have finished. The software can poll the FRZACK bit to find when the SIPI has actually entered Freeze mode. If Freeze mode is requested while SIPI is in any of the low power modes, then the FRZACK bit will only be set when the low power mode is exited.

Table continues on the next page...

SIPI_SR field descriptions (continued)

Field	Description
	0 SIPI not in Freeze mode 1 SIPI in Freeze mode
1 LPMACK	Low Power Mode Acknowledge. This read-only bit indicates that SIPI is in Disable Mode. Disable mode can not be entered until all current transmission or reception processes have finished. The CPU can poll the LPMACK bit to know when SIPI has actually entered low power mode. 0 SIPI is not in low power mode 1 SIPI is in Disable Mode.
2–20 Reserved	This field is reserved.
21 GCRCE	Global CRC Error Bit. 0 No CRC error 1 CRC error occurred
22 MCR	Maximum Count Reached. This bit will be set whenever SIPI_ACR[ADCNT] = SIPI_MAXCR[MXCNT]. An interrupt will be generated when this bit is set only if SIPI_MCR[MCRIE] = 1. This it should be cleared by software.
23 Reserved	This field is reserved.
24–27 TE	Trigger Event on Respective Channels. This field enables interrupts for target nodes. xxx1 TE0 = 1 - Channel 0 trigger event xx1x TE1 = 1 - Channel 1 trigger event x1xx TE2 = 1 - Channel 2 trigger event 1xxx TE3 = 1 - Channel 3 trigger event
28–31 STATE	These bits reflect the transmit state machine status. They can be polled for determination of state machine status. 0000 IDLE 0001 HEADER_AND_ADDRESS_FIELD 0010 HEADER_AND_DATA_FIELD 0011 HEADER_AND_CRC_FIELD 0100 ADDRESS_AND_CRC_FIELD 0101 ADDRESS_AND_DATA_FIELD 0110 DATA_AND_CRC_FIELD 0111 DATA_FIELD

55.15.31 SIPI Max Count Register (SIPI_MAXCR)

SIPI_MAXCR contains the maximum address count value at target node. It is programmed via direct write request through the initiator. This register can be read or written by software anytime.

Address: 0h base + A4h offset = A4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	MXCNT															
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

R W	MXCNT														Reserved	
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	0	0

SIPI_MAXCR field descriptions

Field	Description
0–29 MXCNT	This field contains the maximum address count value at the target node. It should be programmed via direct write request through the initiator.
30–31 Reserved	This field is reserved.

55.15.32 SIPI Address Reload Register (SIPI_ARR)

The SIPI_ARR contains the reload value for the address counter at the target node. It should be configured by direct write request from the initiator.

NOTE

This register is writeable only when SIPI_MCR[INIT] = 1.

Address: 0h base + A8h offset = A8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	ADRLD															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	ADRLD														Reserved	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SIPI_ARR field descriptions

Field	Description
0–29 ADRLD	ADRLD contains the reload value for the address counter at the target node. It should be configured by direct write request from the initiator.
30–31 Reserved	This field is reserved.

55.15.33 SIPI Address Count Register (SIPI_ACR)

This register reflects the count value of address counter at target node. It should be configured by direct write request from initiator. This register can be read/written by software anytime.

NOTE

SIPI_ARR, SIPI_ACR and SIPI_MAXCR will be configured by direct write operation through the initiator.

NOTE

When a streaming write command is received, the target will start the write operation from the address present in SIPI_ACR (address count register).

NOTE

After each 32-bit write has completed, SIPI_ACR[ADCNT] is compared against SIPI_MAXCR[MXCNT]. If they are equal, SIPI_ACR[ADCNT] is loaded with the value stored in SIPI_ARR[ADRLD]. If they are not equal, the SIPI_ACR[ADCNT] will increment by 4, decrement by 4 or remain the same (depending on configuration). In both cases, the SIPI_ACR[ADCNT] will contain the address at which the next streaming write will occur.

Address: 0h base + ACh offset = ACh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

SIPI_ACR field descriptions

Field	Description
0–29 ADCNT	Feflects the count value of address counter at target node. It should be configured by direct write request from the initiator. This register can be read/written by software anytime. At the end of the streaming operation, SIPI_ACR will point to the next address to be written.
30–31 Reserved	This field is reserved.

55.15.34 SIPI Error Register (SIPI_ERR)

This register contains the error bits for the last transaction(s) for all the channels. Communication errors are generated only for out of range address accesses, areas that are read only and where accesses do not lead to generation of transfer errors. Also, writing to read only registers will not generate errors.

Address: 0h base + B0h offset = B0h

Chapter 56
LVDS Fast Asynchronous Serial Transmission (LFAST) – Interprocessor Communications

56.1 Introduction

This chapter describes the specifications of the LFAST module, which implements the LVDS Fast Asynchronous Serial Transmission (LFAST) module. LFAST is used in dual mode (software configurable master/slave operation) for interprocessor communications.

56.2 Block diagram

The following figure depicts LFAST interaction with other modules on the device.

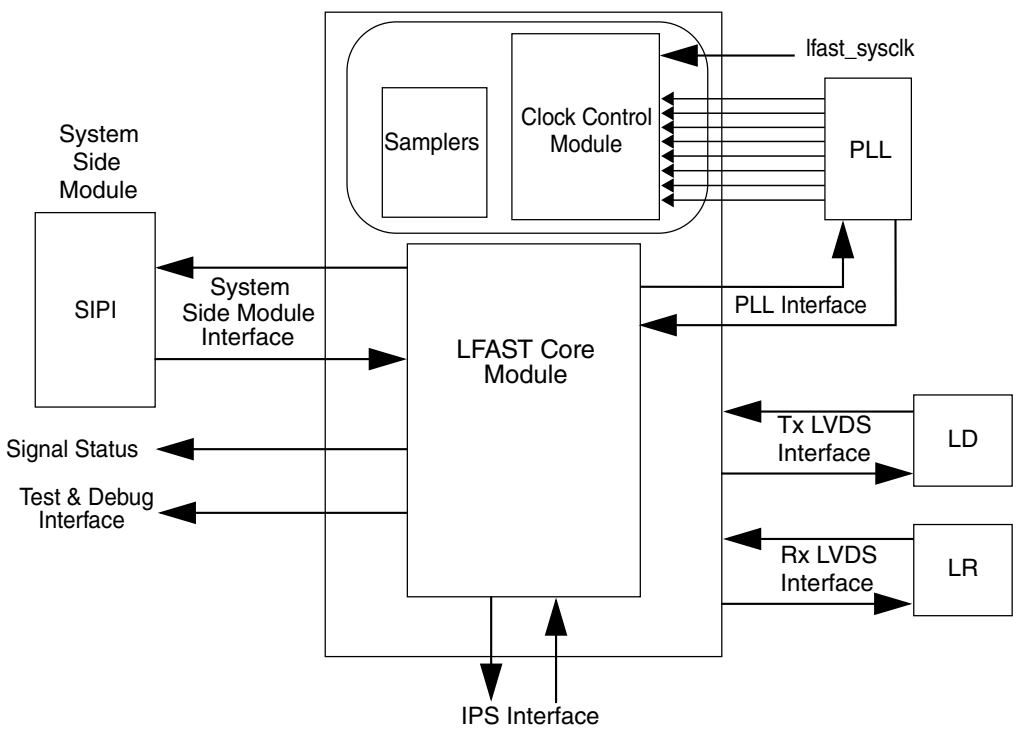

Figure 56-1. LFAST block diagram

56.3 External signals

LFAST is a five pin interface with the following signals :

- lfast_sysclk
  - Reference clock of the LFAST master and slave
- txdatap/txdatan
  - Differential transmit (Tx) interface pair
- rxdatap/rxdatan
  - Differential receive (Rx) interface pair

LFAST interface is an asynchronous high speed LVDS interface.

56.3.1 LFAST operating data rates

The change of data rate is controlled by the LFAST master by issuing appropriate Interface Control Logical Channel (ICLC) packets to the LFAST slave. Henceforth, the data rate 6.5 Mbps/5 Mbps (lfast_sysclk ÷ 4 or lfast_sysclk ÷ 2) is referred to as low data rate, and the high data rate is in the Data Sheet.

56.4 LFAST frame structure

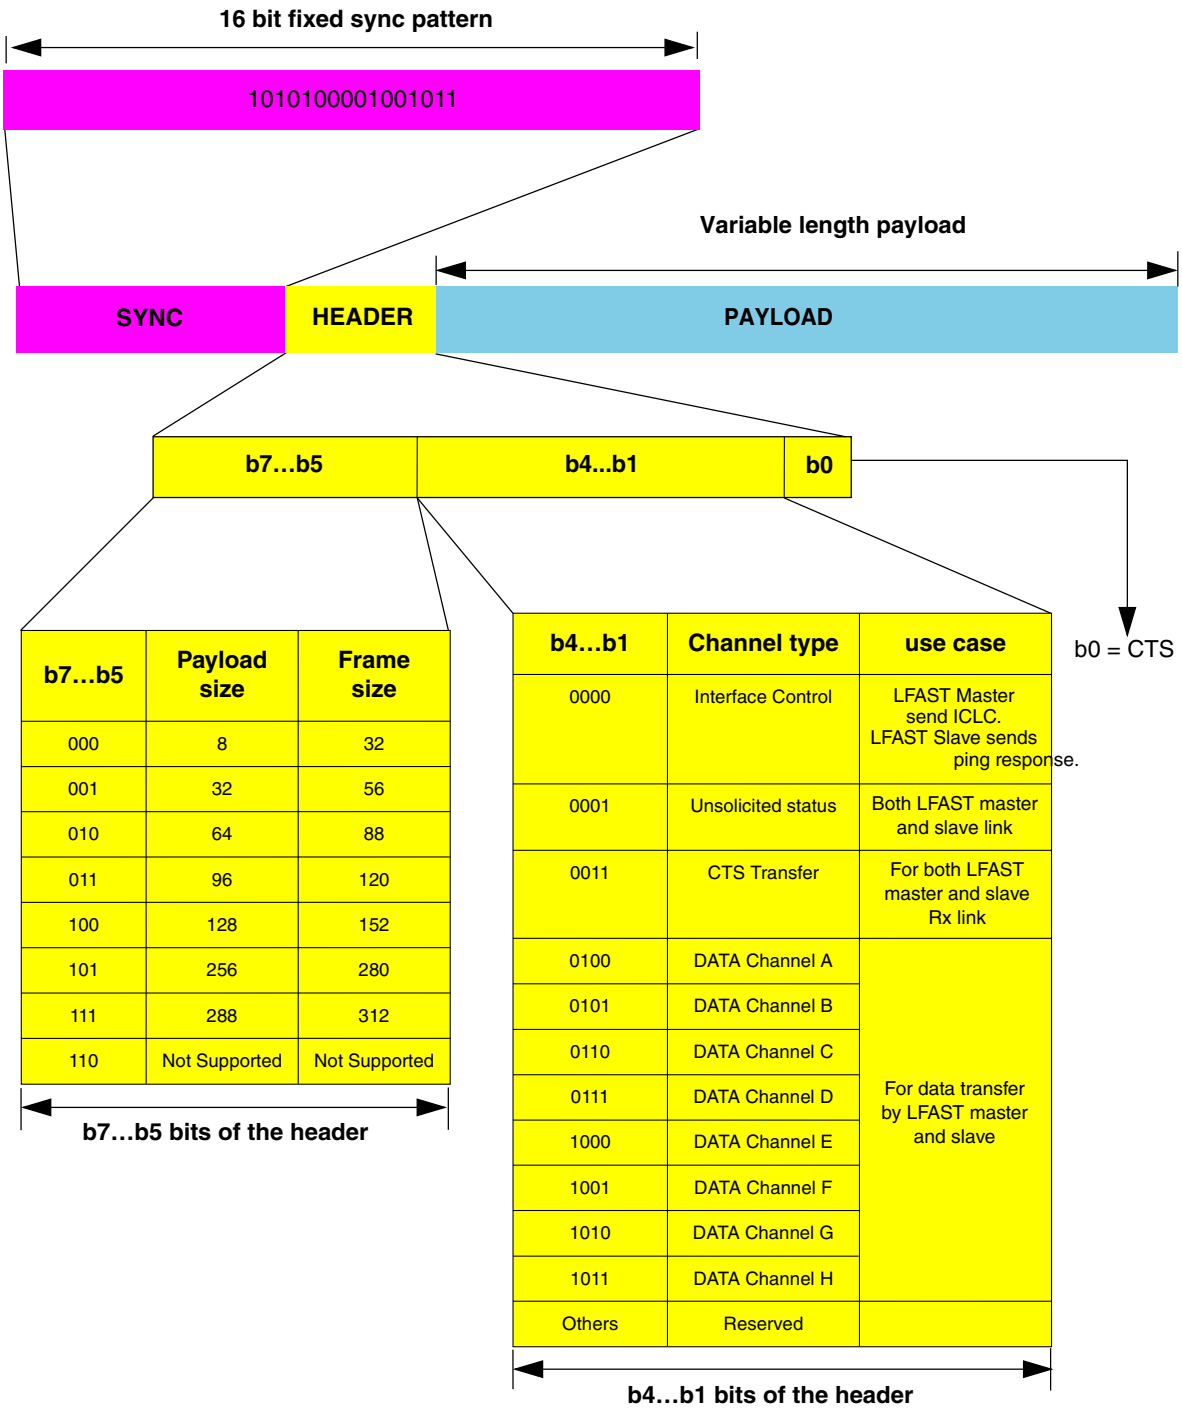
A LFAST frame is made up of three fields:

- Sync pattern
- Header
- Payload

Sync pattern and header fields are of fixed length.

Sync pattern is used to synchronize incoming data stream in LFAST module.

Header field of the frame distinguishes various types of data and control transferred and also contains information about the length of the payload. The payload field is the actual data that is transferred across the channel. See Figure 56-2 for details of the LFAST frame.



b7…b5	Payload size	Frame size
000	8	32
001	32	56
010	64	88
011	96	120
100	128	152
101	256	280
111	288	312
110	Not Supported	Not Supported

b4…b1	Channel type	use case
0000	Interface Control	LFAST Master send ICLC. LFAST Slave sends ping response.
0001	Unsolicited status	Both LFAST master and slave link
0011	CTS Transfer	For both LFAST master and slave Rx link
0100	DATA Channel A	For data transfer by LFAST master and slave
0101	DATA Channel B	
0110	DATA Channel C	
0111	DATA Channel D	
1000	DATA Channel E	
1001	DATA Channel F	
1010	DATA Channel G	
1011	DATA Channel H	
Others	Reserved	

Figure 56-2. LFAST frame structure

The same protocol is used on both transmit and receive interfaces for communications of data, control and status information. A synchronization pattern (16 bits) and header (8 bits) are present in every frame.

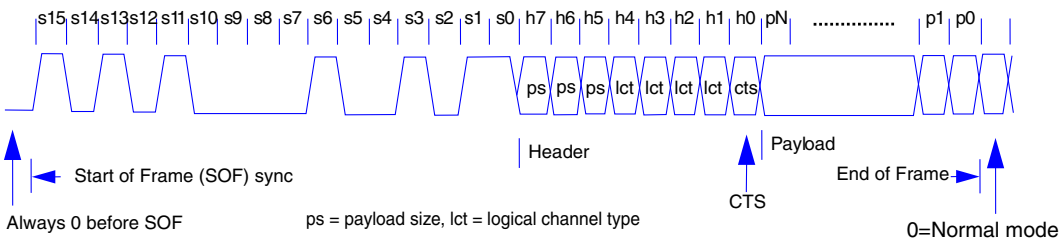


Figure 56-3. Serial frame structure

The frame structure is shown in Figure 56-3 and consists of the following:

- **16-bit synchronization pattern:** Used for clock synchronization and pattern recognition. The frame synchronization code at the start of every frame is a unique reserved word that is used to identify whether the data received is the start of the frame and for synchronization (clock phase extraction) with the stream data. A synchronous sequence is used to give a high quality auto correlation. The LFAST 16-bit synchronization sequence = 1010_1000_0100_1011b = A84Bh.
- **Header - 3 MSB (b7 - b5):** Defines the payload size as shown in Table 56-1 :

Table 56-1. Header payload sizes

b7-b5(bin)	Payload Size	Frame Size
000	8	32
001	32	56
010	64	88
011	96	120
100	128	152
101	256	280
110	—	—
111	288	312

- **Header - (b4 - b1):** Defines the logical channel types, which indicate the type of payload that the frame carries. How the payload field of a frame is used for any other logical channel type is system side module specific except in the case of the interface control logical channel type and clear to send (CTS) frame.
- **Header - (b0):** CTS on the both LFAST master and slave devices.

- **Payload:** Content dependent upon frame type.
- **Bit after frame:** This bit determines entry into Sleep mode (1 = Sleep mode, 0 = normal mode)

56.5 Features

- Supports dual mode (register configurable Master/Slave).
- Supports asynchronous data transfer up to the maximum data rate shown in the product Data Sheet.
- Transmits and receives data, CTS, ICLC and unsolicited frames.
- Receives ICLC frames
- Provision of five interrupts for Tx and Rx channels.
- Supports processor controlled transfer of ICLC frame with 8-bit payload size to implement the data rate changes and test modes.
- Supports LFAST defined CTS controlled data transfer. No dependency between data transmission and reception unless CTS mode is enabled.
- Supports flow control using sliding window protocol.
- Provides configurable frame length for data frame with variable payload sizes of 32, 64, 96, 128, 256 or 288 bits.
- Provides transmit of data frame length with 96 bits of payload size and reception of data frame with 128 bits of payload size.
- Provides configurable frame length for unsolicited frame with variable payload sizes of 8, 32, 64, 96, 128, 256 or 288 bits.
- Supports PLL configuration (for example, feedback loop divider, etc.) through registers.
- Supports LVDS configuration through registers.
- Supports multiple loopback modes for checking the physical interface.
- Supports automatic ping response generation in slave mode.
- Supports for detection of unsupported channel number and unsupported payload size.

56.6 Memory map and register definition

All registers are 32 bits wide.

NOTE

Read/Write accesses to all unimplemented registers and write accesses to Read only register will return a Transfer Error.

LFAST memory map

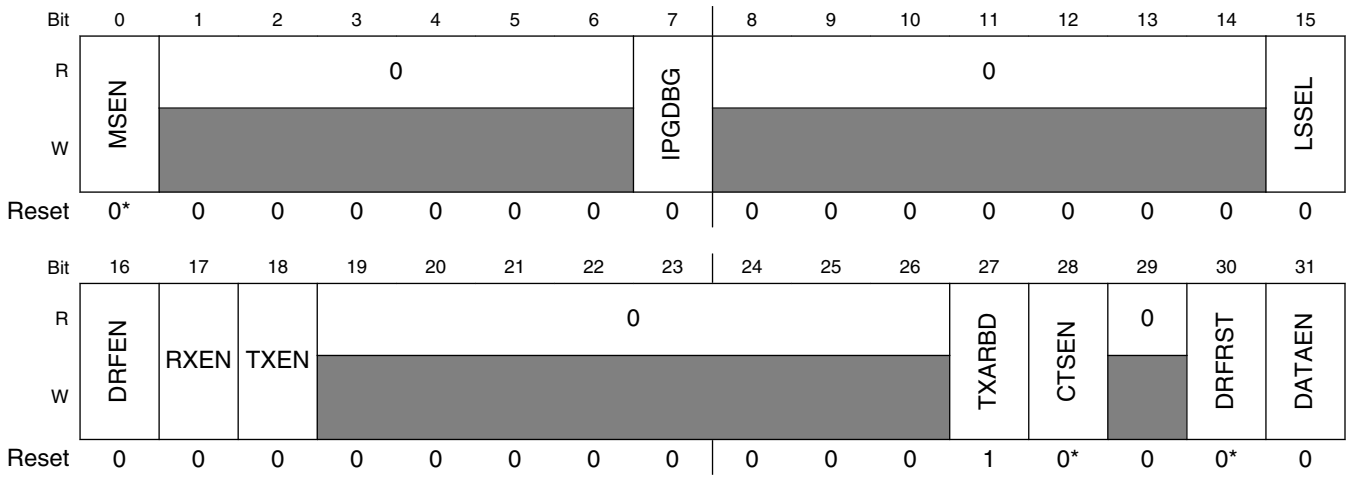
56.6.1 LFAST Mode Configuration Register (LFAST_MCR)

Address: 0h base + 0h offset = 0h



* Notes:
- DRFRST field: Set by user software and then cleared by system hardware.
- CTSEN field: Only writable when MCR[DRFEN] = 0.
- MSEN field: Writable only once after the asynchronous reset.

LFAST_MCR field descriptions

Field	Description
0 MSEN	LFAST Master or Slave mode Enable. This bit selects either the LFAST master or slave functionality. 0 Enable the modules LFAST Slave functionality only. 1 Enable the modules LFAST Master functionality only.
1–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 IPGDBG	Control bit to enable support for IPG Debug mode. This mode is indicated by assertion of IPG debug mode signal. 0 IPG debug mode enable signal will be ignored. 1 IPG debug mode enable signal will not be ignored.
8–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 LSSEL	Selects the fraction of sysclk in Low Speed Select mode (see Slow speed clock for details). 0 Low Speed Mode in which the lfast_sysclk input is used to generate 4 phases of lfast_sysclk/2. 1 Low Speed Mode in which the lfast_sysclk input is used to generate 4 phases of lfast_sysclk/4.
16 DRFEN	LFAST Enable. This bit enables/disables the reception and transfer of LFAST device. 0 LFAST is immediately disabled. All current/pending requests are terminated and the Tx and Rx data FIFOs are flushed. If this bit is cleared in the middle of a transmit/receive operation, then that operation is terminated immediately and nothing is transmitted/received further. All the programmable

Table continues on the next page...

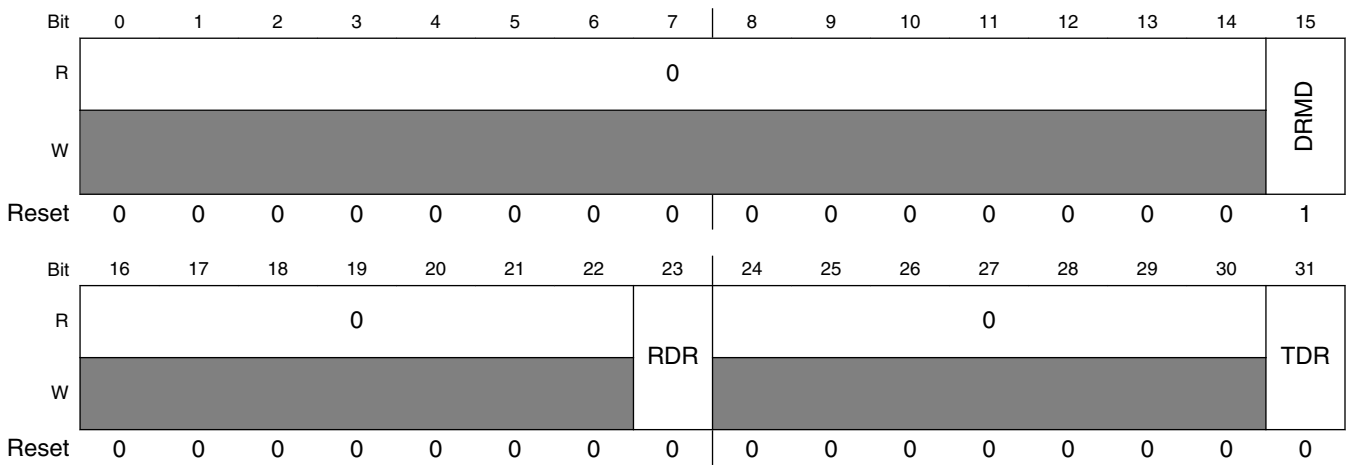
LFAST_MCR field descriptions (continued)

Field	Description
	registers retain their values and status registers are cleared to their reset values. Registers read/write operations can be performed through the IPS Bus. 1 LFAST is Enabled.
17 RXEN	LFAST Receiver Enable. This bit controls the reception of the frames and decoding on the LFAST device. This bit also disables the Rx LVDS Line Receiver (LR). 0 Receiver Interface is disabled. If this bit is cleared during a data transfer, the current frame is received and then the Rx block is disabled. After the Rx block is disabled, all new frames from LFAST peer device are ignored. System Side Module Rx interface isn't disabled by this bit. 1 Receiver Interface is Enabled.
18 TXEN	LFAST Transmitter Enable. This bit controls the transmission of frames from the LFAST device and disables the Tx LVDS LD. This bit can also be modified by LFAST slave H/W on reception of an ICLC command frame. This field can only be written in dual mode (LFAST_GSR[DUALMD] = 1). 0 LFAST transmitter Interface is disabled. No new request is accepted but ongoing request is served. 1 LFAST transmitter Interface is enabled. New requests are accepted.
19–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 TXARBD	Tx Arbiter Disable. This bit enables/disables the Tx block arbiter. Current frame transfer is completed, but new frame requests are ignored. 0 Enable Tx arbiter and framer. When enabled it takes all the frame request and services based on priority. 1 Disable Tx arbiter and framer. All frame requests are ignored.
28 CTSEN	CTS Enable. This bit defines the Push-Pull mode of the LFAST devices receiver. This bit is used to enable/disable CTS mode of the Tx block. This bit is only writable when MCR[DRFEN] = 0. 0 CTS mode is disabled. Indicates that the device is in Push mode. The CTS bit of frames transmitted is 1. The CTS bit doesn't represent the status of Rx FIFO. 1 CTS mode is enabled. The CTS bit of all transmit frames is set when the Rx FIFO empty space is on or above higher threshold, and cleared when the Rx FIFO empty space is on or below lower threshold.
29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 DRFRST	LFAST Soft Reset. This bit is automatically cleared after Reset.. 0 No Soft Reset 1 Soft Reset to LFAST is asserted. When set it causes a reset of the LFAST module; all the registers will be reset to their default values and all the FIFOs will be flushed.
31 DATAEN	DATA Frame Enable. This bit enables/disables the transmission and reception of data frames between the LFAST master and slave devices. 0 Data frame transmission and reception is disabled. Tx data frame requests are ignored by the transmitter. Frame with LCT of data frame is ignored by the receiver. 1 Data frame transmission and reception is enabled. Tx data frame requests are serviced by the transmitter. Frame with LCT of data frame is received and placed into the Rx data FIFO.

56.6.2 LFAST Speed Control Register (LFAST_SCR)

The SCR is used to configure the Rx and Tx data rate of the LFAST.

Address: 0h base + 4h offset = 4h



LFAST_SCR field descriptions

Field	Description
0–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 DRMD	Data Rate Controller mode. Defines the mode setting for LFAST slave device by S/W or LFAST master. 0 S/W controls the Data Rate controller mode. In LFAST Slave the ICLC frames for rate change have no affect on the Data rate. 1 In LFAST Slave the reception of ICLC frame for rate change sets appropriate speed mode. In LFAST Master the SCR[DRMD] should be 0.
16–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 RDR	Receiver Data Rate. This bit defines the receiver data rate. For LFAST Master: • S/W should program this bit only after transmission of an ICLC frame changing the speed mode of the slaves Tx interface. For LFAST Slave: • When SCR[DRMD] = 1, the H/W programs this bit on reception of ICLC frame for changing speed mode of Slaves Rx interface. • The S/W can program this bit when SCR[DRMD] = 0. • This bit is cleared on MCR[DRFEN] negation. 0 Data rate of Rx block is low speed. 1 Data rate of Rx block is high speed.

Table continues on the next page...

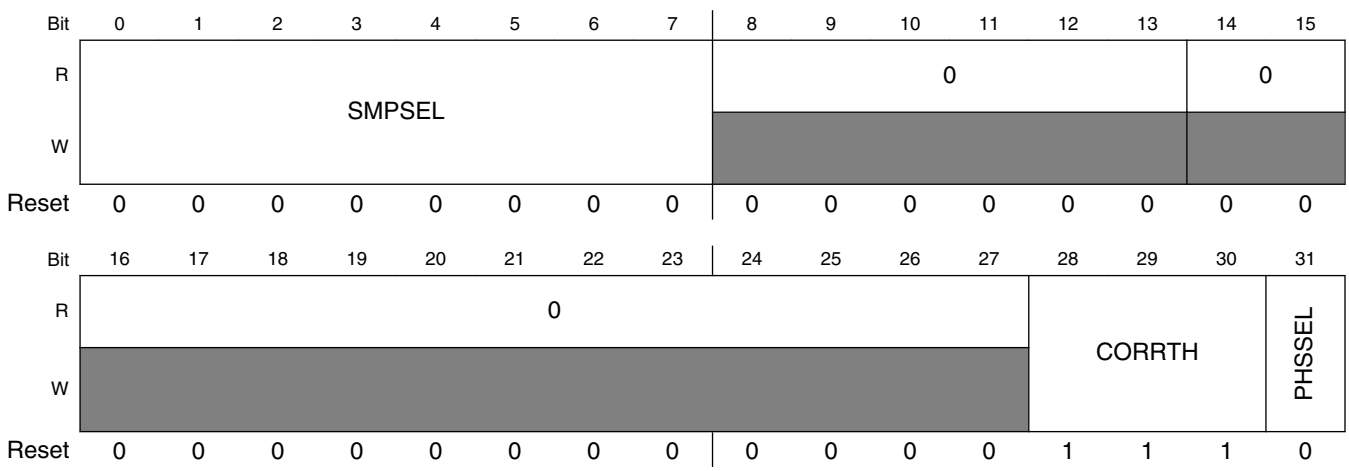
LFAST_SCR field descriptions (continued)

Field	Description
24–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 TDR	Transmit Data Rate. This bit defines the transmitter data rate. For LFAST Master: • S/W should program this bit only after transmission of an ICLC frame changing the speed mode of the slaves Rx interface. For LFAST Slave: • When SCR[DRMD] = 1, the H/W programs this bit on reception of ICLC frame for changing speed mode of Slaves Tx interface. • The S/W can program this bit when SCR[DRMD] = 0. • This bit is cleared on MCR[DRFEN] negation. 0 Data rate of Tx block is low speed. 1 Data rate of Tx block is high speed.

56.6.3 LFAST Correlator Control Register (LFAST_COCR)

The COCR is used to select the sampler data path and the number of bits of correlation to be used.

Address: 0h base + 8h offset = 8h



LFAST_COCR field descriptions

Field	Description
0–7 SMPSEL	Sampler Data Path Selector (overrides the correlator selection). Defines the sampler data path to be activated at all the times. All the bits should be 0 (00h) for Sampler Data Path to be selected by the correlator. In Low Speed mode only Sampler Data Paths 0-3 are valid. This field can only be written when MCR[RXEN] = 0.

Table continues on the next page...

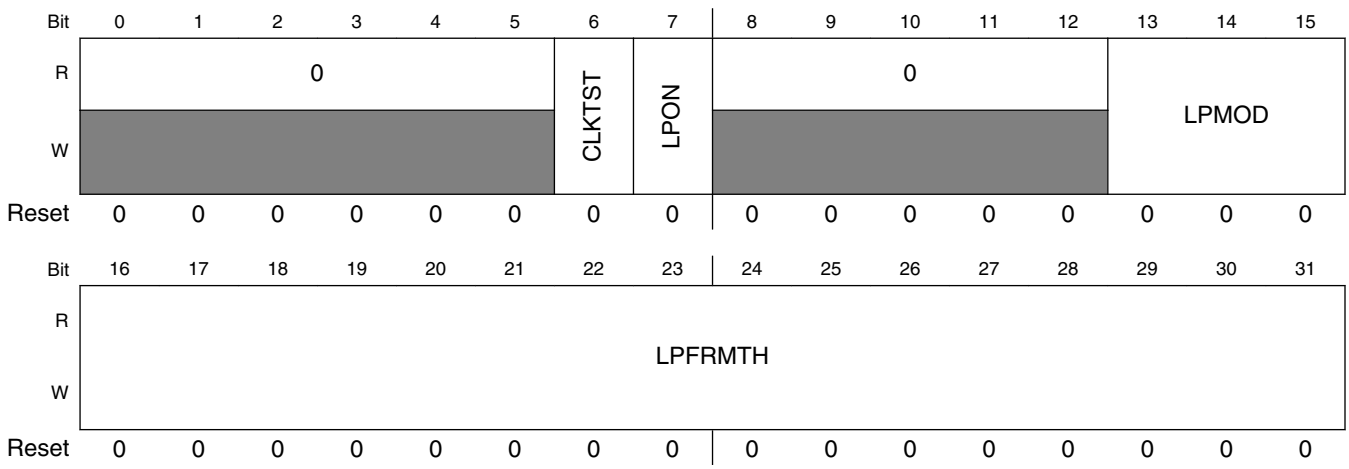
LFAST_COCR field descriptions (continued)

Field	Description
	00h Sampler Data Path selected by correlator 01h Sampler Data Path 0 selected 02h Sampler Data Path 1 selected 04h Sampler Data Path 2 selected 08h Sampler Data Path 3 selected 10h Sampler Data Path 4 selected 20h Sampler Data Path 5 selected 40h Sampler Data Path 6 selected others Sampler Data Path 7 selected
8–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–30 CORRTH	Correlator threshold level. Defines the correlation threshold level. This field can only be written when MCR[RXEN] = 0. 000 9 Bits of correlation 001 10 Bits of correlation ... 110 15 Bits of correlation 111 16 Bits of correlation
31 PHSSEL	Polyphase 8 or 4 phase selection. Defines the number of phases for the polyphase generator used. This bit is ignored in low speed mode since only 4 Phases are used in low speed mode. In High Speed mode phase 0, 2, 4 and 6 are used when 4 phase mode is selected. This field can only be written when MCR[RXEN] = 0 0 8 phases 1 4 phases

56.6.4 LFAST Test Mode Control Register (LFAST_TMCR)

The TMCR enables and configures the LFAST clock test and loopback modes.

Address: 0h base + Ch offset = Ch



LFAST_TMCR field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 CLKTST	Clock Test mode. S/W can define when the clock test mode is enabled. This bit can also be set and cleared by LFAST slave H/W on reception of an ICLC command. This field can only be written when MCR[DRFEN] = 1. 1 Clock Test mode enabled 0 Clock Test mode disabled
7 LPON	Loopback mode Logic Enable. S/W can define when the loopback logic is enabled. This bit can also be written by LFAST slave H/W on reception of an ICLC command. This field can only be written when MCR[DRFEN] = 1. 1 Loopback mode is enabled 0 Loopback mode is disabled
8–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–15 LPMOD	Loopback mode. Defines the type of loopback mode enabled. This field can only be written when TMCR[LPON] = 0. 000 Rx loopback 001 Rx LVDS loopback 010 Tx loopback without automatic frame generation 011 Tx loopback with automatic frame generation 100 Tx LVDS loopback (external) with automatic frame generation 101 Reserved

Table continues on the next page...

LFAST_TMCR field descriptions (continued)

Field	Description
	110 Reserved 111 Reserved
16–31 LPFRMTH	Loopback check mode valid pass frames threshold value. Defines the number of frames to verify before setting GCR[LPFPDV] when running in Automatic Loopback Frame mode. The loopback frame is considered pass when the payload is CBh, header is 13h and sync is valid. This mode is valid only when TMCR[LPMOD] = 011b or TMCR[LPMOD] = 100b. This field can only be written when TMCR[LPON] = 0. 0000h Reserved.(Not to be used) 0001h Check 1 frame have correct sync, header and payload. ... FFFEh Check 65534 frames have correct sync, header and payload. FFFFh Check 65535 frames have correct sync, header and payload.

56.6.5 LFAST Auto Loopback Control Register (LFAST_ALCR)

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

LFAST_SLCR field descriptions

Field	Description
0–7 HSCNT	High Speed Sleep mode Exit Time. Defines 1/4 of the number of the high speed clock cycle wait after the negation of the LVDS LD sleep signal, and before the start of new frame. This wait is the summation of settling time of the Line Driver (LD) after negation of its sleep signal, and the wakeup time of the LR of the peer LFAST. This field can only be written when MCR[DRFEN] = 0. 00h 0 cycle 01h 1 cycle ...

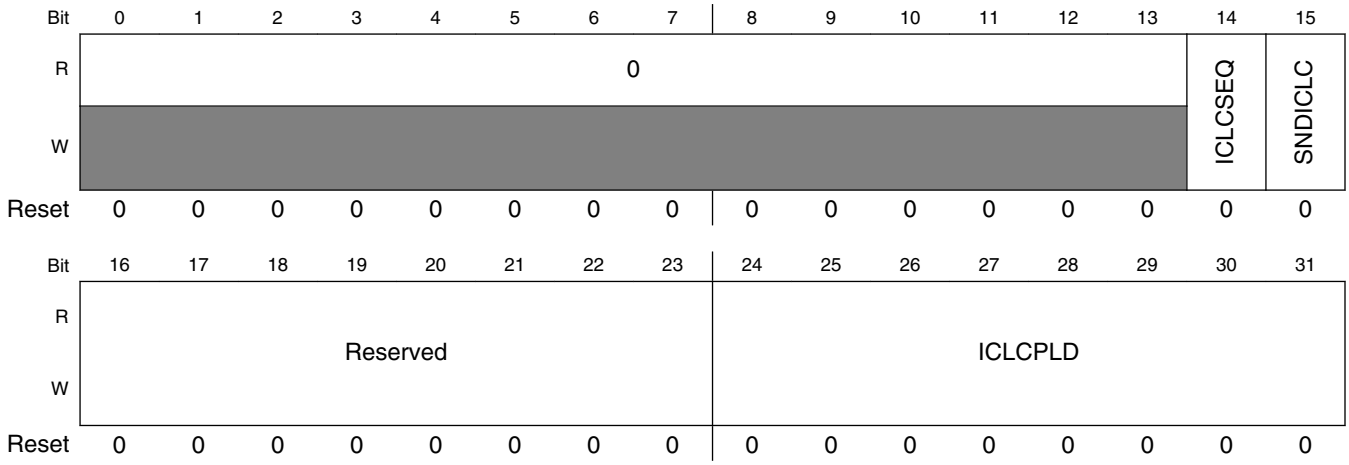
Table continues on the next page...

LFAST_SLCR field descriptions (continued)

Field	Description
	12h 18 cycles (200 ns + 8 cycles of High speed clock) ... FEh 254 cycles FFh 255 cycles
8–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 LSCNT	Low Speed Sleep mode Exit Time. Defines 1/4 of the number of Low speed clock cycle wait after the negation of LVDS LD sleep signal, and before the start of new frame. This wait is the summation of settling time of LD after negation of LVDS LD sleep signal, and the wakeup time of the LR of the peer LFAST. This field can only be written when MCR[DRFEN] = 0. 0h 0 cycle 1h 1 cycle (200ns + 1 cycle of Low speed clock) ... Eh 14 cycles Fh 15 cycles
16–23 HWKCNT	Wake Up time for the LD. Defines the 1/4 of the number of High speed clock cycles used during the wakeup of the LD from shutdown mode. This is time required by the LD to move from moving from Shutdown to Normal State in High speed mode. This field can only be written when MCR[DRFEN] = 0. 00h 0 cycles 01h 1 cycle ... 5Fh 95 cycles (1.18 µs) ... FFh 255 cycles Maximum
24–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 LWKCNT	Wake Up time for the LD. Defines the 1/4 of the number Low speed clock used during the wakeup of the LD from shutdown mode. This is time required by the LD to move from Shutdown to Normal State in Low speed mode. This field can only be written when MCR[DRFEN] = 0. 0h 0 cycle 1h 1 cycle 2h 2 cycles (1.18 µs) ... Eh 14 cycles Fh 15 cycles

56.6.8 LFAST ICLC Control Register (LFAST_ICR)

Address: 0h base + 1Ch offset = 1Ch

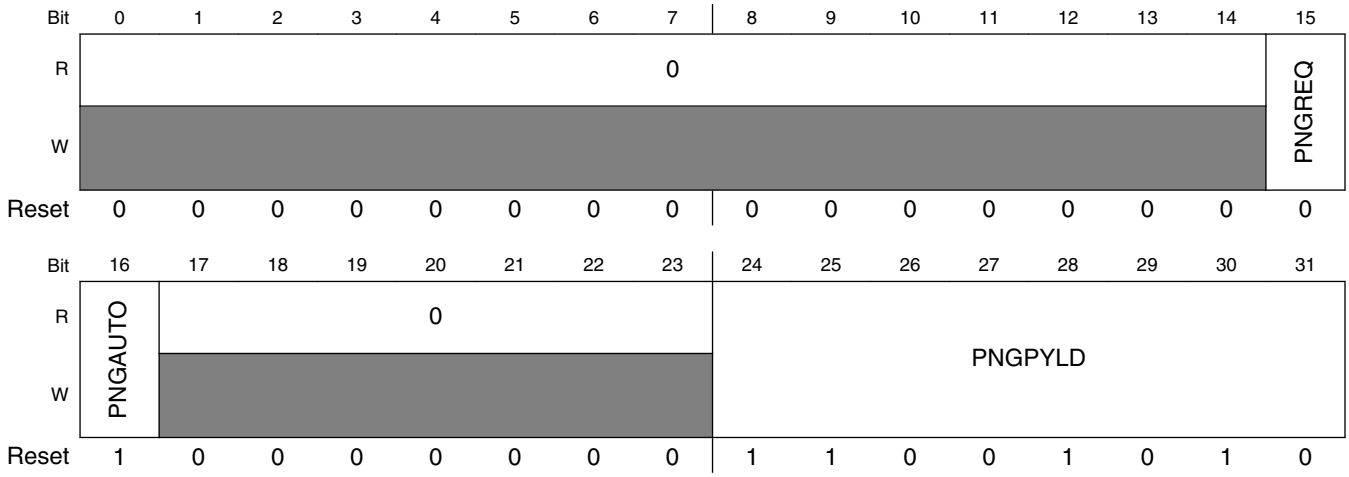


LFAST_ICR field descriptions

Field	Description
0–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 ICLCSEQ	ICLC enabled. This bit should be set whenever the S/W is performing a series of ICLC frame transfers. This bit ensures only ICLC frame transmission request is serviced, other pending frames request are ignored. 0 Single ICLC frame transfer. 1 S/W is performing ICLC frame transfers. Only the ICLC frames will be scheduled during this period. All the other frames will be scheduled only after ICR[ICLCSEQ] = 0.
15 SNDICLC	ICLC frame request. This bit is set to initiate the transfer of ICLC frame by LFAST master. This bit should be set (ICR[SNDICLC] = 1) after writing the required ICLC payload to be transmitted in the ICLCPLD field of the register. This bit is self clearing, which will be cleared when ICLC frame transfer is complete. Set by user software and cleared by system hardware. 0 No Valid ICLC frame for transfer. 1 Valid ICLC frame for transfer.
16–23 Reserved	This field is reserved.
24–31 ICLCPLD	ICLC Payload. This field is used to program the payload of the ICLC frame to be transmitted. New ICLC payload should be set when ICR[SNDICLC] = 0. This field can only be written when ICR[SNDICLC] = 0 (see Table 56-8 for supported ICLC payloads).

56.6.9 LFAST Ping Control Register (LFAST_PICR)

Address: 0h base + 20h offset = 20h



LFAST_PICR field descriptions

Field	Description
0–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 PNGREQ	Ping Response Frame Request. This bit is set to initiate the transfer of Ping response frame. Cleared after transmission of Ping response frame. Set by user software and cleared by system hardware. This field can only be written when MCR[DRFEN] = 1. 1 Ping response frame transmission request is queued 0 No pending Ping response frame transmission request
16 PNGAUTO	Ping Response Enable. Defines when ping response should be automatically sent on reception of Ping ICLC frame from LFAST master. This field can only be written when MCR[DRFEN] = 0. 0 Ping response should not be automatically sent. 1 Ping response should be automatically sent.
17–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 PNGPYLD	LFAST Slave: Defines the LFAST slaves ping reply frame payload content. This field can only be written when MCR[DRFEN] = 0. LFAST Master: Defines the expected payload of ping response frame. Used for comparison with ping frame received.

56.6.10 LFAST Rx FIFO CTS Control Register (LFAST_RFCR)

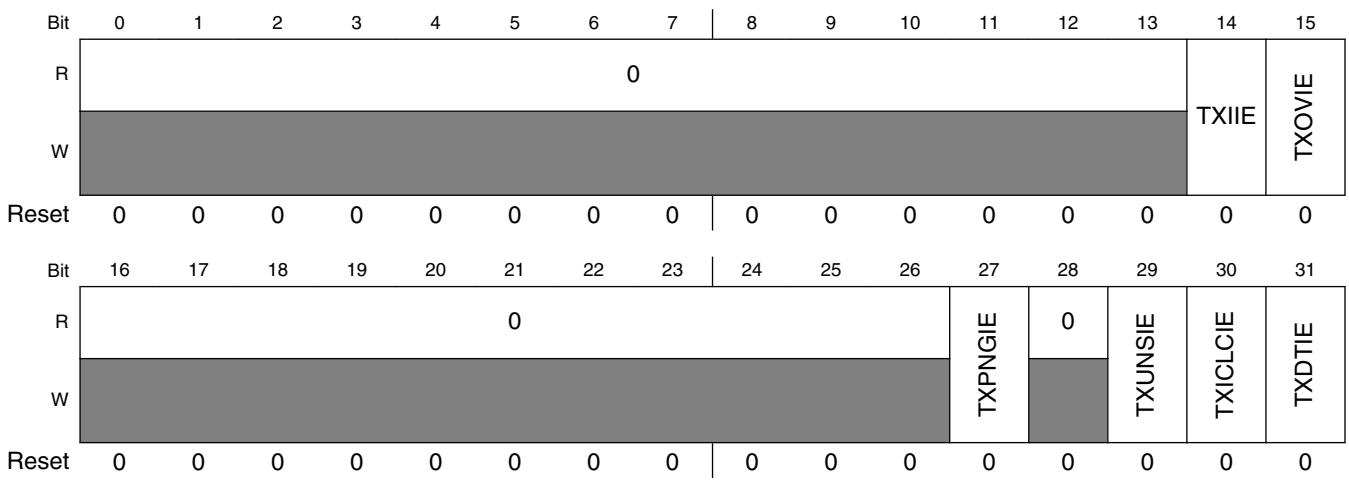
Address: 0h base + 2Ch offset = 2Ch

LFAST_RFCR field descriptions

Field	Description
0–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–15 RCTSMX	Rx FIFO Maximum Threshold. Defines the condition for CTS bit of frames to be negated. This field can only be written when LFAST_MCR[DRFEN] = 0.
16–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 RCTSMN	Rx FIFO Minimum Threshold. Defines the condition for CTS bit of frames to be set. This field can only be written when LFAST_MCR[DRFEN] = 0.

56.6.11 LFAST Tx Interrupt Enable Register (LFAST_TIER)

Address: 0h base + 30h offset = 30h



LFAST_TIER field descriptions

Field	Description
0–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 TXIIE	Tx Data Interface Not Enabled - (Mask) Enables or disables the interrupt. Tx Data Interface not enabled and a frame is ready to be transmitted

Table continues on the next page...

LFAST_TIER field descriptions (continued)

Field	Description
	0 Interrupt is disabled 1 Interrupt is enabled
15 TXOVIE	Transmit Data FIFO Overflow Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled
16–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 TXPNGIE	Ping Response Frame Transmitted Interrupt Enable. 0 Interrupt is disabled 1 Interrupt is enabled
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 TXUNSIE	Unsolicited Frame transmitted Interrupt Enable 0 Interrupt is disabled 1 Interrupt is enabled
30 TXICLCIE	ICLC Frame transmitted Interrupt Enable 0 Interrupt is disabled 1 Interrupt is enabled
31 TXDTIE	Data Frame transmitted Interrupt Enable 0 Interrupt is disabled 1 Interrupt is enabled

56.6.12 LFAST Rx Interrupt Enable Register (LFAST_RIER)

Address: 0h base + 34h offset = 34h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0								RXUOIE	RXMNIE	RXMXIE	RXUFIE	RXOFIE	RXSZIE	RXICIE	RXLCEIE
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0												RXCTSIE	RXDIE	RXUNSIE	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LFAST_RIER field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 RXUOIE	Unsolicited frame register overflow. Indicates existing unsolicited frame hasn't been read and a new unsolicited frame has arrived. 0 Interrupt is disabled 1 Interrupt is enabled
9 RXMNIE	Rx Data FIFO Min Threshold reached 0 Interrupt is disabled 1 Interrupt is enabled
10 RXMXIE	Rx Data FIFO Max Threshold reached 0 Interrupt is disabled 1 Interrupt is enabled
11 RXUFIE	Rx Data FIFO Underflow 0 Interrupt is disabled 1 Interrupt is enabled
12 RXOFIE	Rx Data FIFO Overflow 0 Interrupt is disabled 1 Interrupt is enabled
13 RXSZIE	Frame with unsupported frame size received. Valid frame sizes are defined in Table 56-12 0 Interrupt is disabled 1 Interrupt is enabled
14 RXICIE	Invalid ICLC code Received 0 Interrupt is disabled 1 Interrupt is enabled
15 RXLCEIE	Invalid Logical Channel Type 0 Interrupt is disabled 1 Interrupt is enabled
16–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 RXCTSIE	Frame with CTS bit Low Received 0 Interrupt is disabled 1 Interrupt is enabled
29 RXDIE	Data frame received 0 Interrupt is disabled 1 Interrupt is enabled
30 RXUNSIE	Unsolicited Frame received 0 Interrupt is disabled 1 Interrupt is enabled

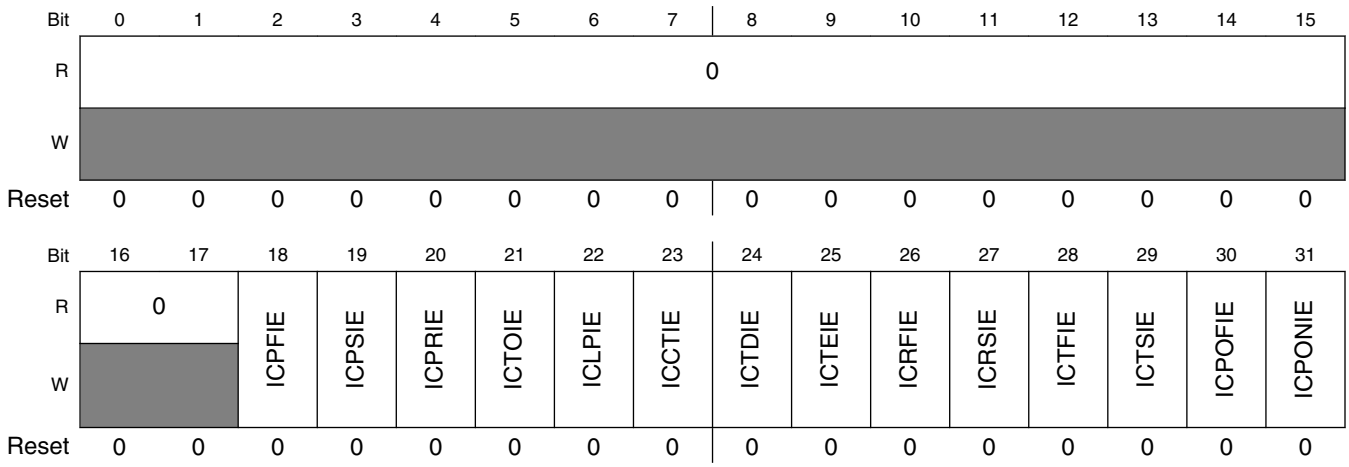
Table continues on the next page...

LFAST_RIER field descriptions (continued)

Field	Description
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

56.6.13 LFAST Rx ICLC Interrupt Enable Register (LFAST_RIIER)

Address: 0h base + 38h offset = 38h



LFAST_RIIER field descriptions

Field	Description
0–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 ICPFIE	Ping Frame Response failed 0 Interrupt is disabled 1 Interrupt is enabled
19 ICPSIE	Ping Frame Response successful 0 Interrupt is disabled 1 Interrupt is enabled
20 ICPRIE	ICLC frame for Ping Frame Request received 0 Interrupt is disabled 1 Interrupt is enabled
21 ICTOIE	ICLC frame for Test mode off received 0 Interrupt is disabled 1 Interrupt is enabled
22 ICLPIE	ICLC frame for Loopback On received 0 Interrupt is disabled 1 Interrupt is enabled

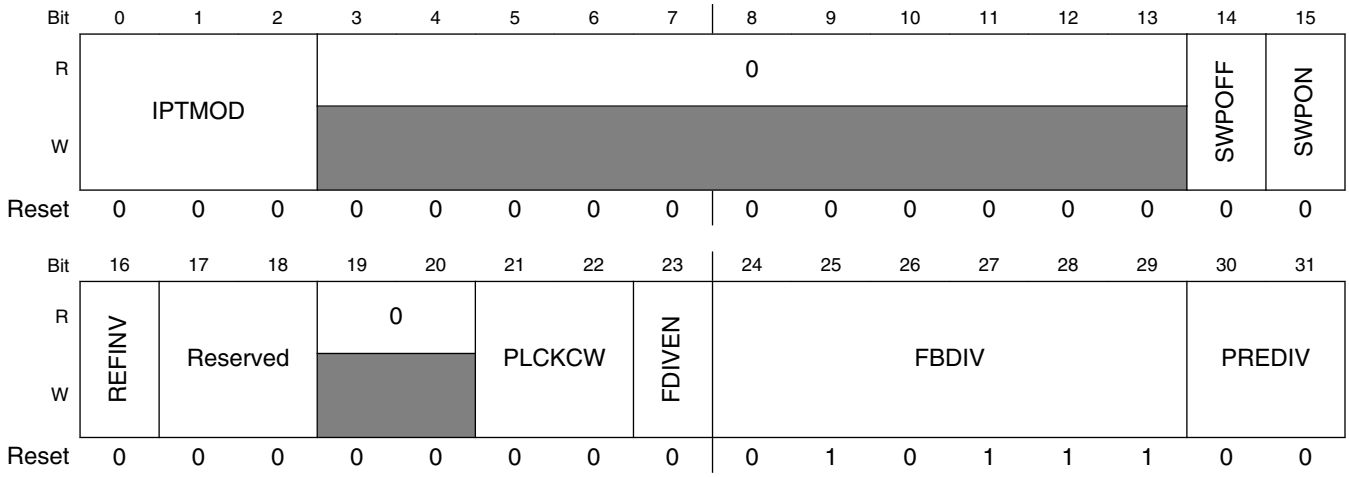
Table continues on the next page...

LFAST_RIIER field descriptions (continued)

Field	Description
23 ICCTIE	ICLC frame for Clk Test mode on received 0 Interrupt is disabled 1 Interrupt is enabled
24 ICTDIE	ICLC frame for LFAST Slaves Tx Interface Disable received 0 Interrupt is disabled 1 Interrupt is enabled
25 ICTEIE	ICLC frame for LFAST Slaves Tx Interface Enable received 0 Interrupt is disabled 1 Interrupt is enabled
26 ICRFIE	ICLC frame for LFAST Slaves Rx Interface fast mode switch received 0 Interrupt is disabled 1 Interrupt is enabled
27 ICRSIE	ICLC frame for LFAST Slaves Rx Interface slow mode switch received 0 Interrupt is disabled 1 Interrupt is enabled
28 ICTFIE	ICLC frame for LFAST Slaves Tx Interface fast mode switch received 0 Interrupt is disabled 1 Interrupt is enabled
29 ICTSIE	ICLC frame for LFAST Slaves Tx Interface slow mode switch received 0 Interrupt is disabled 1 Interrupt is enabled
30 ICPOFIE	ICLC frame for PLL OFF received 0 Interrupt is disabled 1 Interrupt is enabled
31 ICPONIE	ICLC frame for PLL ON received 0 Interrupt is disabled 1 Interrupt is enabled

56.6.14 LFAST PLL Control Register (LFAST_PLLCR)

Address: 0h base + 3Ch offset = 3Ch



LFAST_PLLCR field descriptions

Field	Description
0–2 IPTMOD	Test mode programmability 000 Functional mode 001 Closed Loop 1 010 Force Vctrl 011 Charge Pump Up 100 Charge Pump Up Internal Test 101 Charge Pump Idle 110 Charge Pump Down 111 Closed Loop 2
3–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 SWPOFF	SW signal to turn OFF the PLL. Set by user software and cleared by system hardware. 0 No effect 1 PLL will be turned OFF.
15 SWPON	SW signal to turn ON the PLL. Set by user software and cleared by system hardware. 0 No effect 1 PLL will be turned ON
16 REFINV	Inverts reference clock edge to PFD. If System PLL PFD using same reference clock, enabling this feature will minimize noise injection crosstalk via the substrate. 0 Do not inverted 1 Invert

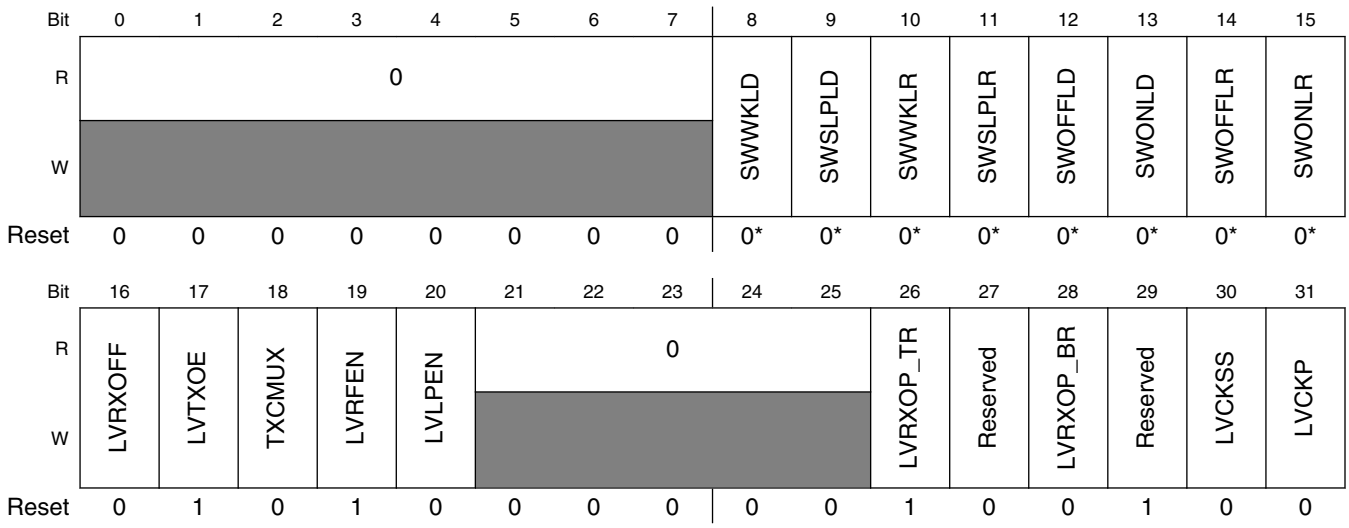
Table continues on the next page...

LFAST_PLLCR field descriptions (continued)

Field	Description
17–18 Reserved	This field is reserved.
19–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–22 PLCKCW	PLL Lock Ready Count Width. Defines the number of cycles PLL waits for before asserting lock_ready flag High 00 1040 cycles 01 520 cycles 10 320 cycles 11 200 cycles
23 FDIVEN	Enable fraction division mode in feedback divider. Enables the division of vco clock output by a factor of (FBDIV + 0.5). 0 Fraction division mode not enabled 1 Fraction division mode enabled
24–29 FBDIV	Feedback Division factor for VCO output clock. This field can only be written when LFAST_MCR[DRFEN] = 0. 00h No clock output 01h – 0Ah Reserved 0Bh Divide by 12 (11.5, if FDIVEN = 1) ... ... 1Fh Divide by 32 (31.5, if FDIVEN = 1) 20h – 3Fh Reserved
30–31 PREDIV	Division factor for PLL Reference Clock input. This field can only be written when LFAST_MCR[DRFEN] = 0. 00 Direct clock passed 01 Divide by 2 10 Divide by 3 11 Divide by 4

56.6.15 LFAST LVDS Control Register (LFAST_LCR)

Address: 0h base + 40h offset = 40h



* Notes:
- SWONLR field: Set by user software and cleared by system hardware.
- SWOFFLR field: Set by user software and cleared by system hardware.
- SWONLD field: Set by user software and cleared by system hardware.
- SWOFFLD field: Set by user software and cleared by system hardware.
- SWSLPLR field: Set by user software and cleared by system hardware.
- SWWKLR field: Set by user software and cleared by system hardware.
- SWSLPLD field: Set by user software and cleared by system hardware.
- SWWKLD field: Set by user software and cleared by system hardware.

LFAST_LCR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 SWWKLD	SW signal to take LVDS LD out of Sleep mode. This field can only be written when LFAST_MCR[DRFEN] = 1. **NOTE:** Writes are not reflected in the read of this field. 0 No effect 1 LVDS LD will be taken out of sleep (provided no other source is trying to put it in sleep)
9 SWSLPLD	SW signal to put LVDS LD into Sleep mode. This field can only be written when LFAST_MCR[DRFEN] = 1. **NOTE:** Writes are not reflected in the read of this field. 0 No effect 1 LVDS LD will be put in sleep

Table continues on the next page...

LFAST_LCR field descriptions (continued)

Field	Description
10 SWWKLR	SW signal to take LVDS LR out of Sleep mode. This field can only be written when LFAST_MCR[DRFEN] = 1. **NOTE:** Writes are not reflected in the read of this field. 0 No effect 1 LVDS LR will be taken out of sleep (provided no other source is trying to put it in sleep)
11 SWSLPLR	SW signal to put LVDS LR into Sleep mode. This field can only be written when LFAST_MCR[DRFEN] = 1. **NOTE:** Writes are not reflected in the read of this field. 0 No effect 1 LVDS LR will be put in sleep (provided no other source is trying to wake it up)
12 SWOFFLD	SW signal to turn OFF the LVDS LD. This field can only be written when LFAST_MCR[DRFEN] = 1. **NOTE:** Writes are not reflected in the read of this field. 0 No effect 1 LVDS LD will be turned OFF(provided no other source is trying to turn the LD ON)
13 SWONLD	SW signal to turn ON the LVDS LD. This field can only be written when LFAST_MCR[DRFEN] = 1. **NOTE:** Writes are not reflected in the read of this field. 0 No effect 1 LVDS LD will be turned ON
14 SWOFFLR	SW signal to turn OFF the LVDS LR. This field can only be written when LFAST_MCR[DRFEN] = 1. **NOTE:** Writes are not reflected in the read of this field. 0 No effect 1 LVDS LR will be turned OFF (provided no other source is trying to turn the LR ON)
15 SWONLR	SW signal to turn ON the LVDS LR. This field can only be written when LFAST_MCR[DRFEN] = 1. **NOTE:** Writes are not reflected in the read of this field. 0 No effect 1 LVDS LR will be turned ON
16 LVRXOFF	Indicates the value driven onto LVDS LR output when in shutdown mode
17 LVTXOE	LVDS LD output buffer enable. 0 LVDS LD output buffer enable is disabled. 1 LVDS LD output buffer enabled
18 TXCMUX	Tx and Clock Mux. The bit can be used to bring out PLL Phase 0 clock on Tx LVDS pad. 0 No effect 1 PLL Phase 0 clock will be brought out to Tx LVDS pad
19 LVRFEN	LVDS pad reference enable 0 LVDS reference pad disabled 1 LVDS reference pad enabled

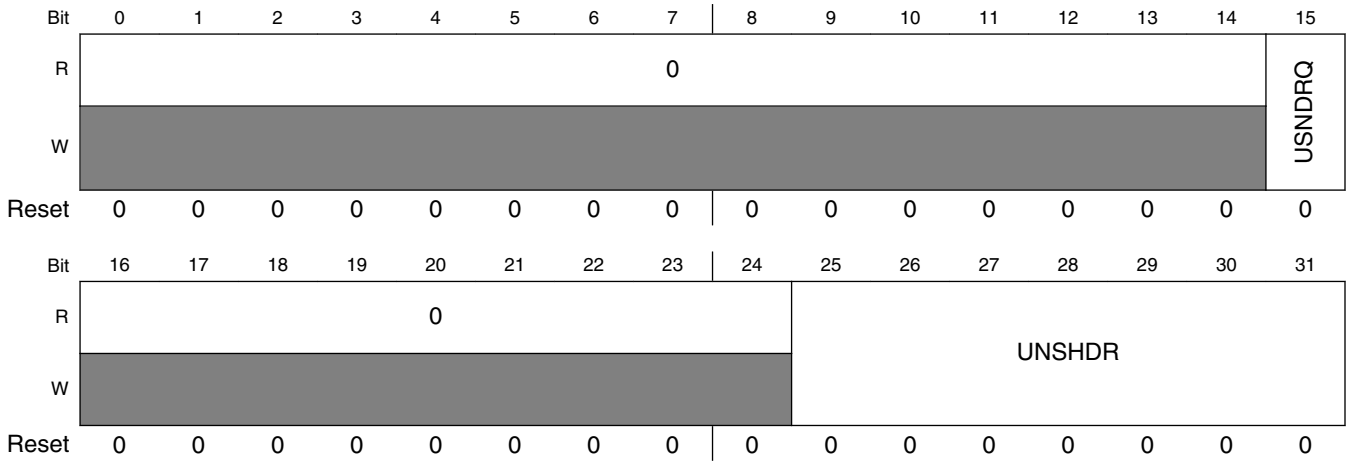
Table continues on the next page...

LFAST_LCR field descriptions (continued)

Field	Description
20 LVLPEN	Tx LVDS internal loopback enable The bit is reflected by output signal ipp_digrf_lvds_lpbk_en.The internal loopback is not intended for board level functionality, so this feature should not be implemented. 0 Tx LVDS normal mode enabled 1 Tx LVDS internal loopback mode enabled
21–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 LVRXOP_TR	Used to enable or disable the on-chip receiver termination resistor in LFAST mode (applies to LVDS pad use for LFAST only): 1 Disable on-chip LFAST receiver termination 0 Enable on-chip LFAST receiver termination
27 Reserved	This field is reserved.
28 LVRXOP_BR	Used to set the bias current for the receiver in LFAST mode. It is recommended to always write 1 to this bit when using the LFAST interface. Writing 0 will allow for a small power savings during lower baud rates (applies to LVDS pad use for LFAST only): 0 Use for LFAST receiver baud rates less than the maximum baud rate. 1 Required for LFAST receiver maximum baud rate.
29 Reserved	This field is reserved.
30 LVCKSS	LVDS Clock Sync Select This bit is used to adjust the LVDS data sampling to the duty cycle of the clock. It is recommended that a value of zero is used in all cases. A value of one is reserved for specific devices/revisions with different clock timing. 0 normal clock used to sample the LVDS data 1 adjusted clock used to sample the LVDS data
31 LVCKP	LVDS clock select. This bit is used for selecting use of direct pll clock or inverted pll clock in LVDS. 0 Direct pll clock to be used inside the LVDS 1 Inverted pll clock to be used inside the LVDS

56.6.16 LFAST Unsolicited Tx Control Register (LFAST_UNSTCR)

Address: 0h base + 44h offset = 44h

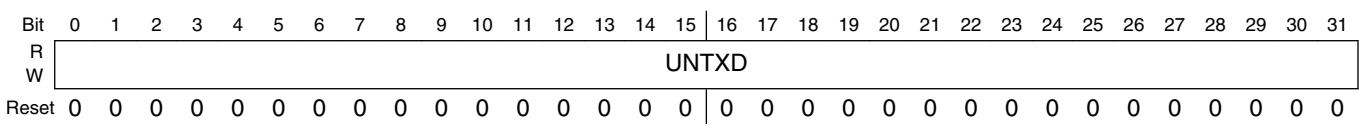


LFAST_UNSTCR field descriptions

Field	Description
0–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 USNDRQ	Tx Unsolicited send request. Set by user software and cleared by system hardware. This field can only be written when MCR[DRFEN] = 1. 0 No valid Unsolicited frame exists 1 Valid Unsolicited frame exists for transmission
16–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–31 UNSHDR	Tx Unsolicited message header. This field can only be written when LFAST_UNSTCR[USNDRQ] = 0

56.6.17 LFAST Unsolicited Tx Data Registers (LFAST_UNSTDR*n*)

Address: 0h base + 48h offset + (4d × i), where i=0d to 8d

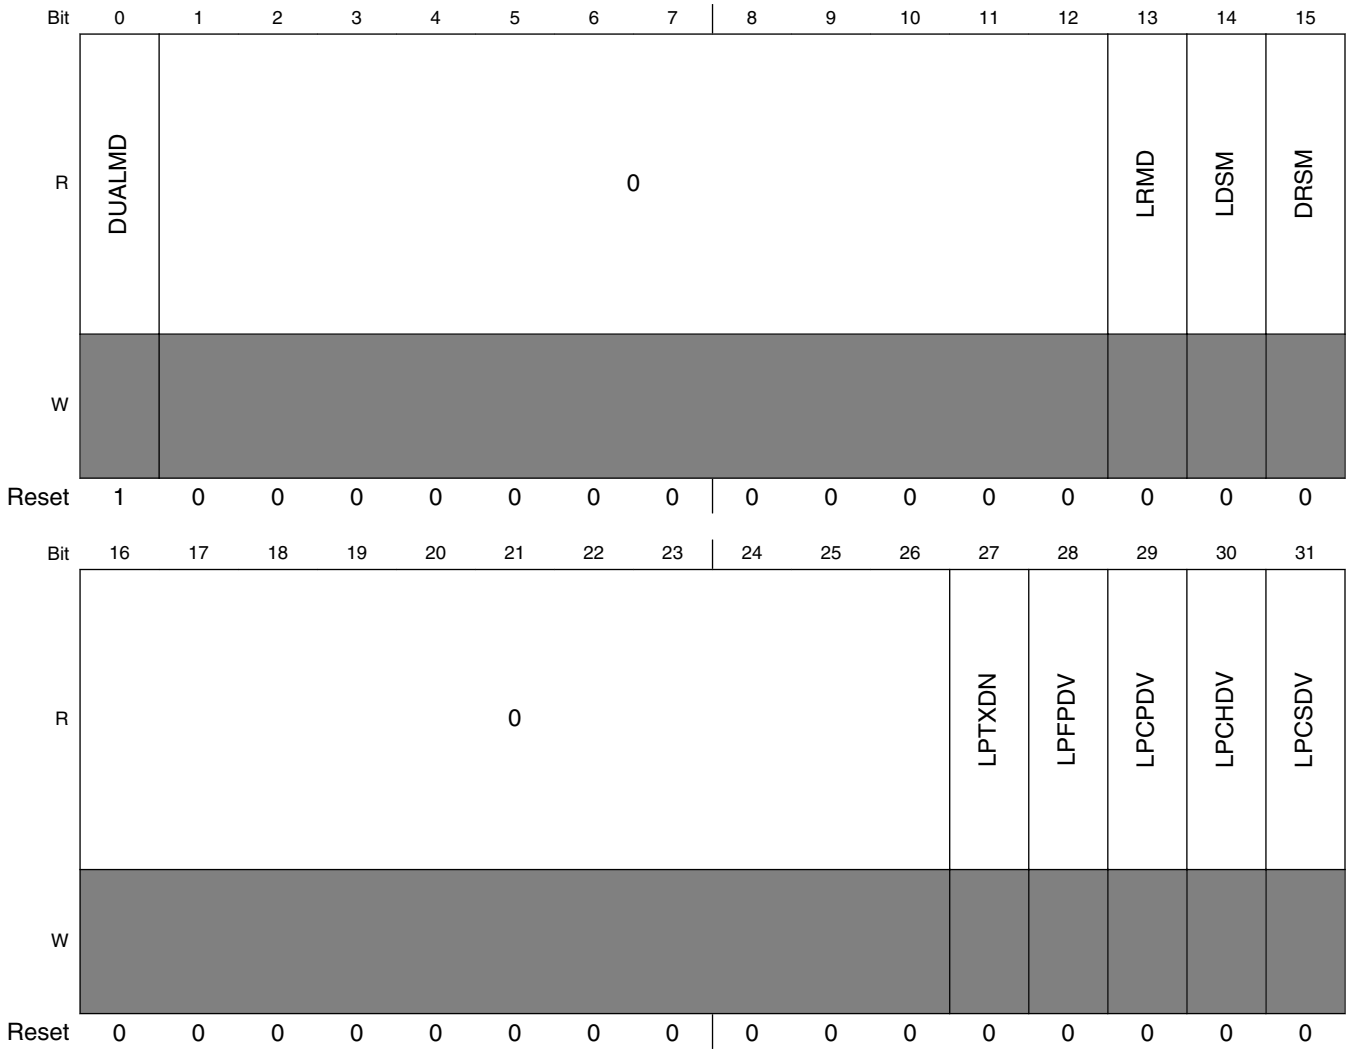


LFAST_UNSTDR*n* field descriptions

Field	Description
0–31 UNTXD	Unsolicited Transmit Data 8-0. This represents 9 registers for Unsolicited transmit data. The first bit to transmitted as part of the payload will be from UNTXD8[31], second bit from UNTXD8[30], and so on. So the last bit transmitted will be from UNTXD0[0] in case of 288 bit payload.

56.6.18 LFAST Global Status Register (LFAST_GSR)

Address: 0h base + 80h offset = 80h



LFAST_GSR field descriptions

Field	Description
0 DUALMD	Indicates the LFAST module is in Dual mode 0 LFAST Module in Slave only mode 1 LFAST Module in Dual mode
1–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 LRMD	Indicates if the Rx Controller is idle/active and that the Rx clocks are enabled. In functional mode this will always be active.

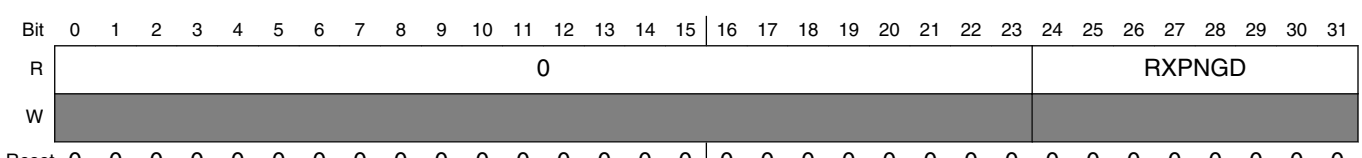
Table continues on the next page...

LFAST_GSR field descriptions (continued)

Field	Description
	0 Rx Controller is in Idle state 1 Rx Controller is active
14 LDSM	Transmit Interface Data Rate Status. Indicates the current speed rate of the Tx controller 0 Data rate of LOW speed mode 1 Data rate of HIGH speed mode
15 DRSM	Receive Interface Data Rate Status. Indicates the current speed rate of the Rx controller 0 Data rate of LOW speed mode 1 Data rate of HIGH speed mode
16–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 LPTXDN	Auto loopback frame transmission count reached. The Count of frame is defined by LFAST_ALCR[LPFMCNT]. 0 Auto loopback frame transmission count not reached. 1 Auto loopback frame transmission count reached.
28 LPFPDV	Loopback frame pass threshold reached. 0 Pass frame threshold not reached. 1 Pass frame threshold achieved
29 LPCPDV	Valid payload received during loopback check mode. Indicates whether the Loop back frame received payload is CBh. 0 Payload received is not CBh 1 Payload received is CBh
30 LPCHDV	Valid header received during loopback check mode. Indicates whether the Loop back frame received header is 13h. 0 Header received is not 13h 1 Header received is 13h
31 LPCSDV	Valid synchronization received. 0 Valid Synchronization pattern not detected 1 Valid Synchronization pattern detected

56.6.19 LFAST Ping Status Register (LFAST_PISR)

Address: 0h base + 84h offset = 84h



LFAST_PISR field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 RXPNGD	Ping Data Register. In LFAST Master mode the Ping response ICLC frame received is stored into this register.

56.6.20 LFAST Data Frame Status Register (LFAST_DFSR)

Address: 0h base + 94h offset = 94h

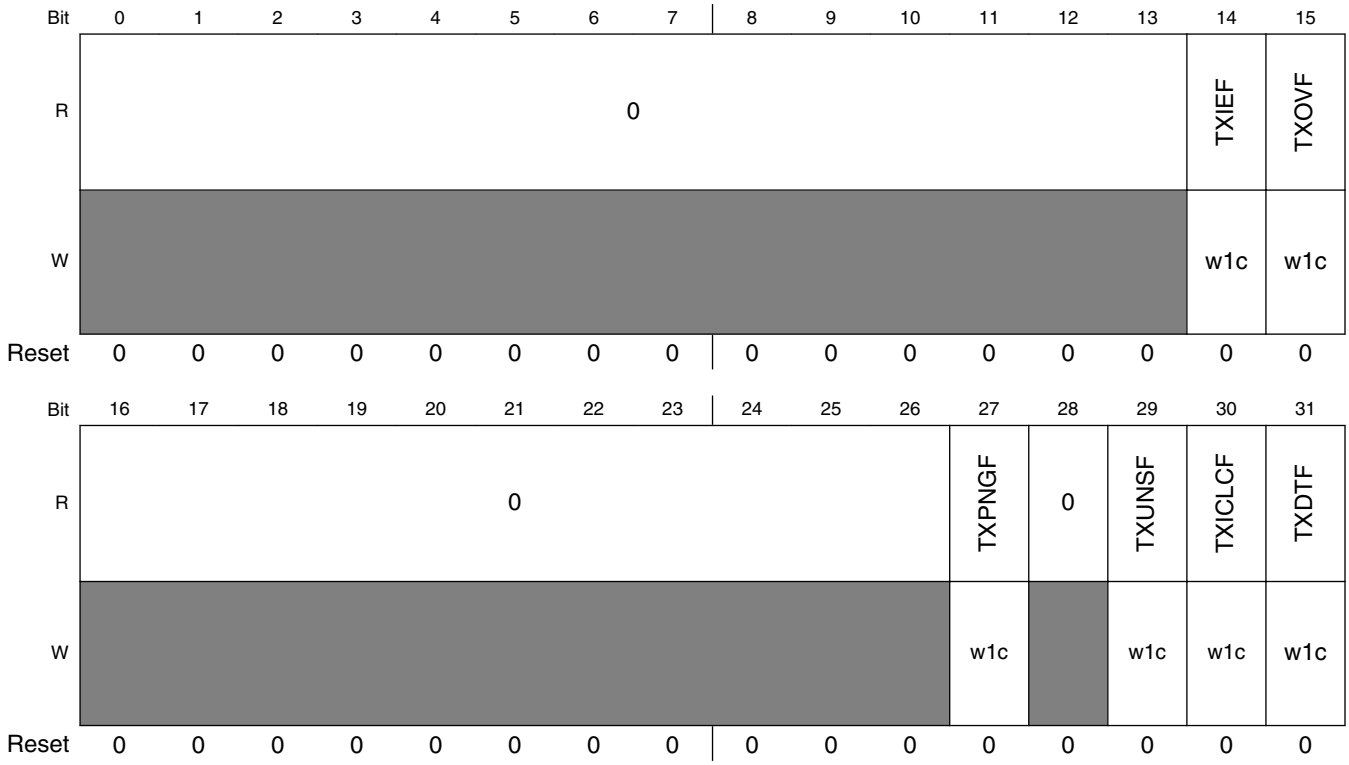
Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0		RXDCNT						0					RXFCNT			0		TXDCNT						0					TXFCNT		
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LFAST_DFSR field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–7 RXDCNT	Unread Rx Frame Data Count. Indicates the number of unread data stored in the Rx Data FIFO.
8–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–15 RXFCNT	Unread Rx Frame Count. Indicates the number of unread data frames stored in the Rx Data FIFO.
16–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–23 TXDCNT	Unread Tx Frame Data Count. Indicates the number of unread data stored in the Tx Data FIFO.
24–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 TXFCNT	Unread Tx Frame Count.Count of pending Data Frames programed by System Side Module.

56.6.21 LFAST Tx Interrupt Status Register (LFAST_TISR)

Address: 0h base + 98h offset = 98h



LFAST_TISR field descriptions

Field	Description
0–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 TXIEF	TxData Interface not enabled. Tx Data Interface not enabled and a frame is ready to be transmitted 0 Interrupt event has not occurred 1 Interrupt event has occurred
15 TXOVF	Transmit Data FIFO Overflow Interrupt 0 Interrupt event has not occurred 1 Interrupt event has occurred
16–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 TXPNGF	Ping response frame transmitted interrupt 0 Interrupt event has not occurred 1 Interrupt event has occurred
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

LFAST_TISR field descriptions (continued)

Field	Description
29 TXUNSF	Unsolicited Frame transmitted Interrupt 0 Interrupt event has not occurred 1 Interrupt event has occurred
30 TXICLCF	ICLC Frame transmitted Interrupt 0 Interrupt event has not occurred 1 Interrupt event has occurred
31 TXDTF	Data Frame transmitted Interrupt 0 Interrupt event has not occurred 1 Interrupt event has occurred

56.6.22 LFAST Rx Interrupt Status Register (LFAST_RISR)

Address: 0h base + 9Ch offset = 9Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0								RXUOF	RXMNF	RXMXF	RXUFF	RXOFF	RXSZF	RXICF	RXLCEF

W													w1c	w1c	w1c	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LFAST_RISR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

LFAST_RISR field descriptions (continued)

Field	Description
8 RXUOF	Unsolicited frame register overflow. Indicates existing unsolicited frame hasn't been read and a new unsolicited frame has arrived. 0 Interrupt event has not occurred 1 Interrupt event has occurred
9 RXMNF	Rx Data FIFO Min Threshold reached. 0 Interrupt event has not occurred 1 Interrupt event has occurred
10 RXMXF	Rx Data FIFO Max Threshold reached. 0 Interrupt event has not occurred 1 Interrupt event has occurred
11 RXUFF	Rx Data FIFO Underflow. 0 Interrupt event has not occurred 1 Interrupt event has occurred
12 RXOFF	Rx Data FIFO Overflow. 0 Interrupt event has not occurred 1 Interrupt event has occurred
13 RXSZF	Frame with unsupported frame size received. See "Frames Supported by LFAST interfaces" table for details. 0 Interrupt event has not occurred 1 Interrupt event has occurred - On reception of frame with payload size for a frame other than mentioned in the "Frames Supported by LFAST interfaces" table.
14 RXICF	Invalid ICLC code Received. 0 Interrupt event has not occurred 1 Interrupt event has occurred
15 RXLCEF	Invalid Logical Channel Type. 0 Interrupt event has not occurred 1 Interrupt event has occurred - On reception of frame other than mentioned in the "Frames Supported by LFAST interfaces" table.
16–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 RXCTSF	Frame with CTS bit Low Received. 0 Interrupt event has not occurred 1 Interrupt event has occurred
29 RXDF	Data frame received. 0 Interrupt event has not occurred 1 Interrupt event has occurred
30 RXUNSF	Unsolicited Frame received. 0 Interrupt event has not occurred 1 Interrupt event has occurred

Table continues on the next page...

LFAST_RISR field descriptions (continued)

Field	Description
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

LFAST_UNSRDR*n* field descriptions

Field	Description
0–31 UNRXD	Unsolicited Receive Data. This represents 9 registers for Unsolicited received data.It is read only register. The first bit received as part of the payload will be stored at UNRXD8[31], second bit at UNRXD8[30], and so on. So the last bit will be stored at UNRXD0[0] in case of 288 bit payload.

56.7 Functional description

56.7.1 Startup procedure

The LFAST requires a sequence of operations before it can be used for communication. The procedure to enable LFAST for proper operation is listed below.

56.7.1.1 LFAST master interface startup procedure

1. After reset the SLCR and RCDCR are programed according to the LVDS parameters in the device data sheet.

2. The PLLCR is programmed with configuration parameters for the PLL.
3. The LCR is programed with configuration parameters of the LVDS.
4. Write MCR[MSEN] = 1. Then select LFAST modes by configuring MCR[CTSEN]and MCR[DATAEN].
5. Write MCR[DRFEN] = 1 to enable the LFAST.
6. Write MCR[RXEN] = 1 and MCR[TXEN] = 1 to negate the LD powerdown, LR disable and LR powerdown signals.
7. Write ICR[ICLCPLD] = 31h to enable the Slaves Tx Interface.
8. Write ICR[SNDICLC] = 1 and ICR[ICLCSEQ] = 1.
9. Write MCR[TXARBD] = 0.
10. The ICLC transmission is confirmed by verifying one of the following:
    - ICR[SNDICLC] = 0.
    - TISR[TXICLCF] = 1.
11. Write ICR[ICLCPLD] = 00h to check the LFAST slaves status.
12. Write ICR[SNDICLC] = 1.
13. The LFAST slave status is confirmed by occurrence of one of the following:
    - LFAST slave is enabled if RIISR[ICPSF] = 1. Proceed to step 14.
    - LFAST slave is disabled if RIISR[ICPFF] = 1. The LFAST master must wait and restart from Step 7.

Speed mode change:

14. Write PLLCR[SWPON] = 1 to enable the LFAST masters PLL.
15. Write ICLC start PLL frame, ICR[ICLCPLD] = 02h.
16. Write ICR[SNDICLC] = 1.
17. The ICLC transmission is confirmed by occurrence of one of the following:
    - ICR[SNDICLC] = 0.
    - TISR[TXICLCF] = 1.
18. To change LFAST masters Tx interface speed both of the following operations are performed:

Note

(The slaves Rx interface speed should be changed first.)

- Write ICR[ICLCPLD] = 10h for Tx data fast frame.
- Write ICR[SNDICLC] = 1.

19. Both of the following operations are performed to change the LFAST masters Rx interface speed:

Note

(The slaves Tx interface speed mode should be changed first)

- Write ICR[ICLCPLD] = 80h to select Rx data fast frame.
- Write ICR[SNDICLC] = 1.

20. The ICLC transmission is confirmed by the occurrence of one of the following:
    - ICR[SNDICLC] = 0
    - TISR[TXICLCF] = 1.
21. Write SCR[TDR] = 1 to change the LFAST masters Tx interface speed.
22. Write SCR[RDR] = 1 to change the LFAST masters Rx interface speed.
23. Write ICR[ICLCPLD] = 00h to confirm the change in speed of the LFAST slave. This frame should be written after waiting for the expected delay in the start of the PLL and speed mode change delay at the LFAST slave.
24. Write ICR[SNDICLC] = 1
25. Write MCR[TXARBD] = 1, after some delay to ensure the step 24 ICLC frame is send but no other frame is sent to arbitation.
26. The LFAST slaves speed mode is confirmed by the occurrence of the following:
    - If RIISR[ICPSF] = 1. The LFAST slave is in High Speed mode.
    - If RIISR[ICPFF] = 1. The LFAST slave is in Low Speed mode.
27. If RIISR[ICPSF] = 1, then all frame arbitration is enabled by both of the following operations:

- Write ICR[ICLCSEQ] = 0.
- Write MCR[TXARBD] = 0.

28. If RIISR[ICPFF] = 1 modifying the LFAST slaves speed needs to be repeated by:
    - Write SCR[TDR] = 0 to return the Tx interface to Low Speed mode.
    - Write MCR[TXARBD] = 0, to enable frame transmission.
    - The operations from step 14 need to be executed again.

56.7.1.2 LFAST slave interface startup procedure

1. After reset the SLCR and RCDCR are programed according to the LVDS datasheet.
2. The PLLCR is programed with the configuration parameters for the PLL.
3. The LCR is programed with the configuration parameters for the LVDS.
4. Write MCR[MSEN] = 0. Then select LFAST modes by configuring MCR[CTSEN] and MCR[DATAEN].
5. Write MCR[DRFEN] = 1 to enable the LFAST.
6. The LR is enabled by writing MCR[RXEN] = 1. This negates the LR disable signaland LR's power down signal.
7. The LD enable signal needs to be asserted. This is done when one of the following are true:
    - When an ICLC frame with payload 31h is received the H/W will write RIISR[ICTEF] = 1 and MCR[TXEN] = 1.
    - MCRMCR[TXEN] = 1.
8. After a write to MCR[TXARBD] = 0, a ping frame will be sent on one of the following conditions:
    - When PICR[PNGAUTO] = 1 and an ICLC frame with payload 00h frame is received. H/W writes [ICRPF] = 1.
    - PICR[PNGREQ] = 1.

Speed mode change:

9. The PLL will start when one of the following conditions is met:

- When an ICLC frame with payload 02h is received. H/W writes RIISR[IPONF] = 1.
- Write PLLCR[SWPON] = 1.

10. The speed of the Tx interface is changed on one of the following conditions:
    - When SCR[DRMD] = 1 and an ICLC frame with payload 80h is received. H/W writes RIISR[ICTFF] = 1 and SCR[TDR] = 1.
    - SCR[TDR] = 1, when SCR[DRMD] = 0.
11. The speed of the Rx interface is changed on one of the following conditions:
    - When SCR[DRMD] = 1 and an ICLC frame with payload 10h is received. H/W writes RIISR[ICRFF] = 1 and SCR[RDR] = 1.
    - SCR[RDR] = 1, when SCR[DRMD] = 0.
12. A Ping Frame is sent on one of the following conditions:
    - When PICR[PNGAUTO] = 1 and an ICLC frame with payload 00h is received. H/W writes RIISR[ICRPF] = 1.
    - Write PICR[PNGREQ] = 1.
    - Write PICR[PNGREQ] = .

56.7.2 Line Receiver

This section describes the Line Receiver.

56.7.2.1 Introduction

The LR detects the voltage swing on the differential pair and converts it to a CMOS logic level that feeds the adaptive auto correlation block. The received data is sampled using the best of the 8 (default) or 4 (alternative setting) possible sampling edges from the high speed clock or 4 phases using the low speed clock. The sampling edge is chosen by checking which of the 8/4 Correlators provide the maximum correlation. If more than one sampling edge provides the maximum then the state machine will choose the sampling edge based on a defined selection algorithm.

After the correct sampling edge is chosen, the remaining unused sampling edges are turned off. Once the header is received the length of the frame (payload size) and logical channel definition can be obtained. The logical channel definition will determine the data

type of the payload and therefore will determine the destination for the payload. Decoding of the ICLC commands from the payload is required in order to extract the interface control, rate mode and PLL commands.

Figure 56-4 shows the block diagram of Uplink Controller.

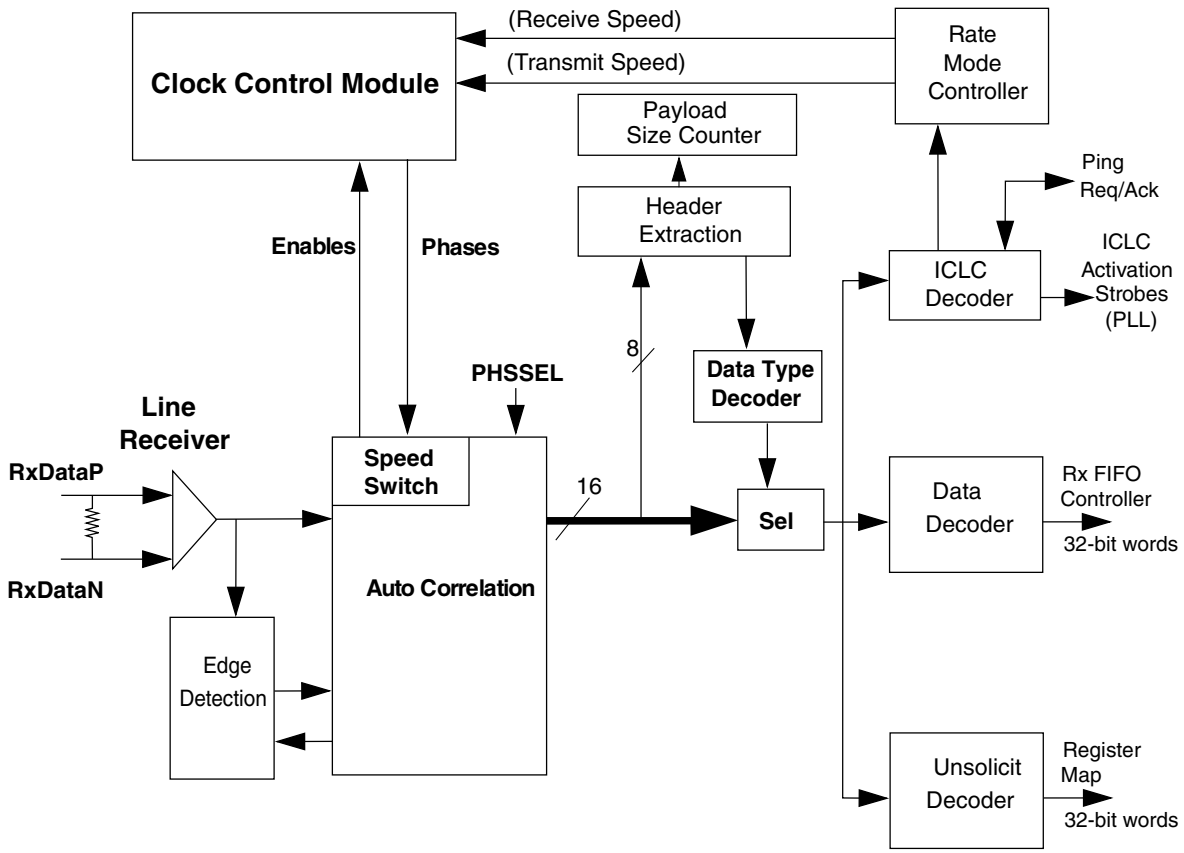

Figure 56-4. Top Level Receive Controller

56.7.2.2 Edge detection and auto-correlation

The edge detection and auto correlation are described together, as the mode setting of the auto-correlation block impacts largely on whether the edge detection circuitry is used or not. The edge detection will be performed first if required before auto-correlation.

56.7.2.2.1 Auto-Correlation modes

This section describes the Auto-Correlation modes.

56.7.2.2.1.1 Hunt Correlation mode

On reset the Receive Controller will always come up in Hunt Correlation mode. In this mode all the Correlators are enabled and the Receive Controller is always hunting for the synchronization pattern. The phase enables (either 8 or 4) to the external clock control module are always high. There is no edge detection for the first bit of the synchronization pattern. Hunt Correlation mode is considered the safest mode as the Receive Controller is always checking for the synchronization pattern, but it is the mode that consumes the most power. In Hunt Correlation mode the correlation is performed over all 16 bits of the synchronization pattern.

Figure 56-5 shows the block diagram of Hunt Correlation mode.

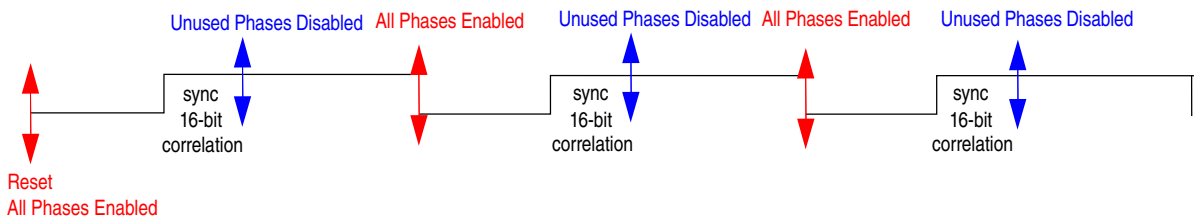

Figure 56-5. Hunt Correlation mode

56.7.2.2.2 Edge Detection

The edge detector is disabled in Hunt Correlation mode.

56.7.2.2.3 Auto correlation

The data transmission between the 2 devices LD and LR is asynchronous in nature. Hence the Receive Controller does not have the knowledge about the correct clock phase to be used for extracting the data. The task of the auto correlation (or synchronization) scheme is to estimate the best clock phase (8 or 4) for extraction of data as shown in the following figure.

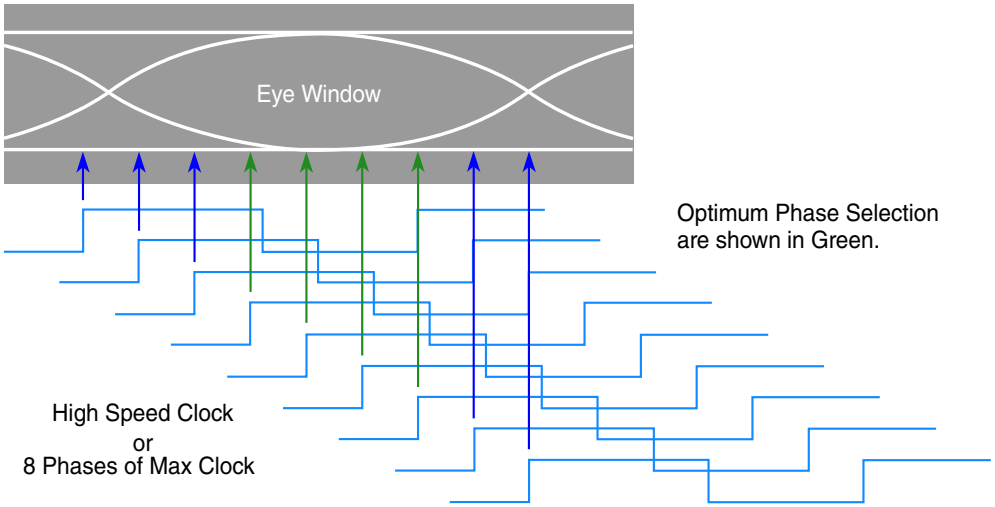

Figure 56-6. High Speed 8 Phase Selection

The objective of the auto correlation is to select the clock phase that occurs closest to the center of the eye diagram window. For 8 Phase clock alignment the worst case selection is when the clock edge is just after the LR output transition. The 8 clock phases will sample the correct value but the middle clock phases are the ideal selection. If one of the middle phases are selected then the minimum distance to the LR transition is 3 clock phases as shown in the following figure.

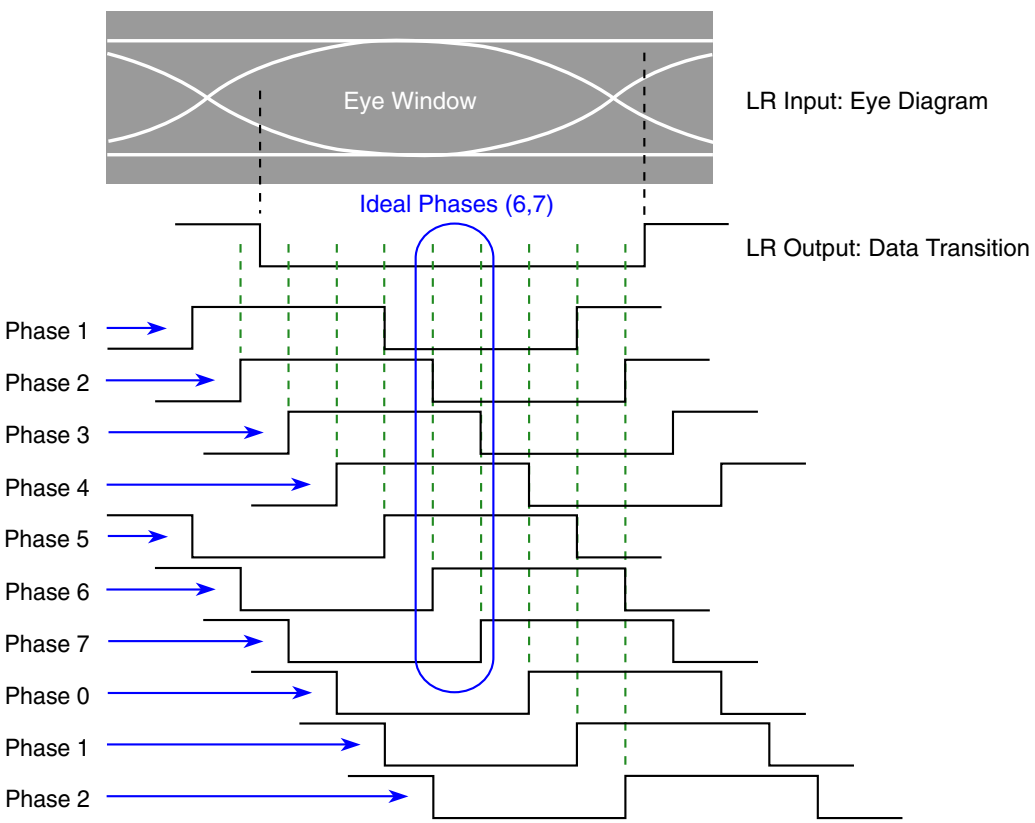

Figure 56-7. High Speed 8 Phase Clock Alignment Example

Each of the 8 high speed phases are 45 degrees separated. For 4 phases, whether high or low speed, the phases are 90 degrees separated but can have different phases enabled as shown in Figure 56-8 and Figure 56-9.

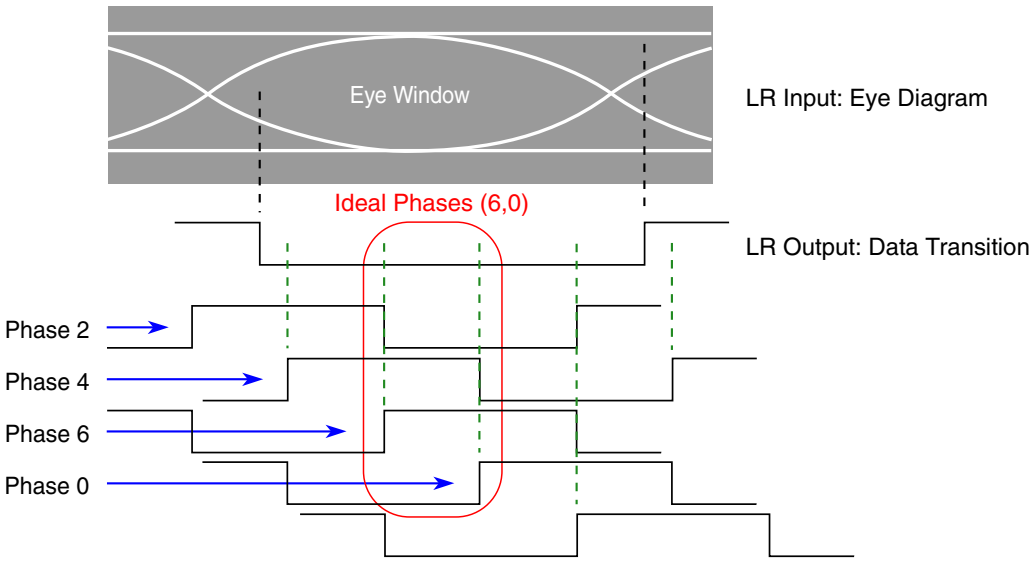

Figure 56-8. High Speed 4 Phase Clock Alignment Example

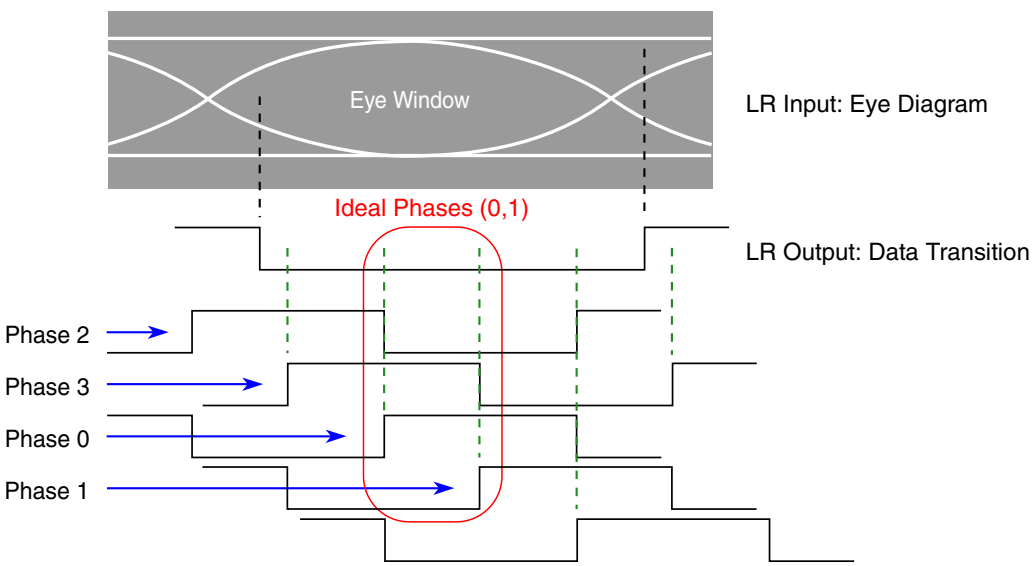

Figure 56-9. Low speed 4 phase clock alignment example

The auto correlation and selection of the correct clock phase starts after the edge detection finds a 0 to 1 transition. The high speed 8 or 4 phases from the PLL and the low speed 4 phases (generated inside the Clocking Module) are muxed inside the clocking module. The LFAST interface block will determine which phases are to be enabled and disabled. The only time the interface does not choose the phases is when the Clocking Module overrides the phase enables using COCR[SMPSEL].

The input data path can be sampled by different samplers depending on the configuration:

- High speed 8-phases: Samplers 0,1,2,3,4,5,6,7
- High speed 4-phases: Samplers 0,2,4,6
- Low Speed 4-phases: Samplers 0,1,2,3

Each sampler block samples the data path with a different clock phase from the Clocking Module, and resamples it to a intermediate phase as shown in Table 56-2, Table 56-3, and Table 56-4 before resampling it to Phase 0. The intermediate phase is used to make static timing between the initial phase and the final phase 0. The final phase, Phase 0 is chosen so all the clock trees after the sampler are clocked by the same clock.

Table 56-2. High speed 8 phase selection - sampling procedure

Samplers	InitialSample	Intermediate Sample	Final Sample
0	Phase 0	Phase 0	Phase 0
1	Phase 1	Phase 0	Phase 0
2	Phase 2	Phase 0	Phase 0
3	Phase 3	Phase 0	Phase 0
4	Phase 4	Phase 2	Phase 0
5	Phase 5	Phase 2	Phase 0
6	Phase 6	Phase 4	Phase 0
7	Phase 7	Phase 4	Phase 0

Table 56-3. High speed 4 phase selection - sampling procedure

Samplers	InitialSample Phase	Intermediate Sample Phase	Final Sample Phase
0	Phase 0	Phase 0	Phase 0
1	Disabled	Disabled	Disabled
2	Phase 2	Phase 0	Phase 0
3	Disabled	Disabled	Disabled
4	Phase 4	Phase 2	Phase 0
5	Disabled	Disabled	Disabled
6	Phase 6	Phase 4	Phase 0
7	Disabled	Disabled	Disabled

For High speed 4 Phase selection, See Table 56-3, Samplers 1, 3, 5, 7 are disabled. In the Phase Select algorithm Phase 1 is mapped to Phase0, Phase 3 is mapped to Phase 2, Phase 5 is mapped to Phase 4, Phase 7 is mapped to Phase 6 so it simplifies the algorithm and allows the algorithm to be the same independent of 4 or 8 Phases in high speed.

Table 56-4. Low speed 4 phase selection - sampling procedure

Samplers	InitialSample Phase	Intermediate Sample Phase	Final Sample Phase
0	Phase 0	Phase 0	Phase 0

Table continues on the next page...

Table 56-4. Low speed 4 phase selection - sampling procedure (continued)

Samplers	InitialSample Phase	Intermediate Sample Phase	Final Sample Phase
1	Phase 1	Phase 0	Phase 0
2	Phase 2	Phase 0	Phase 0
3	Phase 3	Phase 0	Phase 0
4	Disabled	Disabled	Disabled
5	Disabled	Disabled	Disabled
6	Disabled	Disabled	Disabled
7	Disabled	Disabled	Disabled

For low speed 4 Phase selection, See Table 56-4, Samplers 4, 5, 6, 7 are disabled.The first four Samplers (0,1,2,3) of the low 4 phase speed selection algorithm are the same as the four samplers required for the high 8 phase speed. Therefore the same architecture can be used for both high speed and low speed with the other four data paths disabled for low speed.

56.7.2.2.4 Sampler block and phase enable and disable

There are 8 data sampler paths in total inside the auto correlation block, each data sampler has 3 sampling registers with the possibility of each register being clocked by a different phase (in example, Sampler 5 for high speed can have Phases 5, 2 and 0). Therefore, after the correct data sampler has been selected for either high or low speed, the block can turn off all the sampler paths except for one, therefore 3 out of 24 registers will remain enabled while the others are disabled, as shown in the following figure.

After correlation and the correct data sampler has been selected all the other data samplers whose initial phase does not match the select phase are disabled. The selected sampler will then keep the required phases needed enabled, this can be max 3 phases (for example, Sampler 5 has Phases 5, 2, 0) or min 1 phase (in example below, Sampler 0 has all Phase 0 content).

The end result is that the Rx Controller can disable the required number of unused sampler registers and disable any unnecessary phases from the Clocking Module by deasserting the respective phase enables.

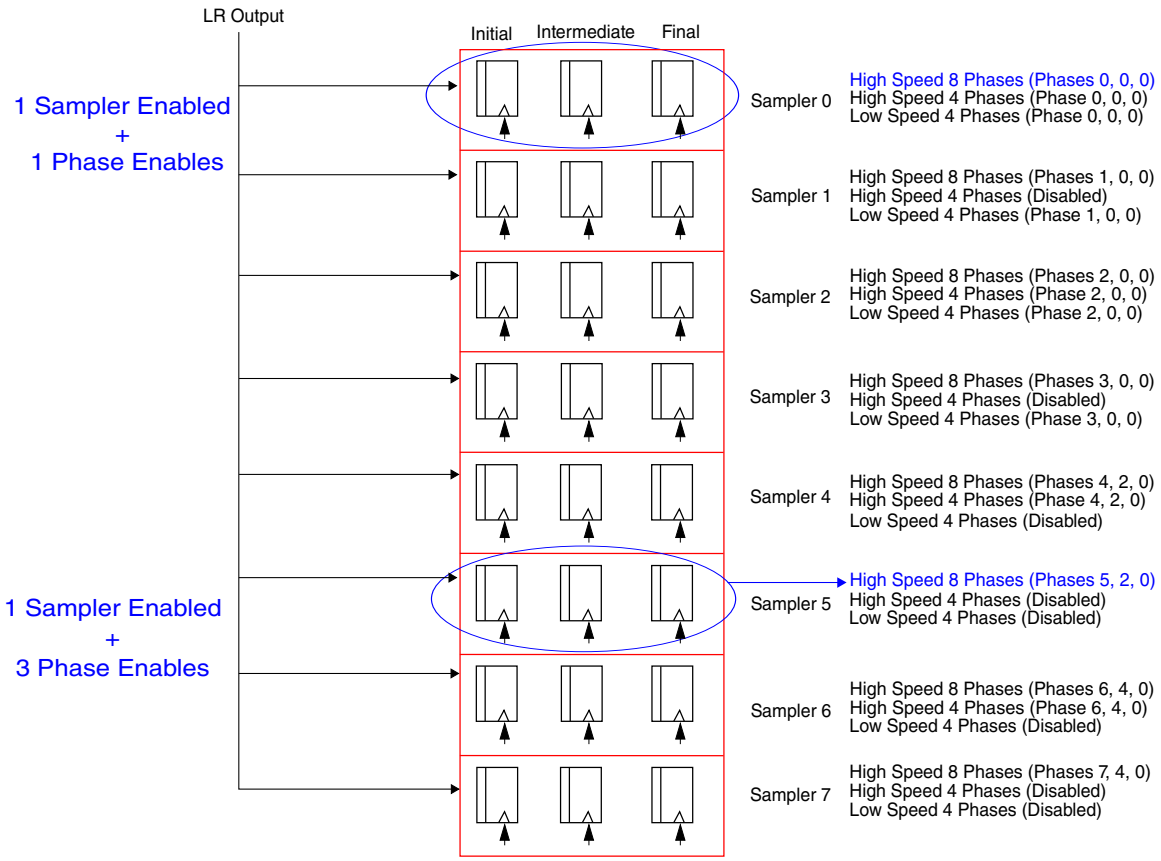

Figure 56-10. 8 Samplers, each Sampler has 3 Registers

In order to achieve the sampler and phase enable requirements each Sampler block will require the logic as shown in the following figure.

The Clock Gating Element resides inside the Clocking Module block. The interface will provide the enables to the Clocking Module and the Clocking Module will in return provide the individual clocks to the sampling registers.

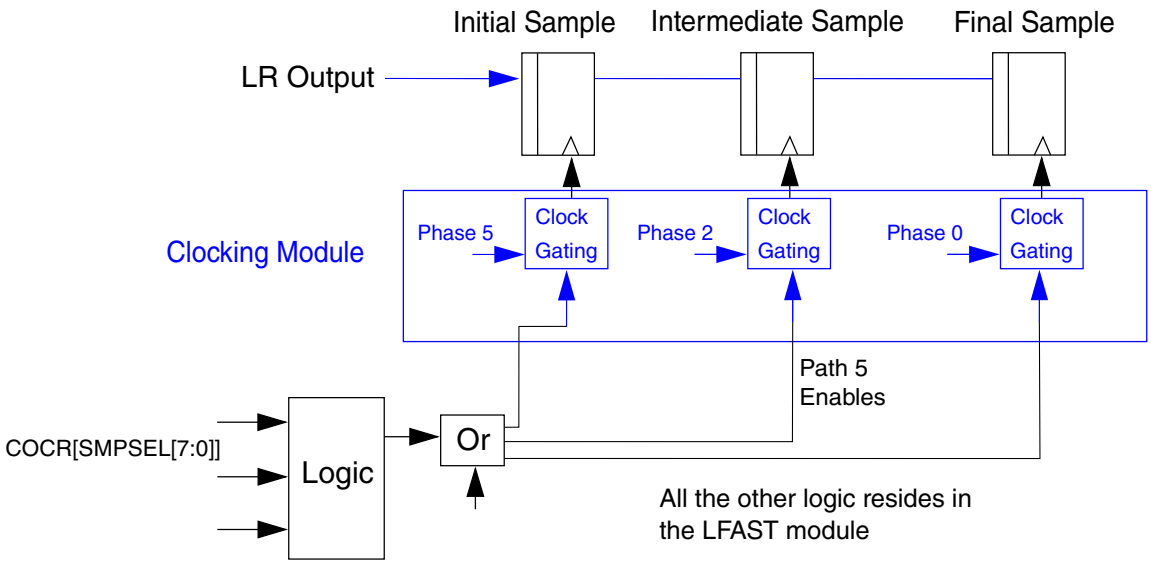

Figure 56-11. Sampler 5 Logic

56.7.2.3 Header and Payload Extraction

Once the Phases/Samplers are chosen after Synchronization and Correlation the next part of the flow is the header extraction. The Receive Controller will output a 16 bit word, bit shifted every Phase 0 clock as shown in the Figure 56-12.

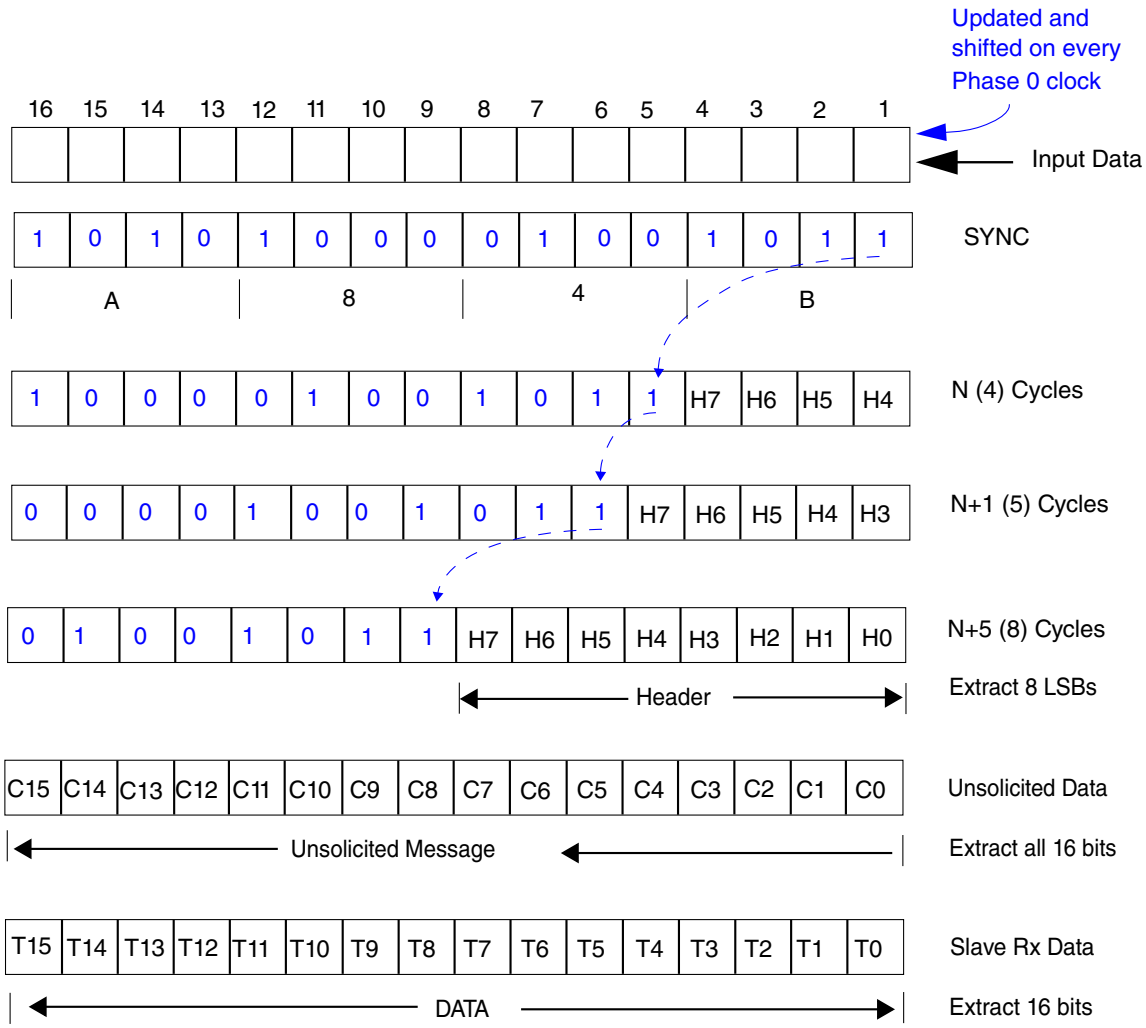

Figure 56-12. Extracting Header and Payload from the 16-bit output from Auto correlation.

56.7.3 Transmit Controller

This section describes the Transmit Controller.

56.7.3.1 Introduction

The Transmit Controller uses Rx information, status information and error control data and codes them into the appropriate frame structure for transmission to the LD. This includes the synchronization and header, in preparation for the LD, which transmits the frame to peer LFAST IC at either low or high speed. The Transmit Controller creates a frame structure that is converted to a serial format for the LD.

An arbitration block will determine which message has higher priority data, unsolicited, ICLC, CTS, ping, and so on. The data frames are extracted from the FIFO controller, the unsolicited message from the register block, the CTS messages from the Receive Controller and the ping response from the register block.

The Tx interface has two speed modes:

- Low Speed
- Fast Speed

The Transmit Controller consists of the following blocks as shown in the following figure.

- Arbitrator
- Framer
- Request Clock Control

The arbitrator will grant access to the framer from the request that has the highest priority. The framer block will extract the payload data from the granted request source and build the frame (adding synchronization or header if required). The frame is fed into a PISO (Parallel In Serial Out) and eventually sent to the LD.

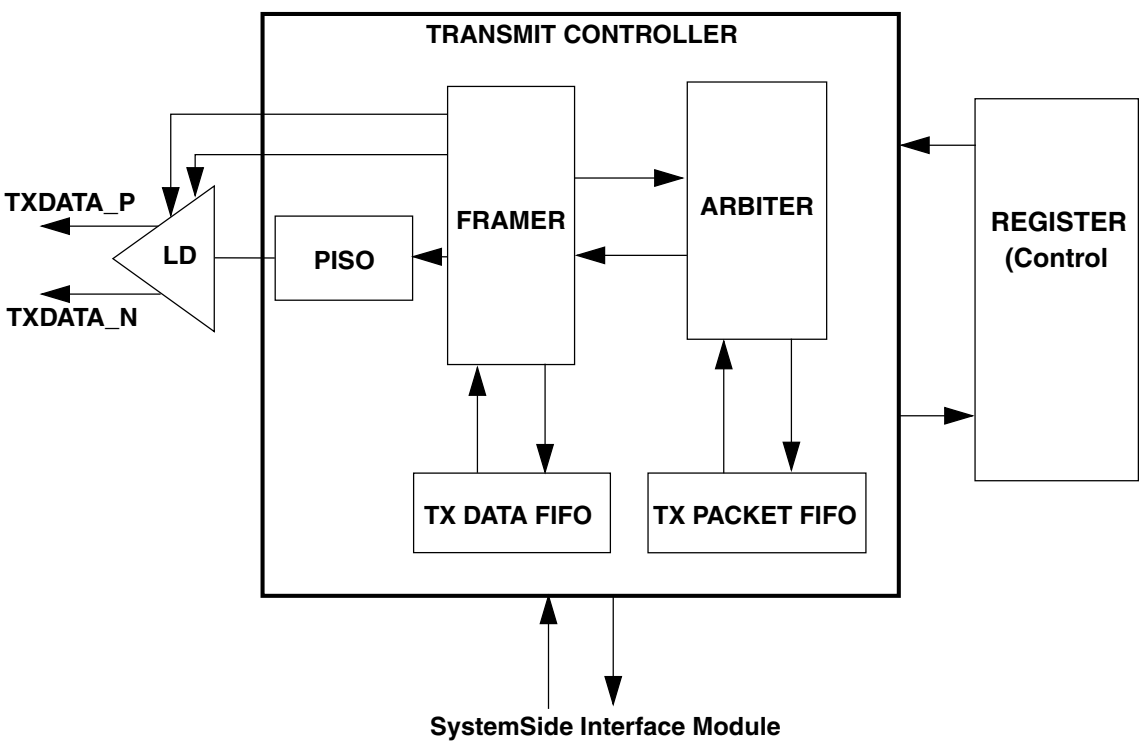

Figure 56-13. Transmit Controller Connections

56.7.3.2 Arbitration

The arbitration block prioritizes between requests from multiple sources like

- S/W programmable registers
- System side interface FIFO
- Rx interface controller

The level of priority for each request is shown in Table 56-5

Table 56-5. Priority Levels for the Transmit Controller

Request	LFAST MasterPriority	LFAST SlavePriority	Triggering Conditions *(at least one of the listed)*
LFAST interface enable	1	1	• LFAST interface enable is asserted • LFAST interface enable is negated
Tx Interface disabled	2	2	• MCR[DRFEN] = 0 • MCR[TXEN] = 0 • MCR[DRFRST] = 1 • MCR[TXARBD] = 1 • LFAST Slave: ICLC frame with payload for "Disable Rx interface" received
Tx Interface speedmode change	3	3	• SCR[TDR] is modified • LFAST Slave: ICLC frame with payload for changing Rx interface speed received
Loopback frame in Loopback mode	4	4	• TMCR[LPON] = 1Dig • RF Slave: ICLC frame with payload for loopback mode enable received **Note:** Valid only for following TMCR[LPMOD] settings: LPMOD[2:0] = 011b LPMOD[2:0] = 100b
ICLC frame request	5	-	• LFAST Master: ICR[SNDICLC] = 1 • LFAST Master: ICR[ICLCSEQ] = 1
Ping response request	-	5	• LFAST Slave: ICLC frame with payload for ping request received and PICR[PNGAUTO] = 1 • LFAST Slave: PICR[PNGREQ] = 1

Table continues on the next page...

Table 56-5. Priority Levels for the Transmit Controller (continued)

Request	LFAST MasterPriority	LFAST SlavePriority	Triggering Conditions *(at least one of the listed)*
Unsolicited frame request	6	6	• Last Frame with CTS = 1 received from the peer LFAST device • UNSTCR[USNDRQ] = 1
Data frame from Tx FIFO	7	7	• Tx FIFO contains one or more frames • Last Frame with CTS = 1 received from the peer LFAST device • MCR[DATAEN] = 1
CTSFrame	8	8	• MCR[CTSEN] = 1 • Rx FIFO reaches High/Low threshold, defined by TISR and no frame pending
Clock mode test	9	9	• TMCR[CLKTST] = 0 • LFAST Slave: ICLC frame with payload for clock test mode enable received

Once the arbitrator has granted access to a request, the Framer will commence building the frame. Any new requests for frame or data rate change will not be granted access until the framer has finished transmitting the current frame. If a data rate change request for the Tx interface is received while the Transmit controller is in the middle of sending a frame then the rate change request to the Clocking Module will be delayed. This allows for the frame to be completed before the change in speed mode. This prevents any speed mode change during the transmission of a frame. Once the speed mode request is sent to the Clocking Module by the Tx Interface Controller, it will then not allow any new requests to be processed for a specific time period defined by the bit field RCDCR[DRCNT].

56.7.3.3 Line Driver digital connections

56.7.3.3.1 Line Driver states

The LD has the following states:

- Shutdown

The LD enters the Shutdown state when the LD powerdown signal and the output buffer enable is high. In this state, the LD regulator is not supplying power and the LD outputs are connected to ground. Once LD powerdown signal is negated, a settling time is required before the LD may be used for communication.The settling time is defined by the SLCR[LWKCNT] and SLCR[HWKCNT] bitfields.

- Sleep

  The LD enters in sleep state when the signal is asserted. In this state, the LD is enabled, but held in a power-saving state. Sleep mode may be used during inter-frame gaps that are long compared to the frame durations but not long enough to allow the interface(s) or high-speed clock generators to be powered down completely. In the sleep state the LD outputs are connected to Vcm (common mode voltage). To exit from Sleep mode the LD sleep signal is negated. The LD is required to transmit a logic 0 level on the interface for a pre-defined minimum time. The minimum time is the summation of settling time of LD after negation of LD sleep signal and the wakeup time of the LR on the other side. This delay is programed in the SLCR[HSCNT] and SLCR[LSCNT] bitfields.

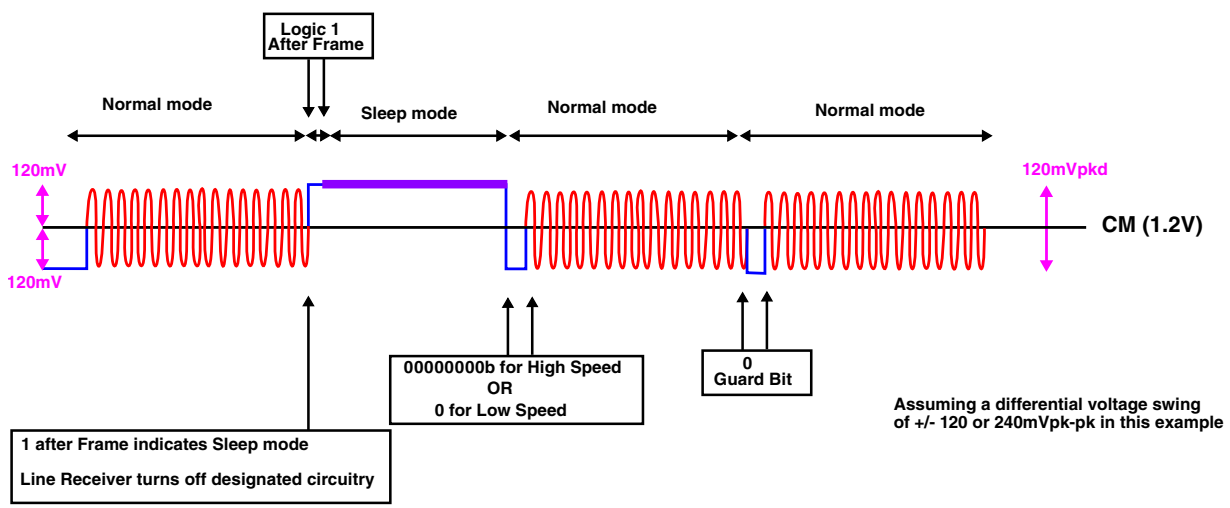

Figure 56-14. Example of Sleep mode

As shown in Figure 56-14 before every normal mode burst on the txdatap line there is one guard bit period (minimum inter-frame gap) where a logic 0 will be transmitted.

- Normal

  In the Normal state the LD is primed for transmission. The LD shall drive the interface as dictated by the input data bit that is supplied by a shift register under the control of a finite state machine. If the LD is not enabled, and the framer is activated,

and has a frame to transmit, an interrupt (TISR[TXIEF]) will be generated. The LD moves back to the shutdown state when the LFAST master sends an ICLC Rx data off command.

Table 56-6. Line Driver States

LD State	LFAST Master Triggers	LFAST Slave Triggers
Shutdown	• Programing LVDS[SWOFFLD] and LVDS[SWONLD] • Programing MCR[TXEN] and MCR[DRFEN]	• LFAST interface enable negation/assertion • Programing LVDS[SWOFFLD] and LVDS[SWONLD] • ICLC command from LFAST master • Programing MCR[TXEN] and MCR[DRFEN]
Sleep	• Programing LVDS[SWSLPLD] and LVDS[SWWKLD]	• No pending frame for transmission • Programing LVDS[SWSLPLD] and LVDS[SWWKLD]
Normal	Absence of above mentioned conditions	Absence of above mentioned conditions

56.7.4 CTS mode support

LFAST module supports flow control methods. The CTS (Clear to send) is a protocol defined method to ensure no loss of frame, due to Rx FIFO unavailability. The optimal use of bandwidth of LFAST, without losing frames, is ensured by proper programing of the Rx FIFO Lower threshold (RFCR[CTSMN]) and Higher threshold (RFCR[CTSMX]). The CTS is supported by both the LFAST Master and Slave.

CTS Transmission:

The LFAST device sends CTS information with each frame to the peer LFAST device.

If the CTS mode is enabled by write MCR[CTSEN] = 1 then:

- Sends CTS bit as 0 in LFAST frame (bit[0] of Header field) whenever the Rx FIFO reaches the higher threshold defined by the bitfield TISR[CTSMX]. This indicates that the LFAST device doesn't want the peer device to send data. The CTS bit of all frame are sent 0 untill the Rx FIFO pointer reaches the lower threshold, as described below.

- Sends CTS bit as 1 in LFAST frame (bit[0] of Header field) whenever the Rx FIFO reaches the Lower threshold defined by the bitfield TISR[CTSMN]. This indicates that the LFAST device is ready to receive data from the peer device. The CTS bit of all frame are sent 1 untill the Rx FIFO pointer reaches the Higher threshold, as described above.
- The CTS bit can be sent through any type of frame (data, unsolicited or ICLC). When there are no frames available in LFAST to send to the peer device, a CTS frame is sent. In this frame, bit[4-1] of Header field are sent as 0011b and 8-bit payload of 0.

If the CTS mode is not enabled (for example, bit MCR[CTSEN] = 0) then:

- All the frame sent will have CTS bit as 1 in LFAST frame (bit[0] of Header field).

CTS Reception:

The reception of a LFAST frame with CTS bit 0 indicates that the peer device is not ready to receive data frames. The transmission of all pending data and unsolicited frames are postponed untill a frame with CTS bit 1 is received.

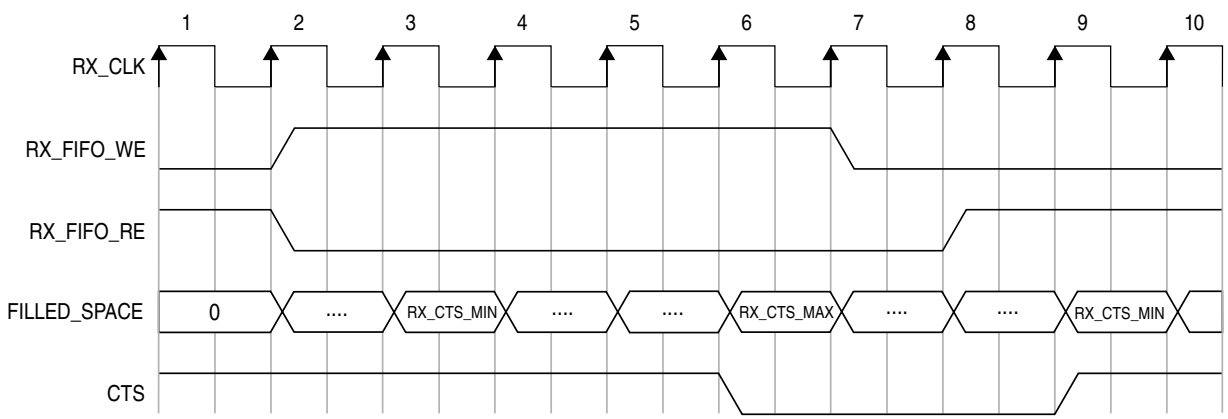

Figure 56-15. CTS generation

56.7.5 Frames supported

Table 56-7 provides the frames supported and their permissible payload sizes

Table 56-7. Frames supported by LFAST interfaces

Frame Type	LCT Code	Supported by 1. LFAST Master Tx2. LFAST Slave Rx	Supported by1. LFAST Slave Tx2. LFAST Master Rx	Payload Size (bits)
Data Frame	0100b – 1011b	YES	YES	32, 64, 96, 128, 256, 288
Unsolicited Frame	0001b	YES	YES	8, 32, 64, 96, 128, 256 and 288
ICLC Frame	0000b	YES	NO[1]	8
CTS Frame	0011b	YES	YES	8
Reserved	All others	—	—	—

1. Except the ICLC PING response frame.

If logical channel type (LCT) code other than the above mentioned are received then the interrupt flag RISR[RXLCEF] = 1. If the payload size received does not match any value in Table 56-7 then the flag RISR[RXSZF] = 1. In both these error conditions the received frame is ignored. The S/W may have to take the necessary steps to recover from such an error.

56.7.6 Frame flow

Following sections describe Data Frame Flow, ICLC Flow and Rx Unsolicited Data Flow.

56.7.6.1 Data flow

LFAST supports the transfer of data between master and slave LFAST devices.

56.7.6.1.1 Data transmit

System Side Module is the initiator of all the Tx data frame to LFAST peer device. Data frame transmit is triggered whenever the Tx Data FIFO has at least one valid frame. The MCR[DATAEN], MCR[DRFEN] and MCR[TXEN] bits, should be set to enable the transfer of Tx data.

If MCR[DATAEN] = 0, then the valid frames in the in Tx data FIFO will be ignored for transmission. The Payload Size and channel type of each frame is specified by the System Side Module interface during transfer of the frame to the LFAST interface. The frame header is stored in the Tx packet FIFO and the payload in the Tx data FIFO.Whenever the Tx FIFO has at least one frame then a data transmit request is made to the Tx arbiter of the LFAST. Tx block arbitrates the data transmit request and

schedules it depending on the priority of all the pending transmit requests. When data request is scheduled by Tx block, the required data is fetched from Tx data FIFO. The number of frames present in the Tx FIFO for transmission is indicated by the bitfield DFSR[TXFCNT].

56.7.6.1.1.1 Programing model for Tx data transmit

1. Program MCR[DATAEN] = 1, MCR[TXEN] = 1 and MCR[DRFEN] = 1 to enable the Tx path of LFAST device
2. Select the desired clock rate at which data should be transmitted, using ICLC transfers and appropriate programing of SCR[TDR] bits.
3. Frame present in TX FIFO (Data and Packet FIFO) are sent.
4. TISR[TXDTF] = 1 after each frame transfer
5. CTS is set depending on the push/pull mode setting defined by MCR[CTSEN].

56.7.6.1.2 Data receive

LFAST master and slave supports reception of data frame. The received frame is determined to be of data frame type by decoding channel type field of the header present in the received frame. The MCR[DATAEN], MCR[RXEN] and MCR[DRFEN] bits should be set to enable the data frame reception.When MCR[DATAEN] = 0 the received data frames will be ignored and will not be placed in the Rx data FIFO.

The Rx data frames received by Rx block are stored in the Rx FIFO. Whenever the frame is received in the Rx FIFO the System Side Module is indicated by assertion of LFAST Rx FIFO ready signal. The frame size and the Channel type is passed to the LFAST. The frame boundaries are indicated by start of frame and end of frame signals. The number of unread frames in the Rx Data FIFO are indicated by DFSR[RXFCNT]. When Rx DATA FIFO is full and cannot accommodate current frame completely, then the remaining data of the Rx frame is discarded. In this case, UNSRSR[RXOF] = 1 and an interrupt is generated if the RIER[RXOFIE] = 1.

56.7.6.2 Unsolicited flow

56.7.6.2.1 Unsolicited frame transmit flow

The S/W is the initiator for unsolicited frames to the LFAST peer device. The unsolicited frame header and payload is programed into the Unsolicited Data and Control registers. Once the Payload is programed UNSTCR[USNDRQ] is set, generating a request for unsolicited frame transfer to the Tx arbiter.

56.7.6.2.1.1 Programing model for unsolicited frame transmit

1. Program MCR[TXEN] = 1 and MCR[DRFEN] = 1 in the Mode Configuration Register (MCR) to enable the Tx path
2. Select the desired clock rate at which data should be transmitted, using ICLC transfers and appropriate programing of SCR[TDR].
3. Read the UNSTCR[USNDRQ].
   - If UNSTCR[USNDRQ] = 1 then wait for either of the following:
     - UNSTCR[USNDRQ] = 0
     - TISR[TXUNSF] = 1
   - If UNSTCR[USNDRQ] = 0 then:
     - Program the unsolicited payload in UNSTDR0–UNSTDR8, and can be written up to a payload of frame of a maximum of 288 bits.
     - Program the unsolicited frame header in UNSTCR[UNSHDR].
     - Program UNSTCR[USNDRQ] = 1.
4. UNSTCR[USNDRQ] is cleared by the Tx Block after the frame transfer.
5. TISR[TXUNSF] = 1 when the frame is transmitted.
6. CTS is set depending on the Push-Pull mode setting defined by MCR[CTSEN].

56.7.6.2.2 Unsolicited frame receive flow

Whenever an Unsolicited frame is received from the peer device, the following steps are performed:

If UNSRSR[URXDV] = 0 then:

1. The payload size field of the header is first saved into the UNSRSR[URPCNT].
2. The payload is stored in the UNSTDR0–UNSTDR8.

3. UNSRSR[URXDV] = 1 and the RISR[RXUNSF] = 1 indicating the successful reception of the frame.

If UNSRSR[URXDV] = 1 then:

1. The current unsolicited frame is ignored.
2. RISR[RXUOF] = 1.

Typical steps by the processor after RISR[RXUNSF] = 1 is as follows:

1. The processor reads UNSRSR to get the payload size of the frame.
2. It then reads the complete frame by reading UNSRDR8–UNSRDR0 for the payload size as received in the frame.
3. Then it clears the interrupt (write RISR[RXUNSF] = 1) and also the UNSRSR[URXDV] bit.

56.7.6.3 ICLC flow

The ICLC (Interface Control Logical Channel) is a separate logical channel type, which is mainly meant for implementing the data rate change in the LFAST interface and initiating the test modes.

56.7.6.3.1 ICLC data transmit flow

Whenever the processor intends to transfer an ICLC frame to the LFAST slave then the following steps are to be followed.

1. Write the ICLC frame payload in the ICR[ICLCPLD] (see Table 56-8 for payloads as defined by the standard).
2. Program ICR[SNDICLC] = 1 to initiate the ICLC frame transfer. This bit clears itself when the ICLC frame has been transmitted. The processor needs to poll this bit to make sure it is cleared before setting this bit again (even when ICR[ICLCSEQ] = 1).
3. TISR[TXICLCF] = 1 after the transfer of the ICLC frame.
4. CTS is set depending on the Push-Pull mode setting defined by MCR[CTSEN].

To determine whether the ICLC frame has been sent or not, either the ICR[SNDICLC] bit can be polled, or wait for TISR[TXICLCF] = 1.

Table 56-8. Supported ICLC Payloads

ICLC Code(hex)	ICLC Function
00	Ping Request from LFAST Master to LFAST Slave
01	Reserved
02	Start PLLIn preparation for High Speed mode
04	Stop PLL Fallback to low speed mode
08	Select TxData Slow (LFAST Slave Rx Interface)
10	Select TxData Fast (LFAST Slave Rx Interface)
20	Select RxData Slow (LFAST Slave Tx Interface)
40	Not Supported
80	Select RxData Fast (LFAST Slave Tx Interface)
31	Enable RxData Interface (LFAST Slave Tx Interface)
32	Disable RxData Interface (LFAST Slave Tx Interface)
34	Clock Test mode Send 101010… continuously using the currently configured clock rate (slow, fast);
FF	Turn payload loopback on
38	Turn Test mode (Loopback and Clock Test) off

Programing model for ICLC frame transmit:

1. Set the ICR[ICLCSEQ] bit (optional)
2. Write the ICLC frame payload in the ICR[ICLCPLD], corresponding to the desired Tx/Rx data rate change, as described in the Table 56-8.
3. Write ICR[SNDICLC] = 1 to initiate the ICLC frame transfer.
4. LFAST master will schedule the ICLC transfer. Data present in ICR[ICLCPLD] is transmitted to the LFAST slave at the old Tx data rate. LFAST slave will configure its Tx/Rx interface data rate accordingly.
5. Reset the ICR[ICLCSEQ] to allow the scheduling of other types of frames, which will be sent at the new data rate.

When ICR[ICLCSEQ] = 0, though the ICLC frame transfer still has highest arbitration priority, other frames may be scheduled if no valid ICLC frame request exist.

Note

ICLC frame transmit will not trigger the internal data rate change of LFAST Master Tx/Rx interface. LFAST master Tx/Rx interface data rate will only be changed, when corresponding SCR[TDR] and SCR[RDR] bits are appropriately configured.

Processor requires to take care that no data frames are to be transmitted while data rate change is happening or ICLC is transmitting frames by setting ICR[ICLCSEQ] bit in Table 56-8.

56.7.6.3.2 ICLC data receive flow

When the bits 4 to 1 of a receive frame are 0000b it indicates that the payload is an ICLC. ICLC payloads are always 8 bits.

The reception of an ICLC frame is indicated by an interrupt to the system. The ICLC status register RISR indicates the type of the ICLC frame received. The Rx block will decode and generate the appropriate signals. An invalid ICLC code besides the ones listed in Table 56-8 will cause RISR[RXICF] = 1.

56.7.6.3.2.1 Ping request ICLC

The LFAST slaves ICLC decoder will decode the ping request and set RIISR[ICPRF]. The S/W can also write to PICR[PNGREQ] to indicate to the Tx block that a ping response frame needs to be transmitted. The PICR[PNGAUTO] indicates whether Tx block can respond automatically to the request by the LFAST master ICLC Ping Request frame. The Tx block will arbitrate the ping response frame request and send a ping frame with ping data defined by bitfield PICR[PNGPLYD]. Once the ping response frame has been sent the Tx block will set TISR[TXPNGF] and clear PICR[PNGREQ], if set.

56.7.6.3.2.2 LFAST Slaves RxData Interface Slow/Fast ICLC

The LFAST Slaves Rx Interface has two speed modes supported: slow (Low speed) and fast (High speed). The ICLC command will write RIISR[ICRSF] = 1 (Low speed) or RIISR[ICRFF] = 1 (High speed).

56.7.6.3.2.3 LFAST Slaves TxData Interface Slow/Fast ICLC

The LFAST slaves Tx Interface Controller has two speed modes: slow (Low speed), and fast (High speed). The ICLC command will write RIISR[ICTSF] = 1 (Low speed) or RIISR[ICTFF] = 1 (High speed).

56.7.6.3.2.4 Enable/Disable LFAST Slaves TxData Interface ICLC

The ICLC commands, Enable RxData Interface and Disable RxData Interface are decoded and the appropriate enable/disable signal sent to the Tx block Controller. These ICLC command writes RIISR[ICTEF] = 1 and RIISR[ICTDF] = 1. The ICLC Tx enable command will write MCR[TXEN] = 1.

No frames can be sent on the LFAST Slave Tx interface until the either LFAST master has enabled it via an ICLC frame or S/W programs MCR[TXEN] = 1.

56.7.6.3.2.5 Clock Test mode ICLC

This ICLC command is decoded, and then is used to write TMCR[CLKTST] = 1. This indicates to the Tx interface to output an alternating pattern of 1 and 0 at the currently configured clock rate. The Rx interface generates RIISR[ICCTF] = 1 on reception of this ICLC command.

The exit from this mode happens on reception of Test mode off ICLC command.

56.7.6.3.2.6 Loopback payload on ICLC

This ICLC command is decoded and TMCR[LPON] = 1 to indicate to the Tx Block that the received payload is to be sent back. The exit from this mode happens on reception of Test mode off ICLC command. The Rx interface causes RIISR[ICLPF] = 1 on reception of this ICLC command.

56.7.6.3.2.7 Test mode off ICLC

This ICLC command is decoded and TMCR[LPON] and TMCR[CLKTST] are cleared to indicate to the Tx block to exit from loopback mode or clock test mode.

Another option is for the payload loopback option to remain enabled until negated on the toggling of LFAST interface enable.

56.7.6.3.2.8 Ping response ICLC

The LFAST master considers any ICLC frame payload as ping response data. The LFAST masters Rx block will store the received ping data in PISR[RXPNGD] and match it with PICR[PNGPYLD]. RIISR[ICPSF] = 1 if the Ping received matches with the one stored in PICR[PNGPYLD], or RIISR[ICPFF] = 1.

56.7.6.4 CTS flow

56.7.6.4.1 CTS Tx flow

The CTS frame, if enabled by the S/W, indicates the status of the Receive Data FIFO. CTS frame is triggered whenever Rx Data FIFO reaches either the High/Low threshold and no data, ICLC or unsolicited frame is ready for transmission.

Programing model for CTS frame transmit:

- Program RFCR[CTSMX] and RFCR[CTSMN].
- Enable the CTS frame Transmission by programming MCR[CTSEN] = 1.
- Program MCR[TXEN] = 1 and MCR[DRFEN] = 1 to enable the Tx path.
- The CTS bit sent with a valid frame (for example, data, ICLC and unsolicited) is 1 until the Rx Data FIFO reaches High Threshold.
- When the Rx Data FIFO reaches higher threshold and no valid frame (data, ICLC and unsolicited) is pending for transmission, then the CTS frame is triggered, with CTS bit of header = 0 and the status bit RISR[RXMXF] = 1.
- When the Rx Data FIFO reaches Low Threshold, due to system side reads and no valid frame (data, ICLC and unsolicited) is pending for transmission, then the CTS frame is triggered, with CTS bit of header = 1, and status bit RISR[RXMNF] = 1.

56.7.6.4.2 CTS Rx flow

Whenever a CTS frame header or any other frame with valid header is received with CTS bit = 0, then RISR[RXCTSF] = 1. The Tx Interface arbitration for unsolicited frame and data frame transmit request is turned off on reception of frame with CTS bit 0. The arbitration for unsolicited frame and data frame is enabled on reception of frame with CTS bit 1. Frame with LCT type CTS are not stored in the LFAST.

56.7.7 Test and Debug Support

The test and debug interface helps to debug the LFAST module. These signals can be brought out for ease of validation.

56.7.7.1 Loopback Test mode

The loopback function allows to verify the correct operation of the physical interface and the basic checks for the LFAST module without a peer device.

There are certain prerequisites before entering the Loopback mode:

- LD and LR should be turned on.
- Tx and Rx mode should be enabled.
- Interrupts needed for S/W should be enabled.
- Both Tx and Rx interface should be in same speed mode.
- For Automatic Test mode TMCR[LPFRMTH] should be programed.

The LFAST module supports four loopback modes, defined by TMCR[LPMOD].

Table 56-9. Loopback modes

LPMOD[2:0]	Mode Selected
000	Rx Loopback (default)
001	Rx LVDS Loopback
010	Tx Loopback without Automatic frame generation
011	Tx Loopback with Automatic frame generation
100	Tx LVDS Loopback (external) with Automatic frame generation

The TMCR[LPON] bit controls the state of the loopback function, and the default setting is 0 (off). This can be written by S/W, or in the case of the LFAST slave, the TMCR[LPON] bit can be modified by the Rx interface controller on decoding of a valid ICLC loopback on or Test mode off commands. The LPMOD should not be changed when the LPON bit is set.

In all loopback modes, except Tx loopback without automatic frame generation, the decoding of frame and error flags is stopped. Only decoding of following is done:

- ICLC Turn Test mode Off frame.

- CTS bit of all frames.
- Automatic Loopback frame decoding (only in Automatic frame generation mode).

56.7.7.1.1 Rx Loopback mode

For Rx loopback mode the output of the LR is passed to the LD with manipulation via the Rx and Tx Interface controllers. CTS bit (Bit 0) of the header is guaranteed to be asserted when the incoming data from the other device is looped back. In Rx Loopback mode the Rx Interface controller operates in normal mode, decoding the frames (header, payloads). This allows the LFAST Master to control the Loopback mode on and off by sending ICLC commands.

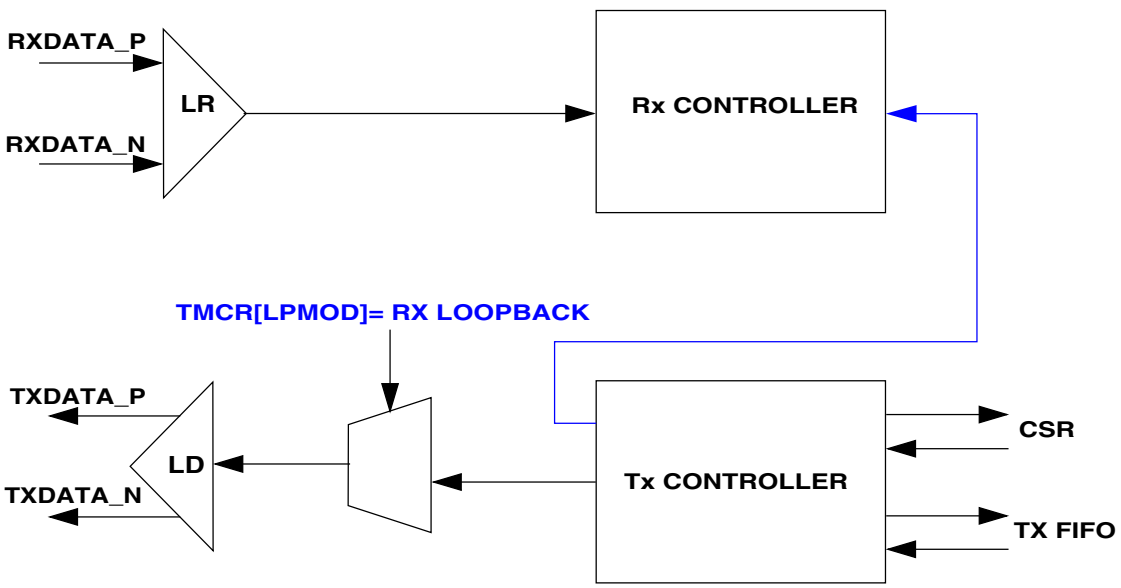

Figure 56-16. Rx LoopBack mode

Entry to Rx Loopback mode:

1. S/W programs TMCR[LPMOD] = 000b.
2. Loopback can be turned on by either of the following methods:
   - S/W programs TMCR[LPON] = 1.
   - For Slave Only: - Reception of ICLC Frame with Payload FFh (Loopback mode on), from LFAST Master

Exit from Rx Loopback mode can be done by any of the following methods:

- S/W programs TMCR[LPON] = 0
- For LFAST Slave: - Transmission of ICLC Frame with payload 38h (Test mode off), from LFAST Master

The peer LFAST device is required to maintain at least 2-bit IFG between two Loopback frames in this mode.

56.7.7.1.2 Rx LVDS LoopBack mode

This loopback mode is provided to verify and characterize the LVDS pads. In this loopback mode the data received by LFAST on Rx LVDS input is loopback to Tx LVDS output, bypassing LFAST. For LVDS loopback the output of the LR is passed to the LD via "Rx LVDS LoopBack Mux". Bit 0 of the header cannot be guaranteed to be asserted when the incoming data from the other device is looped back. In this loopback, the Rx Interface Controller operates in normal mode, decoding the frames (header, payloads) but the Tx Interface Controller is ignored.

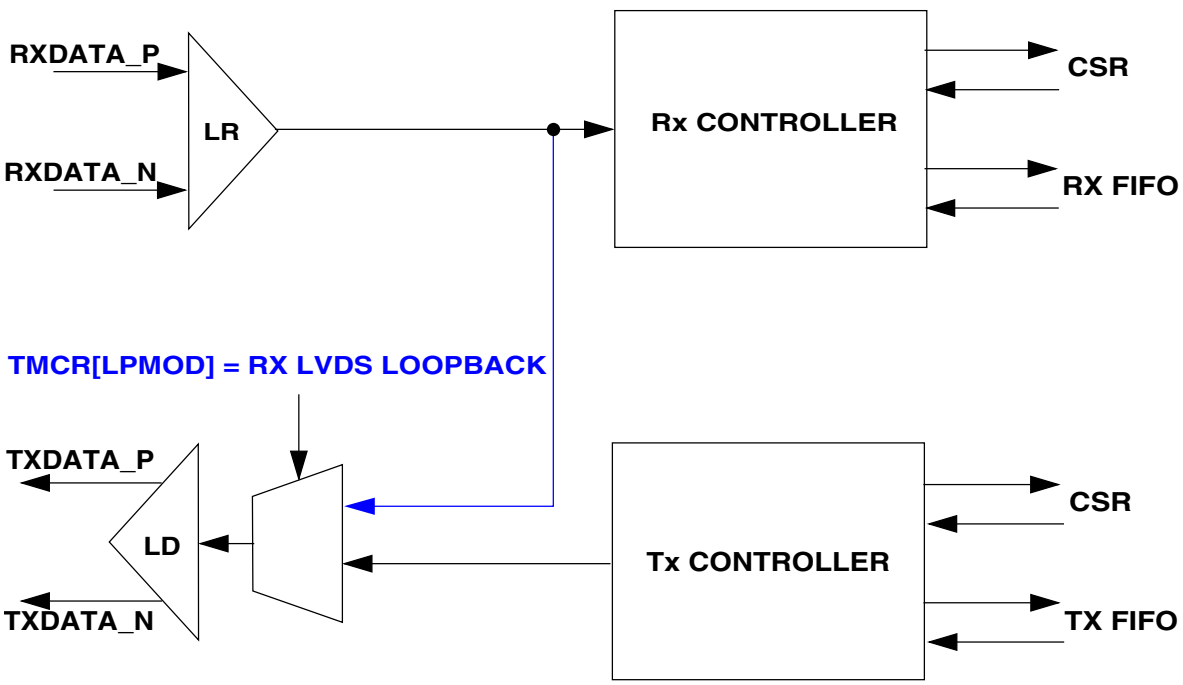

Figure 56-17. Rx LVDS LoopBack mode

Entry to Rx LVDS Loopback mode:

1. S/W programs TMCR[LPMOD] = 001b.
2. Loopback can be turned ON by either of the following methods:

- S/W writes TMCR[LPON] = 1.
- For Slave Only: - Reception of ICLC Frame with Payload = FFh (Loopback mode ON), from LFAST Master.

Exit from Rx LVDS Loopback mode can be done by any of the following methods:

- S/W programs TMCR[LPON] = 0.
- For LFAST Slave:
  - Transmission of ICLC frame with payload 38h (Test mode off), from LFAST Master.

56.7.7.1.3 Tx loopback mode without automatic frame generation

This loopback mode is provided to verify the LFAST functionality, if LVDS pads are not functional. In this loopback mode the data transmitted by LFAST on Tx LVDS output is loopbacked internally on Rx LVDS input, bypassing LVDS pads.

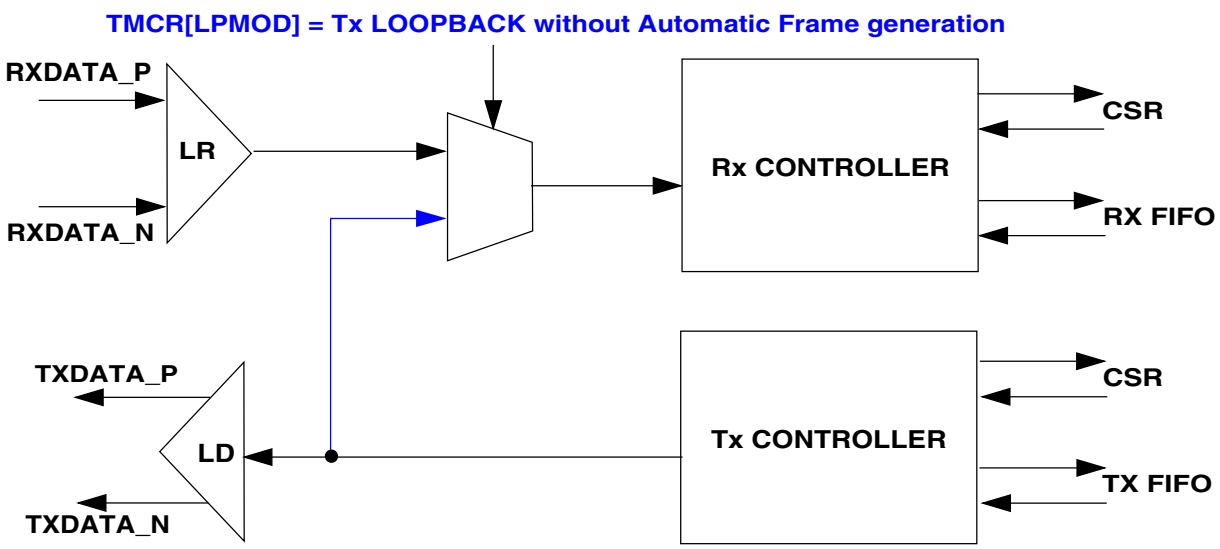

Figure 56-18. Tx LoopBack mode without automatic frame generation

Entry to Tx Loopback without Automatic frame generation mode:

1. S/W programs TMCR[LPMOD] = 010b.
2. Loopback can be turned on by either of the following methods:
   - S/W programs TMCR[LPON] = 1.
   - For Slave Only: Reception of ICLC frame with payload FFh (Loopback mode on), from LFAST Master

Exit from Tx Loopback without Automatic frame generation mode can be done by any of the following methods:

- S/W programs TMCR[LPON] = 0.
- For LFAST Slave: Reception of ICLC frame with payload 38h (Test mode off), from Tx interface (using unsolicited frame).

All frames and error flags are decoded in this mode.

56.7.7.1.4 Automatic frame generation

The LFAST module supports two Loopback modes where pre-defined frames are generated automatically by the Tx Interface and Rx Interface indicates its successful reception by dedicated signals and status registers. These modes are defined for BIST like check for the LFAST, with minimal S/W intervention.

The Control register used for these modes are:

- ALCR[LPCNTEN] defines whether fixed number of auto loopback frames to be transmitted
- ALCR[LPFMCNT] defines the number of loopback frames to be transmitted if ALCR[LPCNTEN] = 1.

The Status signals and register used for these modes are:

- GSR[LPCSDV]: Valid Synchronization received.
- GSR[LPCHDV]: Frame with Header of 13h received.
- GSR[LPCPDV]: Frame with Payload of CBh received.
- GSR[LPTXDN]: Number of Auto Loopback frame transmitted with valid Synchronization, Header (13h) and Payload (CBh) is equal to ALCR[LPFMCNT].

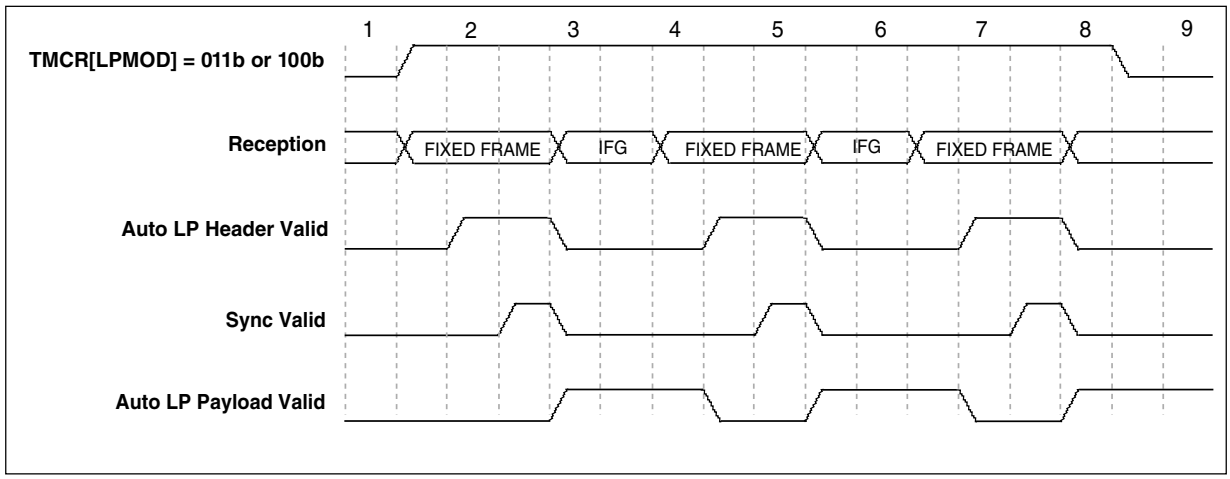

Figure 56-19. Automatic Loopback Test status signal timings

The two Loopback with automatic frame generation modes are:

1. Tx Loopback with Automatic frame generation
2. Tx LVDS (external) with Automatic frame generation

56.7.7.1.4.1 Tx loopback mode with automatic frame generation

When TMCR[LPMOD] = 011b (Tx Loopback mode with Automatic frame generation) the frames are generated by the Tx Interface. This mode helps to validate the Tx and Rx Path with minimal intervention from the S/W. The frames generated have fixed header of 13h and payload of CBh. The successful reception of this frame is indicated by the status signals and registers.

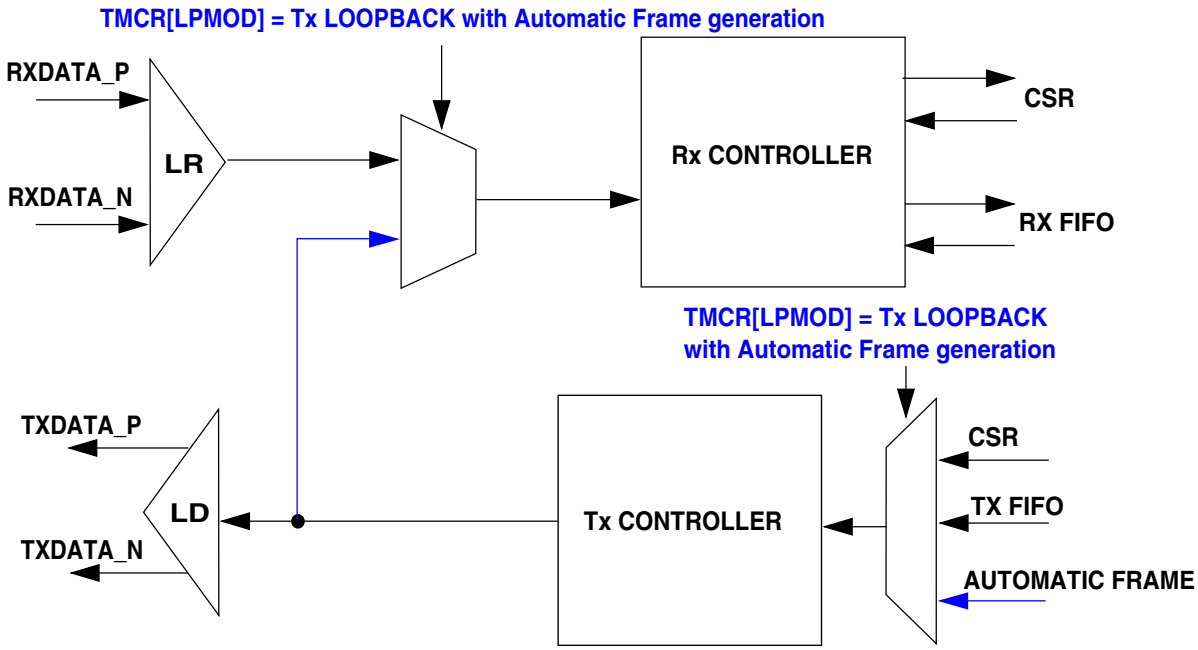

Figure 56-20. Tx LoopBack mode with automatic frame generation

Entry to Tx Loopback with automatic frame generation mode:

1. S/W programs TMCR[LPMOD] = 011b.
2. Loopback can be turned on by either of the following methods:
   - S/W programs TMCR[LPON] = 1.
   - For Slave Only: Reception of ICLC frame with payload FFh (Loopback mode on), from LFAST Master

Exit from Tx Loopback with Automatic frame generation mode can be done by any of the following methods:

- S/W programs TMCR[LPON] = 0.

56.7.7.1.4.2 Tx LVDS loopback (external) mode with automatic frame generation

In this mode the LD/Tx Controller is used to test the LR/Rx Controller. The idea is to use a test frame (predefined) from the Tx Controller out through the LD, loopback completed on the DUT-board (LD connected to LR via a transmission line), back into the LR, synchronized and correlated in the Rx Controller and compared to what was sent in the Downlink controller.

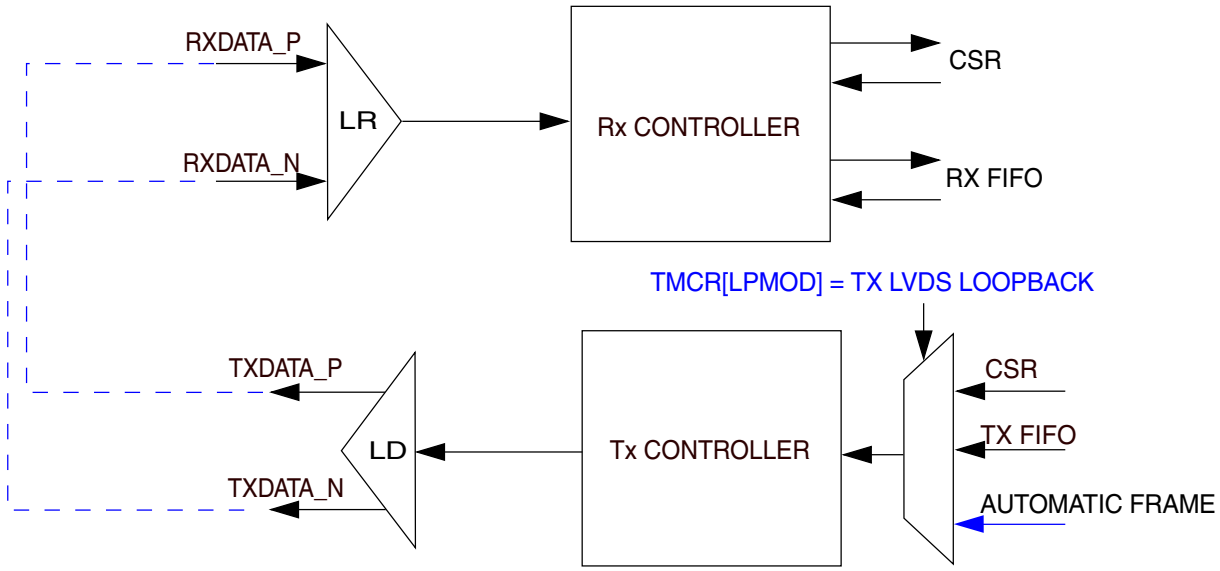

Figure 56-21. Tx LVDS loopback (external) mode with automatic frame generation

Entry to Tx LVDS loopback with automatic frame generation mode:

1. S/W programs TMCR[LPMOD] = 100b.
2. Loopback can be turned on by either of the following methods:
   - S/W programs TMCR[LPON] = 1.
   - For Slave Only: Reception of ICLC frame with payload FFh (Loopback mode on), from LFAST Master

Exit from Tx LVDS loopback with automatic frame generation mode can be done by the following method:

- S/W programs TMCR[LPON] = 0.

56.7.7.2 Clock test mode

The bit TMCR[CLKTST] enables or disables the Clock Test mode of the LFAST module. In this mode the LFAST sends fixed pattern out on the LD at the current configured RxData clock rate. It is a RWM bitfield and the default setting is 0 (off). This bit can be set under one of the following conditions:

- S/W programs TMCR[CLKTST].

The Tx Controller will send out a pattern of alternating 1 and 0 (pattern 101010...). This provides a divide by 2 test clock of the current Tx clock.

The Clock Test mode can be cancelled by either of the following methods:

- S/W programs TMCR[CLKTST] = 0.
- For LFAST Slave: Reception of ICLC frame with payload 38h (Test mode off) from LFAST Master

In clock test mode the Tx Controller does not output any synchronization pattern or header, just a pattern of alternating 1's and 0's.

This mode doesn't affect the functionality of the Rx Interface.

56.7.8 Interrupts

The LFAST module generates five interrupts to the processor:

- Transmit complete interrupt
- Transmit exception interrupt
- Receive complete interrupt
- Receive exception interrupt
- ICLC recieve interrupt

Each interrupt is asserted when any one of their status conditions is met.

56.7.8.1 Transmit complete interrupt

This interrupt indicates a transfer compeletion of a frame. This interrupt is asserted whenever any of the following bits are set in the TISR and also the corresponding mask bits are set in the TIER.

- TXDTF
- TXICLCF
- TXUNSF
- TXPNGF

Each of these bits can be individually maskable. So, those bits that are not required to generate an interrupt to the processor can be masked. Once the interrupt is asserted, it can be negated by clearing the corresponding flag bit in the TISR.

56.7.8.2 Transmit exception interrupt

This interrupt indicates occurrence of an exception condition in the Tx block. This interrupt is asserted whenever any of the following bits are set in the TISR along with the corresponding mask bits in the TIER.

- TXOVF
- TXIEF

Each of these bits can be individually masked. So, those bits that are not required to generate an interrupt to the processor can be masked. Once the interrupt is asserted, it can be negated by clearing the corresponding flag bit in the TISR.

Table 56-10. Recommended transmit exception handling

Exception	Recommendation
TXOVF	• MCR[TXEN] = 0 • The system level interfaces transmit is reseted and enabled again • For Slave: After reception of ICLC Ping Response Request the MCR[TXEN] may be set • For Master: The MCR[TXEN] should be set and an ICLC frame Ping Response Request should be sent
TXIEF	• The MCR[TXEN] should be set

56.7.8.3 Receive complete interrupt

This interrupt indicates a reception of a frame. This interrupt is asserted whenever any of the following bits is set in the RISR along with the corresponding interrupt enable bit is also set in the RIER.

- RXCTSF
- RXDF
- RXUNSF

Each of these bits are individually maskable. So, the bits that are not required to generate an interrupt to the processor can be masked by clearing its bit in the RIER. Once the interrupt is asserted, it can be negated by clearing the corresponding flag bit in the RISR.

56.7.8.4 Receive exception interrupt

This interrupt indicates occurrence of an exception condition in Rx block. This interrupt is asserted whenever any of the following bits is set in the RISR and corresponding enable mask bit is also set in the RIER.

- RXLCEF
- RXICF
- RXSZF
- RXUOF
- RXUFF
- RXMXF
- RXMNF
- RXOFF

Each of these bits are individually maskable. So, those bits that are not required to generate an interrupt to the processor can be masked by clearing the appropriate bit in the RIER. For details on the cause of assertion of each bit refer to the RISR description. Once the interrupt is asserted, it can be negated by clearing the corresponding flag bit in the RISR.

Table 56-11. Recommended receive exception handling mechanism

Exception	Recommendation
RXLCEF	The MCR[RXEN] may be set and cleared, as this exception can result in loss of subsequent packet
RXICF	No action required
RXSZF	The MCR[RXEN] may be set and cleared, as this exception can result in loss of subsequent packet
RXOFF	• The MCR[RXEN] may be cleared • The system level interfaces receive may be reset and enabled, as current transfer may be corrupted
RXUFF	No action required
RXMXF	The system level interfaces receive should be enabled, if not enabled
RXMNF	No action required
RXUNSF	No action required

56.7.8.5 ICLC receive interrupt

This interrupt indicates reception of a valid ICLC frame. This interrupt is asserted whenever any of the following bits is set in the RIISR along with the corresponding enable bit mask bit is set in the RIIER.

- ICPONF
- ICPOFF
- ICTSF
- ICTFF
- ICRSF
- ICRFF
- ICTEF
- ICTDF
- ICCTF
- ICLPF
- ICTOF
- ICPRF
- ICPSF
- ICPFF

Each of these bits are individually maskable. So those bits that are not required to generate an interrupt to the processor can be masked. For details on the cause of assertion of each bit, refer RIISR. Once the interrupt is asserted, it can be negated by clearing the corresponding flag bit in RIISR.

56.8 Packet memory

The LFAST stores packet frames for transmission, and reads packet frames after reception. The transmitter has its own dedicated buffer and the receiver has it own dedicated buffer, and they are not shared between each other.

Table 56-12. Frames Supported by LFAST interfaces

Frame Type	Tx Buffer(in bits)	Rx Buffer(in bits)	Memory Type
Data Frame	38 × 32 max 6 packets	38 × 32 max 6 packets	FIFO
Unsolicited Frame	9 × 32 max 1 packet	9 × 32 max 1 packet	Registers UNSTD[8-0], UNSRDR[8-0]
ICLC Frame	1 × 7 max 1 packet[1]	1 × 8 max 1 packet[2]	Registers ICR, PISR
CTS Frame	N/A	N/A	N/A

1. Only for MCR[MSEN] = 1
2. Only for ping response data when MCR[MSEN] = 1

56.9 Resets

The various blocks in LFAST are reset as described in the table below.

Table 56-13. Recommended receive exception handling mechanism

Reset	Blocks Reset
Asynchronous Hardware reset	Polarity: Active Low • Clock control module (CCM) • LFAST Domain Logic (Rx and Tx block) • System Side Module Interface FIFOs • LFAST Register Space
DRFRST bit of Mode Configuration Register (MCR)	Polarity: Active High • Clock control module (CCM) • LFAST Domain Logic (Rx and Tx block) • System Side Module Interface FIFOs • LFAST Register Space
DRFEN bit of Mode Configuration Register (MCR)	Polarity: Active Low • Clock control module (CCM) • LFAST Domain Logic (Rx and Tx block) • System Side Module Interface FIFOs • LFAST Status Registers • SCR[RDR] and SCR[TDR] • TMCR[CLKTST] and TMCR[LPON] • ICR[ICLCSEQ] and ICR[SNDICLC] • PICR[PNGREQ] • UNSTCR[USNDRQ]

56.10 Clocks

The LFAST mainly works on three clocks:

- System Bus Clock used to program the registers.
- Protocol clock, which is either High Speed PLL clock or Low Speed clock depending on the speed mode, used for LFAST protocol operation.
- System Side Module clock, which is synchronous to the System Bus clock.

56.10.1 Clocking strategy

The following figure shows the clock domain in which each module functions. The PLL provides eight phases of the high speed clock to the Clock Muxing portion of the Clock Control Module. The Clock Module will then generate four phases of slow speed clock using both the edges of lfast_sysclk, muxes high speed and low speed clocks and provides a muxed clock to the Sampler Module.

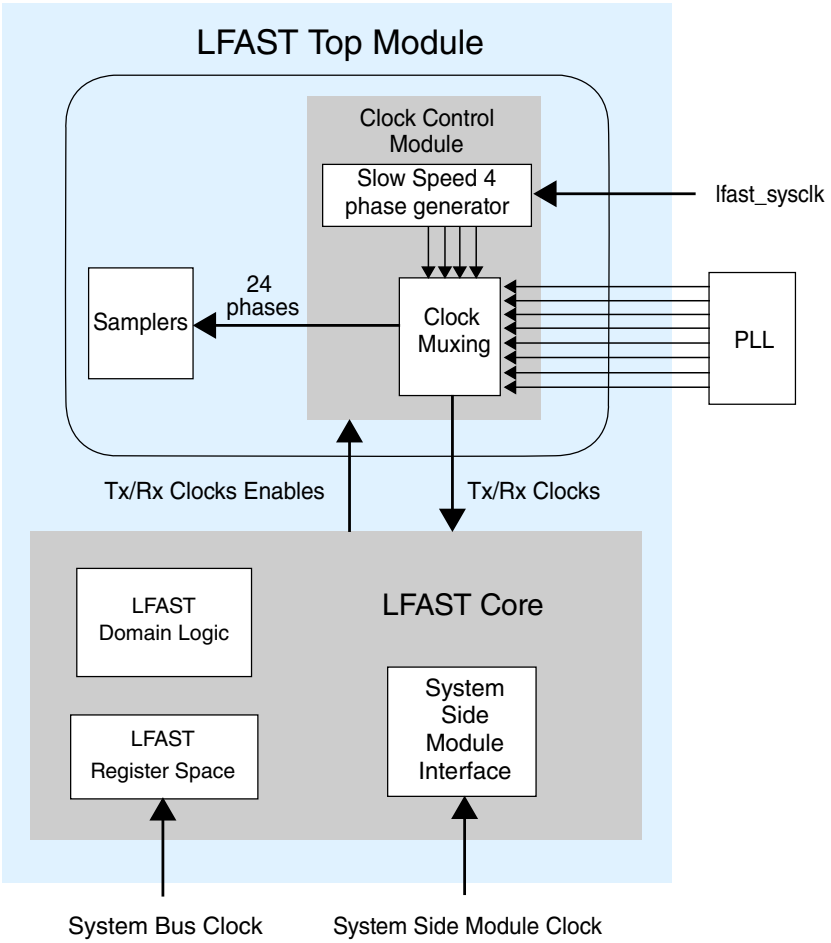

Figure 56-22. LFAST module clock domains

56.10.2 Slow speed clock

56.10.2.1 External muxing

The Clock Control Module will receive lfast_sysclk from the clocking subsystem as shown in Figure 56-23, Figure 56-24 and Figure 56-25.

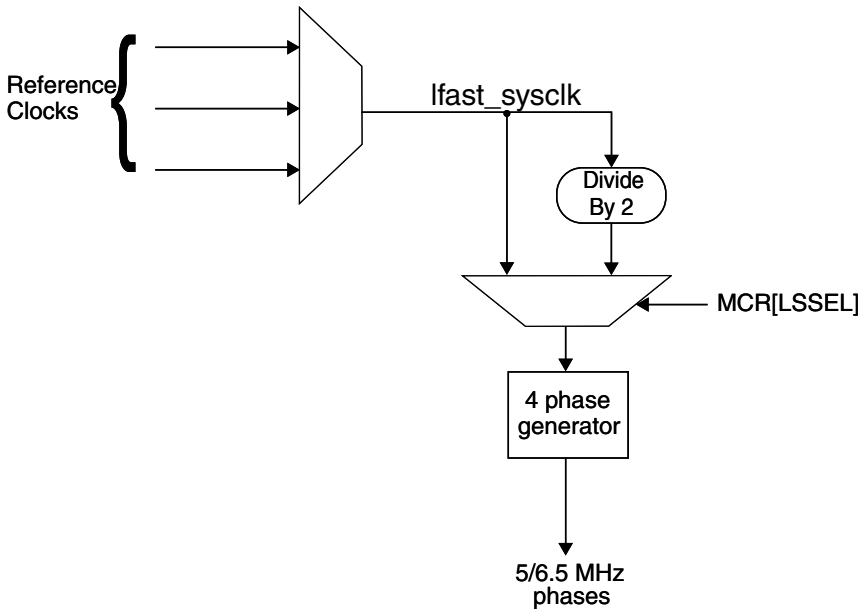

Figure 56-23. External clock muxing of lfast_sysclk

All the reference clocks will be muxed first to provide lfast_sysclk to the module and then either div/2 or direct muxed clock will be used to generate 4 slow speed phases in the Clock Control Module of LFAST as shown in Figure 56-23.

The lfast_sysclk could be either 20/26 MHz or 10/13 MHz. When lfast_sysclk is 20/26 MHz frequency, the clock control module will generate 4 phases of slow speed clock of frequency lfast_sysclk/4 when MCR[LSSEL] = 1. If lfast_sysclk is 20/26 MHz it needs to be first divided by 2 before using it for 4 phase generation in LFAST Clock Module, which generates 4 phases of half of the input frequency as shown in Figure 56-24 (selected clock path shown in green).

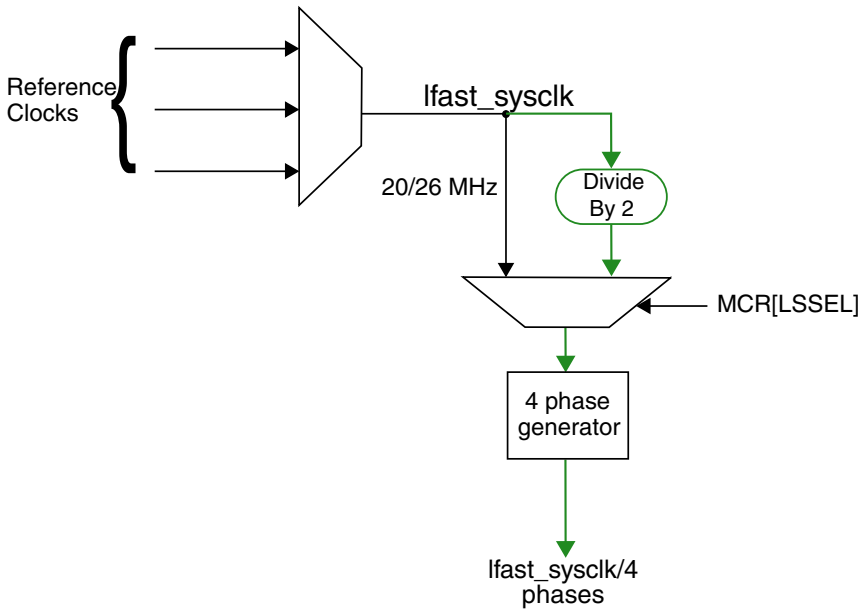

Figure 56-24. External clock muxing of lfast_sysclk of 20/26 MHz

In this case, lfast_sysclk is 10/13 MHz frequency, the clock control module will generate 4 phases of slow speed clock of frequency lfast_sysclk/2 when MCR[LSSEL] = 0. If lfast_sysclk is 10/13 MHz then it does not need to be first divided by 2 before using it for 4 phase generation in LFAST Clock Module, which generates 4 phases of half of the input frequency as shown in Figure 56-25 (selected clock path selected shown in magenta).

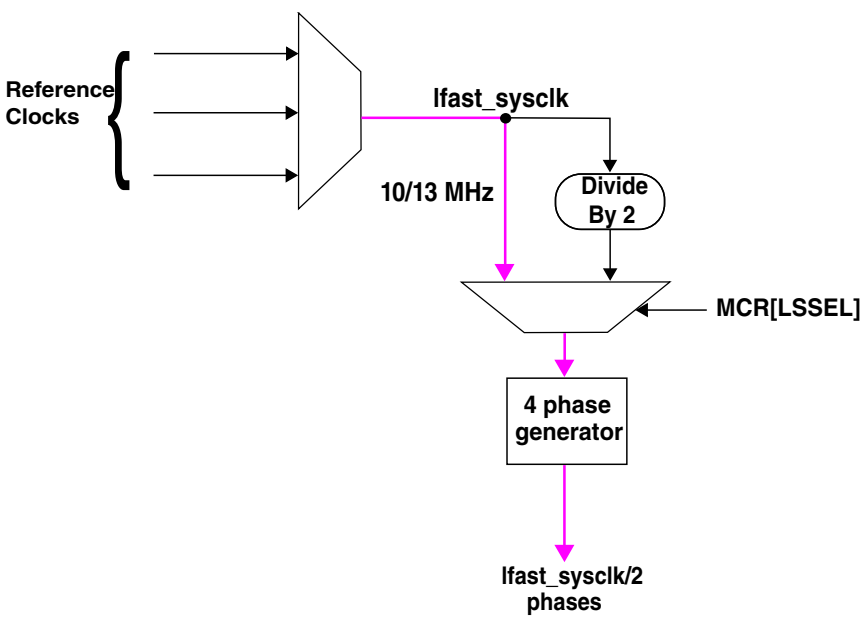

Figure 56-25. External clock muxing of lfast_sysclk of 10 MHz

56.10.2.2 Slow Speed 4 phase generator

Clock control module will generate 4 phases of slow speed clock of frequency of 10/13 MHz. For instance, if lfast_sysclk is 10 MHz then 4 phases of 5 MHz will be generated. The following figure shows 4 phases getting generated using lfast_sysclk.

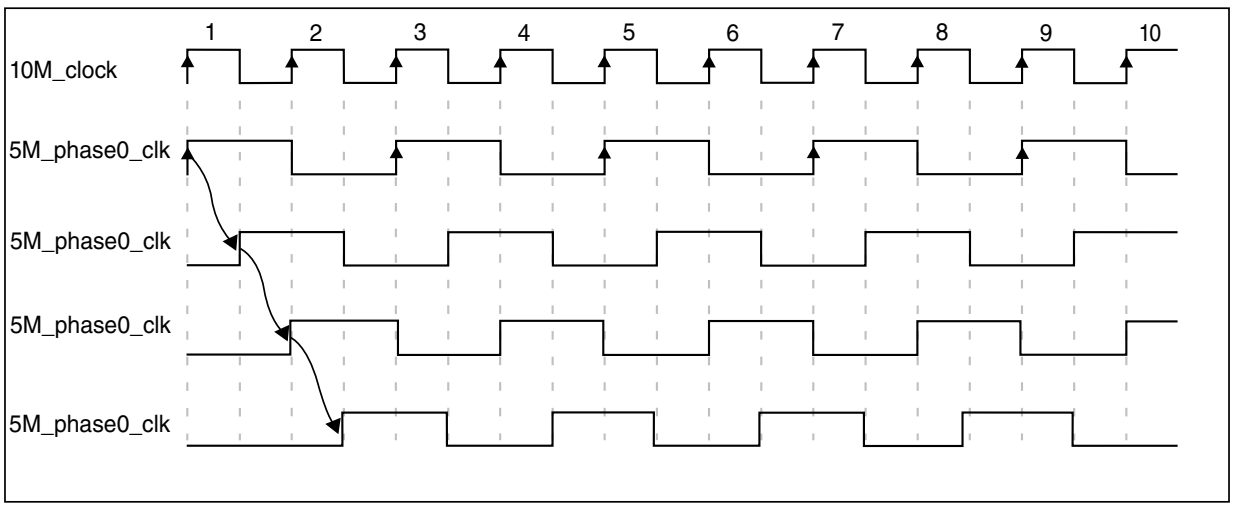

Figure 56-26. Slow speed 4 phases generation

56.10.3 Rx Controller Clocks

56.10.4 Clocking Module Requirements for High Speed Phases

The high speed phases are obtained from the PLL via the Clocking Module as shown in the following figure.

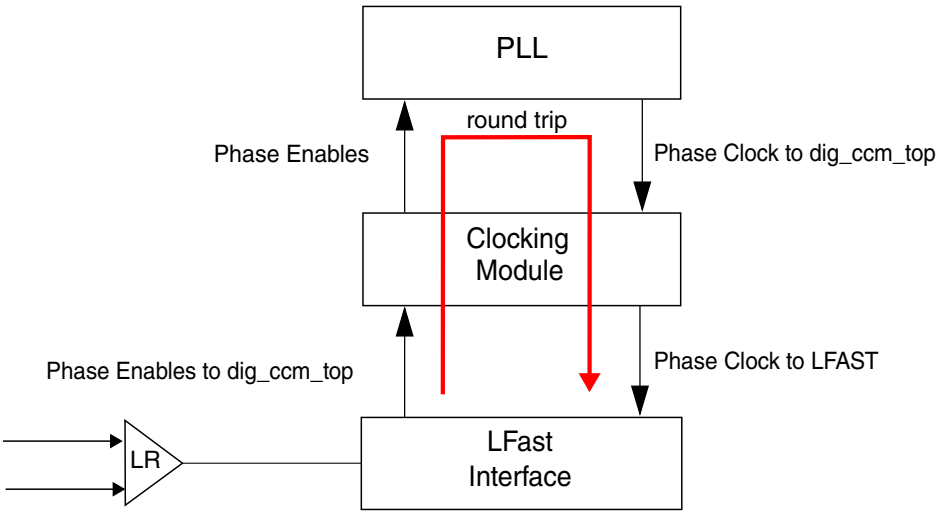

Figure 56-27. Clock enables and clock paths

The LFAST block will know which of the phases will be required for the different modes of operations. Therefore the LFAST block will provide enables and speed mode switches to the Clocking Module. The Clocking Module will use these signals to control the enables to the clock phases to reduce the power consumption.

The 8 phases of clocks signal are fed to the Clocking Module and muxed with the low speed phases. Depending on enables and data rate speed modes, the selected clocks are passed to the Sampler block and interface block.

COCR[PHSSEL] is connected to the Clocking Module, which selects whether 8 or 4 phases are selected for High Speed mode. It is only valid for high speed.

The routing of the 8 high speed phases to the interface is critical. Each clock phase will need to have the same routing track length from the PLL to the interface of Clocking Module. Each of the 8 high speed phases are separated by 45 degrees. This separation needs to be maintained from the phase generator to the interface.

56.10.5 Clock module requirements for low speed phases

56.10.5.1 Low speed

The low speed clock phases are generated in Clocking Module. These four phases are required to sample the data correctly at Low Speed mode. The LFAST block will provide the enable for the phases. The clock source for the low speed phases is SYSCLK. The Clocking Module block will need to generate the 4 phases of low speed clock 90 degrees apart.

Using the Low Speed mode on the interface allows the polyphase generation logic to be turned off and the requirement of high-speed-freq × 8 MHz clock from the PLL is not needed.

Table 56-14. Rx clocks summary

Rx Speed mode	Source
Low Speed	lfast_sysclk
High Speed	PLL

56.10.6 Tx Controller Clocks

56.10.6.1 Clocking Module Requirements for Speed Phases

The low speed phase 0 clock is sourced from the lfast_sysclk and the high speed phase 0 clock is sourced from the PLL. See the following table.

Table 56-15. Tx clocks summary

Tx Speed mode	Source
Low Speed	lfast_sysclk
High Speed	PLL

56.10.6.2 Transmit Clock Muxing

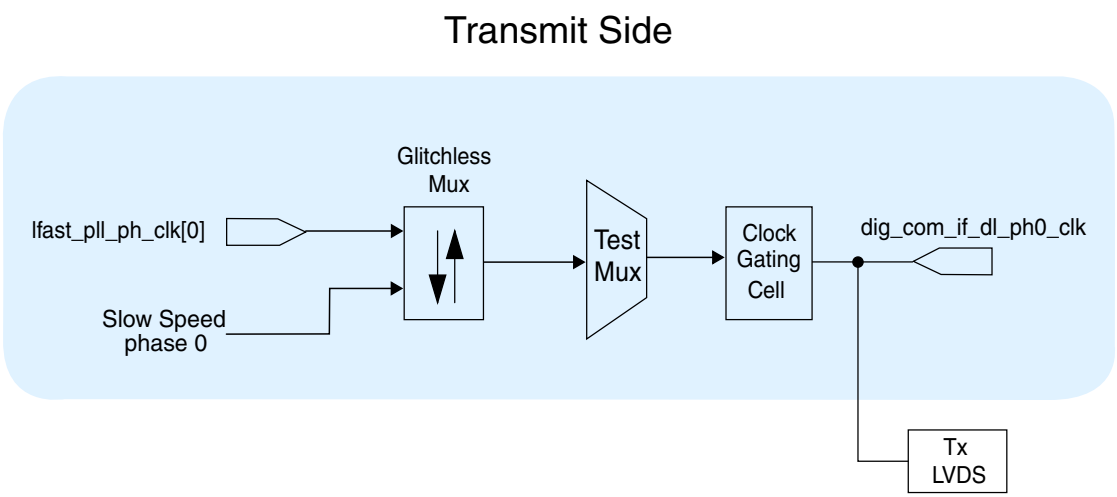

Figure 56-28. Transmit Clocks Muxing

56.10.6.3 Tx Request Clock Control

The Tx phase 0 clock is enabled when all the resets are negated.

56.11 PLL configuration example

This is a typical configuration for 320 MHZ LFAST high-speed clock when the reference clock is 20 MHz.

1. Program the LFAST_PLLCR[FBDIV] for the Feedback Division factor, in this case 15 (divide by 16)
2. Program the LFAST_PLLCR[PREDIV] for the Division factor for PLL Reference Clock, in this case 0 (divide by 1)
3. Program the LFAST_PLLCR[SWPON] to 1, for switching the PLL ON

The user should wait for:

1. The LFAST_PLLLSR[PLLDIS] =’0’, indicating that the PLL is enabled
2. Then, the LFAST_PLLLSR[PLDCR] =’1’, indicating that the PLL is locked and ready for use

Chapter 57
Serial Peripheral Interface (SPI)

57.1 Chip-specific Serial Peripheral Interface (SPI) information

57.1.1 SPI modules configuration

The device contains two SPI module.

57.1.2 Number of CTARs

SPI CTAR registers define different transfer attribute configurations. The SPI module supports up to eight CTAR registers.

In master mode, the CTAR registers define combinations of transfer attributes, such as frame size, clock phase, clock polarity, data bit ordering, baud rate, and various delays. In slave mode only CTAR0 is used, and a subset of its bitfields sets the slave transfer attributes; while in master mode, two CTARs provides enough flexibility to set different attributes to the type of device connected on the SPI.

57.1.3 TX FIFO size

Table 57-1. SPI transmit FIFO size

SPI Module	Transmit FIFO size
SPI_1	5
SPI_2	5

57.1.4 RX FIFO Size

Table 57-2. SPI receive FIFO size

SPI Module	Receive FIFO size
SPI_1	5
SPI_2	5

57.1.5 Number of PCS signals

The following table shows the number of peripheral chip select signals available per SPI module.

Table 57-3. SPI PCS signals

SPI Module	PCS Signals
SPI_1	SPI_PCS[7:0]
SPI_2	SPI_PCS[3:0]

NOTE

When configured in slave mode,once SPI is enabled do NOT assert SPI module disable (SPI_MCR[MDIS]). Allow the Mode Entry function to disable the SPI module.

57.2 Introduction

The serial peripheral interface (SPI) module provides a synchronous serial bus for communication between a chip and an external peripheral device.

57.2.1 Block Diagram

The block diagram of this module is as follows:

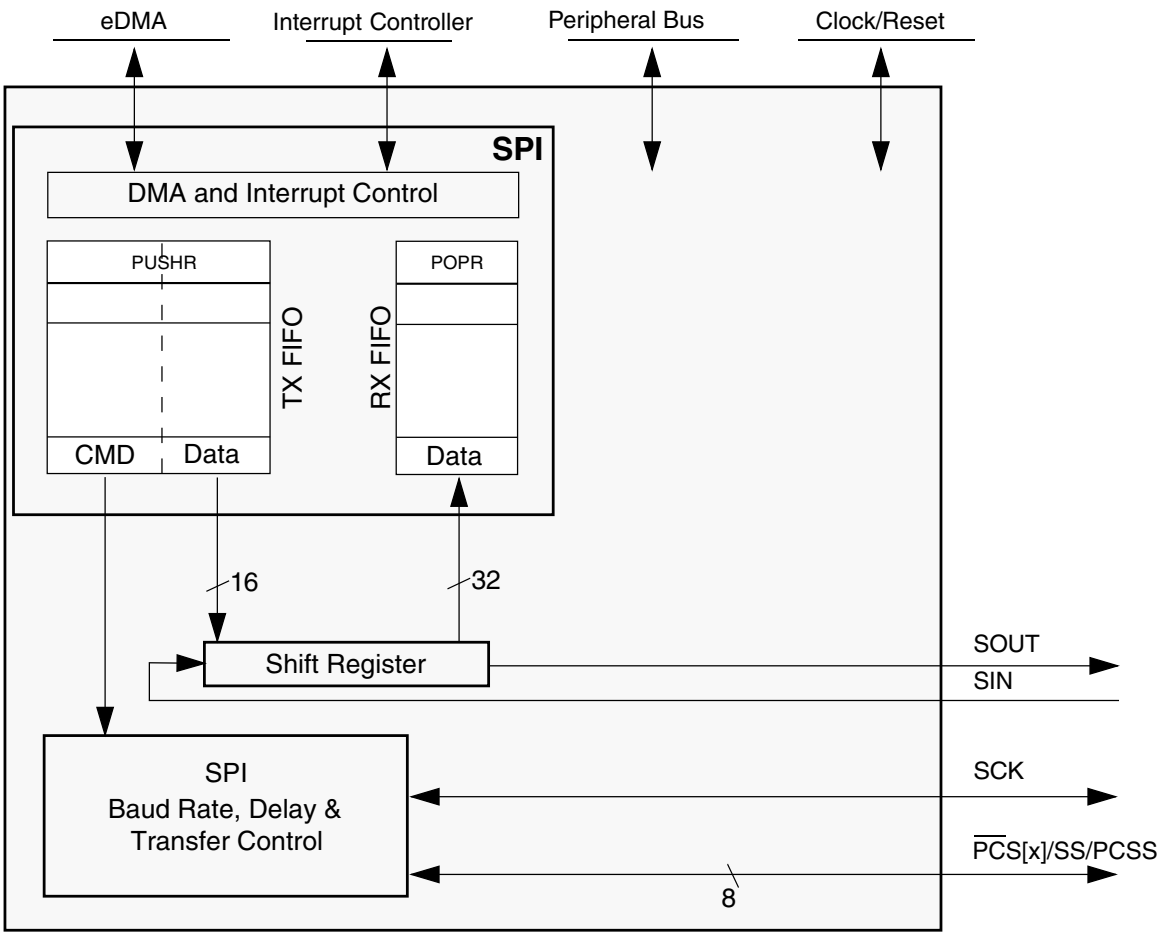

Figure 57-1. SPI Block Diagram

57.2.2 Features

The module supports the following features:

- Full-duplex, three-wire synchronous transfers
- Master mode
- Slave mode
- Data streaming operation in Slave mode with continuous slave selection
- Buffered transmit operation using the transmit first in first out (TX FIFO) with depth of 5 entries
- Buffered receive operation using the receive FIFO (RX FIFO) with depth of 5 entries
- Asynchronous clocking scheme for Register and Protocol Interfaces

- TX and RX FIFOs can be disabled individually for low-latency updates to SPI queues
- Visibility into TX and RX FIFOs for ease of debugging
- Programmable transfer attributes on a per-frame basis:
  - eight transfer attribute registers
  - Serial clock (SCK) with programmable polarity and phase
  - Various programmable delays
  - Programmable serial frame size: 4 to 16
    - SPI frames longer than 16 bits can be supported using the continuous selection format.
  - Continuously held chip select capability
  - Parity control
- 8 peripheral chip selects (PCSes), expandable to 256 with external demultiplexer
- Deglitching support for up to 128 peripheral chip selects (PCSes) with external demultiplexer
- DMA support for adding entries to TX FIFO and removing entries from RX FIFO:
  - TX FIFO is not full (TFFF)
  - RX FIFO is not empty (RFDF)
- Interrupt conditions:
  - End of Queue reached (EOQF)
  - TX FIFO is not full (TFFF)
  - Transfer of current frame complete (TCF)
  - Attempt to transmit with an empty Transmit FIFO (TFUF)
  - RX FIFO is not empty (RFDF)
  - Frame received while Receive FIFO is full (RFOF)
  - SPI Parity Error (SPEF)
- Global interrupt request line
- Modified SPI transfer formats for communication with slower peripheral devices
- Power-saving architectural features:

- Support for Stop mode

57.2.3 Interface configurations

57.2.3.1 SPI configuration

The Serial Peripheral Interface (SPI) configuration allows the module to send and receive serial data. This configuration allows the module to operate as a basic SPI block with internal FIFOs supporting external queue operation. Transmitted data and received data reside in separate FIFOs. The host CPU or a DMA controller read the received data from the Receive FIFO and write transmit data to the Transmit FIFO.

For queued operations, the SPI queues can reside in system RAM, external to the module. Data transfers between the queues and the module FIFOs are accomplished by a DMA controller or host CPU. The following figure shows a system example with DMA, SPI, and external queues in system RAM.

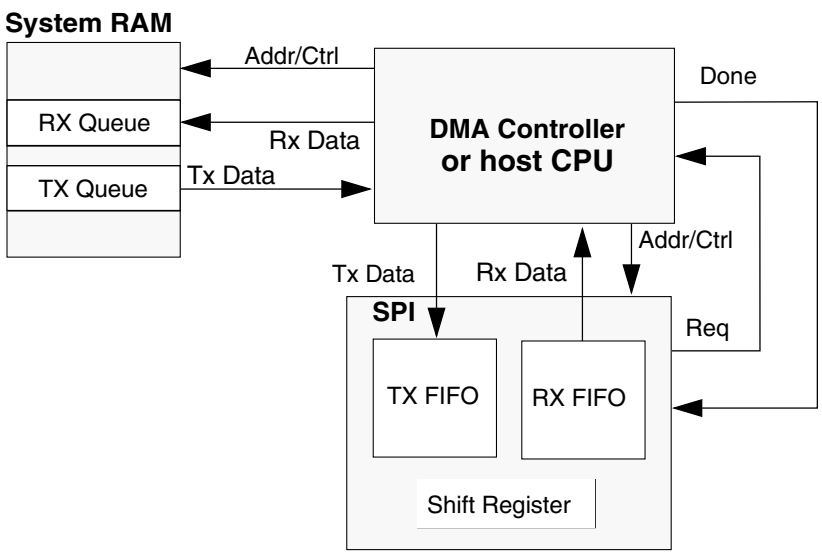

Figure 57-2. SPI with queues and DMA

57.2.4 Modes of Operation

The module supports the following modes of operation that can be divided into two categories:

- Module-specific modes:

- Master mode
- Slave mode
- Module Disable mode

- Chip-specific modes:
  - External Stop mode
  - Debug mode

The module enters module-specific modes when the host writes a module register. The chip-specific modes are controlled by signals external to the module. The chip-specific modes are modes that a chip may enter in parallel to the block-specific modes.

57.2.4.1 Master Mode

Master mode allows the module to initiate and control serial communication. In this mode, these signals are controlled by the module and configured as outputs:

- SCK
- SOUT
- PCS[*x*]

57.2.4.2 Slave Mode

Slave mode allows the module to communicate with SPI bus masters. In this mode, the module responds to externally controlled serial transfers. The SCK signal and the PCS[0]/$\overline{\text{SS}}$ signals are configured as inputs and driven by an SPI bus master.

57.2.4.3 Module Disable Mode

The Module Disable mode can be used for chip power management. The clock to the non-memory mapped logic in the module can be stopped while in the Module Disable mode.

57.2.4.4 External Stop Mode

External Stop mode is used for chip power management. The module supports the Peripheral Bus Stop mode mechanism. When a request is made to enter External Stop mode, it acknowledges the request and completes the transfer that is in progress. When the module reaches the frame boundary, it signals that the protocol clock to the module may be shut off.

57.2.4.5 Debug Mode

Debug mode is used for system development and debugging. The MCR[FRZ] bit controls module behavior in the Debug mode:

- If the bit is set, the module stops all serial transfers, when the chip is in debug mode.
- If the bit is cleared, the chip debug mode has no effect on the module.

57.3 Module signal descriptions

This table describes the signals on the boundary of the module that may connect off chip (in alphabetical order).

Table 57-4. Module signal descriptions

Signal	Master mode	Slave mode	I/O
PCS0/$\overline{SS}$	Peripheral Chip Select 0 (O)	Slave Select (I)	I/O
PCS[1:3]	Peripheral Chip Selects 1–3	(Unused)	O
PCS4	Peripheral Chip Select 4	(Unused)	O
PCS5/ $\overline{PCSS}$	Peripheral Chip Select 5 /Peripheral Chip Select Strobe	(Unused)	O
PCS[6:7]	Peripheral Chip Selects 6–7	(Unused)	O
SCK	Serial Clock (O)	Serial Clock (I)	I/O
SIN	Serial Data In	Serial Data In	I
SOUT	Serial Data Out	Serial Data Out	O

57.3.1 PCS0/$\overline{SS}$—Peripheral Chip Select/Slave Select

Master mode: Peripheral Chip Select 0 (O)—Selects an SPI slave to receive data transmitted from the module.

Slave mode: Slave Select (I)—Selects the module to receive data transmitted from an SPI master.

NOTE

Do not tie the SPI slave select pin to ground. Otherwise, SPI cannot function properly.

57.3.2 PCS1–PCS3—Peripheral Chip Selects 1–3

Master mode: Peripheral Chip Selects 1–3 (O)—Select an SPI slave to receive data transmitted by the module.

Slave mode: Unused

57.3.3 PCS4—Peripheral Chip Select 4

Master mode: Peripheral Chip Select 4 (O)—Selects an SPI slave to receive data transmitted by the module.

Slave mode: Unused

57.3.4 PCS5/$\overline{\text{PCSS}}$—Peripheral Chip Select 5/Peripheral Chip Select Strobe

Master mode:

- Peripheral Chip Select 5 (O)—Used only when the peripheral-chip-select strobe is disabled (MCR[PCSSE]). Selects an SPI slave to receive data transmitted by the module.
- Peripheral Chip Select Strobe (O)—Used only when the peripheral-chip-select strobe is enabled (MCR[PCSSE]). Strobes an off-module peripheral-chip-select demultiplexer, which decodes the module's PCS signals other than PCS5, preventing glitches on the demultiplexer outputs.

Slave mode: Unused

57.3.5 PCS6–PCS7—Peripheral Chip Selects 6–7

Master mode: Peripheral Chip Selects 6–7 (O)—Select an SPI slave to receive data transmitted by the module.

Slave mode: Unused

57.3.6 SCK—Serial Clock

Master mode: Serial Clock (O)—Supplies a clock signal from the module to SPI slaves.

Slave mode: Serial Clock (I)—Supplies a clock signal to the module from an SPI master.

57.3.7 SIN—Serial Input

Master mode: Serial Input (I)—Receives serial data.

Slave mode: Serial Input (I)—Receives serial data.

57.3.8 SOUT—Serial Output

Master mode: Serial Output (O)—Transmits serial data.

Slave mode: Serial Output (O)—Transmits serial data.

57.4 Memory Map/Register Definition

Register accesses to memory addresses that are reserved or undefined result in a transfer error. Any Write access to the POPR and RXFRn also results in a transfer error.

SPI memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Module Configuration Register (SPI_MCR)	32	R/W	0000_4001h	57.4.1/2683

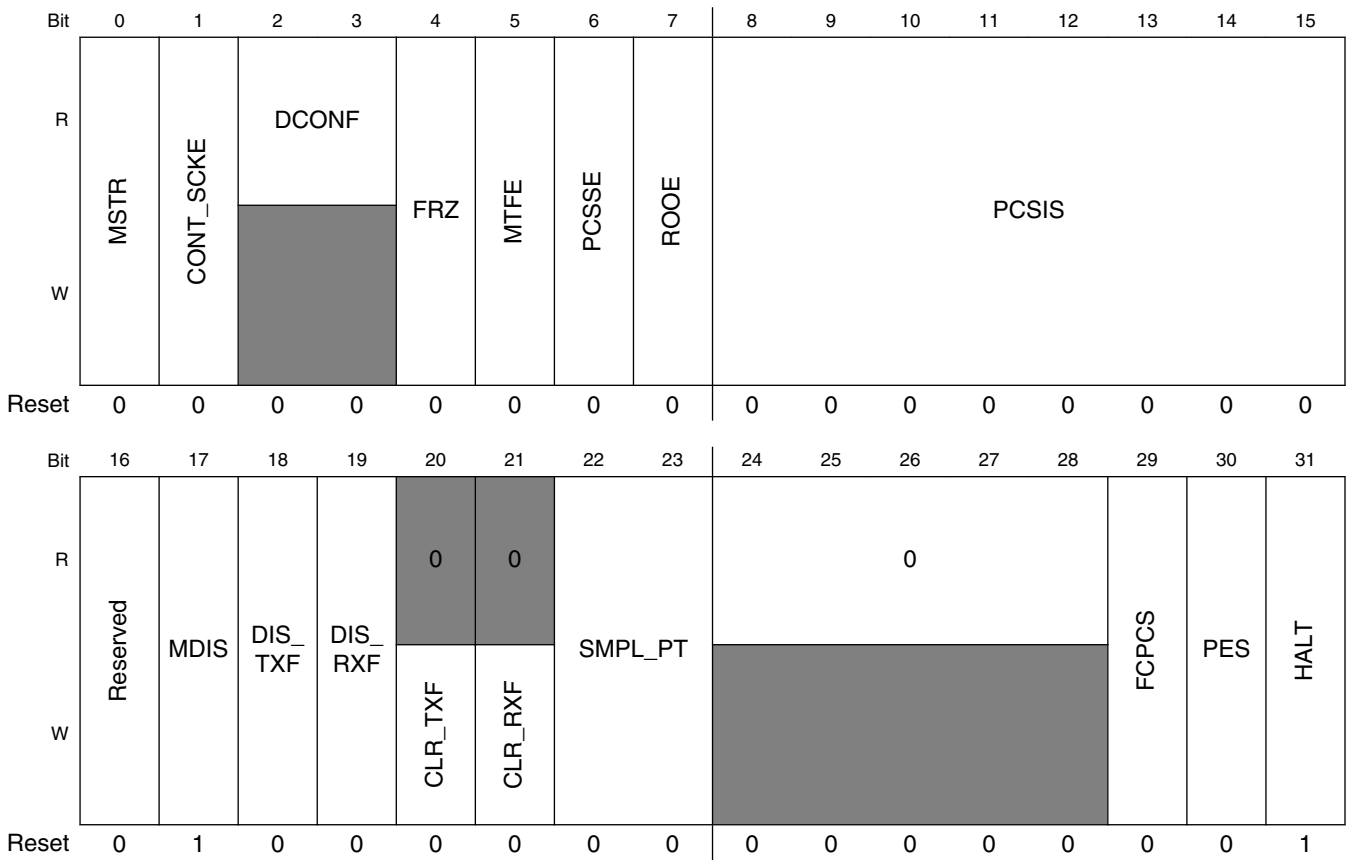
80	Receive FIFO Registers (SPI_RXFR1)	32	R	0000_0000h	57.4.11/ 2703
84	Receive FIFO Registers (SPI_RXFR2)	32	R	0000_0000h	57.4.11/ 2703
88	Receive FIFO Registers (SPI_RXFR3)	32	R	0000_0000h	57.4.11/ 2703
8C	Receive FIFO Registers (SPI_RXFR4)	32	R	0000_0000h	57.4.11/ 2703

57.4.1 Module Configuration Register (SPI_MCR)

Contains bits to configure various attributes associated with the module operations. The HALT and MDIS bits can be changed at any time, but the effect takes place only on the next frame boundary. Only the HALT and MDIS bits in the MCR can be changed, while the module is in the Running state.

Address: 0h base + 0h offset = 0h



SPI_MCR field descriptions

Field	Description
0 MSTR	Master/Slave Mode Select Enables either Master mode (if supported) or Slave mode (if supported) operation. 0 Enables Slave mode 1 Enables Master mode
1 CONT_SCKE	Continuous SCK Enable Enables the Serial Communication Clock (SCK) to run continuously.

Table continues on the next page...

SPI_MCR field descriptions (continued)

Field	Description
	0 Continuous SCK disabled. 1 Continuous SCK enabled.
2–3 DCONF	SPI Configuration. Selects among the different configurations of the module. 00 SPI 01 Reserved 10 Reserved 11 Reserved
4 FRZ	Freeze Enables transfers to be stopped on the next frame boundary when the device enters Debug mode. 0 Do not halt serial transfers in Debug mode. 1 Halt serial transfers in Debug mode.
5 MTFE	Modified Transfer Format Enable Enables a modified transfer format to be used. **NOTE:** When MTFE=1 with continuous SCK enabled (MCR [CONT_SCKE] =1) in master mode, configure CTAR[LSBFE]=0 for correct operations while receiving unequal length frames. If PUSHR[CONT] is also set for back to back frame transfer, also configure the frame size of the first frame as less than or equal to the frame size of the next frame. In this scenario, make sure that for all received frames, the bits are read equal to their respective frame sizes and any extra bits during POP operation are masked. 0 Modified SPI transfer format disabled. 1 Modified SPI transfer format enabled.
6 PCSSE	Peripheral Chip Select Strobe Enable Enables the PCS5/ $\overline{\text{PCSS}}$ to operate as a PCS Strobe output signal. 0 PCS5/ $\overline{\text{PCSS}}$ is used as the Peripheral Chip Select[5] signal. 1 PCS5/ $\overline{\text{PCSS}}$ is used as an active-low PCS Strobe signal.
7 ROOE	Receive FIFO Overflow Overwrite Enable In the RX FIFO overflow condition, configures the module to ignore the incoming serial data or overwrite existing data. If the RX FIFO is full and new data is received, the data from the transfer, generating the overflow, is ignored or shifted into the shift register. 0 Incoming data is ignored. 1 Incoming data is shifted into the shift register.
8–15 PCSIS	Peripheral Chip Select x Inactive State Determines the inactive state of PCSx when the module is in Master Mode. This field has no effect when the module is in Slave Mode. The Slave Select input to the module in slave mode is always Active Low. **NOTE:** The effect of this bit only takes place when module is enabled. Ensure that this bit is configured correctly before enabling the SPI interface. 0 The inactive state of PCSx is low. 1 The inactive state of PCSx is high.

Table continues on the next page...

SPI_MCR field descriptions (continued)

Field	Description
16 Reserved	This field is reserved.
17 MDIS	Module Disable Allows the clock to be stopped to the non-memory mapped logic in the module effectively putting it in a software-controlled power-saving state. The reset value of the MDIS bit is parameterized, with a default reset value of 1. When the module is used in Slave Mode, it is recommended to leave this bit 0, because a slave doesn't have control over master transactions. 0 Enables the module clocks. 1 Allows external logic to disable the module clocks.
18 DIS_TXF	Disable Transmit FIFO When the TX FIFO is disabled, the transmit part of the module operates as a simplified double-buffered SPI. This bit can be written only when the MDIS bit is cleared. 0 TX FIFO is enabled. 1 TX FIFO is disabled.
19 DIS_RXF	Disable Receive FIFO When the RX FIFO is disabled, the receive part of the module operates as a simplified double-buffered SPI. This bit can only be written when the MDIS bit is cleared. 0 RX FIFO is enabled. 1 RX FIFO is disabled.
20 CLR_TXF	Clear TX FIFO Flushes the TX FIFO. Writing a 1 to CLR_TXF clears the TX FIFO Counter. The CLR_TXF bit is always read as zero. 0 Do not clear the TX FIFO counter. 1 Clear the TX FIFO counter.
21 CLR_RXF	CLR_RXF Flushes the RX FIFO. Writing a 1 to CLR_RXF clears the RX Counter. The CLR_RXF bit is always read as zero. **NOTE:** After every RX FIFO clear operation (MCR [CLR_RXF] = 0b1) following a RX FIFO overflow (SR [RFOF] = 0b1) scenario, immediately perform a single POP from the RX FIFO and discard the read data. The POP and discard operation should be completed before the reception of new incoming frame. 0 Do not clear the RX FIFO counter. 1 Clear the RX FIFO counter.
22–23 SMPL_PT	Sample Point Controls when the module master samples SIN in Modified Transfer Format. This field is valid only when CPHA bit in CTARn[CPHA] is 0. 00 0 protocol clock cycles between SCK edge and SIN sample 01 1 protocol clock cycle between SCK edge and SIN sample 10 2 protocol clock cycles between SCK edge and SIN sample 11 Reserved

Table continues on the next page...

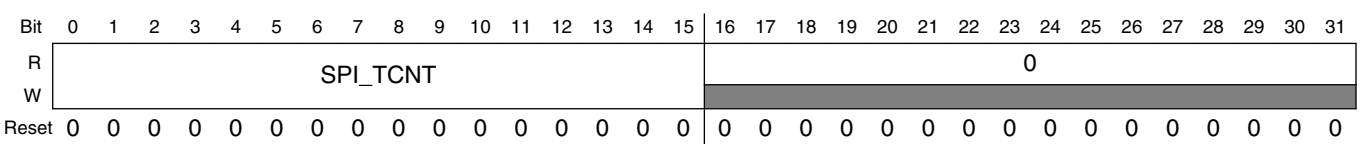
SPI_MCR field descriptions (continued)

Field	Description
24–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 FCPCS	Fast Continuous PCS Mode. This bit enables the masking of “After SCK (t_{ASC})” and “PCS to SCK (t_{CSC})” delays when operating in Continuous PCS mode. This masking is not available if Continuous SCK mode is enabled. The individual delay masks are selected via bits MASC and MCSC of the PUSHR register. The firmware should select appropriate masks when providing continuous frames via the PUSHR register. 0 Normal or Slow Continuous PCS mode. Masking of delays is disabled. 1 Fast Continuous PCS mode. Delays masked via control bits in PUSHR register.
30 PES	Parity Error Stop Controls SPI operation when a parity error is detected in a received SPI frame. 0 SPI frame transmission continues. 1 SPI frame transmission stops.
31 HALT	Halt The HALT bit starts and stops frame transfers. See Start and Stop of Module transfers 0 Start transfers. 1 Stop transfers.

57.4.2 Transfer Count Register (SPI_TCR)

TCR contains a counter that indicates the number of SPI transfers made. The transfer counter is intended to assist in queue management. Do not write the TCR when the module is in the Running state.

Address: 0h base + 8h offset = 8h



SPI_TCR field descriptions

Field	Description
0–15 SPI_TCNT	SPI Transfer Counter Counts the number of SPI transfers the module makes. The SPI_TCNT field increments every time the last bit of an SPI frame is transmitted. A value written to SPI_TCNT presets the counter to that value. SPI_TCNT is reset to zero at the beginning of the frame when the CTCNT field is set in the executing SPI

Table continues on the next page...

SPI_TCR field descriptions (continued)

Field	Description
	command. The Transfer Counter wraps around; incrementing the counter past 65535 resets the counter to zero.
16–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

57.4.3 Clock and Transfer Attributes Register (In Master Mode) (SPI_CTAR*n*)

CTAR registers are used to define different transfer attributes. Do not write to the CTAR registers while the module is in the Running state.

In Master mode, the CTAR registers define combinations of transfer attributes such as frame size, clock phase and polarity, data bit ordering, baud rate, and various delays. In slave mode, a subset of the bitfields in CTAR0 are used to set the slave transfer attributes.

When the module is configured as a SPI master, the CTAS field in the command portion of the TX FIFO entry selects which of the CTAR registers is used. When the module is configured as an SPI bus slave, it uses the CTAR0 register.

SPI_CTAR*n* field descriptions

Field	Description
0 DBR	Double Baud Rate Doubles the effective baud rate of the Serial Communications Clock (SCK). This field is used only in master mode. It effectively halves the Baud Rate division ratio, supporting faster frequencies, and odd division ratios for the Serial Communications Clock (SCK). When the DBR bit is set, the duty cycle of the Serial Communications Clock (SCK) depends on the value in the Baud Rate Prescaler and the Clock

Table continues on the next page...

SPI_CTAR*n* field descriptions (continued)

Field	Description
	Phase bit as listed in the following table. See the BR field description for details on how to compute the baud rate. **Table 57-5. SPI SCK Duty Cycle** DBR / CPHA / PBR / SCK Duty Cycle 0 / any / any / 50/50 1 / 0 / 00 / 50/50 1 / 0 / 01 / 33/66 1 / 0 / 10 / 40/60 1 / 0 / 11 / 43/57 1 / 1 / 00 / 50/50 1 / 1 / 01 / 66/33 1 / 1 / 10 / 60/40 1 / 1 / 11 / 57/43 0 The baud rate is computed normally with a 50/50 duty cycle. 1 The baud rate is doubled with the duty cycle depending on the Baud Rate Prescaler.
1–4 FMSZ	Frame Size The number of bits transferred per frame is equal to the FMSZ value plus 1. Regardless of the transmission mode, the minimum valid frame size value is 4. There is a constraint on the minimum allowable Frame size, which depends on the ratio of the Register Read/Write clock to the Protocol clock. The minimum Frame size (FMSZ + 1) is determined by the following equation. Upper Ceiling must be applied for non-integer values. Minimum Frame Size = ((4 x f_p) + (3 x f_r)) / (n x f_r) f_p = Protocol clock frequency f_r = Register interface clock frequency n = (PBR x BR) / (1 + DBR) = Multiple of protocol clock required to get Baud (SCK) Clock However, the minimum frame size can never be less than 4. There is no constraint on the maximum programmable frame size. Also note that `fp' can be equal to, less than or greater than `fr' purely based on user requirement.
5 CPOL	Clock Polarity Selects the inactive state of the Serial Communications Clock (SCK). This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock polarities. When the Continuous Selection Format is selected, switching between clock polarities without stopping the module can cause errors in the transfer due to the peripheral device interpreting the switch of clock polarity as a valid clock edge. **NOTE:** In case of Continuous SCK mode, when the module goes in low power mode(disabled), inactive state of SCK is not guaranteed. 0 The inactive state value of SCK is low. 1 The inactive state value of SCK is high.
6 CPHA	Clock Phase

Table continues on the next page...

SPI_CTAR*n* field descriptions (continued)

Field	Description
	Selects which edge of SCK causes data to change and which edge causes data to be captured. This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock phase settings. In Continuous SCK mode, the bit value is ignored and the transfers are done as if the CPHA bit is set to 1. 0 Data is captured on the leading edge of SCK and changed on the following edge. 1 Data is changed on the leading edge of SCK and captured on the following edge.
7 LSBFE	LSB First Specifies whether the LSB or MSB of the frame is transferred first. 0 Data is transferred MSB first. 1 Data is transferred LSB first.
8–9 PCSSCK	PCS to SCK Delay Prescaler Selects the prescaler value for the delay between assertion of PCS and the first edge of the SCK. See the CSSCK field description for information on how to compute the PCS to SCK Delay. Refer PCS to SCK Delay (t_{CSC}) for more details. 00 PCS to SCK Prescaler value is 1. 01 PCS to SCK Prescaler value is 3. 10 PCS to SCK Prescaler value is 5. 11 PCS to SCK Prescaler value is 7.
10–11 PASC	After SCK Delay Prescaler Selects the prescaler value for the delay between the last edge of SCK and the negation of PCS. See the ASC field description for information on how to compute the After SCK Delay. Refer After SCK Delay (t_{ASC}) for more details. 00 Delay after Transfer Prescaler value is 1. 01 Delay after Transfer Prescaler value is 3. 10 Delay after Transfer Prescaler value is 5. 11 Delay after Transfer Prescaler value is 7.
12–13 PDT	Delay after Transfer Prescaler Selects the prescaler value for the delay between the negation of the PCS signal at the end of a frame and the assertion of PCS at the beginning of the next frame. The PDT field is only used in master mode. See the DT field description for details on how to compute the Delay after Transfer. Refer Delay after Transfer (t_{DT}) for more details. 00 Delay after Transfer Prescaler value is 1. 01 Delay after Transfer Prescaler value is 3. 10 Delay after Transfer Prescaler value is 5. 11 Delay after Transfer Prescaler value is 7.
14–15 PBR	Baud Rate Prescaler Selects the prescaler value for the baud rate. This field is used only in master mode. The baud rate is the frequency of the SCK. The protocol clock is divided by the prescaler value before the baud rate selection takes place. See the BR field description for details on how to compute the baud rate. 00 Baud Rate Prescaler value is 2. 01 Baud Rate Prescaler value is 3.

Table continues on the next page...

SPI_CTAR*n* field descriptions (continued)

Field	Description
	10 Baud Rate Prescaler value is 5. 11 Baud Rate Prescaler value is 7.
16–19 CSSCK	PCS to SCK Delay Scaler Selects the scaler value for the PCS to SCK delay. This field is used only in master mode. The PCS to SCK Delay is the delay between the assertion of PCS and the first edge of the SCK. The delay is a multiple of the protocol clock period, and it is computed according to the following equation: $t_{CSC} = (1/f_P) \times PCSSCK \times CSSCK$. The following table lists the delay scaler values. **Table 57-6. Delay Scaler Encoding** **Field Value** / **Delay Scaler Value** 0000 / 2 0001 / 4 0010 / 8 0011 / 16 0100 / 32 0101 / 64 0110 / 128 0111 / 256 1000 / 512 1001 / 1024 1010 / 2048 1011 / 4096 1100 / 8192 1101 / 16384 1110 / 32768 1111 / 65536 Refer PCS to SCK Delay (t_{CSC}) for more details.
20–23 ASC	After SCK Delay Scaler Selects the scaler value for the After SCK Delay. This field is used only in master mode. The After SCK Delay is the delay between the last edge of SCK and the negation of PCS. The delay is a multiple of the protocol clock period, and it is computed according to the following equation: $t_{ASC} = (1/f_P) \times PASC \times ASC$ See Delay Scaler Encoding table in CTARn[CSSCK] bit field description for scaler values. Refer After SCK Delay (t_{ASC}) for more details.
24–27 DT	Delay After Transfer Scaler Selects the Delay after Transfer Scaler. This field is used only in master mode. The Delay after Transfer is the time between the negation of the PCS signal at the end of a frame and the assertion of PCS at the beginning of the next frame.

Table continues on the next page...

SPI_CTAR*n* field descriptions (continued)

Field	Description
	In the Continuous Serial Communications Clock operation, the DT value is fixed to one SCK clock period, The Delay after Transfer is a multiple of the protocol clock period, and it is computed according to the following equation: $t_{DT} = (1/f_P) \times PDT \times DT$ See Delay Scaler Encoding table in CTARn[CSSCK] bit field description for scaler values.
28–31 BR	Baud Rate Scaler Selects the scaler value for the baud rate. This field is used only in master mode. The prescaled protocol clock is divided by the Baud Rate Scaler to generate the frequency of the SCK. The baud rate is computed according to the following equation: SCK baud rate = $(f_P / PBR) \times [(1+DBR)/BR]$ The following table lists the baud rate scaler values.

Table 57-7. Baud Rate Scaler

CTARn[BR]	Baud Rate Scaler Value
0000	2
0001	4
0010	6
0011	8

R W	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SPI_CTAR*n*_SLAVE field descriptions

Field	Description
0 Reserved	Always write the reset value to this field. This field is reserved.
1–4 FMSZ	Frame Size The number of bits transferred per frame is equal to the FMSZ field value plus 1. Note that the minimum valid value of frame size is 4.
5 CPOL	Clock Polarity Selects the inactive state of the Serial Communications Clock (SCK). **NOTE:** In case of Continuous SCK mode, when the module goes in low power mode(disabled), inactive state of SCK is not guaranteed. 0 The inactive state value of SCK is low. 1 The inactive state value of SCK is high.
6 CPHA	Clock Phase Selects which edge of SCK causes data to change and which edge causes data to be captured. This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock phase settings. In Continuous SCK mode, the bit value is ignored and the transfers are done as if the CPHA bit is set to 1. 0 Data is captured on the leading edge of SCK and changed on the following edge. 1 Data is changed on the leading edge of SCK and captured on the following edge.

Table continues on the next page...

SPI_CTAR*n*_SLAVE field descriptions (continued)

Field	Description
7 PE	Parity Enable Enables parity bit transmission and reception for the frame. 0 No parity bit included/checked. 1 Parity bit is transmitted instead of last data bit in frame, parity checked for received frame.
8 PP	Parity Polarity Controls polarity of the parity bit transmitted and checked. 0 Even Parity: the number of 1 bits in the transmitted frame is even. The SR[SPEF] bit is set if the number of 1 bits is odd in the received frame. 1 Odd Parity: the number of 1 bits in the transmitted frame is odd. The SR[SPEF] bit is set if the number of 1 bits is even in the received frame.
9 Reserved	This field is reserved.
10–31 Reserved	This field is reserved.

57.4.5 Status Register (SPI_SR)

SR contains status and flag bits. The bits reflect the status of the module and indicate the occurrence of events that can generate interrupt or DMA requests. Software can clear flag bits in the SR by writing a 1 to them. Writing a 0 to a flag bit has no effect. This register may not be writable in Module Disable mode due to the use of power saving mechanisms.

Address: 0h base + 2Ch offset = 2Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

SPI_SR field descriptions

Field	Description
0 TCF	Transfer Complete Flag Indicates that all bits in a frame have been shifted out. TCF remains set until it is cleared by writing a 1 to it. 0 Transfer not complete. 1 Transfer complete.

Table continues on the next page...

SPI_SR field descriptions (continued)

Field	Description
1 TXRXS	TX and RX Status Reflects the run status of the module. 0 Transmit and receive operations are disabled (The module is in Stopped state). 1 Transmit and receive operations are enabled (The module is in Running state).
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 EOQF	End of Queue Flag Indicates that the last entry in a queue has been transmitted when the module is in Master mode. The EOQF bit is set when the TX FIFO entry has the EOQ bit set in the command halfword and the end of the transfer is reached. The EOQF bit remains set until cleared by writing a 1 to it. When the EOQF bit is set, the TXRXS bit is automatically cleared. 0 EOQ is not set in the executing command. 1 EOQ is set in the executing SPI command.
4 TFUF	Transmit FIFO Underflow Flag Indicates an underflow condition in the TX FIFO. The transmit underflow condition is detected only for SPI blocks operating in Slave mode and SPI configuration. TFUF is set when the TX FIFO of the module operating in SPI Slave mode is empty and an external SPI master initiates a transfer. The TFUF bit remains set until cleared by writing 1 to it. 0 No TX FIFO underflow. 1 TX FIFO underflow has occurred.
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 TFFF	Transmit FIFO Fill Flag Indicates whether there is an available location to be filled in the FIFO. Either a DMA request or an interrupt indication can be used to add another entry to the FIFO. Note that this bit is set if at least one location is free in the FIFO. The TFFF bit can be cleared by writing 1 to it or by acknowledgement from the DMA controller to the TX FIFO full request. **NOTE:** The reset value of this bit is 0 when the module is disabled,(MCR[MDIS]=1). 0 TX FIFO is full. 1 TX FIFO is not full.
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 SPEF	SPI Parity Error Flag Indicates that a SPI frame with parity error had been received. The bit remains set until it is cleared by writing a 1 to it. 0 No parity error. 1 Parity error has occurred.

Table continues on the next page...

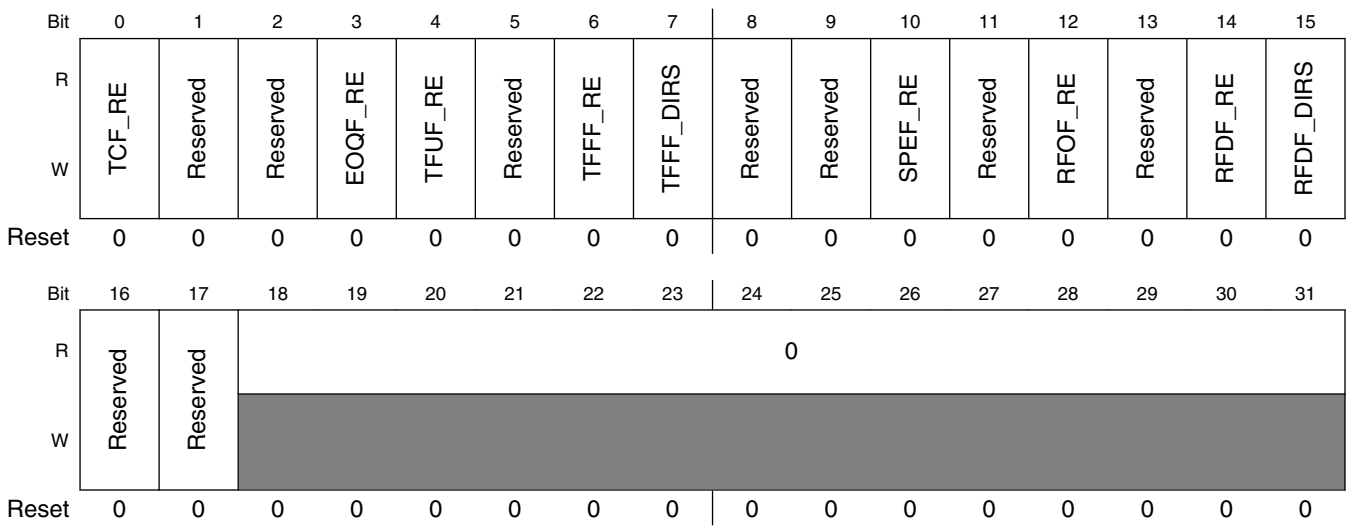
SPI_SR field descriptions (continued)

Field	Description
11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 RFOF	Receive FIFO Overflow Flag Indicates an overflow condition in the RX FIFO. The field is set when the RX FIFO and shift register are full and a transfer is initiated. The bit remains set until it is cleared by writing a 1 to it. 0 No Rx FIFO overflow. 1 Rx FIFO overflow has occurred.
13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 RFDF	Receive FIFO Drain Flag Indicates whether there is an available location to be drained from the FIFO. Either a DMA request or an interrupt indication can be used to read from the FIFO. Note that this bit is set if at least one location can be read from the FIFO. The RFDF bit can be cleared by writing 1 to it or by acknowledgement from the DMA controller when the RX FIFO is empty. 0 RX FIFO is empty. 1 RX FIFO is not empty.
15 Reserved	This field is reserved.
16–19 TXCTR	TX FIFO Counter Indicates the number of valid entries in the TX FIFO. The TXCTR is incremented every time the PUSHR is written. The TXCTR is decremented every time an SPI command is executed and the SPI data is transferred to the shift register.
20–23 TXNXTPTR	Transmit Next Pointer Indicates which TX FIFO entry is transmitted during the next transfer. The TXNXTPTR field is updated every time SPI data is transferred from the TX FIFO to the shift register.
24–27 RXCTR	RX FIFO Counter Indicates the number of entries in the RX FIFO. The RXCTR is decremented every time the POPR is read. The RXCTR is incremented every time data is transferred from the shift register to the RX FIFO.
28–31 POPNXTPTR	Pop Next Pointer Contains a pointer to the RX FIFO entry to be returned when the POPR is read. The POPNXTPTR is updated when the POPR is read.

57.4.6 DMA/Interrupt Request Select and Enable Register (SPI_RSER)

RSER controls DMA and interrupt requests. Do not write to the RSER while the module is in the Running state.

Address: 0h base + 30h offset = 30h



SPI_RSER field descriptions

Field	Description
0 TCF_RE	Transmission Complete Request Enable Enables TCF flag in the SR to generate an interrupt request. 0 TCF interrupt requests are disabled. 1 TCF interrupt requests are enabled.
1 Reserved	Always write the reset value to this field. This field is reserved.
2 Reserved	Always write the reset value to this field. This field is reserved.
3 EOQF_RE	Finished Request Enable Enables the EOQF flag in the SR to generate an interrupt request. 0 EOQF interrupt requests are disabled. 1 EOQF interrupt requests are enabled.
4 TFUF_RE	Transmit FIFO Underflow Request Enable Enables the TFUF flag in the SR to generate an interrupt request.

Table continues on the next page...

SPI_RSER field descriptions (continued)

Field	Description
	0 TFUF interrupt requests are disabled. 1 TFUF interrupt requests are enabled.
5 Reserved	Always write the reset value to this field. This field is reserved.
6 TFFF_RE	Transmit FIFO Fill Request Enable Enables the TFFF flag in the SR to generate a request. The TFFF_DIRS bit selects between generating an interrupt request or a DMA request. 0 TFFF interrupts or DMA requests are disabled. 1 TFFF interrupts or DMA requests are enabled.
7 TFFF_DIRS	Transmit FIFO Fill DMA or Interrupt Request Select Selects between generating a DMA request or an interrupt request. When SR[TFFF] and RSER[TFFF_RE] are set, this field selects between generating an interrupt request or a DMA request. 0 TFFF flag generates interrupt requests. 1 TFFF flag generates DMA requests.
8 Reserved	Always write the reset value to this field. This field is reserved.
9 Reserved	Always write the reset value to this field. This field is reserved.
10 SPEF_RE	SPI Parity Error Request Enable Enables the SPEF flag in the SR to generate an interrupt request. 0 SPEF interrupt requests are disabled. 1 SPEF interrupt requests are enabled.
11 Reserved	Always write the reset value to this field. This field is reserved.
12 RFOF_RE	Receive FIFO Overflow Request Enable Enables the RFOF flag in the SR to generate an interrupt request. 0 RFOF interrupt requests are disabled. 1 RFOF interrupt requests are enabled.
13 Reserved	Always write the reset value to this field. This field is reserved.
14 RFDF_RE	Receive FIFO Drain Request Enable Enables the RFDF flag in the SR to generate a request. The RFDF_DIRS bit selects between generating an interrupt request or a DMA request. 0 RFDF interrupt or DMA requests are disabled. 1 RFDF interrupt or DMA requests are enabled.

Table continues on the next page...

SPI_RSER field descriptions (continued)

Field	Description
15 RFDF_DIRS	Receive FIFO Drain DMA or Interrupt Request Select Selects between generating a DMA request or an interrupt request. When the RFDF flag bit in the SR is set, and the RFDF_RE bit in the RSER is set, the RFDF_DIRS bit selects between generating an interrupt request or a DMA request. 0 Interrupt request. 1 DMA request.
16 Reserved	Always write the reset value to this field. This field is reserved.
17 Reserved	Always write the reset value to this field. This field is reserved.
18–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

57.4.7 PUSH TX FIFO Register In Master Mode (SPI_PUSHR)

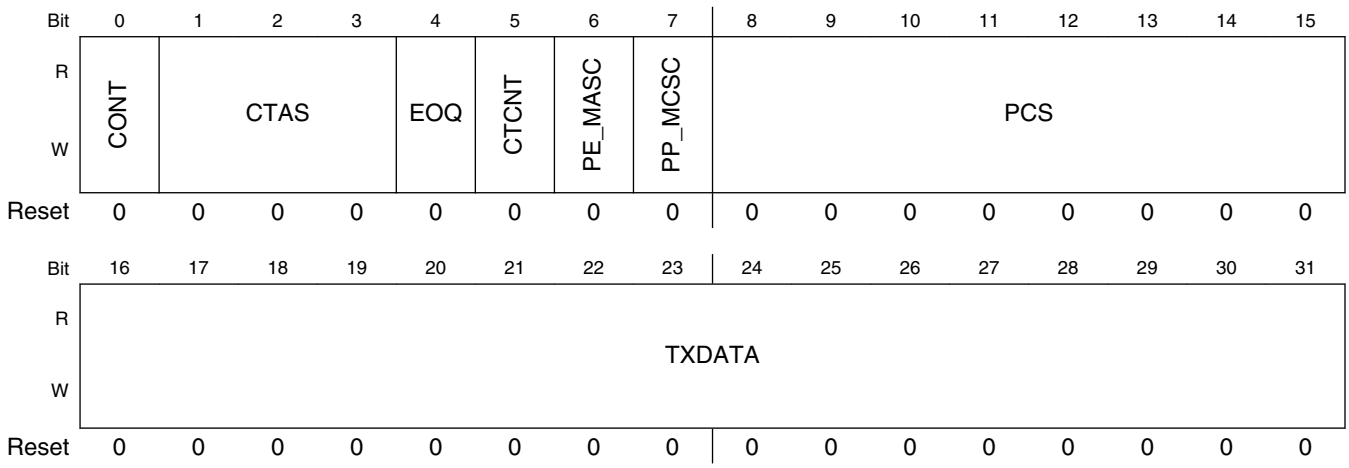
Specifies data to be transferred to the TX FIFO and CMD FIFO. User must write 16-bits data into TXDATA field. An 8- or 16-bit write access to the TXDATA field transfers 16 bits of data bus to the TX FIFO. A write access to the command fields transfers the 16 bits of command information to the CMD FIFO. In Master mode, the register transfers 16 bits of data to the TX FIFO and 16 bits of command information to the CMD FIFO.

The TX FIFO and CMD FIFO must be filled simultaneously. In other words, you must perform write accesses to both the data and command fields for every PUSHR operation. Because both the TX FIFO and CMD FIFO are written to and read from simultaneously, they behave as a single 32 bit FIFO.

A read access of PUSHR returns the topmost TX FIFO and CMD FIFO entries concatenated.

When the module is disabled, writing to this register does not update the FIFO. Therefore, any reads performed while the module is disabled return the last PUSHR write performed while the module was still enabled.

Address: 0h base + 34h offset = 34h



SPI_PUSHR field descriptions

Field	Description
0 CONT	Continuous Peripheral Chip Select Enable Selects a continuous selection format. The bit is used in SPI Master mode. The bit enables the selected PCS signals to remain asserted between transfers. 0 Return PCSn signals to their inactive state between transfers. 1 Keep PCSn signals asserted between transfers.
1–3 CTAS	Clock and Transfer Attributes Select Selects which CTAR to use in master mode to specify the transfer attributes for the associated SPI frame. In SPI Slave mode, CTAR0 is used. See the chip specific section for details to determine how many CTARs this device has. You should not program a value in this field for a register that is not present. 000 CTAR0 001 CTAR1 010 CTAR2 011 CTAR3 100 CTAR4 101 CTAR5 110 CTAR6 111 CTAR7
4 EOQ	End Of Queue Host software uses this bit to signal to the module that the current SPI transfer is the last in a queue. At the end of the transfer, the EOQF bit in the SR is set. 0 The SPI data is not the last data to transfer. 1 The SPI data is the last data to transfer.
5 CTCNT	Clear Transfer Counter Clears the TCNT field in the TCR register. The TCNT field is cleared before the module starts transmitting the current SPI frame. 0 Do not clear the TCR[TCNT] field. 1 Clear the TCR[TCNT] field.

Table continues on the next page...

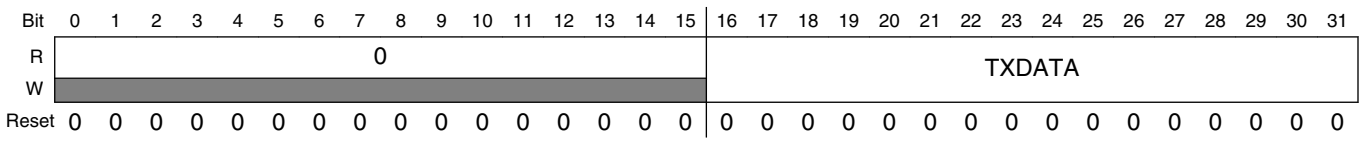
SPI_PUSHR field descriptions (continued)

Field	Description
6 PE_MASC	Parity Enable or Mask T_{ASC} delay in the current frame PE – This bit enables parity bit transmission and parity reception check for the SPI frame. MASC - The current frame has the “after SCK” delay masked if this bit is asserted. See Fast Continuous Selection Format for more details. **NOTE:** This bit is used as Mask T_{ASC} in the Fast Continuous PCS mode when MCR[FCPCS] is set. 0 PE - No parity bit included/checked. MASC - T_{ASC} delay is not masked and the current frame has the after SCK delay. 1 PE - Parity bit is transmitted instead of the last data bit in the frame; parity is checked for the received frame. MASC - T_{ASC} delay is masked in the current frame.
7 PP_MCSC	Parity Polarity or Mask T_{CSC} delay in the next frame PP - It controls the polarity of the parity bit transmitted and checked. MCSC - The next frame has the “PCS to SCK” delay masked if this bit is asserted. See Fast Continuous Selection Format for more details. **NOTE:** This bit is used as Mask T_{CSC} in the Fast Continuous PCS mode when MCR[FCPCS] is set. 0 PP - Even Parity: the number of 1 bits in the transmitted frame is even. The SR[SPEF] bit is set if the number of 1 bits is odd in the received frame. MCSC - T_{CSC} delay is not masked and the next frame has the PCS to SCK delay. 1 PP - Odd Parity: the number of 1 bits in the transmitted frame is odd. The SR[SPEF] bit is set if the number of 1 bits is even in the received frame. MCSC - T_{CSC} delay is masked in the next frame.
8–15 PCS	PCS Select which PCS signals are to be asserted for the transfer. Refer to the chip-specific SPI information for the number of PCS signals used in this chip. 0 Negate the PCS[x] signal. 1 Assert the PCS[x] signal.
16–31 TXDATA	Transmit Data Holds SPI data to be transferred according to the associated SPI command.

57.4.8 PUSH TX FIFO Register In Slave Mode (SPI_PUSHR_SLAVE)

Specifies data to be transferred to the TX FIFO in slave mode. An 8- or 16-bit write access to PUSHR transfers the 16-bit TXDATA field to the TX FIFO.

Address: 0h base + 34h offset = 34h



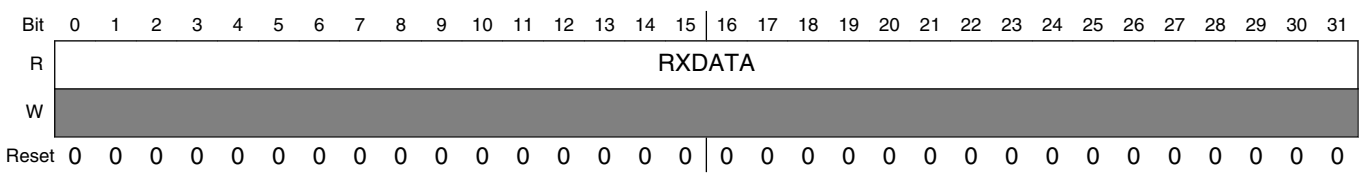
SPI_PUSHR_SLAVE field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 TXDATA	Transmit Data Holds SPI data to be transferred according to the associated SPI command.

57.4.9 POP RX FIFO Register (SPI_POPR)

POPR is used to read the RX FIFO. Eight- or sixteen-bit read accesses to the POPR have the same effect on the RX FIFO as 32-bit read accesses. A write to this register will generate a Transfer Error.

Address: 0h base + 38h offset = 38h



SPI_POPR field descriptions

Field	Description
0–31 RXDATA	Received Data Contains the SPI data from the RX FIFO entry to which the Pop Next Data Pointer points.

57.4.10 Transmit FIFO Registers (SPI_TXFR*n*)

TXFRn registers provide visibility into the TX FIFO for debugging purposes. Each register is an entry in the TX FIFO. The registers are read-only and cannot be modified. Reading the TXFRx registers does not alter the state of the TX FIFO.

Address: 0h base + 3Ch offset + (4d × i), where i=0d to 4d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SPI_TXFR*n* field descriptions

Field	Description
0–15 TXCMD_ TXDATA	Transmit Command or Transmit Data In Master mode the TXCMD field contains the command that sets the transfer attributes for the SPI data. In Slave mode, this field is reserved.
16–31 TXDATA	Transmit Data Contains the SPI data to be shifted out.

57.4.11 Receive FIFO Registers (SPI_RXFR*n*)

RXFRn provide visibility into the RX FIFO for debugging purposes. Each register is an entry in the RX FIFO. The RXFR registers are read-only. Reading the RXFRx registers does not alter the state of the RX FIFO. The field MCR[MDIS] must be 0 when RXFR is read.

Address: 0h base + 7Ch offset + (4d × i), where i=0d to 4d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Field	Description
0–31 RXDATA	Receive Data

SPI_RXFR*n* field descriptions (continued)

Field	Description
	Contains the received SPI data.

57.5 Functional description

The module supports full-duplex, synchronous serial communications between chips and peripheral devices. The SPI configuration transfers data serially using a shift register and a selection of programmable transfer attributes.

The module has the following configuration

- The SPI Configuration in which the module operates as a basic SPI or a queued SPI.

The DCONF field in the Module Configuration Register (MCR) determines the module Configuration. SPI configuration is selected when DCONF within SPIx_MCR is 0b00.

The CTARn registers hold clock and transfer attributes. The SPI configuration allows to select which CTAR to use on a frame by frame basis by setting a field in the SPI command.

See Clock and Transfer Attributes Register (In Master Mode) (SPI_CTAR*n*) for information on the fields of CTAR registers.

Typical master to slave connections are shown in the following figure. When a data transfer operation is performed, data is serially shifted a predetermined number of bit positions. Because the modules are linked, data is exchanged between the master and the slave. The data that was in the master shift register is now in the shift register of the slave, and vice versa. At the end of a transfer, the Transfer Control Flag(TCF) bit in the Shift Register(SR) is set to indicate a completed frame transfer.

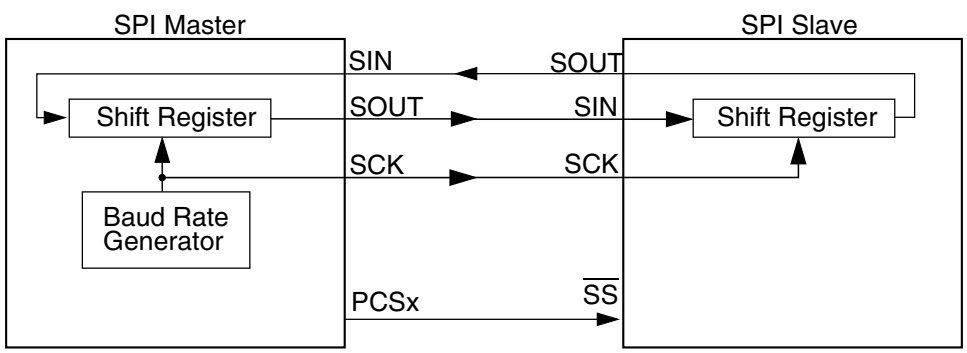

Figure 57-3. Serial protocol overview

Generally, more than one slave device can be connected to the module master. 8 Peripheral Chip Select (PCS) signals of the module masters can be used to select which of the slaves to communicate with. Refer to the chip specific section for details on the number of PCS signals used in this chip.

The SPI configuration shares transfer protocol and timing properties which are described independently of the configuration in Transfer formats. The transfer rate and delay settings are described in Module baud rate and clock delay generation.

57.5.1 Start and Stop of module transfers

The module has two operating states: Stopped and Running. Both the states are independent of it's configuration. The default state of the module is Stopped. In the Stopped state, no serial transfers are initiated in Master mode and no transfers are responded to in Slave mode. The Stopped state is also a safe state for writing the various configuration registers of the module without causing undetermined results. In the Running state serial transfers take place.

The TXRXS bit in the SR indicates the state of module. The bit is set if the module is in Running state.

The module starts or transitions to Running when all of the following conditions are true:

- SR[EOQF] bit is clear
- Chip is not in the Debug mode or the MCR[FRZ] bit is clear
- MCR[HALT] bit is clear

The module stops or transitions from Running to Stopped after the current frame when any one of the following conditions exist:

- SR[EOQF] bit is set
- Chip in the Debug mode and the MCR[FRZ] bit is set
- MCR[HALT] bit is set

State transitions from Running to Stopped occur on the next frame boundary if a transfer is in progress, or immediately if no transfers are in progress.

57.5.2 Serial Peripheral Interface (SPI) configuration

The SPI configuration transfers data serially using a shift register and a selection of programmable transfer attributes. The module is in SPI configuration when the DCONF field in the MCR is 0b00. The SPI frames can be 32 bits long. The host CPU or a DMA controller transfers the SPI data from the external to the module RAM queues to a TX FIFO buffer. The received data is stored in entries in the RX FIFO buffer. The host CPU or the DMA controller transfers the received data from the RX FIFO to memory external to the module. The operation of FIFO buffers is described in the following sections:

- Transmit First In First Out (TX FIFO) buffering mechanism
- Command First In First Out (CMD FIFO) Buffering Mechanism
- Receive First In First Out (RX FIFO) buffering mechanism

The interrupt and DMA request conditions are described in Interrupts/DMA requests.

The SPI configuration supports two block-specific modes—Master mode and Slave mode. In Master mode the module initiates and controls the transfer according to the fields of the executing SPI Command. In Slave mode, the module responds only to transfers initiated by a bus master external to it and the SPI command field space is reserved.

57.5.2.1 Master mode

In SPI Master mode, the module initiates the serial transfers by controlling the SCK and the PCS signals. The executing SPI Command determines which CTARs will be used to set the transfer attributes and which PCS signals to assert. The command field also contains various bits that help with queue management and transfer protocol. See PUSH TX FIFO Register In Master Mode (SPI_PUSHR) for details on the SPI command fields. The data in the executing TX FIFO entry is loaded into the shift register and shifted out on the Serial Out (SOUT) pin. In SPI Master mode, each SPI frame to be transmitted has a command associated with it, allowing for transfer attribute control on a frame by frame basis.

57.5.2.2 Slave mode

In SPI Slave mode the module responds to transfers initiated by an SPI bus master. It does not initiate transfers. Certain transfer attributes such as clock polarity, clock phase, and frame size must be set for successful communication with an SPI master. The SPI Slave mode transfer attributes are set in the CTAR0. The data is shifted out with MSB first. Shifting out of LSB is not supported in this mode.

57.5.2.3 FIFO disable operation

The FIFO disable mechanisms allow SPI transfers without using the TX FIFO, CMD FIFO or RX FIFO. The module operates as a double-buffered simplified SPI when the FIFOs are disabled. The Transmit and Receive side of the FIFOs are disabled separately. Setting the MCR[DIS_TXF] bit disables the TX FIFO and CMD FIFO, and setting the MCR[DIS_RXF] bit disables the RX FIFO.

The FIFO disable mechanisms are transparent to the user and to host software. Transmit data and commands are written to the PUSHR and received data is read from the POPR.

When the TX FIFO and CMD FIFO are disabled:
- SR[TFFF], SR[TFUF] and SR[TXCTR] behave as if there is a one-entry FIFO
- The contents of TXFRs, SR[TXNXTPTR] are undefined

Similarly, when the RX FIFO is disabled, the RFDF, RFOF, and RXCTR fields in the SR behave as if there is a one-entry FIFO, but the contents of the RXFR registers and POPNXTPTR are undefined.

57.5.2.4 Transmit First In First Out (TX FIFO) buffering mechanism

The TX FIFO functions as a buffer of SPI data for transmission. The TX FIFO holds 5 words, each consisting of SPI data. The number of entries in the TX FIFO is device-specific. SPI data is added to the TX FIFO by writing to the Data Field of module PUSH FIFO Register (PUSHR). TX FIFO entries can only be removed from the TX FIFO by being shifted out or by flushing the TX FIFO.

The TX FIFO Counter field (TXCTR) in the module Status Register (SR) indicates the number of valid entries in the TX FIFO. The TXCTR is updated every time a 8- or 16-bit write takes place to PUSHR[TXDATA] or SPI data is transferred into the shift register from the TX FIFO.

The TXNXTPTR field indicates the TX FIFO Entry that will be transmitted during the next transfer. The TXNXTPTR field is incremented every time SPI data is transferred from the TX FIFO to the shift register. The maximum value of the field is equal to the maximum implemented TXFR number and it rolls over after reaching the maximum.

57.5.2.4.1 Filling the TX FIFO

Host software or other intelligent blocks can add (push) entries to the TX FIFO and CMD FIFO by writing to the PUSHR. When the TX FIFO is not full, the TX FIFO Fill Flag (TFFF) in the SR is set. The TFFF bit is cleared when TX FIFO is full and the DMA

controller indicates that a write to PUSHR is complete. Writing a '1' to the TFFF bit also clears it. The TFFF can generate a DMA request or an interrupt request. See Transmit FIFO Fill Interrupt or DMA Request for details.

The module ignores attempts to push data to a full TX FIFO, and the state of the TX FIFO does not change and no error condition is indicated.

57.5.2.4.2 Draining the TX FIFO

The TX FIFO entries are removed (drained) by shifting SPI data out through the shift register. Entries are transferred from the TX FIFO to the shift register and shifted out as long as there are valid entries in the TX FIFO. Every time an entry is transferred from the TX FIFO to the shift register, the TX FIFO Counter decrements by one. At the end of a transfer, the TCF bit in the SR is set to indicate the completion of a transfer. The TX FIFO is flushed by writing a '1' to the CLR_TXF bit in MCR.

If an external bus master initiates a transfer with a module slave while the slave's TX FIFO is empty, the Transmit FIFO Underflow Flag (TFUF) in the slave's SR is set. See Transmit FIFO Underflow Interrupt Request for details.

57.5.2.5 Command First In First Out (CMD FIFO) Buffering Mechanism

The CMD FIFO functions as a buffer of SPI command used for SPI data transmission. The TX FIFO and CMD FIFO must be filled together, i.e. write enables should be given for both the Data and Command fields while performing a PUSHR operation.

The CMD FIFO holds 5 words, each representing SPI command fields. The number of entries in the CMD FIFO is device-specific. SPI Command is added to the CMD FIFO by writing to the command field of DSPI PUSH FIFO Register (PUSHR). CMD FIFO entries can only be removed from the CMD FIFO by being shifted out (to help transmit SPI data) or by flushing the CMD FIFO.

Every CMD FIFO entry has a corresponding single TX FIFO entry attached to it because both these FIFO's are filled simultaneously.

57.5.2.6 Receive First In First Out (RX FIFO) buffering mechanism

The RX FIFO functions as a buffer for data received on the SIN pin. The RX FIFO holds 5 received SPI data frames. The number of entries in the RX FIFO is device-specific. SPI data is added to the RX FIFO at the completion of a transfer when the received data in the shift register is transferred into the RX FIFO. SPI data are removed (popped) from the RX FIFO by reading the module POP RX FIFO Register (POPR). RX FIFO entries can only be removed from the RX FIFO by reading the POPR or by flushing the RX FIFO.

The RX FIFO Counter field (RXCTR) in the module's Status Register (SR) indicates the number of valid entries in the RX FIFO. The RXCTR is updated every time the POPR is read or SPI data is copied from the shift register to the RX FIFO.

The POPNXTPTR field in the SR points to the RX FIFO entry that is returned when the POPR is read. The POPNXTPTR contains the positive offset from RXFR0 in a number of 32-bit registers. For example, POPNXTPTR equal to two means that the RXFR2 contains the received SPI data that will be returned when the POPR is read. The POPNXTPTR field is incremented every time the POPR is read. The maximum value of the field is equal to the maximum implemented RXFR number and it rolls over after reaching the maximum.

57.5.2.6.1 Filling the RX FIFO

The RX FIFO is filled with the received SPI data from the shift register. While the RX FIFO is not full, SPI frames from the shift register are transferred to the RX FIFO. Every time an SPI frame is transferred to the RX FIFO, the RX FIFO Counter is incremented by one.

If the RX FIFO and shift register are full and a transfer is initiated, the RFOF bit in the SR is set indicating an overflow condition. Depending on the state of the ROOE bit in the MCR, the data from the transfer that generated the overflow is either ignored or shifted in to the shift register. If the ROOE bit is set, the incoming data is shifted in to the shift register. If the ROOE bit is cleared, the incoming data is ignored.

57.5.2.6.2 Draining the RX FIFO

Host CPU or a DMA can remove (pop) entries from the RX FIFO by reading the module POP RX FIFO Register (POPR). A read of the POPR decrements the RX FIFO Counter by one. Attempts to pop data from an empty RX FIFO are ignored and the RX FIFO Counter remains unchanged. The data, read from the empty RX FIFO, is undetermined.

When the RX FIFO is not empty, the RX FIFO Drain Flag (RFDF) in the SR is set. The RFDF bit is cleared when the RX_FIFO is empty and the DMA controller indicates that a read from POPR is complete or by writing a 1 to it.

57.5.3 Module baud rate and clock delay generation

The SCK frequency and the delay values for serial transfer are generated by dividing the protocol clock frequency by a prescaler and a scaler with the option for doubling the baud rate. The following figure shows conceptually how the SCK signal is generated.

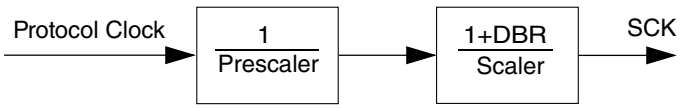

Figure 57-4. Communications clock prescalers and scalers

57.5.3.1 Baud rate generator

The baud rate is the frequency of the SCK. The protocol clock is divided by a prescaler (PBR) and scaler (BR) to produce SCK with the possibility of halving the scaler division. The DBR, PBR, and BR fields in the CTARs select the frequency of SCK by the formula in the BR field description. The following table shows an example of how to compute the baud rate.

Table 57-8. Baud rate computation example

f_P	PBR	Prescaler	BR	Scaler	DBR	Baud rate
100 MHz	0b00	2	0b0000	2	0	25 Mb/s
20 MHz	0b00	2	0b0000	2	1	10 Mb/s

NOTE

The clock frequencies mentioned in the preceding table are given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

57.5.3.2 PCS to SCK Delay (t_{CSC})

The PCS to SCK delay is the length of time from assertion of the PCS signal to the first SCK edge. See Figure 57-6 for an illustration of the PCS to SCK delay. The PCSSCK and CSSCK fields in the CTAR*x* registers select the PCS to SCK delay by the formula in the CSSCK field description. The following table shows an example of how to compute the PCS to SCK delay.

Table 57-9. PCS to SCK delay computation example

f_{SYS}	PCSSCK	Prescaler	CSSCK	Scaler	PCS to SCK Delay
100 MHz	0b01	3	0b0100	32	0.96 µs

NOTE

The clock frequency mentioned in the preceding table is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

57.5.3.3 After SCK Delay (t_{ASC})

The After SCK Delay is the length of time between the last edge of SCK and the negation of PCS. See Figure 57-6 and Figure 57-7 for illustrations of the After SCK delay. The PASC and ASC fields in the CTAR*x* registers select the After SCK Delay by the formula in the ASC field description. The following table shows an example of how to compute the After SCK delay.

Table 57-10. After SCK Delay computation example

f_P	PASC	Prescaler	ASC	Scaler	After SCK Delay
100 MHz	0b01	3	0b0100	32	0.96 µs

NOTE

The clock frequency mentioned in the preceding table is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

57.5.3.4 Delay after Transfer (t_{DT})

The Delay after Transfer is the minimum time between negation of the PCS signal for a frame and the assertion of the PCS signal for the next frame. See Figure 57-6 for an illustration of the Delay after Transfer. The PDT and DT fields in the CTAR*x* registers select the Delay after Transfer by the formula in the DT field description. The following table shows an example of how to compute the Delay after Transfer.

Table 57-11. Delay after Transfer computation example

f_P	PDT	Prescaler	DT	Scaler	Delay after Transfer
100 MHz	0b01	3	0b1110	32768	0.98 ms

NOTE

The clock frequency mentioned in the preceding table is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

When in Non-Continuous Clock mode the t_{DT} delay is configured according to the equation specified in the CTAR[DT] field description. When in Continuous Clock mode, the delay is fixed at 1 SCK period.

57.5.3.5 Peripheral Chip Select Strobe Enable ($\overline{\text{PCSS}}$)

The $\overline{\text{PCSS}}$ signal provides a delay to allow the PCS signals to settle after a transition occurs thereby avoiding glitches. When the Module is in Master mode and the PCSSE bit is set in the MCR, $\overline{\text{PCSS}}$ provides a signal for an external demultiplexer to decode peripheral chip selects other than PCS5 into glitch-free PCS signals. The following figure shows the timing of the $\overline{\text{PCSS}}$ signal relative to PCS signals.

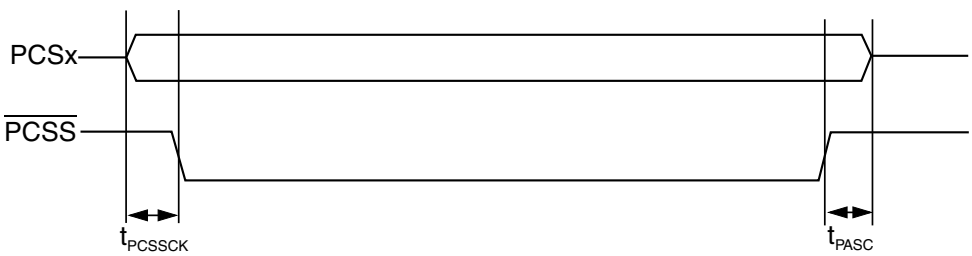

Figure 57-5. Peripheral Chip Select Strobe timing

The delay between the assertion of the PCS signals and the assertion of $\overline{\text{PCSS}}$ is selected by the PCSSCK field in the CTAR based on the following formula:

$$t_{\text{PCSSCK}} = \frac{1}{f_{\text{P}}} \times \text{PCSSCK}$$

At the end of the transfer, the delay between $\overline{\text{PCSS}}$ negation and PCS negation is selected by the PASC field in the CTAR based on the following formula:

$$t_{\text{PASC}} = \frac{1}{f_{\text{P}}} \times \text{PASC}$$

The following table shows an example of how to compute the t_{pcssck} delay.

Table 57-12. Peripheral Chip Select Strobe Assert computation example

f_P	PCSSCK	Prescaler	Delay before Transfer
100 MHz	0b11	7	70.0 ns

The following table shows an example of how to compute the t_{pasc} delay.

Table 57-13. Peripheral Chip Select Strobe Negate computation example

f_P	PASC	Prescaler	Delay after Transfer
100 MHz	0b11	7	70.0 ns

The $\overline{PCSS}$ signal is not supported when Continuous Serial Communication SCK mode is enabled.

NOTE

The clock frequency mentioned in the preceding tables is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

57.5.4 Transfer formats

The SPI serial communication is controlled by the Serial Communications Clock (SCK) signal and the PCS signals. The SCK signal provided by the master device synchronizes shifting and sampling of the data on the SIN and SOUT pins. The PCS signals serve as enable signals for the slave devices.

In Master mode, the CPOL and CPHA bits in the Clock and Transfer Attributes Registers (CTARn) select the polarity and phase of the serial clock, SCK.

- CPOL - Selects the idle state polarity of the SCK
- CPHA - Selects if the data on SOUT is valid before or on the first SCK edge

Even though the bus slave does not control the SCK signal, in Slave mode the values of CPOL and CPHA must be identical to the master device settings to ensure proper transmission. In SPI Slave mode, only CTAR0 is used.

The module supports four different transfer formats:

- Classic SPI with CPHA=0
- Classic SPI with CPHA=1
- Modified Transfer Format with CPHA = 0
- Modified Transfer Format with CPHA = 1

A modified transfer format is supported to allow for high-speed communication with peripherals that require longer setup times. The module can sample the incoming data later than halfway through the cycle to give the peripheral more setup time. The MTFE bit in the MCR selects between Classic SPI Format and Modified Transfer Format.

In the interface configurations, the module provides the option of keeping the PCS signals asserted between frames. See Continuous Selection Format for details.

57.5.4.1 Classic SPI Transfer Format (CPHA = 0)

The transfer format shown in following figure is used to communicate with peripheral SPI slave devices where the first data bit is available on the first clock edge. In this format, the master and slave sample their SIN pins on the odd-numbered SCK edges and change the data on their SOUT pins on the even-numbered SCK edges.

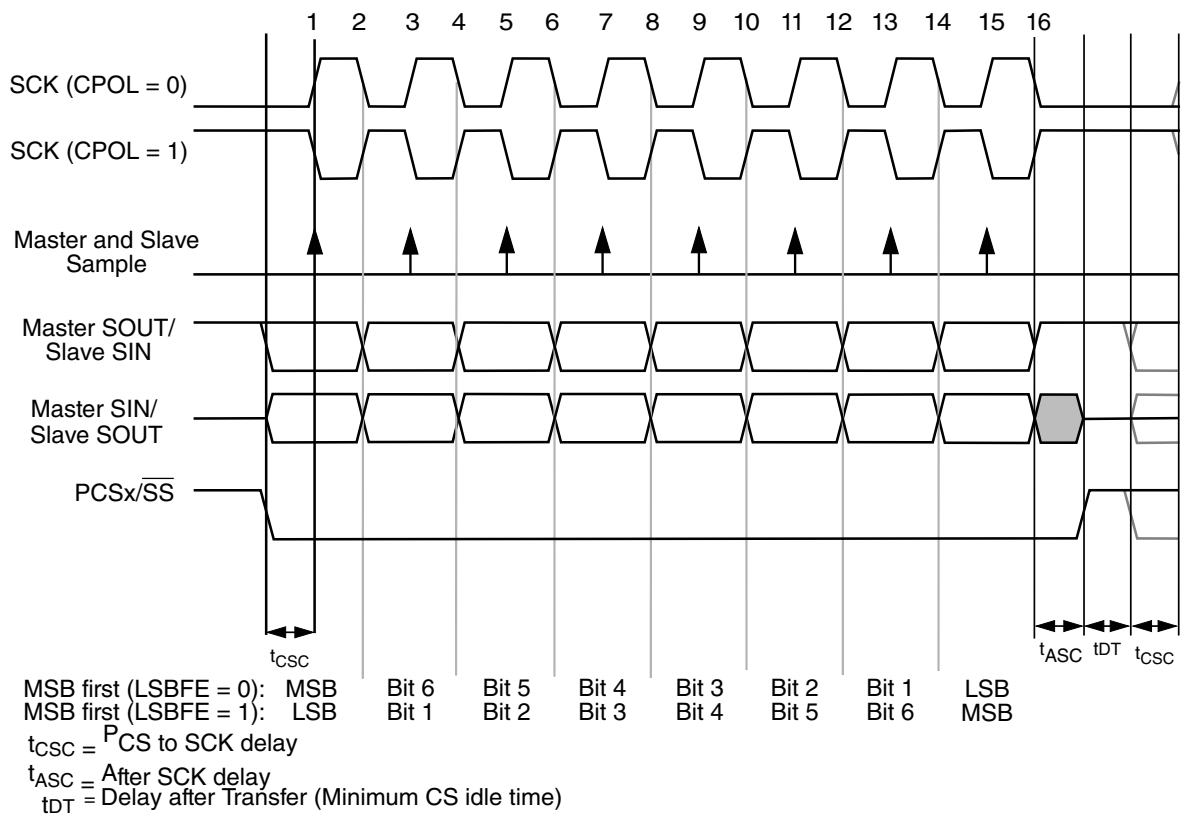

Figure 57-6. Module transfer timing diagram (MTFE=0, CPHA=0, FMSZ=8)

The master initiates the transfer by placing its first data bit on the SOUT pin and asserting the appropriate peripheral chip select signals to the slave device. The slave responds by placing its first data bit on its SOUT pin. After the t_{CSC} delay elapses, the master outputs the first edge of SCK. The master and slave devices use this edge to sample the first input data bit on their serial data input signals. At the second edge of the SCK, the master and

slave devices place their second data bit on their serial data output signals. For the rest of the frame the master and the slave sample their SIN pins on the odd-numbered clock edges and changes the data on their SOUT pins on the even-numbered clock edges. After the last clock edge occurs, a delay of t_{ASC} is inserted before the master negates the PCS signals. A delay of t_{DT} is inserted before a new frame transfer can be initiated by the master.

57.5.4.2 Classic SPI Transfer Format (CPHA = 1)

This transfer format shown in the following figure is used to communicate with peripheral SPI slave devices that require the first SCK edge before the first data bit becomes available on the slave SOUT pin. In this format, the master and slave devices change the data on their SOUT pins on the odd-numbered SCK edges and sample the data on their SIN pins on the even-numbered SCK edges.

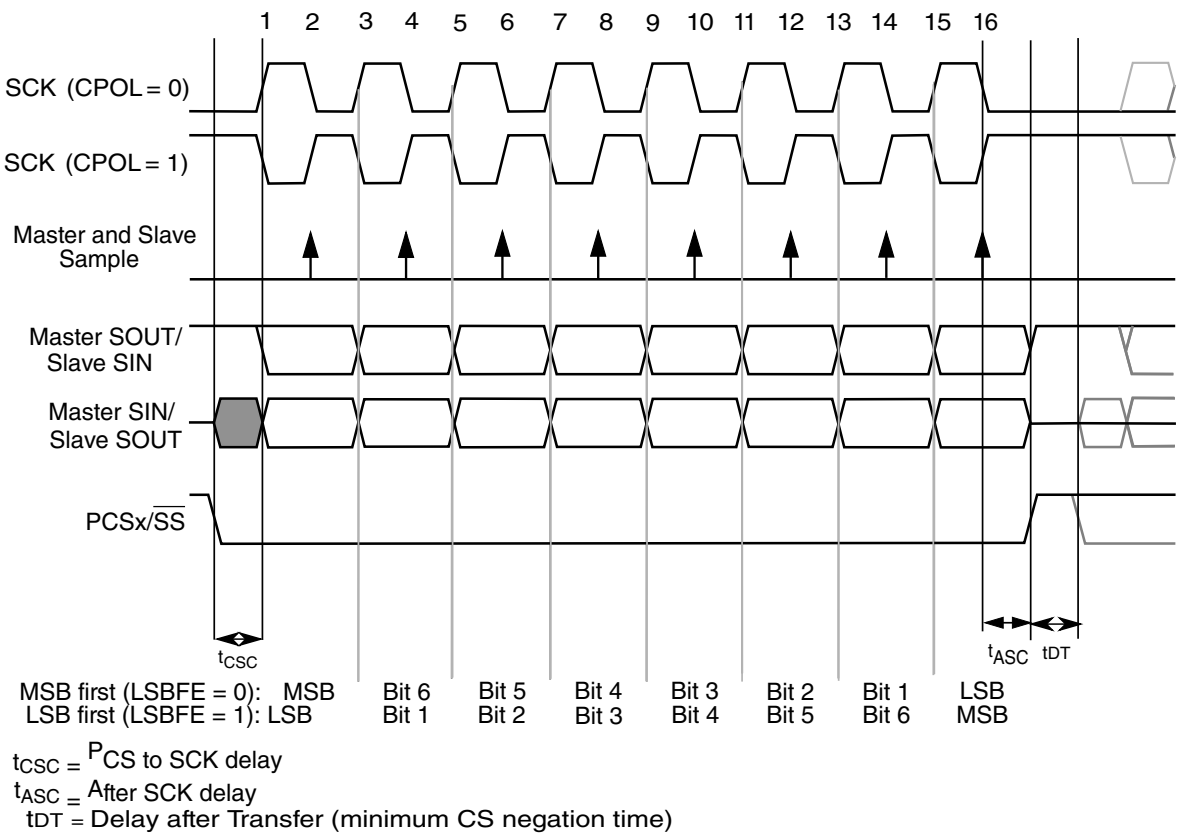

Figure 57-7. Module transfer timing diagram (MTFE=0, CPHA=1, FMSZ=8)

The master initiates the transfer by asserting the PCS signal to the slave. After the t_{CSC} delay has elapsed, the master generates the first SCK edge and at the same time places valid data on the master SOUT pin. The slave responds to the first SCK edge by placing its first data bit on its slave SOUT pin.

At the second edge of the SCK the master and slave sample their SIN pins. For the rest of the frame the master and the slave change the data on their SOUT pins on the odd-numbered clock edges and sample their SIN pins on the even-numbered clock edges. After the last clock edge occurs, a delay of t_{ASC} is inserted before the master negates the PCS signal. A delay of t_{DT} is inserted before a new frame transfer can be initiated by the master.

57.5.4.3 Modified SPI Transfer Format (MTFE = 1, CPHA = 0)

In this Modified Transfer Format both the master and the slave sample later in the SCK period than in Classic SPI mode to allow the logic to tolerate more delays in device pads and board traces. These delays become a more significant fraction of the SCK period as the SCK period decreases with increasing baud rates.

The master and the slave place data on the SOUT pins at the assertion of the PCS signal. After the PCS to SCK delay has elapsed the first SCK edge is generated. The slave samples the master SOUT signal on every odd numbered SCK edge. The DSPI in the slave mode when the MTFE bit is set also places new data on the slave SOUT on every odd numbered clock edge. Regular external slave, configured with CPHA=0 format drives its SOUT output at every even numbered SCK clock edge.

The DSPI master places its second data bit on the SOUT line one protocol clock after odd numbered SCK edge if the protocol clock frequency to SCK frequency ratio is higher than three. If this ratio is below four the master changes SOUT at odd numbered SCK edge. The point where the master samples the SIN is selected by the DSPI_MCR[SMPL_PT] field. The master sample point can be delayed by one or two protocol clock cycles. The SMPL_PT field should be set to 0 if the protocol to SCK frequency ratio is less than 4. However if this ratio is less than 4, the actual sample point is delayed by one protocol clock cycle automatically by the design.

The following timing diagrams illustrate the DSPI operation with MTFE=1. Timing delays shown are:

- T_{csc} - PCS to SCK assertion delay
- T_{acs} - After SCK PCS negation delay
- T_{su_ms} - master SIN setup time
- T_{hd_ms} - master SIN hold time
- T_{vd_sl} - slave data output valid time, time between slave data output SCK driving edge and data becomes valid.

- T_{su_sl} - data setup time on slave data input
- T_{hd_sl} - data hold time on slave data input
- T_{sys} - protocol clock period.

The following figure shows the modified transfer format for CPHA = 0 and Fsys/Fsck = 4. Only the condition where CPOL = 0 is illustrated. Solid triangles show the data sampling clock edges. The two possible slave behavior are shown.

- Signal, marked "SOUT of Ext Slave", presents regular SPI slave serial output.
- Signal, marked "SOUT of DSPI Slave", presents DSPI in the slave mode with MTFE bit set.

Other MTFE = 1 diagrams show DSPI SIN input as being driven by a regular external SPI slave, configured according DSPI master CPHA programming.

Note

In the following diagrams, f_{sys} represents the protocol clock frequency from which the Baud frequency f_{sck} is derived.

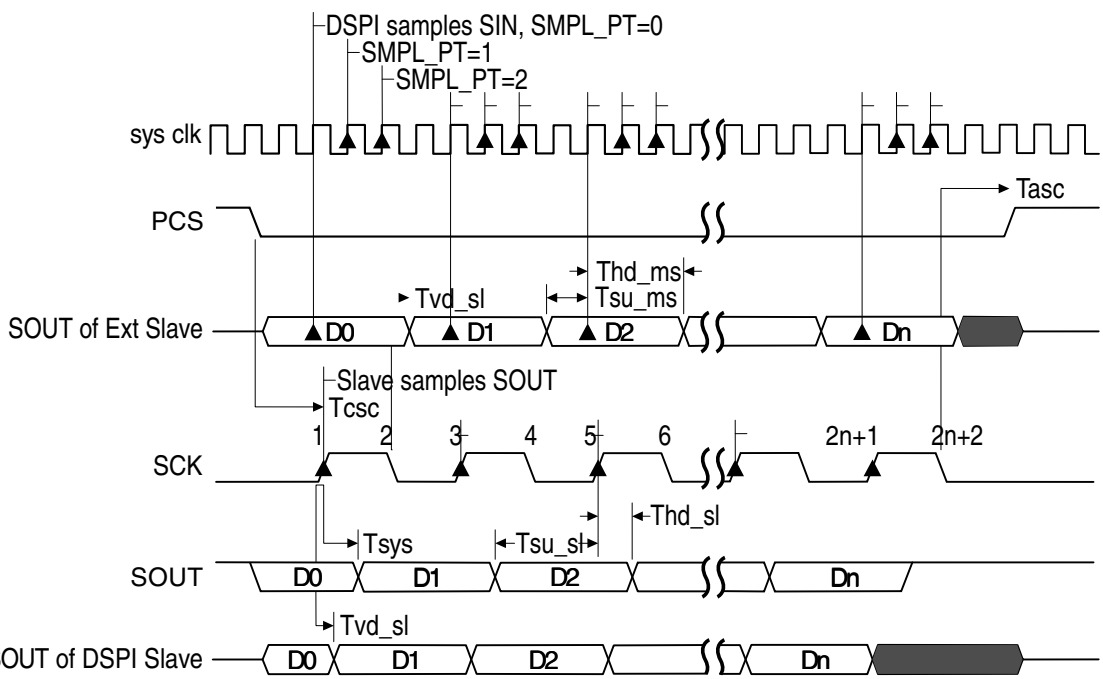

Figure 57-8. DSPI Modified Transfer Format (MTFE=1, CPHA=0, $f_{sck} = f_{sys}/4$)

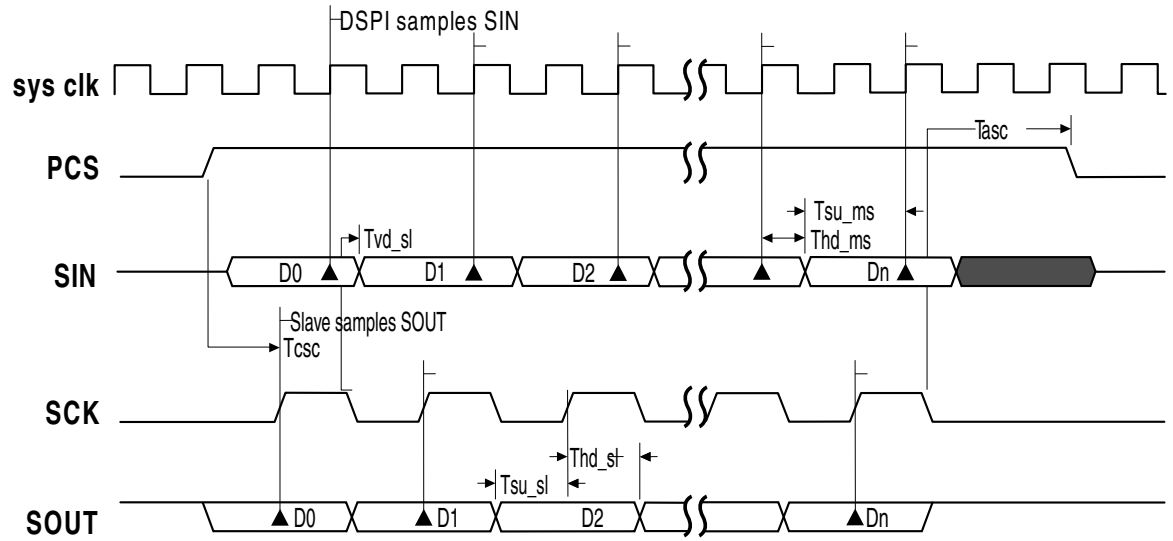

Figure 57-9. DSPI Modified Transfer Format (MTFE=1, CPHA=0, $f_{sck} = f_{sys}/2$)

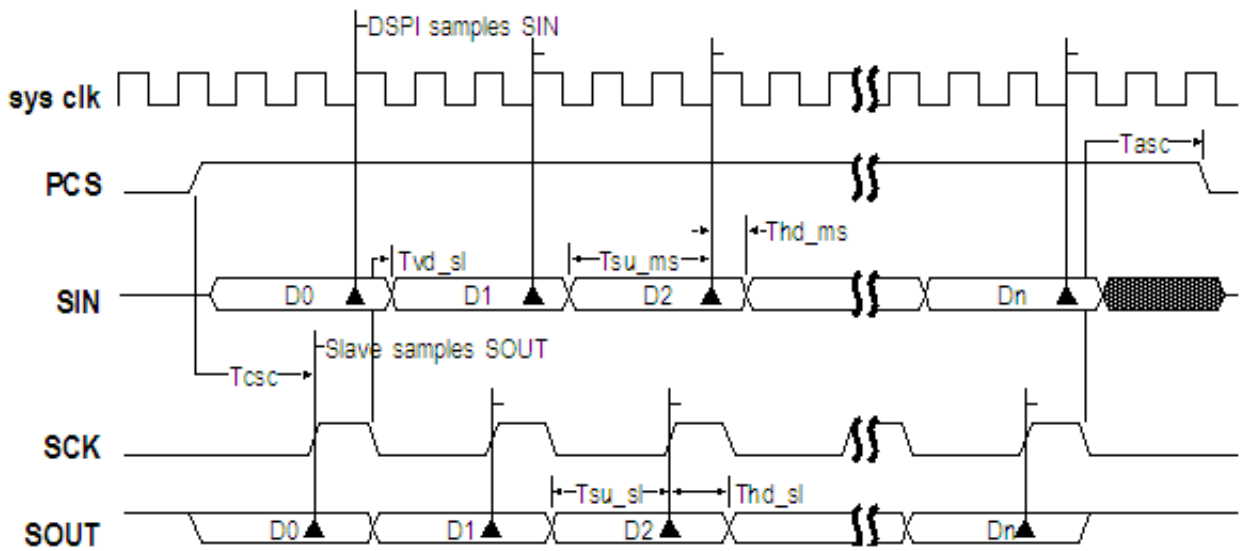

Figure 57-10. DSPI Modified Transfer Format (MTFE=1, CPHA=0, $f_{sck} = f_{sys}/3$)

57.5.4.4 Modified SPI Transfer Format (MTFE = 1, CPHA = 1)

The following figures show the Modified Transfer Format for CPHA = 1. Only the condition, where CPOL = 0 is shown. At the start of a transfer the DSPI asserts the PCS signal to the slave device. After the PCS to SCK delay has elapsed the master and the slave put data on their SOUT pins at the first edge of SCK . The slave samples the master SOUT signal on the even numbered edges of SCK. The master samples the slave SOUT

signal on the odd numbered SCK edges starting with the third SCK edge. The slave samples the last bit on the last edge of the SCK. The master samples the last slave SOUT bit one half SCK cycle after the last edge of SCK. No clock edge will be visible on the master SCK pin during the sampling of the last bit. **The SCK to PCS delay and the After SCK delay must be greater or equal to half of the SCK period.**

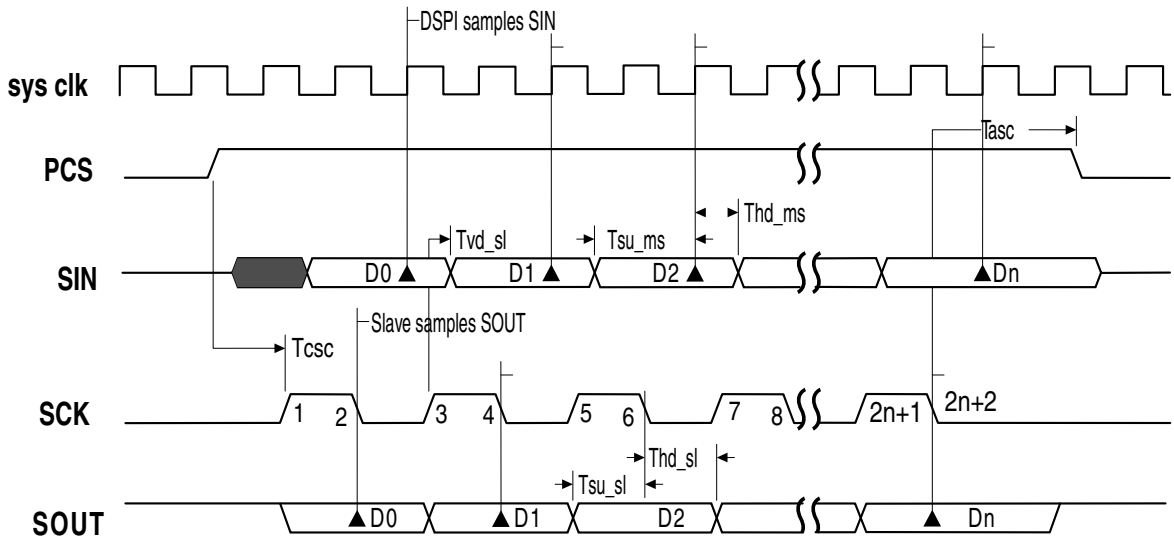

Figure 57-11. DSPI Modified Transfer Format (MTFE=1, CPHA=1, $f_{sck} = f_{sys}/2$)

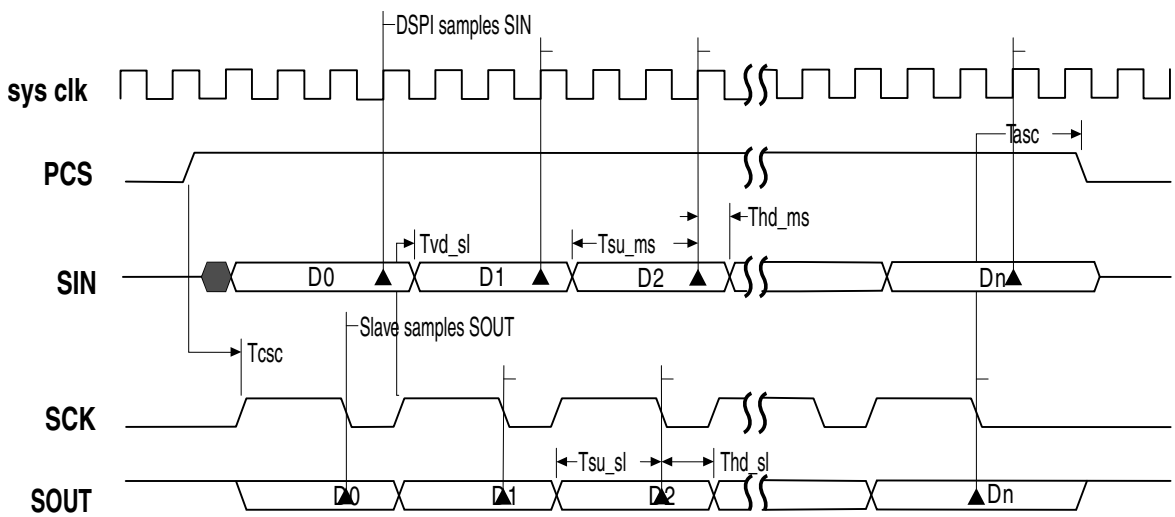

Figure 57-12. DSPI Modified Transfer Format (MTFE=1, CPHA=1, $f_{sck} = f_{sys}/3$)

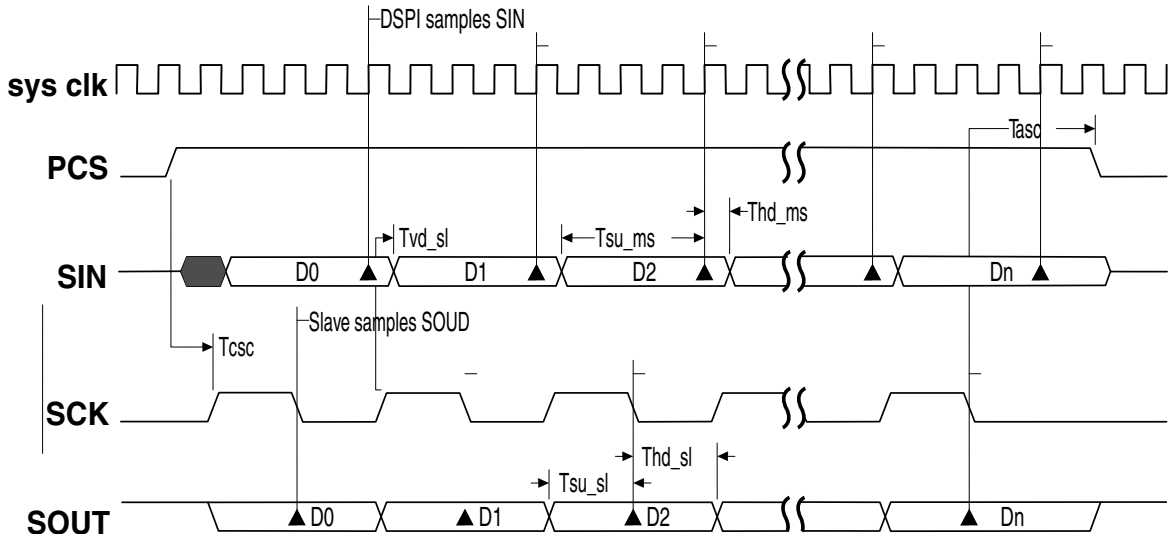

Figure 57-13. DSPI Modified Transfer Format (MTFE=1, CPHA=1, $f_{sck} = f_{sys}/4$)

57.5.4.5 Continuous Selection Format

Some peripherals must be deselected between every transfer. Other peripherals must remain selected between several sequential serial transfers. The Continuous Selection Format provides the flexibility to handle the following case. The Continuous Selection Format is enabled for the SPI configuration by setting the CONT bit in the SPI command.

When the CONT bit = 0, the module drives the asserted Chip Select signals to their idle states in between frames. The idle states of the Chip Select signals are selected by the PCSISn bits in the MCR. The following timing diagram is for two four-bit transfers with CPHA = 1 and CONT = 0.

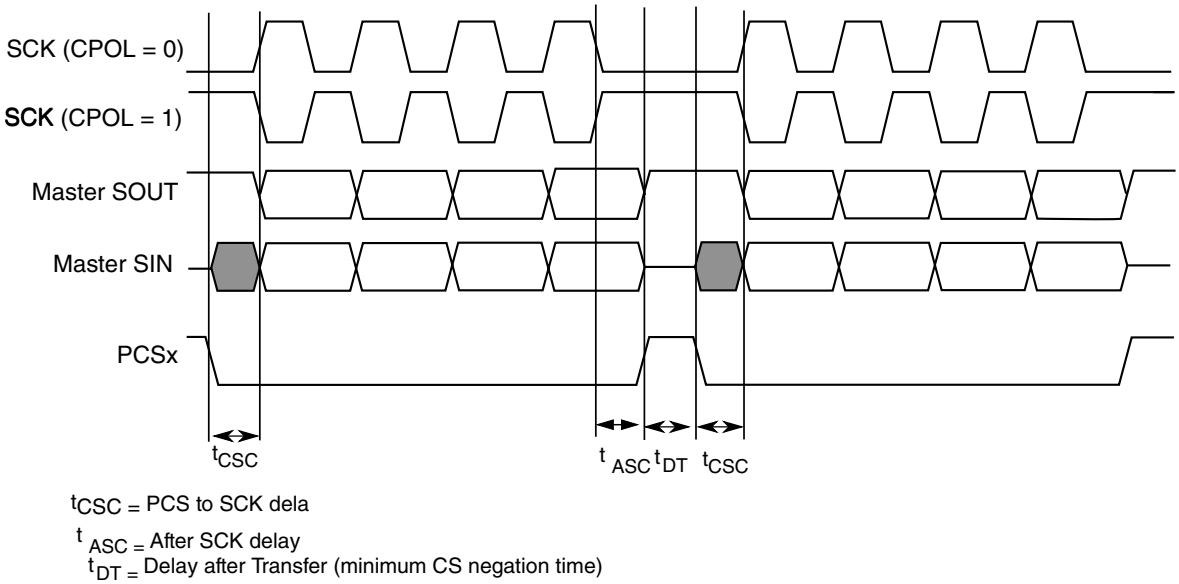

Figure 57-14. Example of non-continuous format (CPHA=1, CONT=0)

When the CONT bit = 1, the PCS signal remains asserted for the duration of the two transfers. The Delay between Transfers (t_{DT}) is not inserted between the transfers. The following figure shows the timing diagram for two four-bit transfers with CPHA = 1 and CONT = 1.

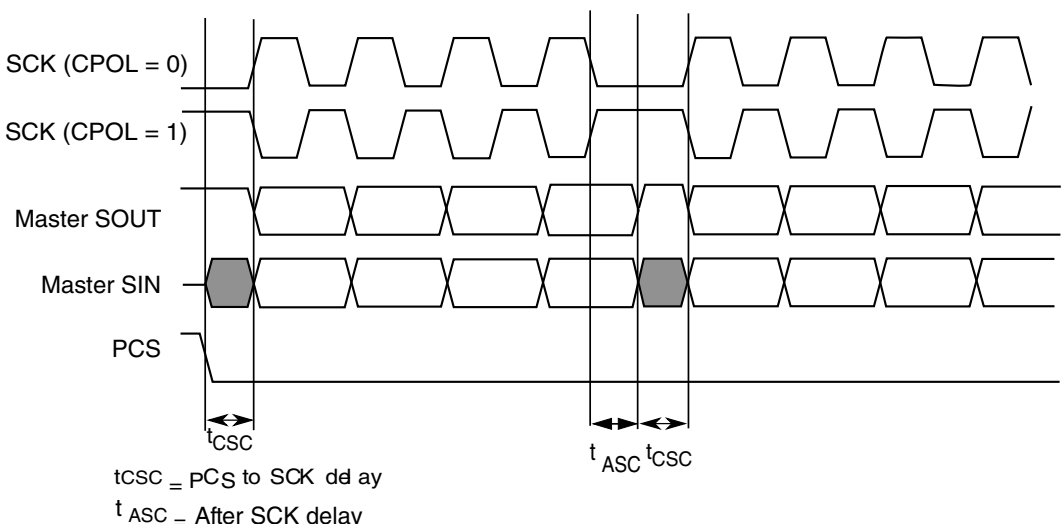

Figure 57-15. Example of continuous transfer (CPHA=1, CONT=1)

When using the module with continuous selection follow these rules:

- All transmit commands must have the same PCSn bits programming.
- The CTARs, selected by transmit commands, must be programmed with the same transfer attributes. Only FMSZ field can be programmed differently in these CTARs.

- When transmitting multiple frames in this mode, the user software must ensure that the last frame has the PUSHR[CONT] bit deasserted in Master mode and the user software must provide sufficient frames in the TX_FIFO to be sent out in Slave mode and the master deasserts the PCSn at end of transmission of the last frame.
- PUSHR[CONT] must be deasserted before asserting MCR[HALT] in master mode. This will make sure that the PCSn signals are deasserted. Asserting MCR[HALT] during continuous transfer will cause the PCSn signals to remain asserted and hence Slave Device cannot transition from Running to Stopped state.

NOTE

User must fill the TX FIFO with the number of entries that will be concatenated together under one PCS assertion for both master and slave before the TX FIFO becomes empty.

When operating in Slave mode, ensure that when the last entry in the TX FIFO is completely transmitted, that is, the corresponding TCF flag is asserted and TXFIFO is empty, the slave is deselected for any further serial communication; otherwise, an underflow error occurs.

57.5.4.6 Fast Continuous Selection Format

The Fast Continuous Selection Format functions similar to Continuous Selection Format except that the inter command delays, t_{ASC} and t_{CSC}, can be masked out and are not inserted by the hardware.

NOTE

The Fast Continuous Selection Format is available in the SPI configuration only and when Continuous Serial Communication Clock mode is disabled. Masking of delays is not allowed if the transfer is non-continuous.

The Fast Continuous Selection Format is enabled by writing ‘1’ into FCPCS bit of the MCR register. When this bit is asserted, MASC and MCSC bits of the PUSHR register perform the function of mask bits for the transmit frame. These bits individually mask the t_{ASC} and t_{CSC} delays as programmed by the user software. A normal Continuous Selection Format has these two delays for each frame that is transmitted with the CONT bit asserted. In order to avoid these delays and to speed up the transfer process, the software can simply mask these delays while programming the command in the PUSHR register.

While masking the delays, the software must follow the following masking rules, else correct operation is not guaranteed.

- MASC bit masks the “After SCK” delay for the current frame.
- MCSC bit masks the “PCS to SCK” delay for the next frame.
- “After SCK” (t_{ASC}) delay must not be masked when the current frame is the last frame in the continuous selection format.
- The “PCS to SCK” delay for the first frame in the continuous selection format cannot be masked.
- Masking of only t_{ASC} is not allowed. If t_{ASC} is masked then t_{CSC} must be masked too.
- Masking of both t_{ASC} and t_{CSC} delays is allowed. In this case, the delay between two frames is equal to half the baud rate set by the user software.
- Masking of only t_{CSC} is allowed. In this case, the delay between two frames is equal to the t_{ASC} time and thus the user software must ensure that the t_{ASC} time is greater than the baud rate.
- The user software must not mask these delays if the continuous selection format is not used and MCR[FCPCS] is asserted.
- Rules applicable to the Continuous Selection Format are applicable here too.

The following figure shows the timing for a Fast Continuous Selection Format transfer. Here seven frames are transferred with both t_{ASC} and t_{CSC} delays masked except for the last frame that terminated the transfer. The last frame has t_{ASC} delay at its end.

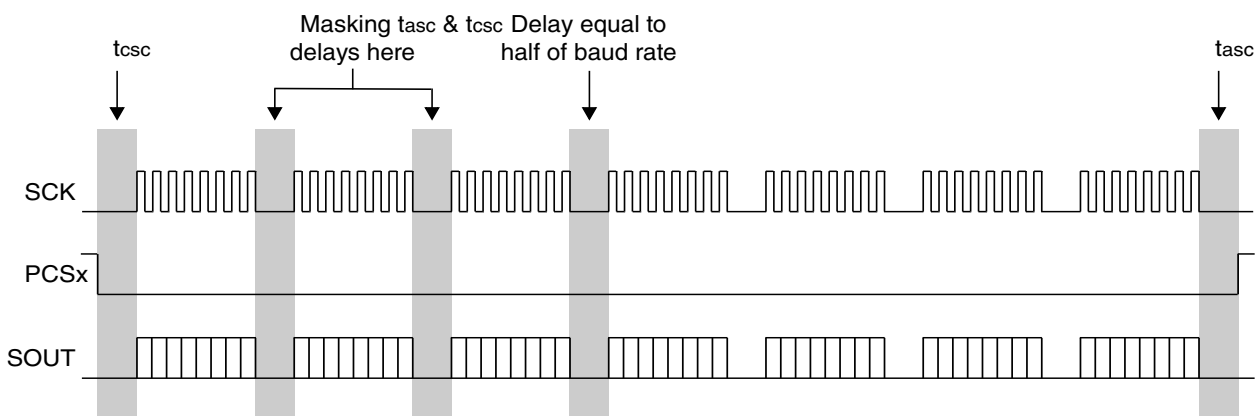

Figure 57-16. Example of Fast Continuous Selection Format

In case any chip select is to be changed, then the fast continuous selection format should be terminated and then the chips selects should change and appropriate delays must be introduced.

57.5.5 Continuous Serial Communications Clock

The module provides the option of generating a Continuous SCK signal for slave peripherals that require a continuous clock.

Continuous SCK is enabled by setting the CONT_SCKE bit in the MCR. Enabling this bit generates the Continuous SCK only if MCR[HALT] bit is low. Continuous SCK is valid in all configurations.

Continuous SCK is only supported for CPHA=1. Clearing CPHA is ignored if the CONT_SCKE bit is set. Continuous SCK is supported for Modified Transfer Format.

Clock and transfer attributes for the Continuous SCK mode are set according to the following rules:

- When the module is in SPI configuration, CTAR0 is used initially. At the start of each SPI frame transfer, the CTAR specified by the CTAS for the frame is used.
- In all configurations, the currently selected CTAR remains in use until the start of a frame with a different CTAR specified, or the Continuous SCK mode is terminated.

It is recommended to keep the baud rate the same while using the Continuous SCK. Switching clock polarity between frames while using Continuous SCK can cause errors in the transfer. Continuous SCK operation is not guaranteed if the module is put into the External Stop mode or Module Disable mode.

Enabling Continuous SCK disables the PCS to SCK delay and the Delay after Transfer (t_{DT}) is fixed to one SCK cycle. The following figure is the timing diagram for Continuous SCK format with Continuous Selection disabled.

NOTE

In Continuous SCK mode, for the SPI transfer CTAR0 should always be used, and the TX FIFO must be cleared using the MCR[CLR_TXF] field before initiating transfer.

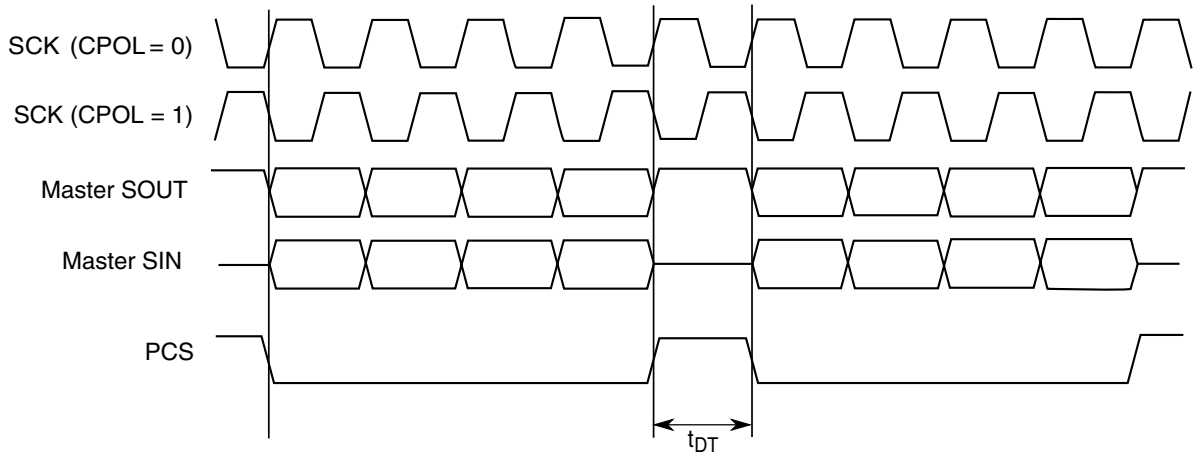

Figure 57-17. Continuous SCK Timing Diagram (CONT=0)

If the CONT bit in the TX FIFO entry is set, PCS remains asserted between the transfers. Under certain conditions, SCK can continue with PCS asserted, but with no data being shifted out of SOUT, that is, SOUT pulled high. This can cause the slave to receive incorrect data. Those conditions include:

- Continuous SCK with CONT bit set, but no data in the TX FIFO.
- Continuous SCK with CONT bit set and entering Stopped state (refer to Start and Stop of module transfers).
- Continuous SCK with CONT bit set and entering Stop mode or Module Disable mode.

The following figure shows timing diagram for Continuous SCK format with Continuous Selection enabled.

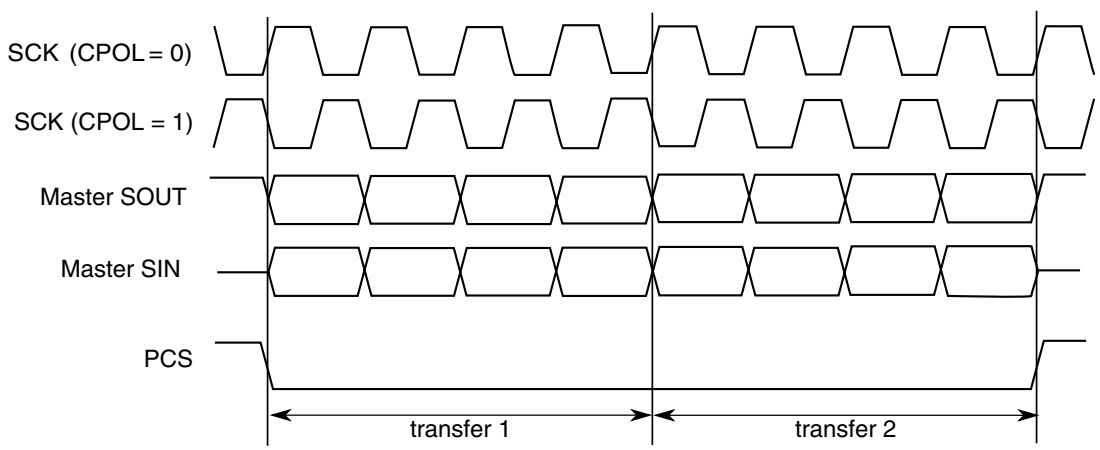

Figure 57-18. Continuous SCK timing diagram (CONT=1)

57.5.6 Slave Mode Operation Constraints

Slave mode logic shift register is buffered. This allows data streaming operation, when the module is permanently selected and data is shifted in with a constant rate.

The transmit data is transferred at second SCK clock edge of the each frame to the shift register if the $\overline{SS}$ signal is asserted and any time when transmit data is ready and $\overline{SS}$ signal is negated.

Received data is transferred to the receive buffer at last SCK edge of each frame, defined by frame size programmed to the CTAR0/1 register. Then the data from the buffer is transferred to the RXFIFO or DDR register.

If the $\overline{SS}$ negates before that last SCK edge, the data from shift register is lost.

57.5.7 Parity Generation and Check

The module can generate and check parity in the serial frame. The parity bit replaces the last transmitted bit in the frame. The parity is calculated for all transmitted data bits in frame, not including the last data bit that would be transmitted. The parity generation/ control is done on frame basis. The registers field setting frame size defines the total number of bits in the frame, including the parity bit. Thus, to transmit/receive the same number of data bits with parity check, increase the frame size by one versus the same data size frame without the parity check.

Parity can be selected as odd or even. Parity Errors in the received frame set Parity Error flags in the Status register. The Parity Error Interrupt Requests are generated if enabled. The module can be programmed to stop frame transmission in case of a frame reception with parity error.

57.5.7.1 Parity for SPI Frames

When the module is in the master mode the parity generation is controlled by PE and PP bits of the CMD FIFO entries (PUSHR). Setting the PE bit enables parity generation for transmitted SPI frames and parity check for received frames. PP bit defines polarity of the parity bit.

When continuous PCS selection is used to transmit SPI data, two parity generation scenarios are available:

- Generate/check parity for the whole frame
- Generate/check parity for each sub-frame separately.

To generate/check parity for the whole frame set PE bit only in the last command/TX FIFO entry, forming this frame (with the PUSHR register).

To generate/check parity for each sub-frame set PE bit in each command/TX FIFO entry, forming this frame.

If the parity error occurs for received SPI frame, the SR[SPEF] bit is set. If MCR[PES] bit is set, the module stops SPI frames transmission. To resume SPI operation clear the SR[SPEF] or the MCR[PES] bits.

In slave mode the parity is controlled by the PE and PP bits of the CTAR0 register similar to the master mode parity generation without continuous PCS selection.

57.5.8 Interrupts/DMA requests

The module has several conditions that can generate only interrupt requests and two conditions that can generate interrupt or DMA requests. The following table lists these conditions.

Table 57-14. Interrupt and DMA request conditions

Condition	Flag	Interrupt	DMA
End of Queue (EOQ)	EOQF	Yes	-
TX FIFO Fill	TFFF	Yes	Yes
Transfer Complete	TCF	Yes	-
TX FIFO Underflow	TFUF	Yes	-
RX FIFO Drain	RFDF	Yes	Yes
RX FIFO Overflow	RFOF	Yes	-
SPI Parity Error	SPEF	Yes	-

Each condition has a flag bit in the module Status Register (SR) and a Request Enable bit in the DMA/Interrupt Request Select and Enable Register (RSER). Certain flags (as shown in above table) generate interrupt requests or DMA requests depending on configuration of RSER register.

The module also provides a global interrupt request line, which is asserted when any of individual interrupt requests lines is asserted.

57.5.8.1 End Of Queue interrupt request

The End Of Queue (EOQ) interrupt request indicates that the end of a transmit queue is reached. The module generates the interrupt request when EOQ interrupt requests are enabled (RSER[EOQF_RE]) and the EOQ bit in the executing SPI command is 1.

The module generates the interrupt request when the last bit of the SPI frame with EOQ bit set is transmitted.

57.5.8.2 Transmit FIFO Fill Interrupt or DMA Request

The Transmit FIFO Fill Request indicates that the TX FIFO is not full. The Transmit FIFO Fill Request is generated when the number of entries in the TX FIFO is less than the maximum number of possible entries, and the TFFF_RE bit in the RSER is set. The TFFF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

NOTE

TFFF flag clears automatically when DMA is used to fill TX FIFO. Configure the DMA to fill only one FIFO location per transfer.

To clear TFFF when not using DMA, follow these steps for every PUSH performed using CPU to fill TX FIFO:

1. Wait until TFFF = 1.
2. Write data to PUSHR using CPU.
3. Clear TFFF by writing a 1 to its location. If TX FIFO is not full, this flag will not clear.

57.5.8.3 Transfer Complete Interrupt Request

The Transfer Complete Request indicates the end of the transfer of a serial frame. The Transfer Complete Request is generated at the end of each frame transfer when the TCF_RE bit is set in the RSER.

57.5.8.4 Transmit FIFO Underflow Interrupt Request

The Transmit FIFO Underflow Request indicates that an underflow condition in the TX FIFO has occurred. The transmit underflow condition is detected only for the module operating in Slave mode and SPI configuration. The TFUF bit is set when the TX FIFO

of the module is empty, and a transfer is initiated from an external SPI master. If the TFUF bit is set while the TFUF_RE bit in the RSER is set, an interrupt request is generated.

57.5.8.5 Receive FIFO Drain Interrupt or DMA Request

The Receive FIFO Drain Request indicates that the RX FIFO is not empty. The Receive FIFO Drain Request is generated when the number of entries in the RX FIFO is not zero, and the RFDF_RE bit in the RSER is set. The RFDF_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated. Configure the DMA to drain only one FIFO location per transfer.

57.5.8.6 Receive FIFO Overflow Interrupt Request

The Receive FIFO Overflow Request indicates that an overflow condition in the RX FIFO has occurred. A Receive FIFO Overflow request is generated when RX FIFO and shift register are full and a transfer is initiated. The RFOF_RE bit in the RSER must be set for the interrupt request to be generated.

Depending on the state of the ROOE bit in the MCR, the data from the transfer that generated the overflow is either ignored or shifted in to the shift register. If the ROOE bit is set, the incoming data is shifted in to the shift register. If the ROOE bit is cleared, the incoming data is ignored.

57.5.8.7 SPI Frame Parity Error Interrupt Request

The SPI Frame Parity Error Flag indicates that a SPI frame with parity error had been received. The SPEF_RE bit in the RSER must be set for the interrupt request to be generated.

57.5.9 Power saving features

The module supports following power-saving strategies:

- External Stop mode
- Module Disable mode – Clock gating of non-memory mapped logic

57.5.9.1 Stop mode (External Stop mode)

This module supports the Stop mode protocol. When a request is made to enter External Stop mode, the module acknowledges the request . If a serial transfer is in progress, then this module waits until it reaches the frame boundary before it is ready to have its clocks shut off . While the clocks are shut off, this module's memory-mapped logic is not accessible. This also puts the module in STOPPED state. The SR[TXRXS] bit is cleared to indicate STOPPED state. The states of the interrupt and DMA request signals cannot be changed while in External Stop mode.

57.5.9.2 Module Disable mode

Module Disable mode is a block-specific mode that the module can enter to save power. Host CPU can initiate the Module Disable mode by setting the MDIS bit in the MCR. The Module Disable mode can also be initiated by hardware.

When the MDIS bit is set, the module negates the Clock Enable signal at the next frame boundary. Once the Clock Enable signal is negated, it is said to have entered Module Disable Mode. This also puts the module in STOPPED state. The SR[TXRXS] bit is cleared to indicate STOPPED state. If implemented, the Clock Enable signal can stop the clock to the non-memory mapped logic. When Clock Enable is negated, the module is in a dormant state, but the memory mapped registers are still accessible. Certain read or write operations have a different effect when the module is in the Module Disable mode. Reading the RX FIFO Pop Register does not change the state of the RX FIFO. Similarly, writing to the PUSHR Register does not change the state of the TX FIFO or CMD FIFO. Clearing either of the FIFOs has no effect in the Module Disable mode. Changes to the DIS_TXF and DIS_RXF fields of the MCR have no effect in the Module Disable mode. In the Module Disable mode, all status bits and register flags in the module return the correct values when read, but writing to them has no effect. Writing to the TCR during Module Disable mode has no effect. Interrupt and DMA request signals cannot be cleared while in the Module Disable mode.

57.6 Initialization/application information

This section describes how to initialize the module.

57.6.1 How to manage queues

The queues are not part of the module, but it includes features in support of queue management. Queues are primarily supported in SPI configuration.

1. When module executes last command word from a queue, the EOQ bit in the command word is set to indicate it that this is the last entry in the queue.
2. At the end of the transfer, corresponding to the command word with EOQ set is sampled, the EOQ flag (EOQF) in the SR is set.
3. The setting of the EOQF flag disables serial transmission and reception of data, putting the module in the Stopped state. The TXRXS bit is cleared to indicate the Stopped state.
4. The DMA can continue to fill TX FIFO until it is full or step 5 occurs.
5. Disable DMA transfers by disabling the DMA enable request for the DMA channel assigned to TX FIFO (and CMD FIFO) and RX FIFO. This is done by clearing the corresponding DMA enable request bits in the DMA Controller.
6. Ensure all received data in RX FIFO has been transferred to memory receive queue by reading the RXCNT in SR or by checking RFDF in the SR after each read operation of the POPR.
7. Modify DMA descriptor of TX and RX channels for new queues
8. Flush TX FIFO (and CMD FIFO) by writing a 1 to the CLR_TXF bit in the MCR. Flush RX FIFO by writing a '1' to the CLR_RXF bit in the MCR.
9. Clear transfer count either by setting CTCNT bit in the command word of the first entry in the new queue or via CPU writing directly to SPI_TCNT field in the TCR.
10. Enable DMA channel by enabling the DMA enable request for the DMA channel assigned to the module TX FIFO, (and CMD FIFO) and RX FIFO by setting the corresponding DMA set enable request bit.
11. Enable serial transmission and serial reception of data by clearing the EOQF bit.

57.6.2 Switching Master and Slave mode

When changing modes in the module, follow the steps below to guarantee proper operation.

1. Halt it by setting MCR[HALT].

2. Clear the transmit and receive FIFOs by writing a 1 to the CLR_TXF and CLR_RXF bits in MCR.
3. Set the appropriate mode in MCR[MSTR] and enable it by clearing MCR[HALT].

57.6.3 Initializing Module in Master/Slave Modes

Once the appropriate mode in MCR[MSTR] is configured, the module is enabled by clearing MCR[HALT]. It should be ensured that module Slave is enabled before enabling it's Master. This ensures the Slave is ready to be communicated with, before Master initializes communication.

57.6.4 Baud rate settings

The following table shows the baud rate that is generated based on the combination of the baud rate prescaler PBR and the baud rate scaler BR in the CTARs. The values calculated assume a 100 MHz protocol frequency and the double baud rate DBR bit is cleared.

Table 57-15. Baud rate values (bps)

		Baud rate divider prescaler values			
		2	3	5	7
Baud Rate Scaler Values	2	25.0M	16.7M	10.0M	7.14M
	4	12.5M	8.33M	5.00M	3.57M
	6	8.33M	5.56M	3.33M	2.38M
	8	6.25M	4.17M	2.50M	1.79M
	16	3.12M	2.08M	1.25M	893k
	32	1.56M	1.04M	625k	446k
	64	781k	521k	312k	223k
	128	391k	260k	156k	112k
	256	195k	130k	78.1k	55.8k
	512	97.7k	65.1k	39.1k	27.9k
	1024	48.8k	32.6k	19.5k	14.0k
	2048	24.4k	16.3k	9.77k	6.98k
	4096	12.2k	8.14k	4.88k	3.49k
	8192	6.10k	4.07k	2.44k	1.74k
	16384	3.05k	2.04k	1.22k	872
	32768	1.53k	1.02k	610	436

57.6.5 Delay settings

The following table shows the values for the Delay after Transfer (t_{DT}) and CS to SCK Delay (T_{CSC}) that can be generated based on the prescaler values and the scaler values set in the CTARs. The values calculated assume a 100 MHz protocol frequency.

NOTE

The clock frequency mentioned above is given as an example in this chapter. See the clocking chapter for the frequency used to drive this module in the device.

Table 57-16. Delay values

		Delay prescaler values			
		1	3	5	7
Delay scaler values	2	20.0 ns	60.0 ns	100.0 ns	140.0 ns
	4	40.0 ns	120.0 ns	200.0 ns	280.0 ns
	8	80.0 ns	240.0 ns	400.0 ns	560.0 ns
	16	160.0 ns	480.0 ns	800.0 ns	1.1 µs
	32	320.0 ns	960.0 ns	1.6 µs	2.2 µs
	64	640.0 ns	1.9 µs	3.2 µs	4.5 µs
	128	1.3 µs	3.8 µs	6.4 µs	9.0 µs
	256	2.6 µs	7.7 µs	12.8 µs	17.9 µs
	512	5.1 µs	15.4 µs	25.6 µs	35.8 µs
	1024	10.2 µs	30.7 µs	51.2 µs	71.7 µs
	2048	20.5 µs	61.4 µs	102.4 µs	143.4 µs
	4096	41.0 µs	122.9 µs	204.8 µs	286.7 µs
	8192	81.9 µs	245.8 µs	409.6 µs	573.4 µs
	16384	163.8 µs	491.5 µs	819.2 µs	1.1 ms
	32768	327.7 µs	983.0 µs	1.6 ms	2.3 ms
	65536	655.4 µs	2.0 ms	3.3 ms	4.6 ms

57.6.6 Calculation of FIFO pointer addresses

Complete visibility of the FIFO contents is available through the FIFO registers, and valid entries can be identified through a memory-mapped pointer and counter for each FIFO. The pointer to the first-in entry in each FIFO is memory mapped. For the TX FIFO the first-in pointer is the Transmit Next Pointer (TXNXTPTR). For the CMD FIFO the first-in pointer is the Command Next Pointer (CMDNXTPTR). For the RX FIFO the first-in pointer is the Pop Next Pointer (POPNXTPTR). The following figure illustrates

the concept of first-in and last-in FIFO entries along with the FIFO Counter. The TX FIFO is chosen for the illustration, but the concepts carry over. See Transmit First In First Out (TX FIFO) buffering mechanism, Command First In First Out (CMD FIFO) Buffering Mechanism and Receive First In First Out (RX FIFO) buffering mechanism for details on the FIFO operation.

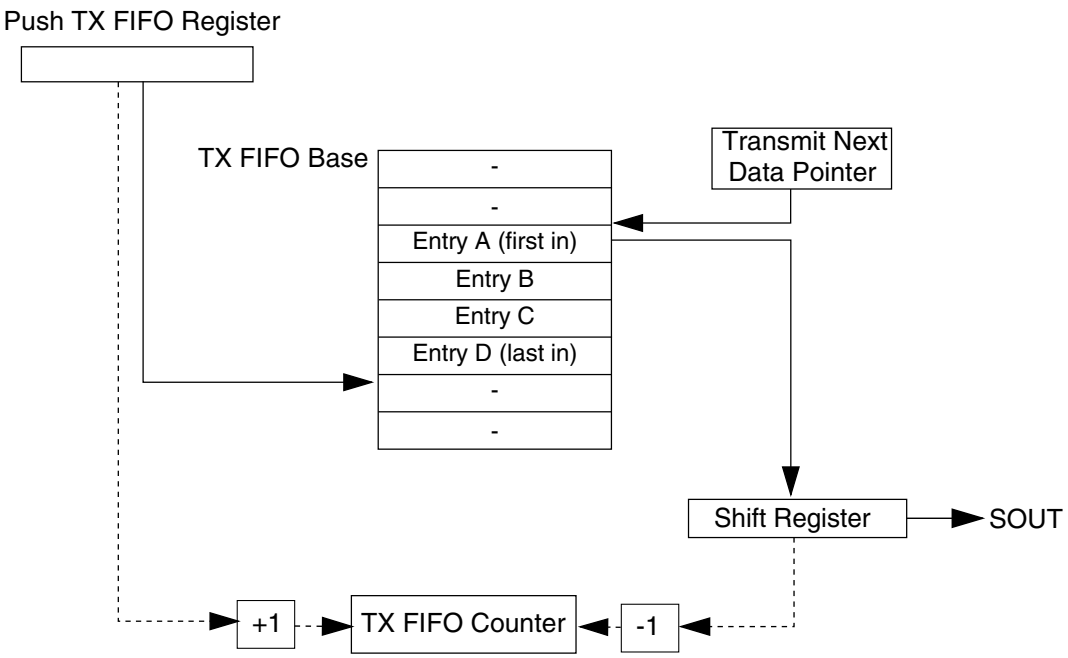

Figure 57-19. TX FIFO pointers and counter

57.6.6.1 Address Calculation for the First-in Entry and Last-in Entry in the TX FIFO

The memory address of the first-in entry in the TX FIFO is computed by the following equation:

$$\text{First-in EntryAddress} = \text{TXFIFOBase} + \left(4 \times \text{TXNXTPTR}\right)$$

The memory address of the last-in entry in the TX FIFO is computed by the following equation:

$$\text{Last-inEntryaddress} = \text{TXFIFOBase} + 4 \times \left(\text{TXCTR} + \text{TXNXTPTR} - 1\right) \bmod \left(\text{TXFIFOdepth}\right)$$

TX FIFO Base - Base address of TX FIFO
TXCTR - TX FIFO Counter
TXNXTPTR - Transmit Next Pointer
TX FIFO Depth - Transmit FIFO depth, implementation specific

57.6.6.2 Address Calculation for the First-in Entry and Last-in Entry in the CMD FIFO

The memory address of the first-in entry in the CMD FIFO is computed by the following equation:

$$\text{First-in EntryAddress} = \text{TXFIFOBase} + (4 \times \text{TXNXTPTR})$$

The memory address of the last-in entry in the CMD FIFO is computed by the following equation:

$$\text{Last-inEntryaddress} = \text{TXFIFOBase} + 4 \times (\text{TXCTR} + \text{TXNXTPTR} - 1) \bmod (\text{TXFIFOdepth})$$

CMD FIFO Base - Base address of CMD FIFO
CMDCTR - CMD FIFO Counter
CMDNXTPTR - Command Next Pointer
CMD FIFO Depth - Command FIFO depth, implementation specific

57.6.6.3 Address Calculation for the First-in Entry and Last-in Entry in the RX FIFO

The memory address of the first-in entry in the RX FIFO is computed by the following equation:

$$\text{First-in EntryAddress} = \text{RX FIFOBase} + (4 \times \text{POPNXTPTR})$$

The memory address of the last-in entry in the RX FIFO is computed by the following equation:

$$\text{Last-inEntryaddress} = \text{RX FIFO Base} + 4 \times (\text{RXCTR} + \text{POPNXTPTR} - 1) \bmod (\text{RXFIFOdepth})$$

RX FIFO Base - Base address of RX FIFO
RXCTR - RX FIFO counter
POPNXTPTR - Pop Next Pointer
RX FIFO Depth - Receive FIFO depth, implementation specific

Chapter 58
LINFlexD

58.1 Chip-specific LINFlexD information

58.1.1 LinFlexD Configuration

The following table shows the LinFlexD configuration.

Description	LINFlexD_1
Number of implemented filters	16
RX_CH_NUM	Number of DMA Rx channel - 1
TX_CH_NUM	Number of DMA Tx channel - 1
LIN operation mode	master/slave
Autosynchronization	Yes
Number of Tx DMA channels	1
Number of Rx DMA channels	1
DMA Support	Yes

58.2 Introduction

The LINFlexD controller is designed to manage a high number of LIN messages efficiently with a minimum of CPU load. To reduce the CPU loading in Master mode, LINFlexD autonomously handles the LIN messages once software has triggered the header transmission, until the next header transmission request in transmitter mode or until checksum reception in the receiver mode.

The LINFlexD supports LIN protocol version 1.3, 2.0, 2.1 , and 2.2. It also consists of an 8-byte buffer for transmission/reception data.

The LINFlexD also provides support for some of the basic UART transfers of 8-bit, 9-bit, 16-bit, and 17-bit frames and also 12-bit data frame + parity reception in UART mode for MSC support.

The LINFlexD supports multi-channels and parametric DMA Tx/Rx interface in LIN/ UART operating mode.

58.2.1 Glossary and acronyms

Table 58-1. Glossary and acronyms

Term	Description
LIN	Local interconnect network
UART	Universal asynchronous transmitter receiver
ID	LIN identifier field
DMA	Direct memory access
TCD	Transfer control descriptor
IPS	Peripheral Bus Interface
IRQ	Interrupt request
FSM	Finite state machine
WS	Wait state
SW	Software
CPU	Central processing unit
SoC	System on a chip

58.2.2 References

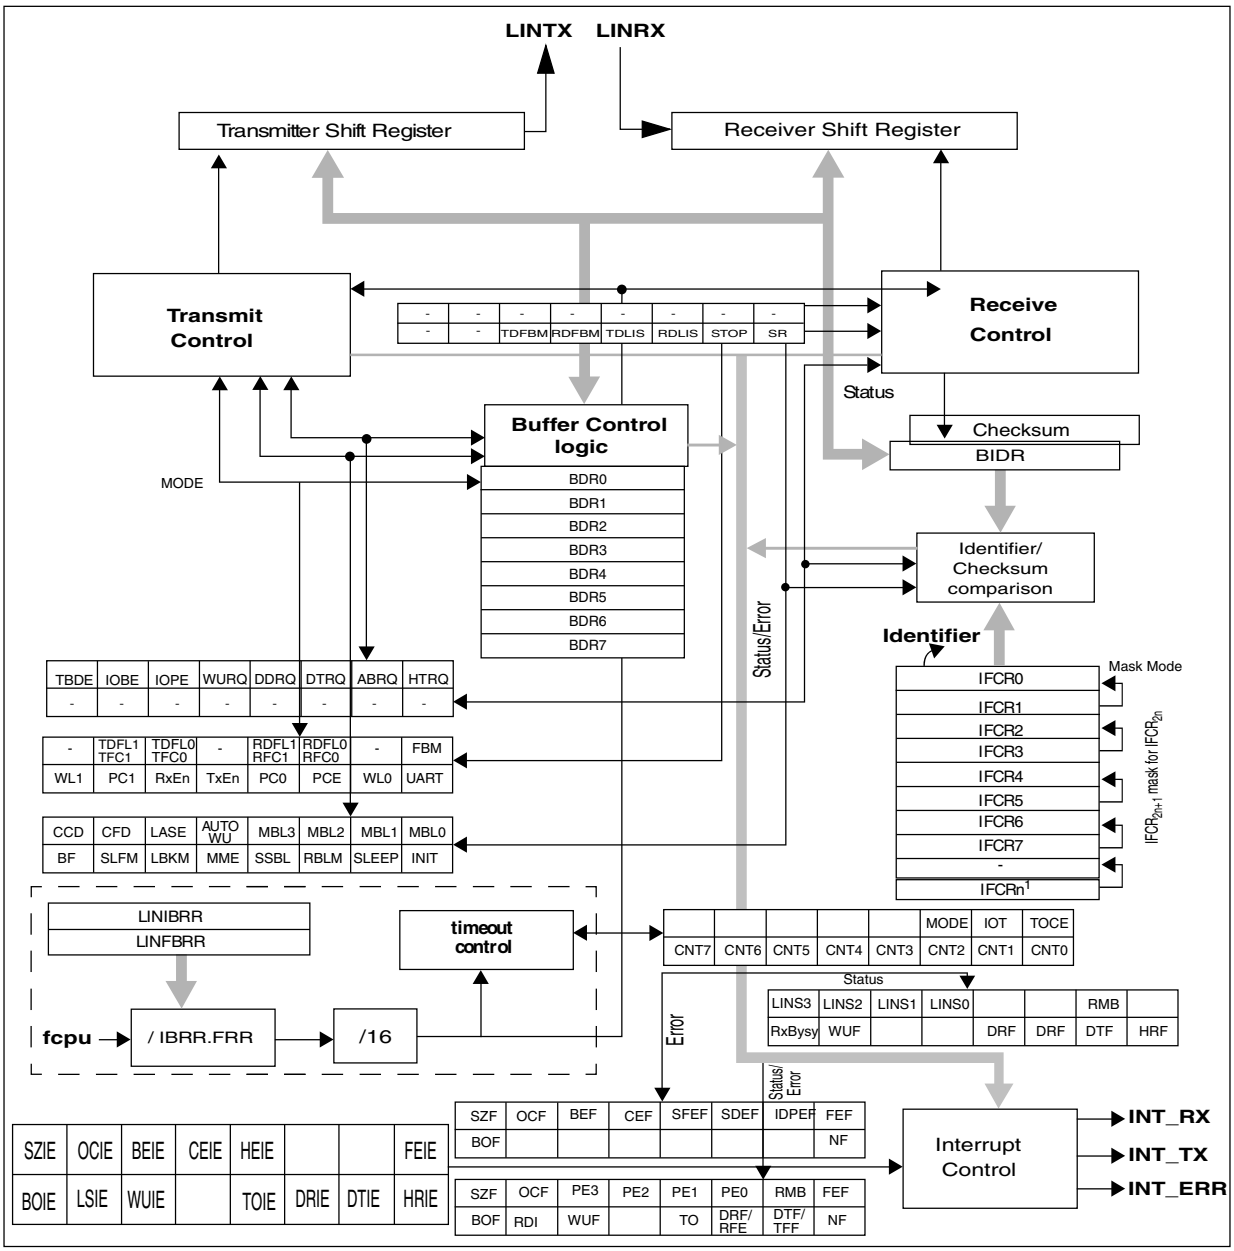

Figure 58-1. Block diagram

Notes:

1: The value of n depends on the no_of_filters. Refer to the chip configuration details to see the number of filters used in this device.

2: For LIN mode N = 16 and N is programmable by user in UART mode.

58.3 Main features

The LINFlexD controller can operate in several modes, each of which has a distinct set of features that are described in the following sections. In addition, the LINFlexD controller has several features common to all modes:

- Fractional baud rate generator
- 3 operating modes for power saving and configuration registers lock
  - Initialization
  - Normal
  - Sleep
- Test Mode:Loop Back
- Maskable interrupts
- A maximum of 16 possible identifiers can be programmed into the identifier list

58.3.1 LIN mode features

- Supports LIN protocol version 1.3, 2.0, 2.1, and 2.2
- Bit rates up to 20 Kbit/s (LIN protocol)
- Master/Slave mode
- Classic and Enhanced Checksum calculation and check
- Single 8-byte buffer or FIFO for Transmission/Reception
- Timeout management
- Identifier filters
- DMA interface
- Supports a maximum of 16 possible identifiers
- Master mode with autonomous message handling
- Wakeup event on dominant bit detection
- True LIN field state machine

- Advanced LIN error detection
- Header, response, and frame timeout
- Slave mode
  - Autonomous header handling
  - Autonomous transmit/receive data handling
- Identifier filters for autonomous message handling in Slave mode
- Separate clock for baud rate calculation
  - The relationship “(2/3)* LIN_CLK > PBRIDGEx_CLK > 1/3*LIN_CLK” should be maintained.

58.3.2 UART mode features

- Full-duplex communication
- Baud rate is a function of baud clock, LINIBRR and LINFBRR registers - see Baud rate generation
- Separate clock for baud rate calculation
  - The relationship “(2/3)* LIN_CLK > PBRIDGEx_CLK > 1/3*LIN_CLK” should be maintained.
- 15/16/7/8 bits data, parity
- 1/2/3 stop bits
- 12-bit + parity reception
- 4-byte buffer for reception, 4-byte buffer for transmission
- 12-bit counter for timeout management
- The maximum baud rate achievable is 25 Mbit/s.
- For bit rate ≤ 6.25 Mbit/s
  - Sixteen times oversampling
  - 3:1 majority voting
- For 6.25 Mbit/s < bit rate ≤ 12.5 Mbit/s

- Reduced over sampling programmable by the user
- 3:1 majority voting for reduced over sampling of 8

- For 12.5 Mbit/s < bit rate ≤ 25 Mbit/s
  - Reduced over sampling programmable by the user
  - 1:1 voting for all reduced over sampling of 4, 5 and 6

58.4 Functional description

58.4.1 LIN protocol

The LIN (Local Interconnect Network) is a serial communication protocol. A LIN cluster consists of one master task and several slave tasks. A master node contains the master task as well as a slave task. All other nodes contain a slave task only. The master node decides when and which frame is transferred on the bus. The slave task provides the data to be transported by the frame.

58.4.1.1 Frames

A frame consists of a header provided by the master task and a response provided by the slave task. The header consists of a break, a sync pattern, and an identifier. The break is followed by the sync pattern and the sync pattern is followed by the identifier. The slave task associated with the identifier provides the response. The response consists of a data field and checksum. The slave task designated to receive the data associated with the identifier receives the response and verifies the checksum.

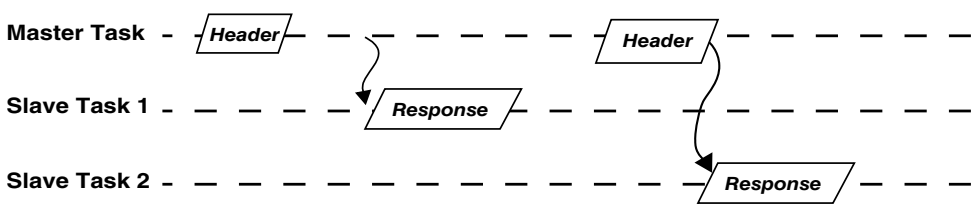

Figure 58-2. Frames

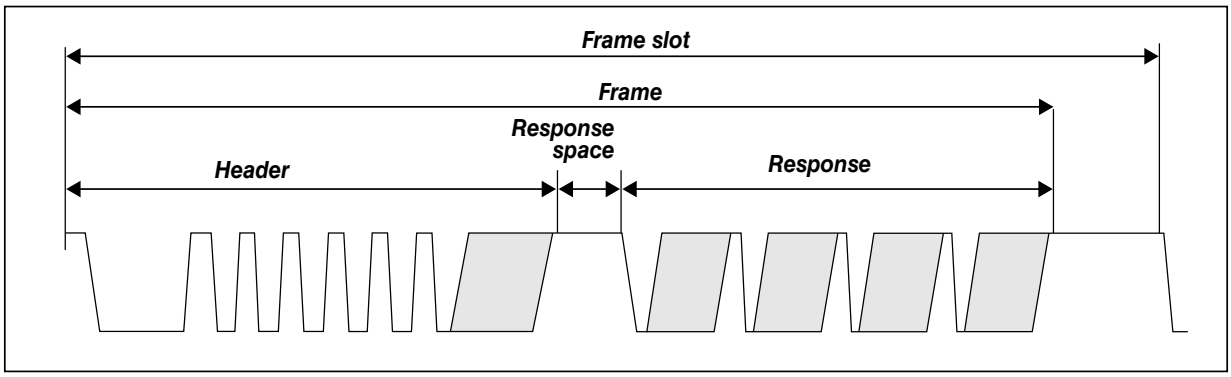

Figure 58-3. Structure of LIN frame

58.4.1.2 Data field

Each byte is transmitted as shown in Figure 58-4. The LSB of the data is sent first and the MSB is sent last. The start bit is encoded as a bit with value zero (dominant) and stop bit is encoded as bit value one (recessive).

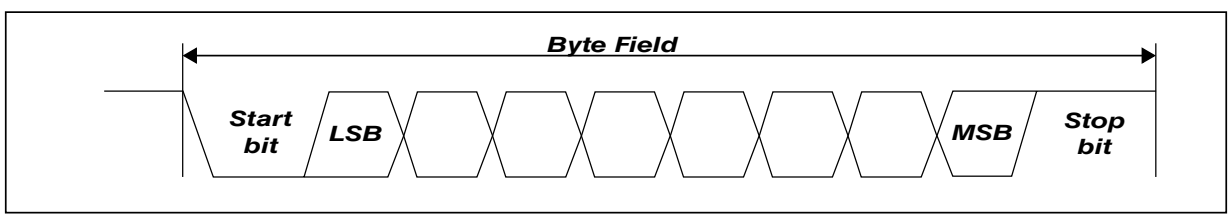

Figure 58-4. Structure of byte field

58.4.1.3 Break

The break symbol is used to signal the beginning of a new frame. It is the only field that does not comply with the above figure. The break is always generated by the master and shall be at least 13 bits of dominant value including the start bit, followed by a break delimiter as shown in Figure 58-5. The break delimiter must be of two-bit duration (to be compliant with LIN protocol 2.1).

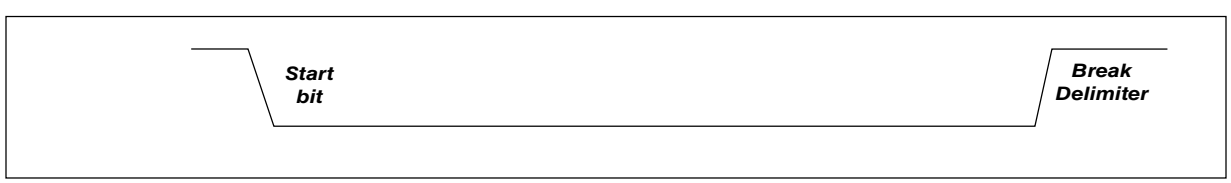

Figure 58-5. Break field

58.4.1.4 Sync byte

Sync is a byte field with the data value of 0x55.

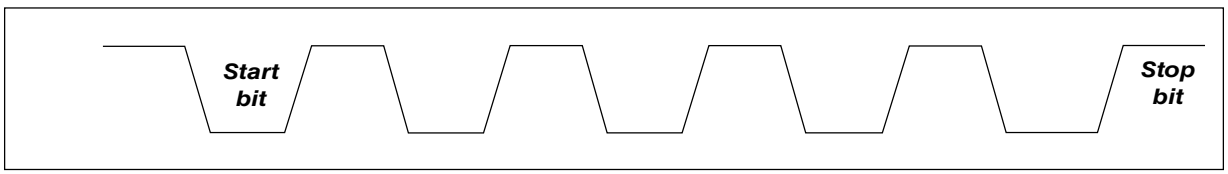

Figure 58-6. Sync byte field

58.4.1.5 Identifier

The Identifier field consists of two sub-fields, the identifier and the identifier parity. Bits 0 to 5 are the identifier and bits 6 and 7 indicate the parity.

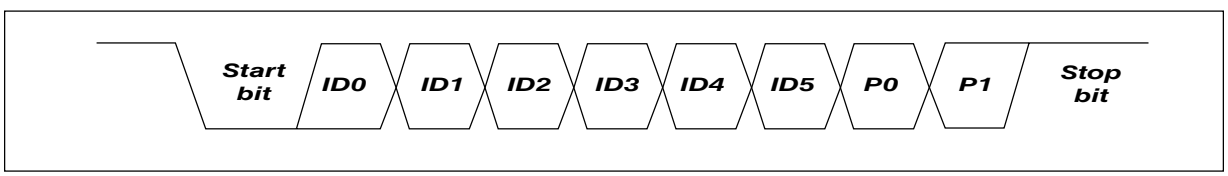

Figure 58-7. Identifier field

P0 = ID0 XOR ID1 XOR ID2 XOR ID4

P1 = NOT (ID1 XOR ID3 XOR ID4 XOR ID5)

58.4.1.6 Checksum

The last field of a frame is the checksum. The checksum contains the inverted 8-bit sum with carryover of all data bytes or all data bytes and the identifier. Checksum calculation over the data bytes only is called classic checksum and is used for communication with LIN 1.3 slaves. Checksum calculation over the data bytes and the protected identifier byte is called enhanced checksum and is used for communication with LIN 2.0 slaves.

58.4.2 LINFlexD features

58.4.2.1 Operating modes

The LINFlexD has three operating modes: **Initialization, Normal** and **Sleep** modes. After hardware reset, the LINFlexD enters sleep mode to reduce power consumption.

Initialization mode (INIT)

To enter this mode, software sets the INIT bit in the LINCR1. To exit the initialization mode, software should reset the INIT bit.

When in initialization mode, all message transfers to and from the LIN bus are stopped and the status of LIN bus output LINTX is recessive (high). If software invokes the initialization mode when a bus transfer is in progress, the transfer is aborted. The software should therefore check the LIN state before setting this bit.

To initialize the LINFlexD controller software must:

1. Set up the baud rate registers
2. Reset UART bit
3. Select the mode (master or slave)
4. Configure checksum control bits
5. Initialize the identifier list (Slave mode)

Normal mode (NM)

Once software has completed initialization of the LINFlexD controller, it can enter the Normal mode by clearing the INIT bit.

Sleep mode (SM)

Sleep mode in LINFlexD reduces power consumption. This mode is entered by setting the SLEEP bit in LINCR1. In this mode the LINFlexD clock is stopped. LINFlexD can be awakened from Sleep mode by clearing the SLEEP bit.

If software detects a wakeup pulse of 150 µs on the LIN Bus, it can request LINFlexD to wake up from Sleep mode. Refer to Wakeup management.

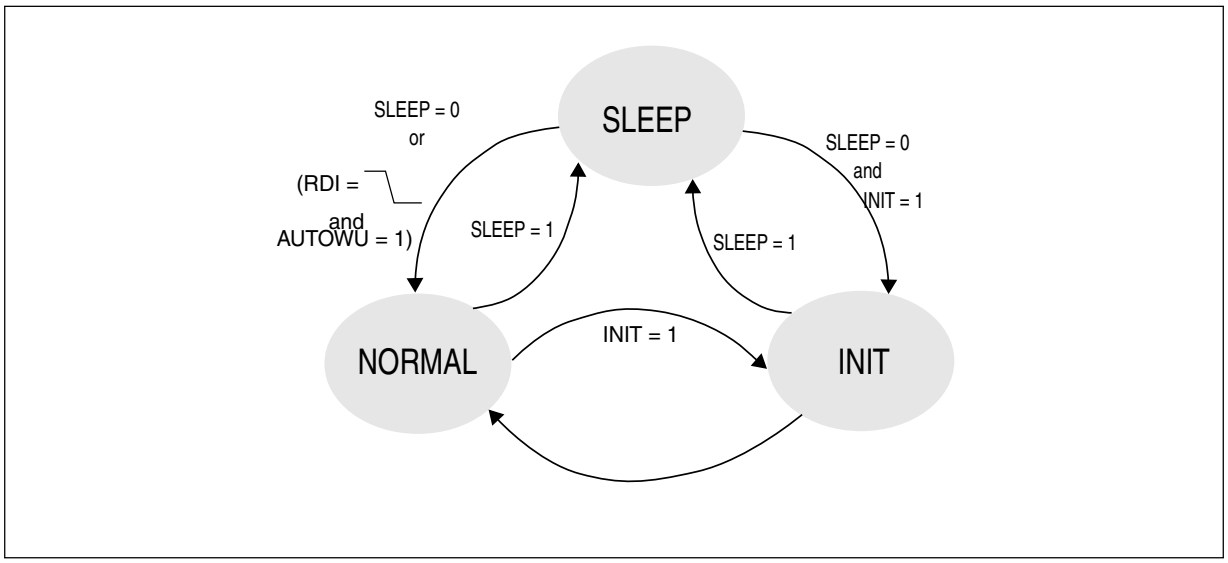

Figure 58-8. Operating modes

58.4.2.2 Test mode

Loop Back mode

This mode is entered by setting the LBKM bit in LINCR1. In this mode, the LINFlexD receives the Identifier and Data transmitted by itself and writes the same in the BIDR and Data buffers respectively. This mode is provided for selftest functions. Bit error is checked in this mode.

The LINFlexD ignores the LINRX signal. There is an internal feedback from its TX output to its RX input. The TX pin can be disconnected from LINTX pin by SIUL2 setting.

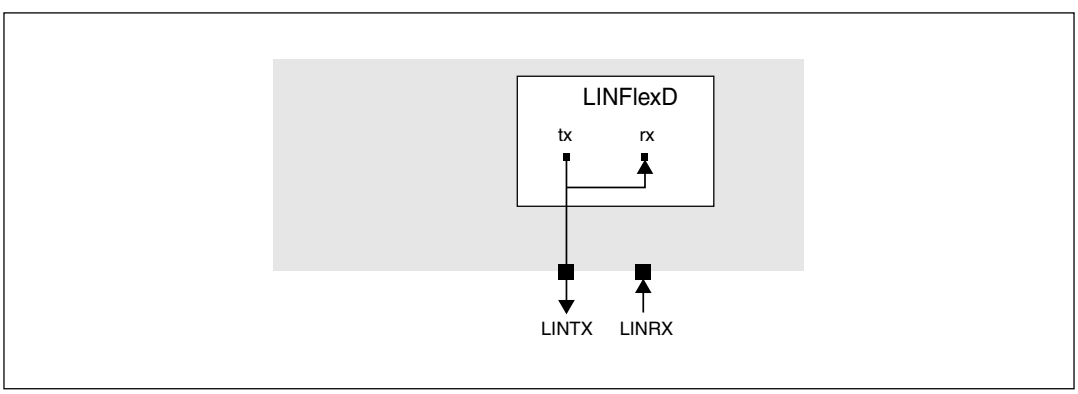

Figure 58-9. LINFlexD in Loop Back Mode

58.4.2.3 Master mode

Master mode is selected by means of the MME bit in LINCR1 register.

Header transmission

According to the LIN protocol any communication on the LIN bus is triggered by the master sending a header. The header is transmitted by the master task of a node while the response is transmitted by the slave task of a node.

To transmit the header, first program the Identifier, data field length, message direction and checksum enable in the BIDR register; then set the HTRQ bit in LINCR2. Once header transmission starts, the user should not modify BIDR register bits until the current frame is complete. The transmitted ID is also received by the master node and copied to BIDR.

Data transmission

When the master node is the publisher of the data corresponding to the Identifier sent by the master, then the slave task of the node should send the data in the response part of the frame. Hence software must provide the data to the LINFlexD before the header transmission is requested. The data to be transmitted is stored in the message buffer BDRL and BDRM. The number of bytes to be transmitted depends on the Data Field length in BIDR. The software uses the BIDR[CCS] bit to configure the checksum type (classic or enhanced) for each message.

If the response has been sent successfully, LINSR[DTF] is set. In case of error, the DTF flag is not set and the corresponding error flag is set in the LINESR (refer to error handling).

The direction of the message buffer is decided by the DIR bit in the BIDR. The transmitted data is also received by the same node and copied to the buffer.

Data reception

To receive data from a slave node, the master sends a header with the corresponding Identifier. The data received from the slave is stored in the message buffer and the status of the message is stored in the LINSR.

If the response has been received successfully, the LINSR (DRF) bit is set. In case of error, the DRF flag is not set and the corresponding error flag is set in the LINESR (refer to Error handling).

Data Discard

If the user wants to discard the data after header transmission, then the DDRQ bit in LINCR2 should be set.

58.4.2.4 Slave mode

This mode is selected when the MME bit of the LINCR1 register is cleared.

Data transmission

On header reception, the HRF bit is set and an RX interrupt is generated. The software must then:

1. Read the received ID in the BIDR register
2. Fill the BDR[0:x] register
3. Program the CCS and DIR bits in the BIDR register
4. Specify the data field length DFL bits in the BIDR register
5. Trigger the data transmission by setting the DTRQ bit

Note that the HRF bit should be reset only after the DTRQ bit is set. For the DTRQ to be effective, the HRF bit must be set. This is to ensure that DTRQ is not set randomly, but only after a header reception. It must be noted that you cannot set the DIR and DTRQ bits once RXbusy is asserted in LINSR.

Alternately, one or more Identifier filters are configured for transmission by setting the DIR bit, and activated by setting the enable bits in IFER. When at least one Identifier filter is active and configured for transmission and the received ID matches the filter, a TX interrupt is generated. The software can use the index in the IFMI register to point directly to the corresponding data array in the RAM and copy this data to the BDR[0:7].

The use of a filter saves software the processing time required to read the ID value in the BIDR, match it, and configure the data field length and checksum type.

If the number of filters provided by LINFlexD are not sufficient for the application, mask mode can be used for the filters.

The transmitted data is also received by the same node and copied to the buffer.

Data reception

When LINFlexD is the subscriber of the data of the received identifier, then on header reception the HRF flag is set and an RX interrupt is generated. The software must read the received ID from the BIDR register and specify the data field length before the reception of the stop bit of the first data byte. When the checksum is received, an RX

interrupt is generated for software to read the received data from BDR[0:7] and the RMB bit is set. Software must then release the data buffer by resetting the RMB bit in the LINSR.

When at least one identifier filter is active and configured for reception, an RX interrupt is generated only after the checksum reception. No interrupt request is generated on reception of the ID.

If the Identifier is filtered by software then you can discard the data by setting the DDRQ bit in the LINCR2, while HRF is set.

Note that for software filtering, software must decide the type of checksum (configure the CCS bit of the BIDR register) before reception of data. Otherwise the previous value of the CCS bit is considered while calculating checksum.

58.4.2.5 Errors

58.4.2.5.1 Header error

A header error is an error during the header reception. The error types are:

1. Sync Del error (SDEF)
2. Sync field error (SFEF)
3. Identifier Parity error (IDPEF)

Sync Del error (SDEF)

The delimiter should be 1 for at least one bit time; otherwise it is considered short and consequently the receiver discards synchronization on the current header. Hence the frame is discarded. An interrupt is generated if *HEIE* bit of LINEIER is set.

Sync field error (SFEF)

The SFEF error condition is monitored differently depending on whether autosynchronization (LASE) is ON or OFF.

Case 1: Autosynchronization ON (LASE bit of LINCR1 = 1):

When Autosynchronization is enabled, the SFEF flag indicates:

- The deviation error on the Sync Field is outside the LIN specification, which allows up to 14% of period deviation between the slave and master oscillators or

- An overflow has occurred during the Sync Field Measurement, which leads to an overflow of the divider registers.
- Doesn't indicate that an inconsistent Sync Field other than 0x55 has been received by the slave.

Deviation error on the Sync Field

The deviation error is checked by comparing the current baud rate (relative to the slave oscillator) with the received LIN Sync Field (relative to the master oscillator).

This check is based on a measurement between the first falling edge and the last falling edge of the Sync Field. Let's refer to this period deviation as D.

If SFEF field is asserted it means that:

D > 14.0625%

If there is no error, it means that:

D < 14.84375%

If 14.0625% < D < 14.84375%, then the Sync Field could be either consistent or inconsistent depending on dephasing between the signal on the RDI line and the LIN_CLK.

Overflow during Sync Field Measurement

This check is based on the measurement of each bit time between both edges of the Sync Field. This checks that each of these bit times is large enough (more than 12 samples) compared to the bit time of the current baud rate.

Case 2: Autosynchronization OFF (LASE bit of LINCR1 = '0')

In this case the Sync character is received as a normal character. If the received character is 0x55 then the Sync Field is OK.

On any occurrence of an inconsistent Sync Field, the receiver immediately exits from Sync_Field state and the frame is consequently discarded. The SFEF bit of LINESR is set.

Identifier Parity error(IDPEF)

There are two parity bits in the identifier field. These bits are checked against the hardware-calculated parity over the other six bits of identifier, according to the formula:

P0 = ID0 XOR ID1 XOR ID2 XOR ID4

P1 = NOT (ID1 XOR ID3 XOR ID4 XOR ID5)

This parity is checked after the ID is transferred to the BIDR register (after stop of ID has been detected properly) and upon parity mismatch, the receiver state machine exits from Identifier state immediately if the IOPE bit of LINCR2 is set.

58.4.2.5.2 Bit error

This error is flagged in transmission mode when the value read back from the bus is different from the value transmitted. Bit error checking on each bit is guaranteed if transceiver delay is less than one bit time minus 6 LIN_CPU cycles. Bit error is not checked during break field transmission.

1-bit time at 20 Kbit/s = 50 µs

6 LIN_CLK cycles at 80 MHz = 75 ns

Thus, (1-bit time) - (6 LIN_CLK cycles) = 49.925 µs

Transmission of the frame is stopped after the corrupted bit if the IOBE bit in LINCR2 is set. If IOBE is reset, the transmitter continues to transmit in spite of the bit error. An interrupt is generated if the BEIER bit is set in LINIER.

Note

If the break delimiter is not detected by the master within one bit time after delimiter transmission due to transceiver delay or error on the bus, then a train of bit error interrupts are generated. In this case, the Identifier may not be replaced in the BIDR.

Similarly, if the start of a falling edge of data is not detected by the transmitter node within one bit time after start bit transmission, then a train of bit error interrupts are generated. In this case also, data and checksum replacements in the BDR and CFR respectively are not guaranteed.

58.4.2.5.3 Framing error

This error is flagged when a dominant state is sampled on stop bit of the current received character (sync field, identifier field, data field, checksum field). LINFlexD discards the current frame and returns to Idle state. An interrupt is generated if FEIE bit is set in LINEIER.

The byte that caused framing error is also shifted to the buffer but DRF is never set in this case.

58.4.2.5.4 Checksum error

This error is flagged when the checksum computed by hardware does not match the received checksum.

LINFlexD discards the received frame and returns to Idle state. An interrupt is generated if the CEIE bit is set in LINEIER.

58.4.2.5.5 Overrun error

Once the message buffer is full (RMB is set), the next valid message reception will lead to an overrun and the message will be lost. The hardware signals the overrun condition by setting the BOF bit. Which message is lost depends on the buffer lock function control bit RBLM.

If RBLM is cleared, the old message in the buffer is overwritten by the most recent message. If RBLM bit is set, the most recent message is discarded and the oldest message is available to the software. In the case of slave, if buffer is not released (RMB is not reset) before reception of next Identifier and if RBLM is set, then the ID along with the data is discarded.

58.4.2.5.6 Timeout error

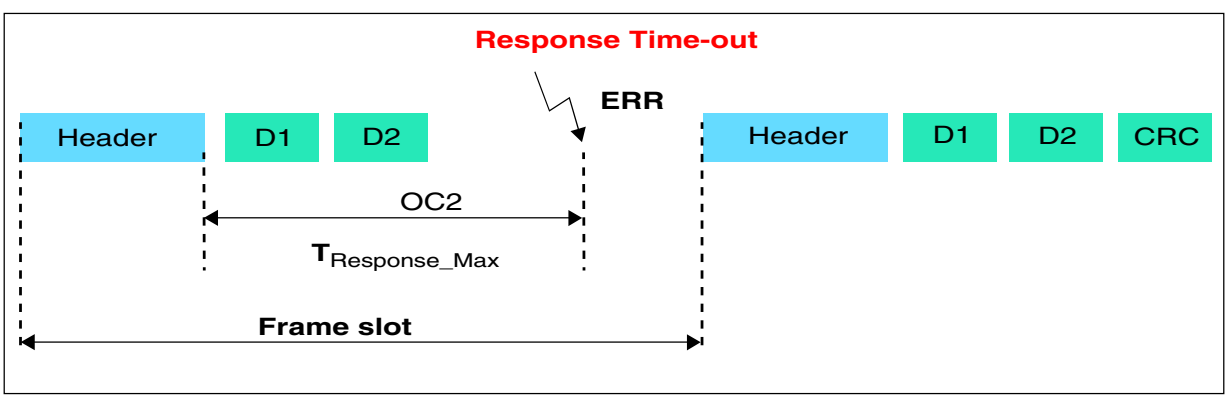

Figure 58-10. Incomplete response (for example, missing checksum)

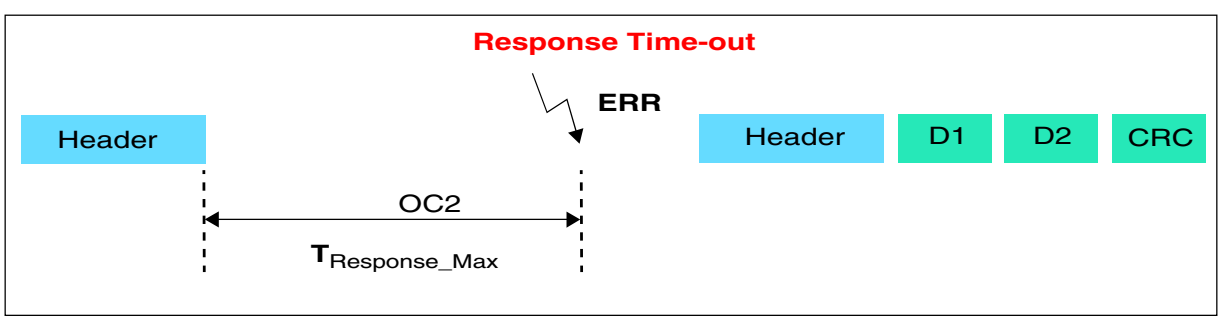

Figure 58-11. No response

Response timeout mechanism

- Master mode
  - OC2 is loaded with Nominal_time_out + LINFlexD_LINTCSR[CNT] at the end of the stop bit of the Identifier field (where nominal_time_out = 1.4 × ((DFL + 2) × 10 bit time).

    This loading takes place at the end of id field (and not at the beginning of data field). Moreover, the correct value, which depends on DFL, is loaded immediately. No further OC2 update is required.
  - In case of no response at all within this time (in other words, start of data is not received), timeout takes place when the counter reaches the OC2 value (no change compared to earlier implementation).
  - In case of an incomplete response, timeout also occurs when the counter reaches the OC2 value (no change compared to earlier implementation).
- Slave mode
  - **Case 1**: The received identifier is managed by a filter. The implementation can be similar to the master mode, because the DFL value is loaded by hardware. Thus, OC2 can be loaded with Nominal_time_out + LINFlexD_LINTCSR[CNT] at the end of the stop bit of the Identifier field (where nominal_time_out = 1.4 × ((DFL + 2) × 10 bit time))
  - **Case 2**: The received identifier is not managed by a filter. As the DFL value needs to be updated by software after the identifier field has been received, the implementation is the following:
    - At the end of the ID, OC2 is loaded with 36 (maximum possible response space) + LINFlexD_LINTCSR[CNT].
    - At the end of the first_data_byte it is reloaded again according to DFL
    - Before reloading, LINFlexD checks the count_val. If count value is higher than the value to be reloaded, timeout takes place immediately and no reloading occurs.

NOTE

The value of nominal_time_out (1.4 × ((DFL +2) × 10 bit time)) shown is as per the reset value of LINTOCR[RTO] and LINCR1[CFD]. It changes with change in value of LINTOCR[RTO] and LINCR1[CFD]. Here, 1.4 corresponds to (LINTOCR[RTO])/10 and 2 corresponds to (2- LINCR1[CFD])

Header timeout mechanism

- Master mode: As the header is generated by the LINFlexD, there are only two cases:
  - no error on the bus and timing is correct (nominal header length),
  - an error occurs on the bus and LINFlexD flags it in LINESR register (typically a bit error).

  Therefore there is no meaning of header timeout in master mode, so it is disabled.
- Slave mode
  - header_nominal = 13 + 2 + 10 + 10 = 35 Tbit
  - header_max = 1.4 × Header_nominal = 49 Tbit
  - taking into account a possible 14% clock deviation, header_max seen by LINFlexD is 49 × 1.14 = 56 Tbit
  - If the counter starts after 11 Tbit (break duration), the HTO value is 56 –11 = 45 Tbit.

  The reset value of HTO is 45, and this register can only be programmed in slave mode. Counter restarts after break duration and OC1 gets loaded with the value of HTO.

  As response space is not included in the response, frame timeout is no longer needed and is removed completely. Indeed, header timeout and response timeout cover all cases.

  The timeout counter can be used to detect other timeouts. In this case, the MODE bit must be reset and the output compare value can be updated in the LINTOCR register by software.

Stuck at zero timeout error

If the dominant pulse lasts for a time of at least 100 bits, the SZF bit in LINESR is set. If the same dominant pulse prolongs, the subsequent SZF setting will be 87 bit times apart (instead of 100 bit times).

58.4.2.5.7 Noise

During reception each bit is sampled 16 times and the value of the bit is obtained by taking the majority value of the 8^{th}, 9^{th} and 10^{th} samples. If any one of these three samples has a value different from the other two, this error is flagged.

When OSR = 8, majority of 2nd, 3rd, and 4th samples are taken into account to determine noise. Noise checking is disabled for all OSR less than eight.

This error is flagged when there is noise detected in the start bit (see LIN Error Status Register (LINFlexD_LINESR).

58.4.2.6 Identifier filtering

In LIN protocol the identifier of a message is not associated with the address of a node but is related to the content of the message. A transmitter broadcasts its message to all the receivers. Based on the header received, the receiver decides whether to receive or transmit a response (depending on the identifier value). If the message does not target the node, it should be discarded.

To fulfill this requirement, the LINFlexD provides configurable filters in order to eliminate software intervention. This hardware filtering saves CPU resources that would otherwise be required to perform filtering by software.

There are a maximum of 16 filters (depending on the generic no_of_filters) in the LINFlexD, which can be programmed by the user only during Initialization mode. In order to activate a filter the corresponding FACT bit in IFER needs to be set. There are two modes possible for each identifier depending on the corresponding IFM bit of IFMR.

Identifier list mode

If the n^{th} bit of IFMR is cleared, then filter number 2n and 2n+1 is in identifier list mode. In this mode, the maximum number of filters that can be configured for transmission/ reception equals no_of_filters, depending on the FACT bit of IFER. In this mode the identifier received should match bit by bit to the ID field of IFCR2n or IFCR2n+1 (if the corresponding FACT bit is set).

Identifier mask mode

If the number of filters required is more than no_of_filters, then filters should be configured in Mask mode. If the n^{th} bit of IFMR is set, then filter number 2n is the filter and 2n+1 acts as a mask for it. The FACT bit for filter 2n+1 has no effect in this case. In this mode, if the x^{th} bit of the mask is set, then the x^{th} bit of the received identifier must match the x^{th} bit of filter.

If there is a match of identifier with the mth filter in any mode, then m+1 is loaded in the IFMI register by hardware. No match condition is denoted by IFMI = 0.

Upon matching DFL (2:0), the CCS and DIR bits of the BIDR register are copied from the filter by hardware and from then on, the BIDR register is read-only until the end of the frame. Now if the DIR bit of BIDR is set, then a TXI interrupt is generated if the

HRIE bit of LINIER is set. In this case, software uses the IFMI register to transfer the relevant data from the RAM area to BDR, and after complete transfer the DTRQ bit of LINCR2 is set to start the transmission. If the DIR bit is cleared then an RXI interrupt is generated (provided DRIE bit of LINIER is set) when the checksum has been received and there is no checksum error.

In case of no filter match condition (IFMI = 0) and if the BF bit of LINCR1 is set, then an RXI is generated. Now it is the responsibility of software to configure BIDR and start transmission (by loading the BDR buffer and setting the DTRQ bit of LINCR2) or discard reception (by setting the DDRQ bit of LINCR2). If the BF bit is reset, then the receiver discards the received identifier and turns to Idle state in search of a new break.

Note

If one identifier matches with two filters (one is in the list and the other in Mask mode) then List mode prevails over Mask mode. In mask mode if two filters match with the identifier then the filter having the lower number prevails.

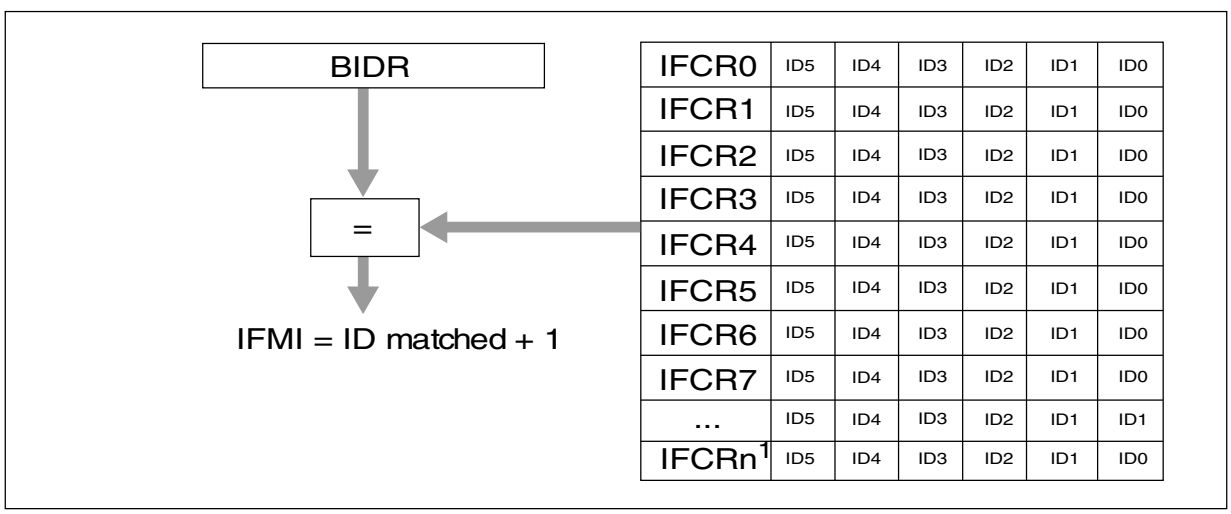

Figure 58-12. Identifier List mode

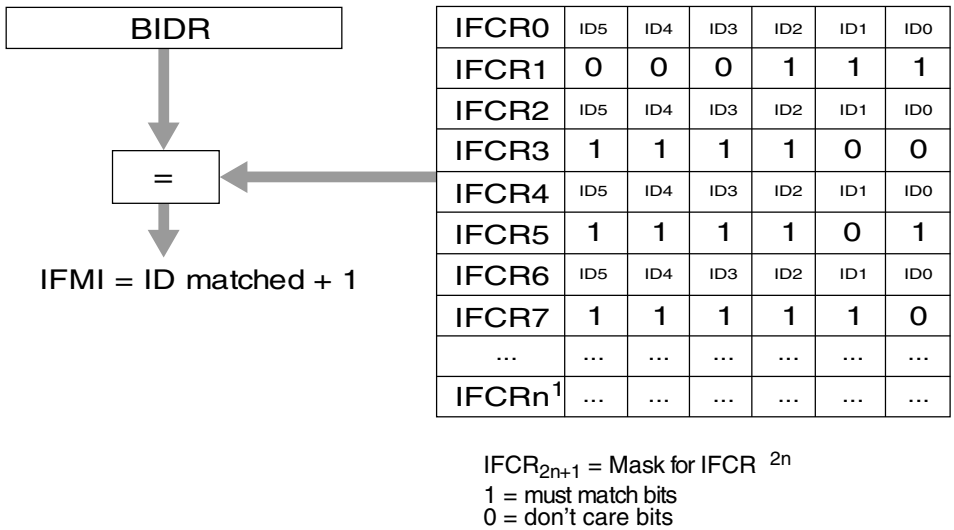

Figure 58-13. Identifier Mask mode

58.4.2.7 Start detection and break delimiter detection in receiver

There is a 10-bit-shift register sample register in the receiver that shifts signal data to the next least significant bit on each incoming sample.

Table 58-2. Start Detection and Delimiter Detection in receiver

9	8	7	6	5	4	3	2	1	0	Sample_reg
—	—	—	—	—	—	—	—	—	RT1	counter = 0

—	—	—	—	—	—	—	RT1	RT2	RT3	counter = 2
—	—	—	—	—	—	RT1	RT2	RT3	RT4	counter = 3
—	—	—	—	—	RT1	RT2	RT3	RT4	RT5	counter = 4
—	—	—	—	RT1	RT2	RT3	RT4	RT5	RT6	counter = 5
—	—	—	RT1	RT2	RT3	RT4	RT5	RT6	RT7	counter = 6
—	—	RT1	RT2	RT3	RT4	RT5	RT6	RT7	RT8	counter = 7
—	RT1	RT2	RT3	RT4	RT5	RT6	RT7	RT8	RT9	counter = 8
RT1	RT2	RT3	RT4	RT5	RT6	RT7	RT8	RT9	RT10	counter = 9
RT2	RT3	RT4	RT5	RT6	RT7	RT8	RT9	RT10	RT11	counter = 10
RT3	RT4	RT5	RT6	RT7	RT8	RT9	RT10	RT11	RT12	counter = 11
RT4	RT5	RT6	RT7	RT8	RT9	RT10	RT11	RT12	RT13	counter = 12
RT5	RT6	RT7	RT8	RT9	RT10	RT11	RT12	RT13	RT14	counter = 13

Table continues on the next page...

Table 58-2. Start Detection and Delimiter Detection in receiver (continued)

9	8	7	6	5	4	3	2	1	0	Sample_reg
RT6	RT7	RT8	RT9	RT10	RT11	RT12	RT13	RT14	RT15	counter = 14
RT7	RT8	RT9	RT10	RT11	RT12	RT13	RT14	RT15	RT16	counter = 15
1	1	1	0	x	0	x	0	x	0	start detect
1	1	1	0	x	0	x	0	x	1	
1	1	1	0	x	0	x	1	x	0	
1	1	1	0	x	1	x	0	x	0	
0	0	0	1	x	1	x	1	x	1	delimiter detect
0	0	0	1	x	1	x	1	x	0	
0	0	0	1	x	1	x	0	x	1	
0	0	0	1	x	0	x	1	x	1	

Hence, a start is detected as soon as it is qualified with 1110 in the sample register and verified with at least two out of three predefined verification samples being zero. Similarly for delimiter detection, qualification samples are 0001 and at least two of the three verification samples are one. The Noise Flag is set if the start is verified with only two valid samples.

58.4.2.7.1 Start detection mechanism

The following steps are followed for detecting a start bit:

1. Refer to Table 58-2 for the status of the sample register (shift register) when count = 6
2. At this point, if RT1 (the first incoming sample) = 0 and the previous three samples already received are all ones, then it might be a start bit.
3. To make sure it is indeed a start bit, the incoming data samples in the sample register (4), sample register (2) and sample register (0) which correspond to RT3, RT5, and RT7 is verified using the steps mentioned below.
4. If the majority (i.e., 2) out of these 3 samples are equal to ‘0’, then start bit is said to be detected.
5. These three samples RT3, RT5, and RT7 are called the “verification samples” which are checked at count = 6.

6. The sample register bits 9, 8, 7, and 6 are called “qualification samples” which are checked at count = 6.
7. At count = 9, if majority value of RT8, RT9, and RT10 is not equal to ‘0’ then Noise flag is set.

58.4.2.7.2 Break delimiter detection mechanism

The following steps are followed for detecting a delimiter bit:

1. Refer to Table 58-2 for the status of the sample register (shift register) when count = 6
2. At this point, if RT1 (the first incoming sample) = 1 and the previous three samples already received are all zeros, then it might be a delimiter bit.
3. To make sure it is indeed a delimiter bit, the incoming data samples in the sample register (4), sample register (2) and sample register (0) which correspond to RT3, RT5, and RT7 is verified using the steps mentioned below.
4. If the majority (i.e., 2) out of these 3 samples are equal to ‘1’, then delimiter bit is said to be detected.
5. These three samples RT3, RT5, and RT7 are called the “verification samples” which are checked at count = 6.
6. The sample register bits 9, 8, 7, and 6 are called “qualification samples” which are checked at count = 6.

Hence, a start is detected as soon as it is qualified with 1110 in the sample register and verified with at least two out of three predefined verification samples being zero. Similarly for delimiter detection, qualification samples are 0001 and at least two out of the three verification samples are one. The Noise Flag is set if the start is verified with only two valid samples.

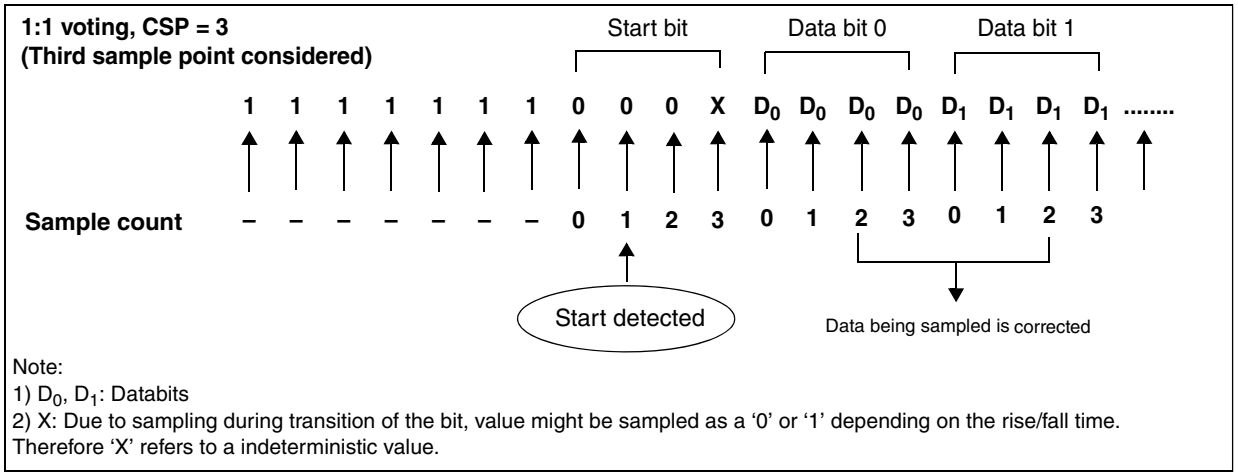

Figure 58-14. Start detection and sampling for over sampling rate = 4 (Case 1)

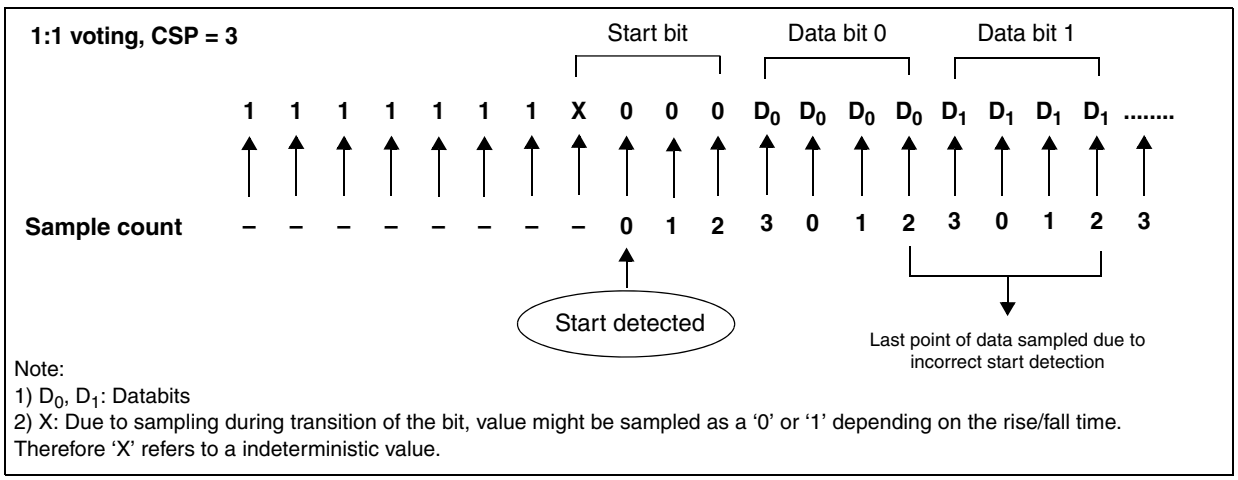

Figure 58-15. Start detection and sampling for over sampling rate = 4 (Case 2a)

The choice of the correct sample points depends on the external Rx signal quality. During the application development process, the error information indicated by the parity error can help to find the best setting for an application-specific hardware signal.

To sample at the correct point therefore, CSP has to be changed to two; resulting in the following situation:

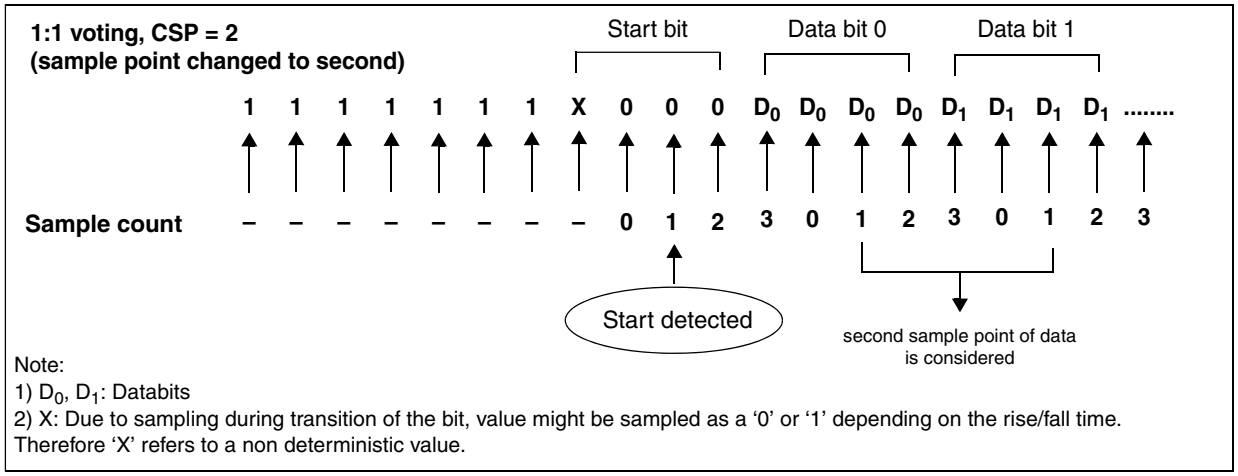

Figure 58-16. Start detection and sampling for over sampling rate = 4 (Case 2b)

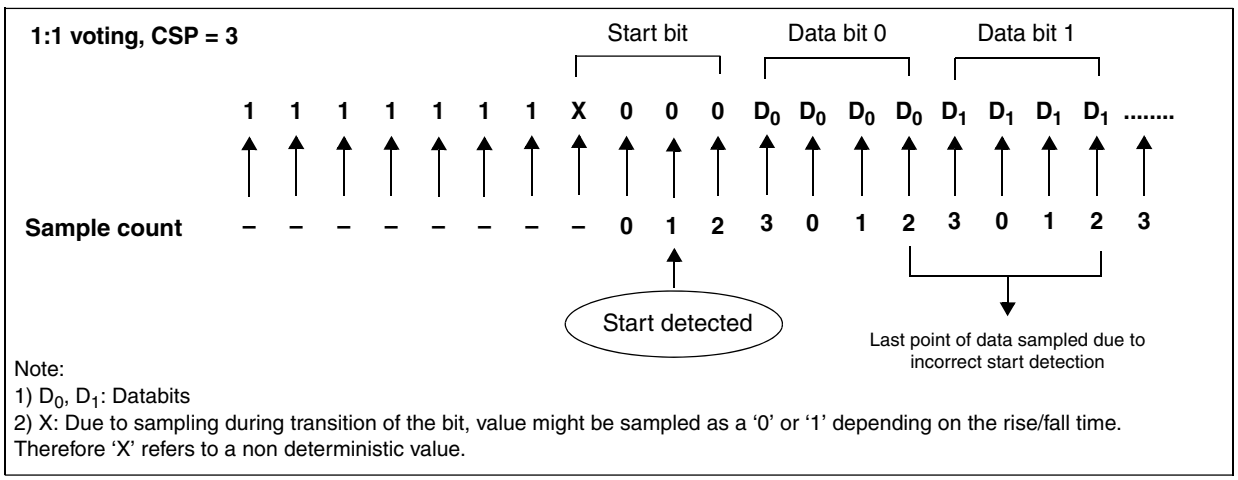

Figure 58-17. Start detection and sampling for over sampling rate = 4 (Case 3)

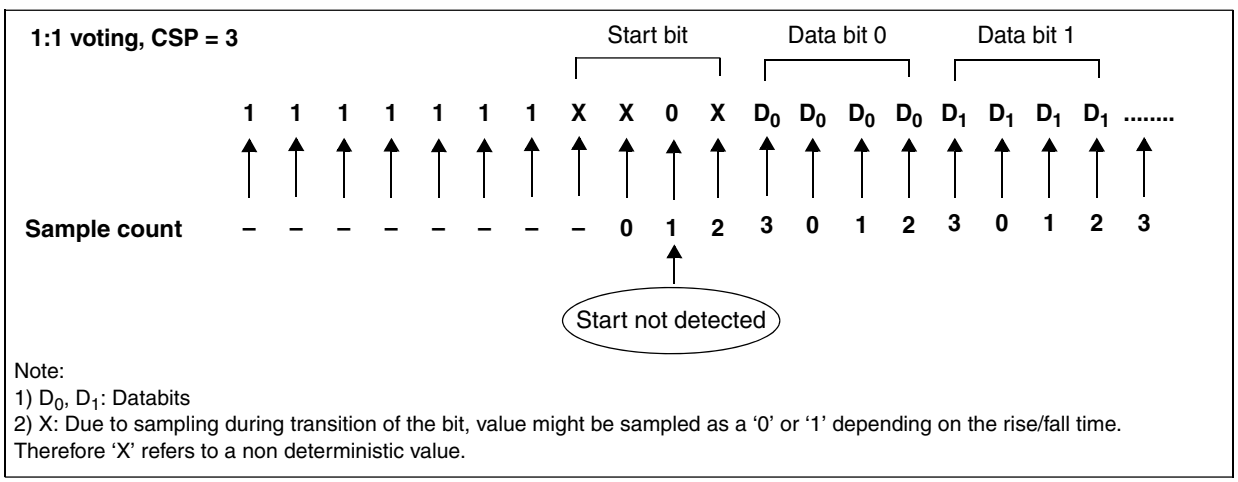

Figure 58-18. Start detection and sampling for over sampling rate = 4 (Case 4)

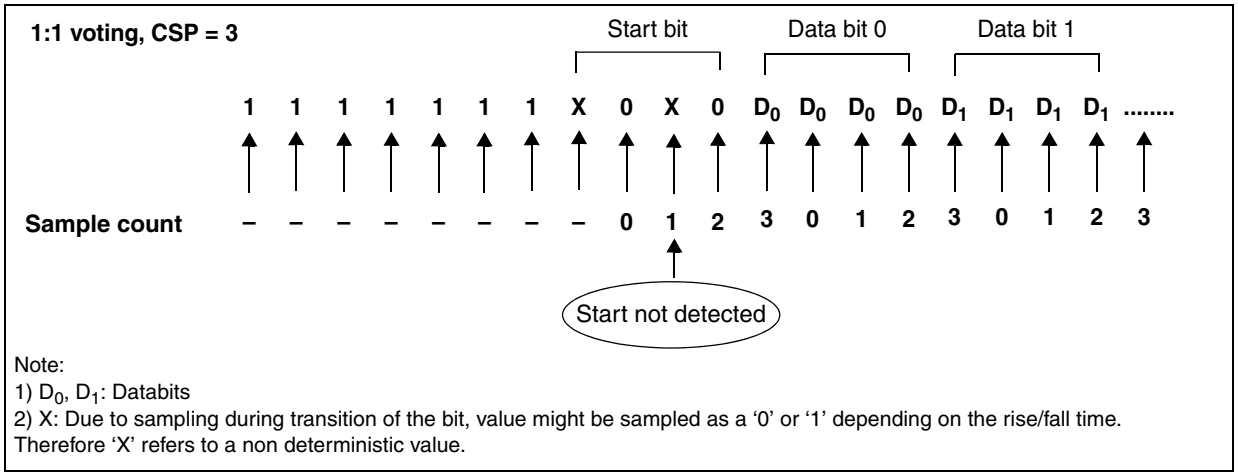

Figure 58-19. Start detection and sampling for over sampling rate = 4 (Case 5)

58.4.2.8 Baud rate generation

The LIN baud rate is programmed in two registers: the LIN Integer Baud Rate Register and the LIN Fraction baud rate register. The Baud Rate Registers can be programmed only during Initialization mode.

Baud rate is calculated with the following formula for both receiver and transmitter.

When ROSE = 1, Tx = Rx = LIN_CLK / (OSR × LDIV). When ROSE = 0, Tx = Rx = LIN_CLK / (16 × LDIV)

Where LIN_CLK is the frequency of the baud clock.

LDIV is an unsigned fixed point number. The mantissa is coded into 20 bits of LINIBRR and the fraction is coded on 4 bits of LINFBRR.

When reduced oversampling is enabled, LINFBRR should not be used and programmed to zero and LDIV contains only the integer part of LINIBRR.

For example: When ROSE = 0 (For LIN and UART mode): LDIV = 468.75 d, LIN_CLK = 36 MHz, LINIBRR = 468 d, LINFBRR = 12 *Baud rate = 36 MHz/ (16 × 468.75) = 4.8 Kbit/s*

For example: When ROSE = 1 (Only for UART mode): LDIV = 10 d, LIN_CLK = 80 MHz, LINIBRR = 4 d, OSR = 4, *Baud rate = LIN_CLK / (OSR × LDIV) = 80 MHz / (4 × 10) = 2 Mbit/s*

58.4.2.9 Automatic resynchronization

To automatically adjust the baud rate based on measurement of the LIN sync field, write the nominal Prescalar value (nominal baud rate) in LINIBRR and LINFBRR, then set the LASE bit in LINCR1 to enable automatic synchronization.

When auto synchronization is enabled, after each LIN Sync Del, the time duration between five falling edges on RDI is sampled on LIN_CLK.

58.4.2.10 Wakeup management

Any node in a sleeping LIN cluster may request a wakeup. The wakeup request is issued by forcing the bus to the dominant state for 250 μs to 5 ms. Every slave node should detect the wakeup request (a dominant pulse longer than 150 μs) and be ready to listen to bus commands within 100 ms, measured from the ending edge of the dominant pulse. The master also wakes on detecting a wakeup request and when the slaves are ready, starts sending frame headers to find out the cause of the wakeup. If the master does not issue a frame header within 150 ms from the wakeup request, then the node issuing a request may try issuing a new wakeup request.

In LINFlexD, a wakeup request can be generated by writing the wakeup character in BDR0 and setting the WURQ bit in LINCR2. On setting the WURQ bit, the character in BDR0 is transmitted. For LIN 2.0, character 0xF0 is sent as the wakeup character.

In LINFlexD, wakeup can be detected in two ways.

1. AUTOWU = 1 On detecting a falling edge in sleep mode, the SLEEP bit is cleared by hardware, the WUF flag is set, and an interrupt is generated if WUPIE is set. LINFlexD is now in normal mode and ready to receive frames.
2. AUTOWU = 0 On detecting a falling edge the WUF flag is set and an interrupt is generated (if WUPIE bit is set). It is then up to the software to clear the SLEEP bit.

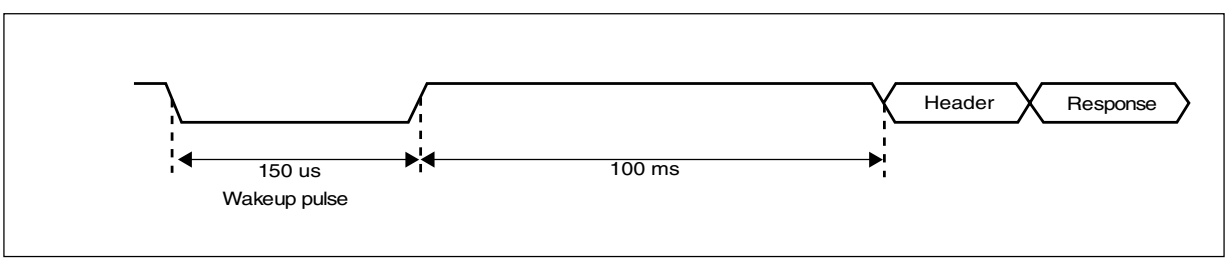

Figure 58-20. Wakeup sequence

58.4.3 Timer

There is an 8-bit counter which has different behavior in different modes as described below:

- **In Output Compare Mode (LINTCSR[MODE]= 1):**

  This counter is running even in Sleep and Initialization mode. The counter value which when matches the two software configurable output compare registers (LINOCR[OC1] or LINOCR[OC2]), generate output compare interrupt (LINESR[OCF]) provided TOCE bit in LINTCSR is set. Once an interrupt occurs subsequent interrupt is generated only when the application has reset the stuck FSM state.
- **In LIN Mode:**

  The software has no control over the TOCE bit and output compare registers are utilized for generation of LIN timeout interrupts (header, frame, response times out). In this case, if LIN moves to Sleep or Init state then this counter remains in Reset state. LIN mode has no meaning if UART is enabled, hence the counter will remain in Reset state.

58.4.4 UART mode

Main features in the UART mode are:

- Full duplex communication
- 8-bit frames, 9-bit frames, 13-bit frames, 16-bit frames, 17-bit frames
- Even/Odd/0/1 Parity
- User programmable over sampling rate to obtain the baud rate of up to 25 Mbit/s

58.4.4.1 8-bit data frames

The eighth bit can be a data or a parity bit. Even/Odd/0/1 parity can be selected by the PC[1:0] bit in the same register. An even parity will be set if the modulo-2 sum of the seven data bits is one. An odd parity will be cleared in this case.

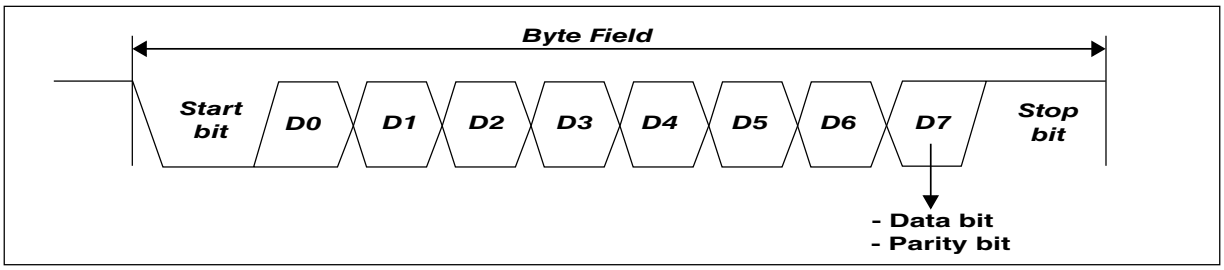

Figure 58-21. UART mode 8-bit data frame

58.4.4.2 9-bit frames

The ninth bit should be a parity bit. Even/Odd/0/1 Parity can be selected by the PC[1:0] field in the same register. An even parity will be set if the modulo-2 sum of the seven data bits is one. An odd parity will be cleared in this case. Parity 0 forces a zero logical value. Parity 1 forces a high logical value.

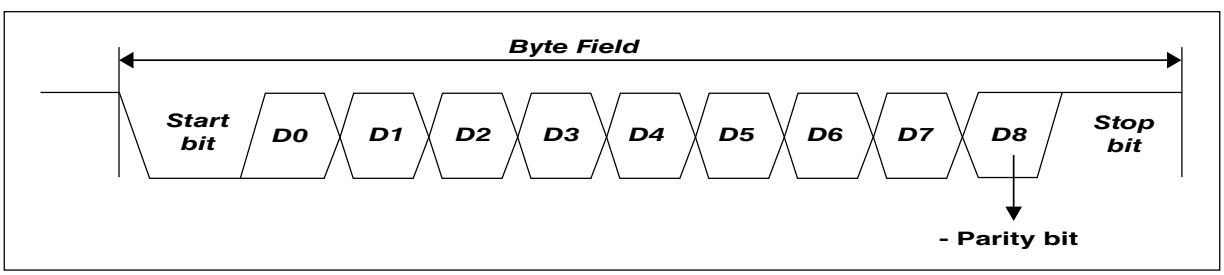

Figure 58-22. UART mode 9-bit data frame

58.4.4.3 16-bit data frames

The sixteenth bit can be a data or a parity bit. Even/Odd/0/1 Parity bit can be selected by the PC[1:0] bit in the same register. Parity 0 forces a zero logical value. Parity 1 forces a high logical value.

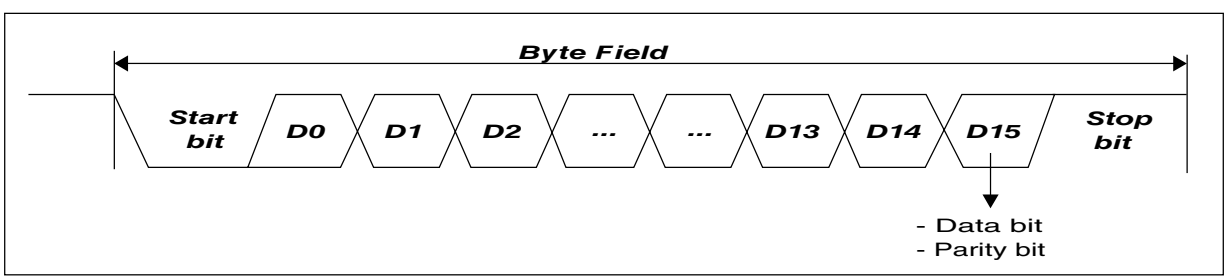

Figure 58-23. UART mode 16-bit data frame

58.4.4.4 17-bit frames

The seventeenth bit is the parity bit. Even/Odd/0/1 Parity bit can be selected by the PC[1:0] bit in the same register. Parity 0 forces a zero logical value. Parity 1 forces a high logical value.

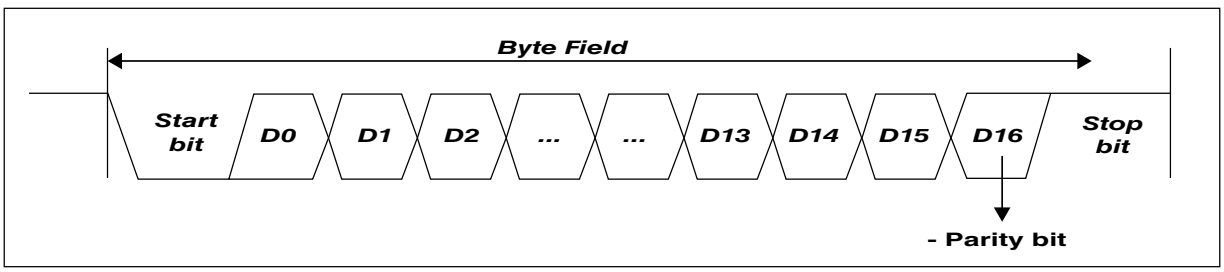

Figure 58-24. UART mode 17-bit data frame

58.4.4.5 13-bit frames

Whenever WLS is one, special word length is selected in UART mode. This bit enables 12-bit + parity bit reception only in FIFO mode.

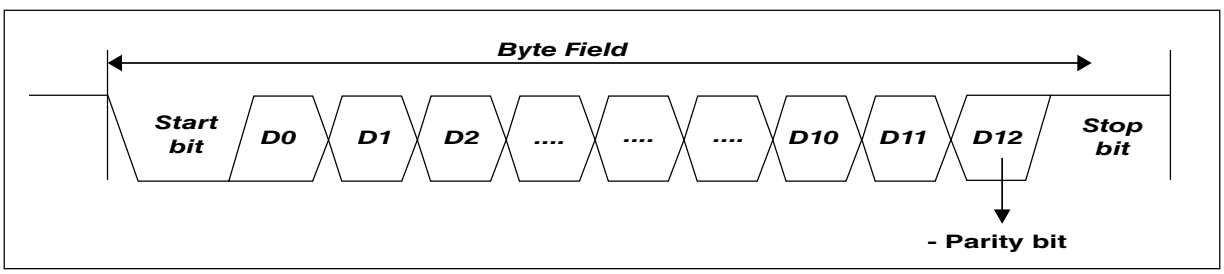

Figure 58-25. UART mode 13-bit data frame

58.4.4.6 Buffer in UART mode

The 8-byte buffer is divided into two parts: one for receiver and one for transmitter, as shown in the following figure:

Tx0	BDR0
Tx1	BDR1
Tx2	BDR2
Tx3	BDR3
Rx0	BDR4
Rx1	BDR5
Rx2	BDR6
Rx3	BDR7

Figure 58-26. Structure of 8-byte buffer

For 16-bit frames, the lower eight bits are written in BDR0 and upper eight bits in BDR1.

The same applies for reception.

58.4.4.7 UART transmitter

UART transmitter

In order to start transmission in the UART mode, UART bit should be set and the transmitter enable bit should be set. Transmission starts when the BDR0 (least significant data byte) is programmed and continues until the number of bytes/halfwords transmitted is equal to the value in the TDFL bits in UARTCR.

The transmit buffer is four bytes (when UARTCR[WL1] = 0) or two halfwords (when UARTCR[WL1] = 1), hence a maximum of four bytes (two halfwords) transmission can be triggered. Once the programmed number of bytes (halfwords) has been transmitted, the DTF flag is set in UARTSR. If the TxEn bit of UART is reset in the middle of a transmission, then the current transmission is completed and no further transmissions can be invoked.

The buffer can be configured in FIFO mode (mandatory when the DMA Tx is enabled) by setting the control bit UARTCR[TFBM].

NOTE

If TFF bit is set and a write is performed to the FIFO, the data transmitted may be erroneous.

Table 58-3. BDRL access in UART mode

IPS operation	Register	Mode (UARTCR[TFBM])	Word length (UARTCR[WL])	IPS operation result
Write Byte0	BDRL	FIFO	Byte	OK
Write Byte1-2-3	BDRL	FIFO	Byte	IPS transfer error
Write Half-word0-1	BDRL	FIFO	Byte	IPS transfer error
Write Word	BDRL	FIFO	Byte	IPS transfer error
Write Byte0-1-2-3	BDRL	FIFO	Half-word	IPS transfer error
Write Half-word0	BDRL	FIFO	Half-word	OK
Write Half-word1	BDRL	FIFO	Half-word	IPS transfer error
Write Word	BDRL	FIFO	Half-word	IPS transfer error
Read Byte0-1-2-3	BDRL	FIFO	Byte/Half-word	IPS transfer error
Read Half-word0-1	BDRL	FIFO	Byte/Half-word	IPS transfer error
Read Word	BDRL	FIFO	Byte/Half-word	IPS transfer error
Write Byte0-1-2-3	BDRL	BUFFER	Byte/Half-word	OK
Write Half-word0-1	BDRL	BUFFER	Byte/Half-word	OK

Table continues on the next page...

Table 58-3. BDRL access in UART mode (continued)

IPS operation	Register	Mode (UARTCR[TFBM])	Word length (UARTCR[WL])	IPS operation result
Write Word	BDRL	BUFFER	Byte/Half-word	OK
Read Byte0-1-2-3	BDRL	BUFFER	Byte/Half-word	OK
Read Half-word0-1	BDRL	BUFFER	Byte/Half-word	OK
Read Word	BDRL	BUFFER	Byte/Half-word	OK

In UART FIFO mode (UARTCR[TFBM] = 1), any read operation causes an IPS transfer error.

58.4.4.8 UART receiver

UART receiver

The reception of a data byte is started as soon as the user exits initialization mode, sets the RxEn bit, and detects start bit. There is a dedicated 4-byte (if UARTCR[WL1] = 0) or 2-half-words (if UARTCR[WL1] = 1) data buffer for received data. Once the programmed number (RDFL bits) of bytes have been received, the DRF flag is set in UARTSR and the current reception gets completed. RxEn bit needs to be set only to start the reception. The reception is automatically completed as soon as the programmed number (RDFL bits) of bytes have been received.

The buffer can be configured in FIFO mode (mandatory when the DMA Rx is enabled) by setting the control bit UARTCR[RFBM].

Table 58-4. BDRM access in UART mode

IPS operation	Register	Mode (UARTCR[RFBM])	Word length (UARTCR:WL)	IPS operation result
Read Byte4	BDRM	FIFO	Byte	OK
Read Byte5-6-7	BDRM	FIFO	Byte	IPS transfer error
Read Half-word2-3	BDRM	FIFO	Byte	IPS transfer error
Read Word	BDRM	FIFO	Byte	IPS transfer error
Read Byte4-5-6-7	BDRM	FIFO	Half-word	IPS transfer error
Read Half-word2	BDRM	FIFO	Half-word	OK
Read Half-word3	BDRM	FIFO	Half-word	IPS transfer error
Read Word	BDRM	FIFO	Half-word	IPS transfer error
Write Byte4-5-6-7	BDRM	FIFO	Byte/Half-word	IPS transfer error
Write Half-word2-3	BDRM	FIFO	Byte/Half-word	IPS transfer error
Write Word	BDRM	FIFO	Byte/Half-word	IPS transfer error
Read Byte4-5-6-7	BDRM	BUFFER	Byte/Half-word	OK

Table continues on the next page...

Table 58-4. BDRM access in UART mode (continued)

IPS operation	Register	Mode (UARTCR[RFBM])	Word length (UARTCR:WL)	IPS operation result
Read Half-word2-3	BDRM	BUFFER	Byte/Half-word	OK
Read Word	BDRM	BUFFER	Byte/Half-word	OK
Write Byte4-5-6-7	BDRM	BUFFER	Byte/Half-word	IPS transfer error
Write Half-word2-3	BDRM	BUFFER	Byte/Half-word	IPS transfer error
Write Word	BDRM	BUFFER	Byte/Half-word	IPS transfer error

Note

Refer to the layout of the registers BDRL and BDRM to identify the mapping between byte x and data bits of the registers BDRL/BDRM.

Note

- If the user does not know in advance how many bytes are to be received, RDFL should not be programmed in advance. The reset value of RDFL is zero. This will ensure that the reception will happen byte by byte. The state machine will move to the Idle state after each byte reception.
- If RDFL is programmed for a certain value but that number of bytes are not received, then reception will hang. In that case, software needs to take care of timeout by seeing the flag. Software has to set the sleep bit to move to Idle state.
- If a STOP request arrives in the middle of one reception, it is only acknowledged after all the programmed number of data bytes have received; it is not served immediately. If the programmed number of data bytes are not received, then software has to take care of timeout. When the state machine moves to Idle state, then only a stop request is served.
- If during reception of any byte a parity error occurs, then the corresponding PEx bit in UARTSR is set. No interrupt is generated in this case. If a framing error occurs in any byte (FE bit in UARTSR is set) then an interrupt is generated if FEIE bit in LINIER is set. As there is only one register bit for framing error, this interrupt will be helpful in identifying which byte has framing error.

- If the last received frame has not been read from the buffer (in other words, RMB is not reset by the user), then upon reception of the next byte, an overrun error occurs (BOF bit in UARTSR will be set) and one message is depending on RBLM bit of LINCR1. An interrupt is generated if the BOIE bit in LINIER is set.
- When WLS bit = 1, BDRM access depends on WL bit setting.
- When WLS bit = 1, WL = 0 or 1 should not be used, since this will lead to incorrect reception of data.
- When IPG_STOP is requested, for UART in FIFO mode, SW has to set the INIT bit in order to send the receiver to idle. This ensures that IPG_STOP_ACK is generated and IP enters STOP mode.

58.4.5 DMA interface

58.4.5.1 Main features

The LINFlexD DMA offers a parametric and programmable solution with the following distinctive features:

- LIN Master node, TX mode: single DMA channel
- LIN Master node, RX mode: single DMA channel
- LIN Slave node, TX mode: 1 to N DMA channels where N = 2^TX_CH_NUM. See chip specific information for the value of TX_CH_NUM used in this device.
- LIN Slave node, RX mode: 1 to N DMA channels where N = 2^RX_CH_NUM. See chip specific information for the value of RX_CH_NUM used in this device.
- UART node, TX mode: single DMA channel
- UART node, RX mode: single DMA channel + time-out

58.4.5.2 Definitions

Control/status register fields of the LINFlexD macrocell are described in Table 58-5 and Table 58-6.

Table 58-5. LINFlexD control/status fields description

Register	Field	Level	Description
LINCR2	DDRQ	High	Data discard request in reception mode
	DTRQ	High	Data transmission request (slave mode) of the LIN data field stored in BDRL/BDRM
	HTRQ	High	Header transmission request (master mode)
BIDR	DFL	—	Data field length: • 1 to 8 bytes: normal frames
	DIR	—	Direction of the data field: • 0 => reception • 1 => transmission
	CCS	—	Checksum type: • 0 enhanced • 1 classic
	ID[5:0]	—	Identifier.
LINSR	RMB	—	Buffer data ready to be read via CPU/DMA. • 0 buffer data is free • 1 buffer data is ready
	DRF	High	Data reception completed
	DTF	High	Data transmission completed
	HRF	High	Header received. Used in slave mode in case of Tx filter match.
IFMI	IFMIx	!= zero	Filter match index (slave mode).
UARTCR	FBM	—	FIFO/Buffer mode • 0 Buffer mode • 1 FIFO mode (mandatory in DMA mode)
UARTSR	RFE	—	Rx FIFO empty • 0 Rx FIFO not empty • 1 Rx FIFO empty
	TFF	—	Tx FIFO full • 0 Tx FIFO not full • 1 Tx FIFO full
DMATXE[2**TX_CH_NUM][1]		High	DMA Tx channel enable (read/write). In UART or LIN master mode only the channel 0 can be programmed. In LIN slave mode: # DMA TX channel = IFMI[3:0] -1.

Table continues on the next page...

Table 58-5. LINFlexD control/status fields description (continued)

Register	Field	Level	Description
			DMATXE[x] = 0b => TX channel x disabled DMATXE[x] = 1b => TX channel x enabled

DMARXE[2**RX_CH_NUM][1]		High	DMA Rx channel enable (read/write). In UART or LIN master mode only the channel 0 can be programmed.
			In LIN slave mode: # DMA RX channel = IFMI[3:0] -1.
			DMARXE[x] = 0b => RX channel x disabled
			DMARXE[x] = 1b => RX channel x enabled

1. ** stands for exponentiation.
1. ** stands for exponentiation

Table 58-6. LINFlexD DMA control fields description

Field	Mode	Value	Level	Description
DMA_TEN	LIN master Tx or UART Tx	DMATXE[0]	High	Logical AND between the 2 DMA enable bits (LINFlexD and eDMA).
DMA_TEN	LIN slave Tx	DMATXE[x] x = IFMI — 1	High	
DMA_REN	LIN master Rx or UART Rx	DMARXE[0]	High	
DMA_REN	LIN slave Rx	DMARXE[x] x = IFMI — 1	High	

Control/status fields of the TCD descriptors referred to in this document are described in Table 58-7.

Table 58-7. TCD control fields description

TCD Field	Level	Description
CITER[14:0]	—	Current "major" iteration count
BITER[14:0]	—	Beginning "major" iteration count
NBYTES[31:0]	—	Inner "minor" byte transfer count. Number of bytes to be transferred in each service request of the channel.
SADDR[31:0]	—	Source address
SOFF[15:0]	—	Source address signed offset applied to the current source address as each source read is completed.
SSIZE[2:0]	—	Source data transfer size 000 => 8-bit 001 => 16-bit

Table continues on the next page...

Table 58-7. TCD control fields description (continued)

TCD Field	Level	Description
		010 => 32-bit 011 => 64-bit
SLAST[31:0]	—	Last source address adjustment
DADDR[31:0]	—	Destination address
DOFF[15:0]	—	Destination address signed offset applied to the current destination address as each destination write is completed.
DSIZE[2:0]	—	Destination data transfer size 000 => 8-bit 001 => 16-bit 010 => 32-bit 011 => 64-bit
DLAST_SGA[31:0]	—	Last destination address adjustment or the memory address for the next TCD to be loaded into this channel (scatter/gather)
INT_MAJ	High	Enable an interrupt when major iteration count completes
START	High	The channel is explicitly started via a software initiated service request.
DONE	High	Channel done (the DMA has completed the outer major loop).
D_REQ	High	Disable request. If this flag is set the DMA hardware automatically clears the corresponding DMAERQ bit when the current major iteration count reaches zero.

58.4.5.3 Master node –TX mode

On a master node, in TX mode the DMA interface requires a single TX channel. Each TCD controls a single frame. The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in the following figure.

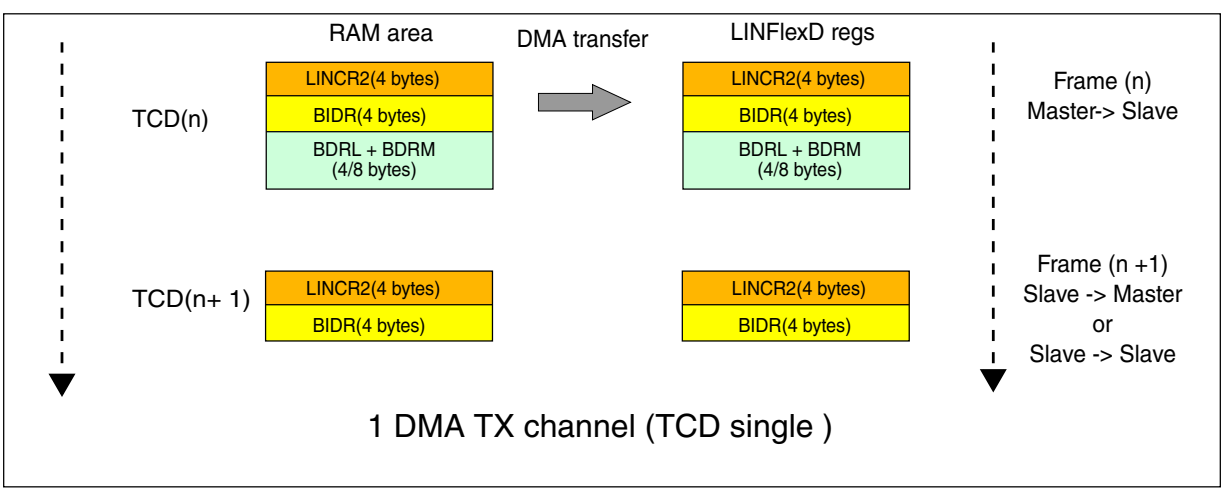

Figure 58-27. Master node –TX memory map

The TCD chain of the DMA Tx channel on a master node supports:

- Master to Slave: transmission of the entire frame (header + data)
- Slave to Master: transmission of the header; the data reception is controlled by the Rx channel on the master node
- Slave to Slave: transmission of the header

The following table provides the register settings of the LINCR2 and BIDR for each class of LIN frame.

Table 58-8. Master node – Tx mode – Register setting

LIN frame	LINCR2	BIDR
Master to Slave	DDRQ = 1 DTRQ = 0 HTRQ = 0	DFL = payload size ID = address CCS = checksum DIR = 1 (TX)
Slave to Master	DDRQ = 0 DTRQ = 0 HTRQ = 0	DFL = payload size ID = address CCS = checksum DIR = 0 (RX)
Slave to Slave	DDRQ = 1 DTRQ = 0 HTRQ = 0	DFL = payload size ID = address CCS = checksum DIR = 0 (RX)

The concept FSM to control the DMA Tx interface is given in the following figure. DMA TX FSM moves to Idle state immediately at next clock edge if DMATXE[0] = 0. The TCD setting (word transfer) is given in Table 58-9. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

Table 58-9. TCD setting – Master node – Tx mode

TCD Field	Value	Description
CITER[14:0]	1	Single iteration for the "major" loop
BITER[14:0]	1	Single iteration for the "major" loop
NBYTES[31:0]	[4 + 4] + 0/4/8 = N	Data buffer is stuffed with dummy bytes if the length is not word aligned. LINCR2 + BIDR + BDRL + BDRM
SADDR[31:0]	-	RAM address
SOFF[15:0]	4	Word increment
SSIZE[2:0]	2	Word transfer

Table continues on the next page...

DOFF[15:0]	4	Word increment
DSIZE[2:0]	2	Word transfer
DLAST_SGA[31:0]	–N	No scatter/gather processing
INT_MAJ	0/1	Interrupt disabled/enabled
D_REQ	1	Only on the last TCD of the chain
START	0	No SW request

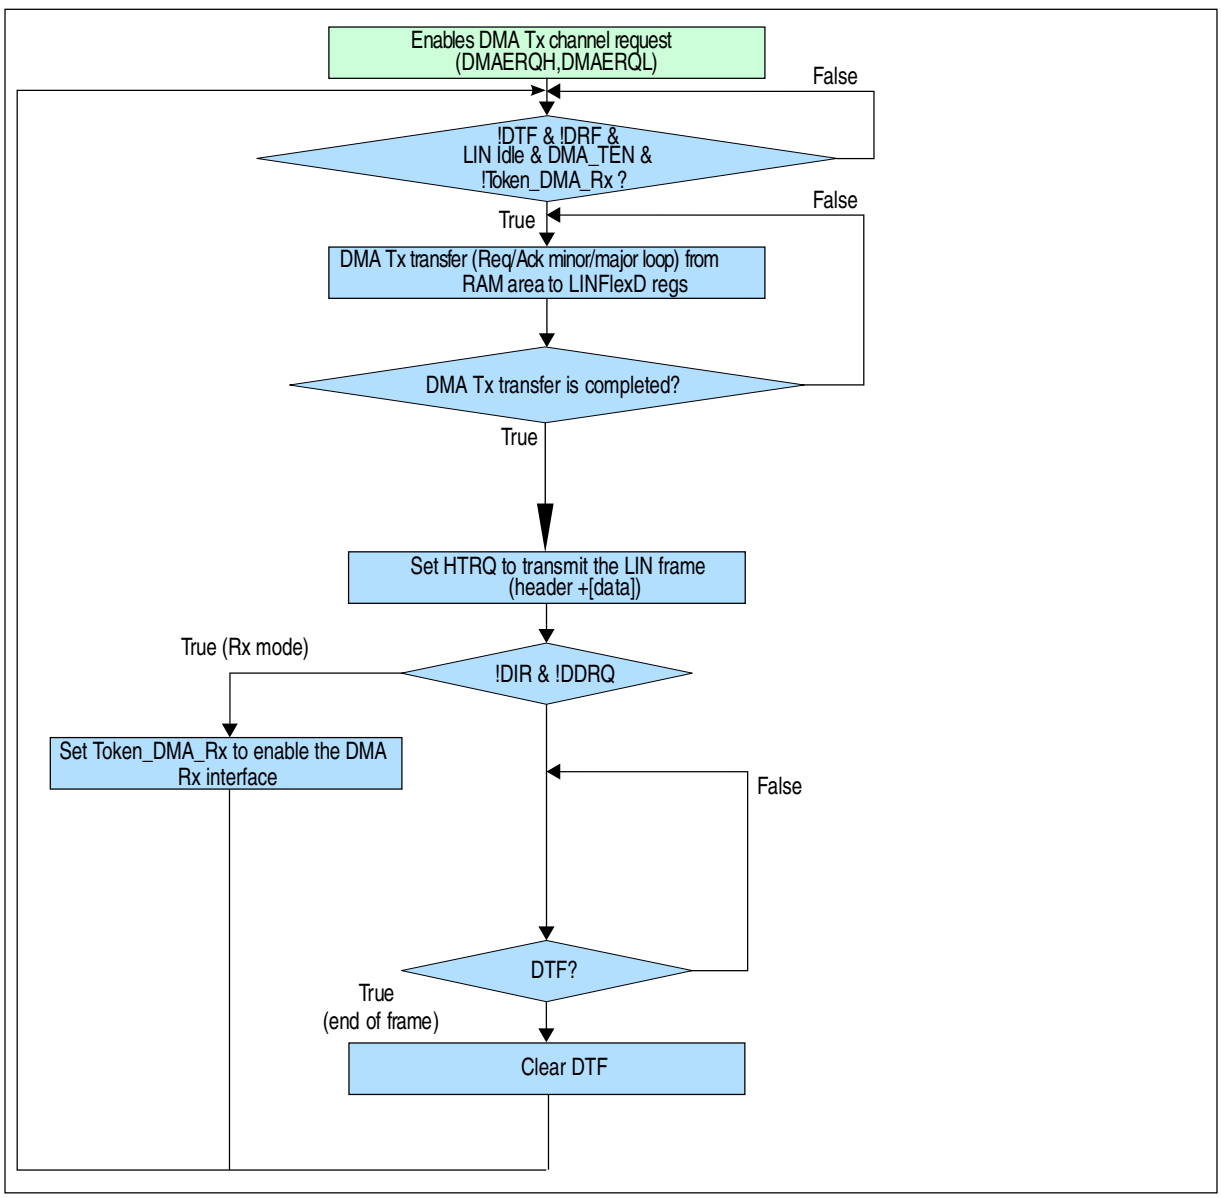

Figure 58-28. Master node – DMA Tx FSM (concept scheme)

58.4.5.4 Master node - RX mode

On a master node in RX mode, the DMA interface requires a single RX channel. Each TCD controls a single frame . The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in the following figure.

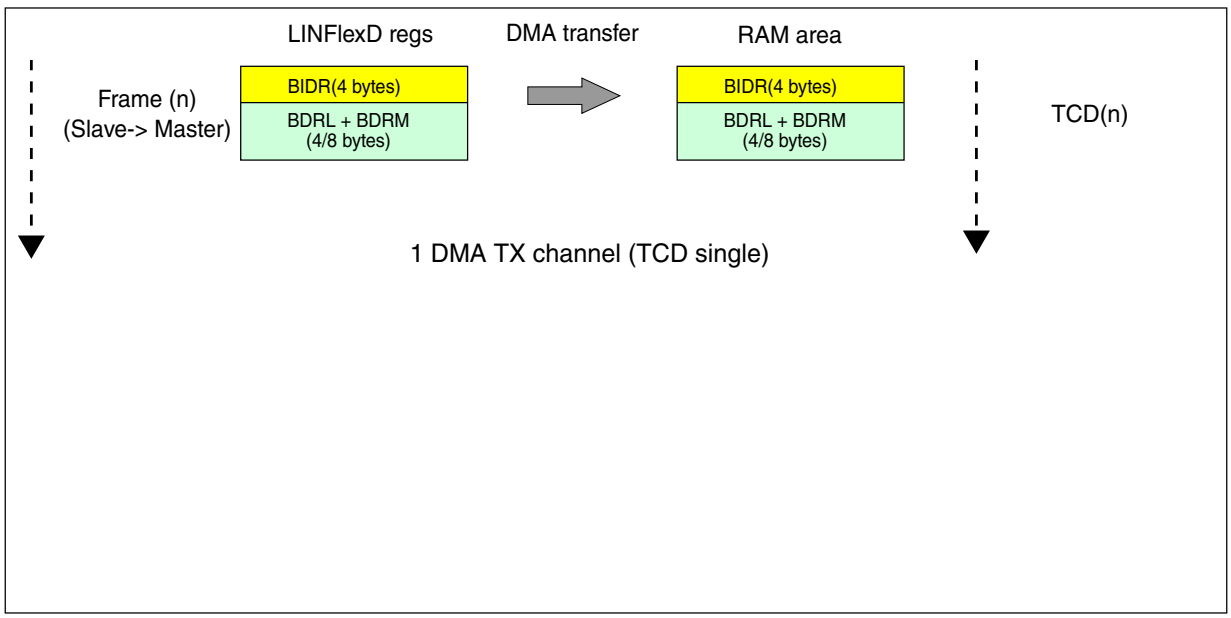

Figure 58-29. Master node – RX memory map

The TCD chain of the DMA Rx channel on a master node supports Slave to Master: reception of the data field of the header

The BIDR register is optionally copied into the RAM area. This BIDR field (part of FIFO data) contains the ID of each message, which only allows the CPU to figure out which ID the LINFlexD DMA received if the single DMA channel setup is used.

The concept FSM to control the DMA Rx interface is given in the following figure. DMA RX FSM moves to Idle state immediately at the next clock edge if DMARXE[0] = 0. The TCD setting (word transfer) is given in the next table. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

Table 58-10. TCD setting – Master node – Rx mode

TCD Field	Value	Description
CITER[14:0]	1	Single iteration for the "major" loop
BITER[14:0]	1	Single iteration for the "major" loop
NBYTES[31:0]	[4] +4/8 = N	Data buffer is stuffed with dummy bytes if the length is not word aligned. BIDR + BDRL + BDRM

Table continues on the next page...

Table 58-10. TCD setting – Master node – Rx mode (continued)

TCD Field	Value	Description

D_REQ	1	Only on the last TCD of the chain
START	0	No SW request

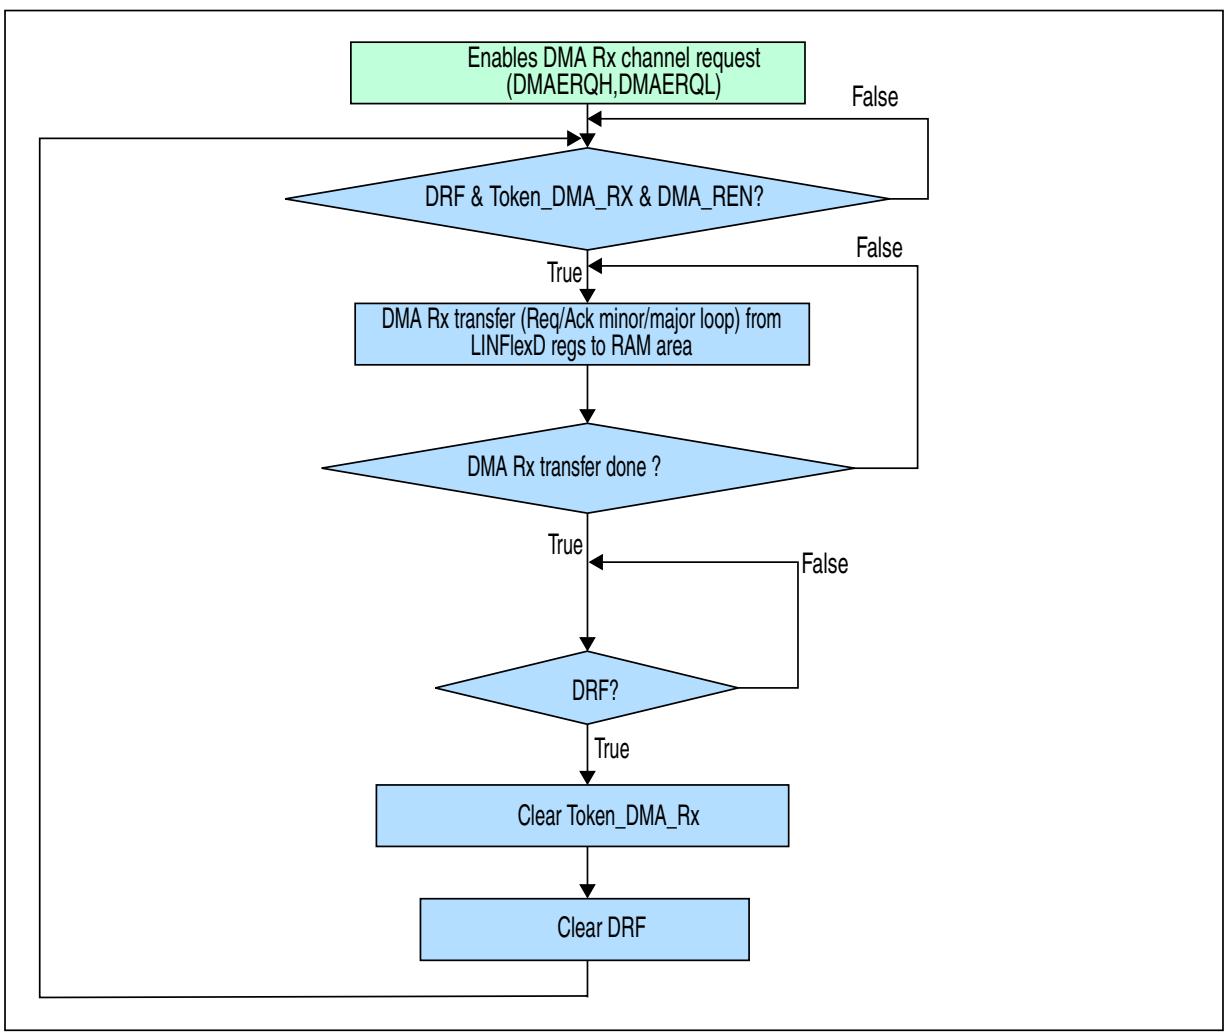

Figure 58-30. Master node – DMA Rx FSM (concept scheme)

58.4.5.5 Slave node – TX mode

On a slave node in TX mode, the DMA interface requires a DMA TX channel for each ID filter programmed in TX mode. In case a single DMA TX channel is available, a single ID field filter must be programmed in TX mode. Each TCD controls a single frame. The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in the following figure.

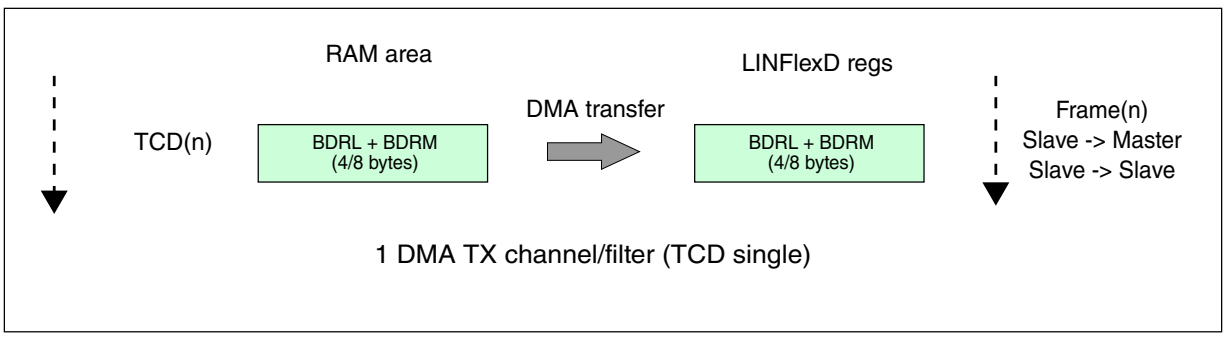

Figure 58-31. Slave node – TX memory map

The TCD chain of the DMA Tx channel on a slave node supports:

- Slave to Master: transmission of the data field
- Slave to Slave: transmission of the data field

The register setting of the LINCR2, IFER, IFMR, and IFCR registers is given in Table 58-11.

Table 58-11. Slave node – Tx mode – Register setting

LIN frame	LINCR2	IFER	IFMR	IFCR
Slave to Master or Slave to Slave	DDRQ = 0 DTRQ = 0 HTRQ = 0	To enable an ID filter (Tx mode) for each DMA TX channel	• Identifier list mode • Identifier mask mode	DFL = payload size ID = address CCS = checksum DIR = 1 (TX)

The concept FSM to control the DMA Tx interface is given in the following figure. DMA TX FSM moves to Idle state if DMATXE[x] = 0 where x = IFMI – 1.The TCD setting (word transfer) is given in Table 58-12. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

Table 58-12. TCD setting – Slave node – Tx mode

TCD Field	Value	Description
CITER[14:0]	1	Single iteration for the "major" loop
BITER[14:0]	1	Single iteration for the "major" loop
NBYTES[31:0]	4/8 = N	Data buffer is stuffed with dummy bytes if the length is not word aligned. BDRL + BDRM
SADDR[31:0]	—	RAM address
SOFF[15:0]	4	Word increment

INT_MAJ	0/1	Interrupt disabled/enabled
D_REQ	1	Only on the last TCD of the chain.
START	0	No SW request

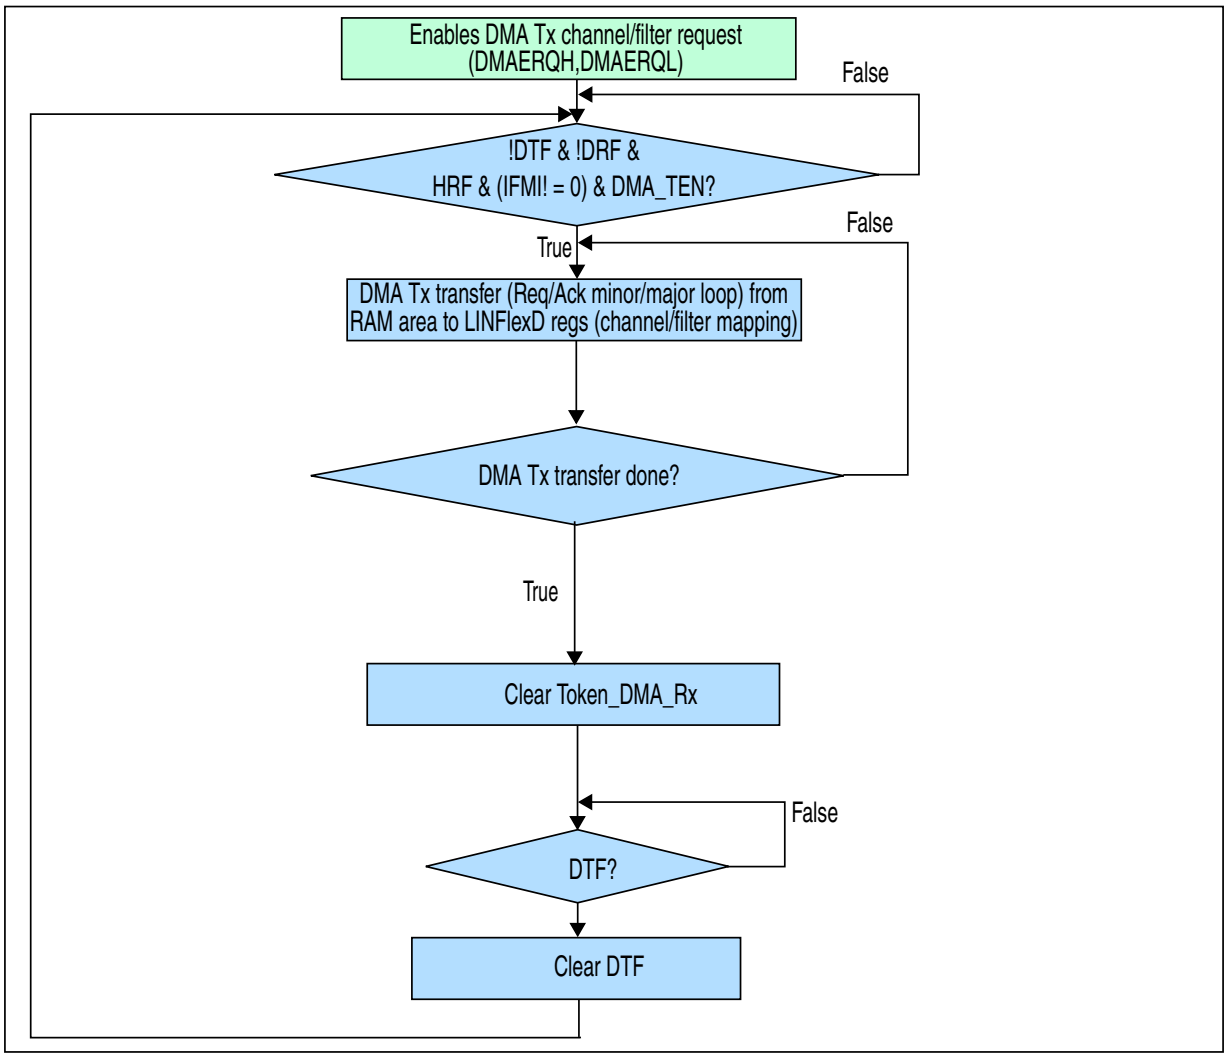

Figure 58-32. Slave node – DMA Tx FSM (concept scheme)

58.4.5.6 Slave node – RX mode

On a slave node in RX mode, the DMA interface requires a DMA RX channel for each ID filter programmed in RX mode. In case a single DMA RX channel is available, a single ID field filter must be programmed in RX mode. Each TCD controls a single frame. The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in the following figure.

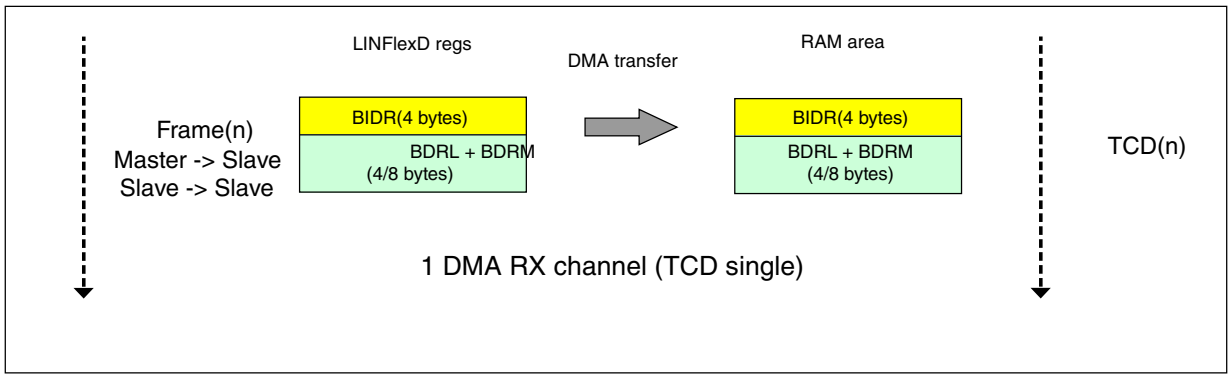

Figure 58-33. Slave node – RX memory map

The TCD chain of the DMA Rx channel on a slave node supports:

- Master to Slave: reception of the data field
- Slave to Slave: reception of the data field

The register setting of the LINCR2, IFER, IFMR, IFCR registers is given in Table 58-13.

Table 58-13. Slave node – Rx mode – Register setting

LIN frame	LINCR2	IFER	IFMR	IFCR
Master to Slave or Slave to Slave	DDRQ = 0 DTRQ = 0 HTRQ = 0	To enable an ID filter (Rx mode) for each DMA RX channel	• Identifier list mode • Identifier mask mode	DFL = payload size ID = address CCS = checksum DIR = 0 (RX)

The concept FSM to control the DMA Rx interface is given in the following figure. DMA Rx FSM moves to Idle state if DMARXE[x] = 0 where x = IFMI – 1. The TCD setting (word transfer) is given in Table 58-14. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

Table 58-14. TCD setting – Slave node – Rx mode

TCD Field	Value	Description
CITER[14:0]	1	Single iteration for the "major" loop
BITER[14:0]	1	Single iteration for the "major" loop

D_REQ	1	Only on the last TCD of the chain.
START	0	No SW request

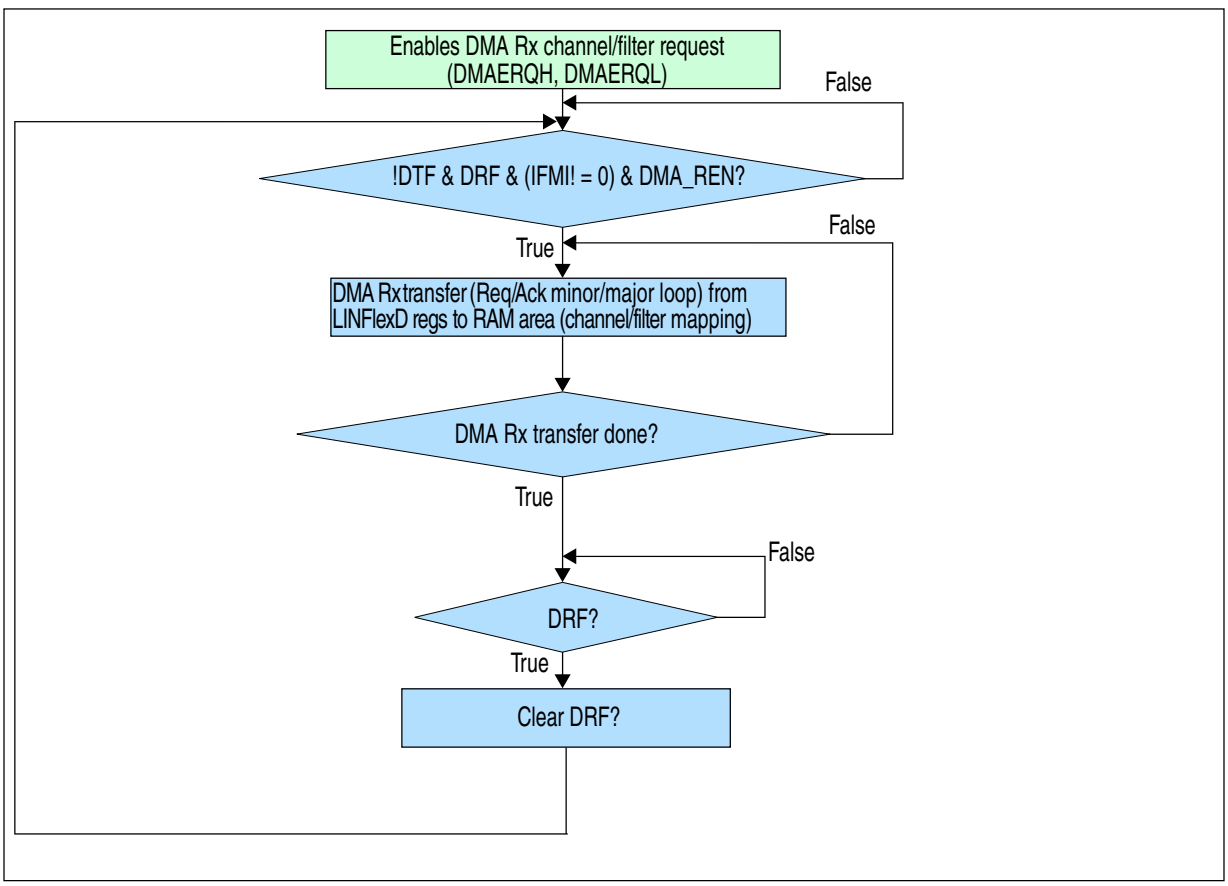

Figure 58-34. Slave node – DMA Rx FSM (concept scheme)

58.4.5.7 UART – TX mode

In UART TX mode, the DMA interface requires a DMA TX channel. A single TCD can control the transmission of an entire Tx buffer. The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in Figure 58-35.

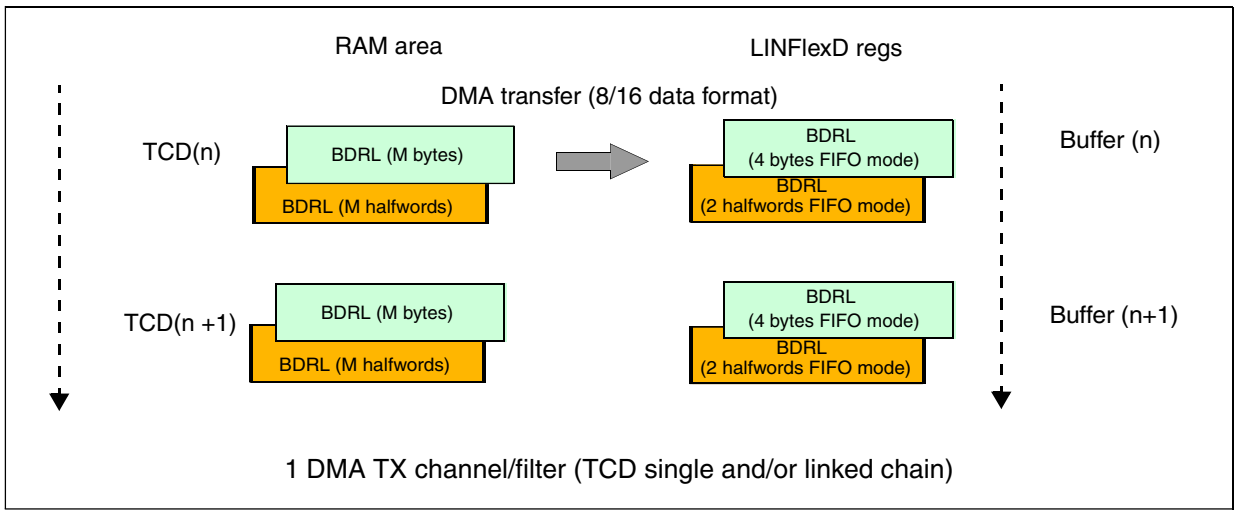

Figure 58-35. UART – TX memory map

The UART TX buffer must be configured in FIFO mode in order to:

- Allow the transfer of large data buffer by a single TCD
- Absorb the latency, following a DMA request (due to the DMA arbitration), to move data from the RAM to the FIFO
- Use low priority DMA channels

The Tx FIFO size is:

- 4 bytes in 8 bit data format
- 2 halfwords in 16-bit data format

A DMA request is triggered by FIFO-not-full (TX) status signals.

The concept FSM to control the DMA Tx interface is given in Figure 58-36. DMA Tx FSM will move to Idle state if DMATXE[0] = 0.The TCD setting (typical case) is given in Table 58-15. All other TCD fields = 0. The minor loop transfers a single byte/halfword as soon as a free entry is available in the Tx FIFO.

Table 58-15. TCD setting – UART – Tx mode

TCD Field	Value		Description
	8 bits data	16 bits data	
CITER[14:0]	M		Multiple iterations for the "major" loop
BITER[14:0]	M		Multiple iterations for the "major" loop
NBYTES[31:0]	1	2	Minor loop transfer = 1 or 2 bytes
SADDR[31:0]	-		RAM address

Table continues on the next page...

Table 58-15. TCD setting – UART – Tx mode (continued)

TCD Field	Value		Description
	8 bits data	16 bits data	
SOFF[15:0]	1	2	Byte/Half-word increment
SSIZE[2:0]	0	1	Byte/Half-word transfer
SLAST[31:0]	–M	–M × 2	-
DADDR[31:0]	-		BDRL address
DOFF[15:0]	0		No increment (FIFO)
DSIZE[2:0]	0	1	Byte/Half-word transfer
DLAST_SGA[31:0]	0		No scatter/gather processing
INT_MAJ	0/1		Interrupt disabled/enabled
D_REQ	1		Only on the last TCD of the chain.
START	0		No SW request

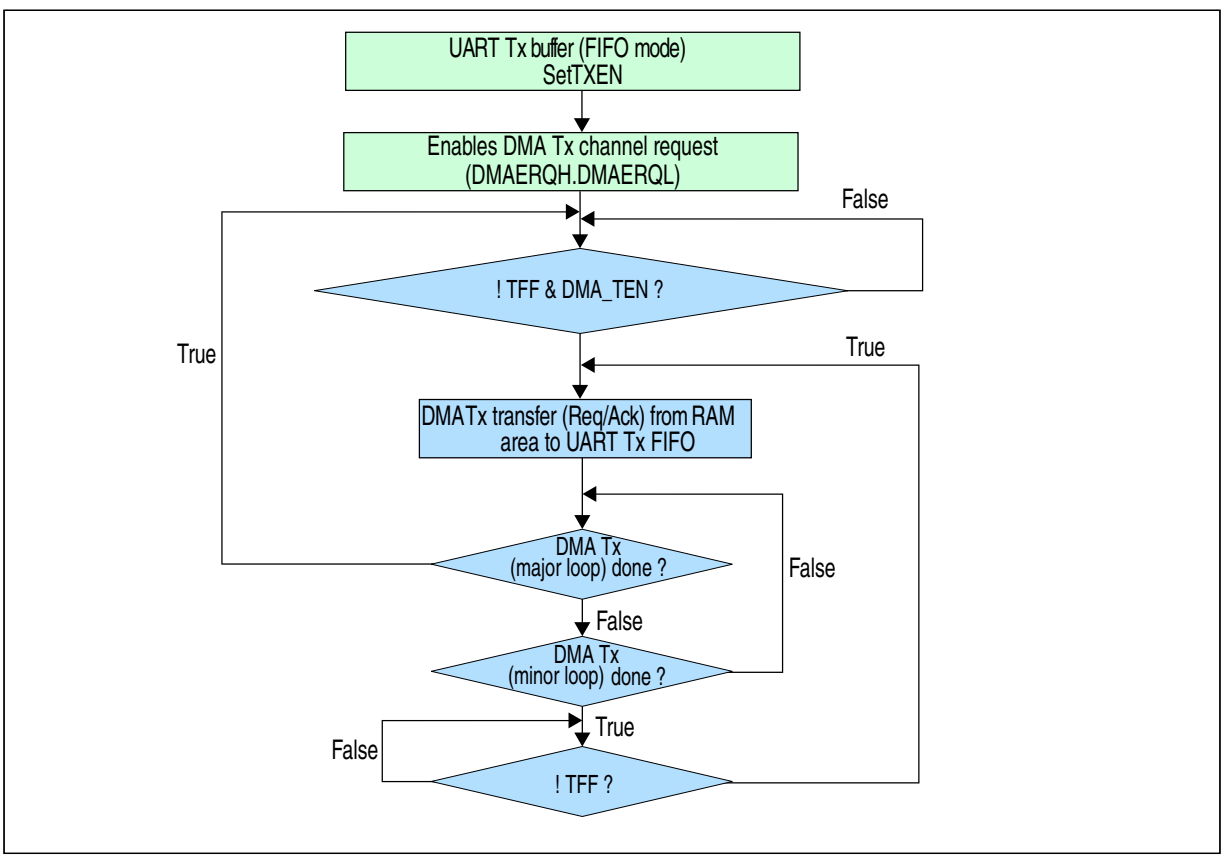

Figure 58-36. UART – DMA Tx FSM (concept scheme)

58.4.5.8 UART – RX mode

In UART RX mode, the DMA interface requires a DMA RX channel. A single TCD can control the reception of an entire Rx buffer. The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in Table 58-16.

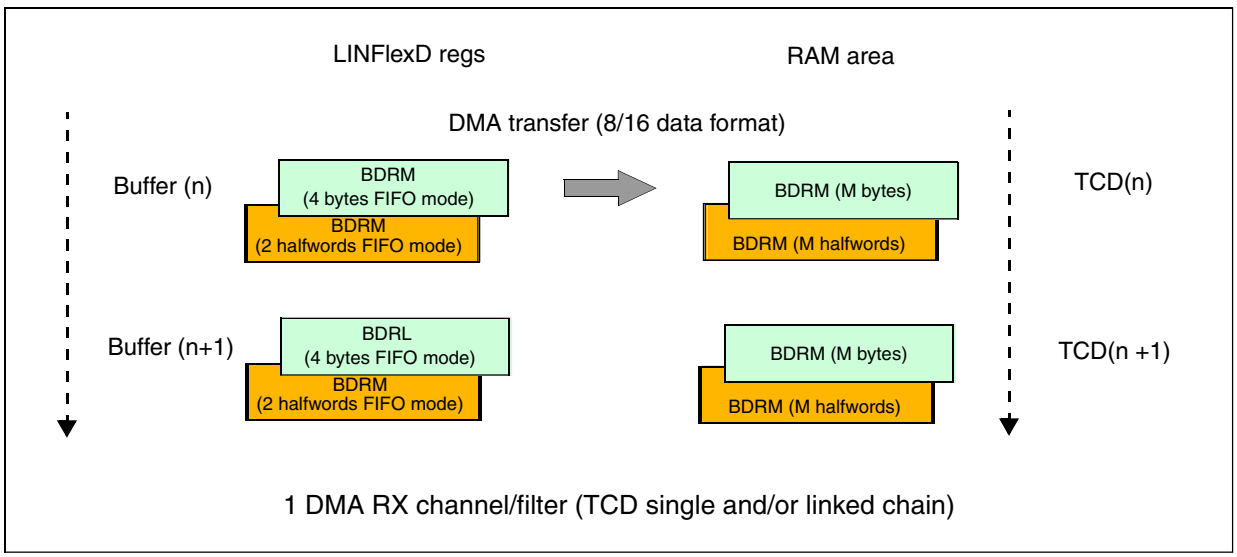

Figure 58-37. UART – RX memory map

The UART RX buffer must be configured in FIFO mode in order to:

- Allow the transfer of large data buffer by a single TCD
- Absorb the latency, following a DMA request (due to the DMA arbitration), to move data from the FIFO to the RAM
- Use low priority DMA channels

The Rx FIFO size is:

- 4 bytes in 8-bit data format

This will sufficient because just one byte allows a reaction time of about 3.8 µs (at 2 Mbit/s) (~450 clock cycles at 120 MHz) before the transmission is affected. A DMA request is triggered by FIFO and not by empty (Rx) status signals.

The concept FSM to control the DMA Rx interface is given in Figure 58-38. DMA Rx FSM will move to Idle state if DMARXE[0] = 0.The TCD setting (typical case) is given in the next table. All other TCD fields equal zero. The minor loop transfers a single byte/ halfword as soon an entry is available in the Rx FIFO. A new software reset bit is

required that allows the LINFlexD FSMs to be reset in case this timeout state is reached or in any other case. The timeout counter can be re-written by software at any time to extend the timeout period.

Table 58-16. TCD setting – UART – Rx mode

TCD Field	Value		Description
	8 bits data	16 bits data	
CITER[14:0]	M		Multiple iterations for the "major" loop
BITER[14:0]	M		Multiple iterations for the "major" loop
NBYTES[31:0]	1	2	Minor loop transfer = 1 or 2 bytes
SADDR[31:0]	-		BDRM address
SOFF[15:0]	0		No increment (FIFO)
SSIZE[2:0]	0	1	Byte/Half-word transfer
SLAST[31:0]	0		
DADDR[31:0]	-		RAM address
DOFF[15:0]	1	2	Byte/Half-word increment
DSIZE[2:0]	0	1	Byte/Half-word transfer
DLAST_SGA[31:0]	–M	–M × 2	No scatter/gather processing
INT_MAJ	0/1		Interrupt disabled/enabled
D_REQ	1		Only on the last TCD of the chain.
START	0		No SW request

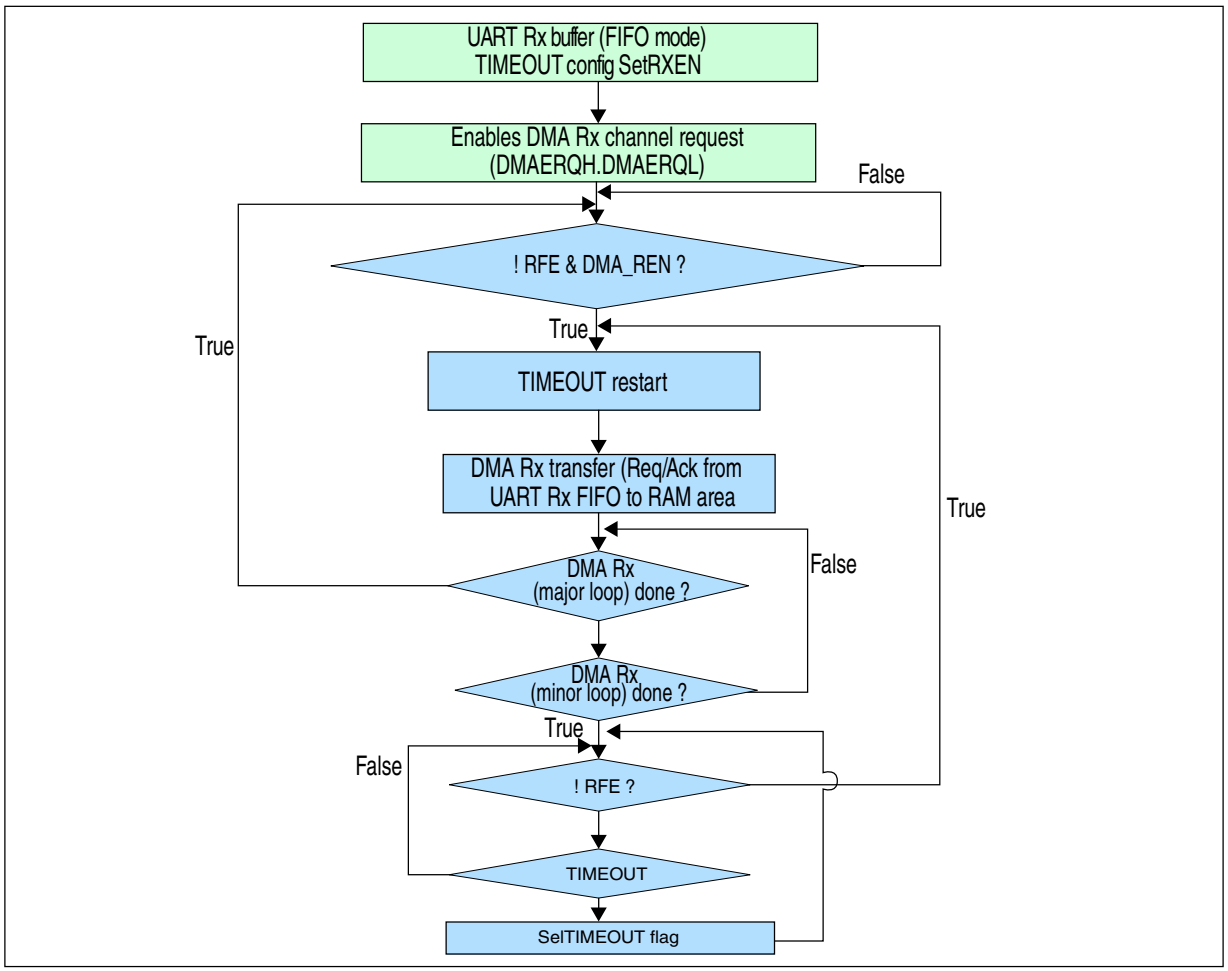

Figure 58-38. UART – DMA Rx FSM (concept scheme)

58.4.5.9 Use cases and limitations

- In LIN slave mode, the DMA capability can be used only if the ID filtering mode is activated. The number of ID filters enabled must be equal to the number of DMA channels enabled. The correspondence between channel number and ID filter is based on IFMI (identifier filter match index)
- In LIN master mode both the DMA channels (TX and RX) must be enabled in case the DMA capability is required
- In UART mode the DMA capability can be used only if the UART Tx/Rx buffers are configured as FIFOs
- DMA and CPU operating modes are mutually exclusive for the data/frame transfer on a UART or LIN node. Once a DMA transfer is finished the CPU can manage subsequent accesses

- Error management must always be executed via the CPU enabling the related error interrupt sources. DMA capability does not provide support for error management. Error management means checking status bits, handling IRQs, and potentially canceling DMA transfers
- The DMA programming model must be coherent with the TCD setting defined in this document
- When IPG_STOP is requested, SW has to first disable DMATXE/DMARXE channel registers, after the current minor loop finishes (indicated by the clearing of ACTIVE bit in DMA TCD register). This ensures that IPG_STOP_ACK is generated and IP enters STOP mode.

58.5 Memory map and register description

The following points should be considered for the below mentioned LINFlexD registers:

- Reset values are with-slave/without-slave (master only) format
- If not specified, then the bit can be configured for both master only and master/slave format; in other words, for both values of (generic) slave = 0 and (generic) slave = 1.

NOTE

In Master mode, the registers IFCR0-IFCR15 are not present and the corresponding absolute address of the below register changes as shown in the following table.

Table 58-17. Offsets of the register from offsets 8C to 9C

Register name	Master/slave mode	Master only mode
LINFlexD_GCR	0x8C	0x4C
LINFlexD_UARTPTO	0x90	0x50
LINFlexD_UARTCTO	0x94	0x54
LINFlexD_DMATXE	0x98	0x58
LINFlexD_DMARXE	0x9C	0x5C

NOTE

In Master Mode, read access to IFMI register and read/write access to IFER and IFMR registers would result in transfer error.

NOTE

Any access to A0 location will not generate a transfer error.

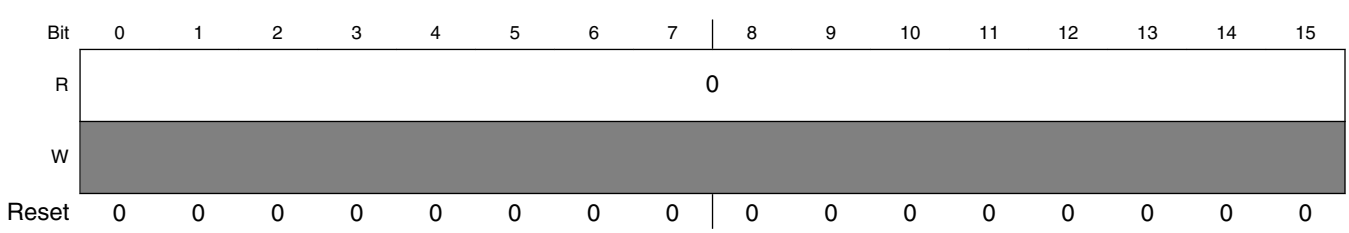
58.5.1 LIN Control Register 1 (LINFlexD_LINCR1)

LINCR1 consists of control bits used to configure features of the LINFlexD.

NOTE

When accessing the LINCR1 register, each reserved bit should be written to its original reset value.

Address: 0h base + 0h offset = 0h



Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	CCD	CFD	LASE	AUTOWU	MBL				BF	Reserved	LBKM	MME	SSBL	RBLM	SLEEP	INIT
Reset	0	0	0	0	0	0	0	0	1	0	0	*	0	0	1	0

* Notes:
- MME field: If slave = 0, then MME bit is 1, else MME bit is 0

LINFlexD_LINCR1 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 CCD	Checksum Calculation disable This bit can be written during Initialization mode only. It is read-only in Normal mode. Register bit can be read in any mode, written only in initialization mode. 0 Checksum calculation is done by hardware. When this bit is reset the LINCFR register is read only. 1 Checksum calculation is disabled. When this bit is set the LINCFR register is read/write. User can program this register to sent a software calculated checksum/CRC (provided CFD is reset).
17 CFD	Checksum field disable This bit can be configured during Initialization mode only. It is read-only in Normal mode. Register bit can be read in any mode, written only in initialization mode. 0 Checksum field is sent after the required number of data bytes are sent 1 No checksum field is sent in the frame
18 LASE	LIN Autosynchronization Enable This bit can be programmed in Initialization mode only. It is read-only in Normal mode. (Note: If generic auto_sync = 0, then this bit will always read a 0). Register bit can be read in any mode, written only in initialization mode. 0 Autosynchronization disabled 1 Autosynchronization enabled
19 AUTOWU	Auto Wakeup This bit can be configured during Initialization mode only. This bit is utilized in UART mode also. Register bit can be read in any mode, written only in initialization mode. 0 Sleep bit is cleared by software only 1 Sleep bit gets cleared by hardware whenever WUF bit of LINSR is set
20–23 MBL	Master Break Length These bits choose the length of the Sync break to be generated by the master. These bits can be programmed in Initialization mode only. They are read-only in Normal mode. Register bit can be read in any mode, written only in initialization mode. 0000 10-bit break length

Table continues on the next page...

LINFlexD_LINCR1 field descriptions (continued)

Field	Description
	0001 11-bit break length 0010 12-bit break length 0011 13-bit break length 0100 14-bit break length 0101 15-bit break length 0110 16-bit break length 0111 17-bit break length 1000 18-bit break length 1001 19-bit break length 1010 20-bit break length 1011 21-bit break length 1100 22-bit break length 1101 23-bit break length 1110 36-bit (cooling) break length 1111 50-bit break length
24 BF	By-pass filter This bit can be programmed during Initialization mode only. **NOTE:** If generic slave = 0 or no_of_filters = 0, then this bit will always read a 1, and cannot be programmed. Register bit can be read in any mode, written only in initialization mode. 0 No IRQ if ID does not match any filter 1 A RX IRQ is generated on ID not matching any filter
25 Reserved	This field is reserved. When accessing the LINCR1 register, each reserved bit should be written to its original reset value.
26 LBKM	Loop Back mode Refer to "Loop back mode" in Test mode . Note that this bit can be programmed only in Initialization mode. This bit is utilized in UART mode also. Register bit can be read in any mode, written only in initialization mode. 0 Loop Back Mode disabled 1 Loop Back mode enabled
27 MME	Master mode enable This bit can be programmed in Initialization mode only. It is read-only in Normal mode. **NOTE:** If generic slave = 0, then this bit will read a '1' always, and cannot be programmed. Register bit can be read in any mode, written only in initialization mode. 0 Slave Mode 1 Master Mode
28 SSBL	Slave Mode Sync Break Length This bit can be programmed in Initialization mode only. It is read only in Normal mode. Register bit can be read in any mode, written only in initialization mode. 0 11 bit break length 1 10 bit break length

Table continues on the next page...

LINFlexD_LINCR1 field descriptions (continued)

Field	Description
29 RBLM	Receiver Buffer Locked mode This bit can be programmed in Initialization mode only. It is read-only in Normal mode. This bit is utilized in UART mode also. Register bit can be read in any mode, written only in initialization mode. 0 Receiver Buffer not locked, next incoming message will overwrite the old one 1 Receiver buffer locked against overrun. Once the buffer is full the next incoming message will be discarded if buffer is not released — in other words, RMB is not reset by software.
30 SLEEP	Sleep Mode Request This bit is set by software to request LINFlexD to enter Sleep mode. This bit is cleared by software or hardware (if AUTOWU bit in LINCR1 and WUF bit in LINSR are set) to exit sleep mode. This bit is utilized in UART mode also.
31 INIT	Initialization Mode Request The software sets this bit to switch the hardware into Initialization mode. On clearing this bit (and if SLEEP bit is also zero) LINFlexD enters normal mode. This bit is utilized in UART mode also.

58.5.2 LIN Interrupt enable register (LINFlexD_LINIER)

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

LINFlexD_LINIER field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 SZIE	Stuck at zero Interrupt Enable An interrupt is generated if this bit is set and the Stuck at Zero Flag (SZF) in LINESR or UARTSR is set.

Table continues on the next page...

LINFlexD_LINIER field descriptions (continued)

Field	Description
	0 No interrupt 1 Interrupt enabled
17 OCIE	Output Compare Interrupt Enable 0 No interrupt 1 Interrupt generated when OCF bit in LINESR or UARTSR is set
18 BEIE	Bit Error Interrupt Enable 0 No interrupt 1 Interrupt generated when BEF bit in LINESR is set
19 CEIE	Checksum Error Interrupt Enable An interrupt is generated if this bit is set and the Checksum Error Flag (CEF) is set in LINESR. 0 No interrupt 1 Interrupt enabled
20 HEIE	Header Error Interrupt Enable An interrupt is generated when this bit is set and either of the following flags are set SFEF, SDEF, IDPEF in LINESR are set. **NOTE:** If generic slave = 0, then this bit will always read a 0 and cannot be programmed. 0 No interrupt 1 Interrupt enabled
21–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 FEIE	Frame Error Interrupt Enable 0 No interrupt 1 Interrupt generated if Frame Error Flag (FEF) bit is set in LINESR or UARTSR
24 BOIE	Buffer Overrun Error Interrupt Enable An interrupt is generated if this bit is set and the Buffer Overrun Flag (BOF) is set in LINESR or UARTSR. 0 No interrupt 1 Interrupt enabled
25 LSIE	LIN state Interrupt enable Interrupt is generated only when entering the above fields. This interrupt can mainly be used for debugging purposes. The interrupt has no status flag. 0 No interrupt 1 Interrupt generated on entering the following states: Sync Del, Sync Field, Identifier field, Checksum
26 WUIE	Wakeup interrupt enable If this bit is set and the WUF in LINSR or UARTSR is set then an interrupt is generated. 0 No interrupt 1 Interrupt enabled
27 Reserved	This field is reserved.

Table continues on the next page...

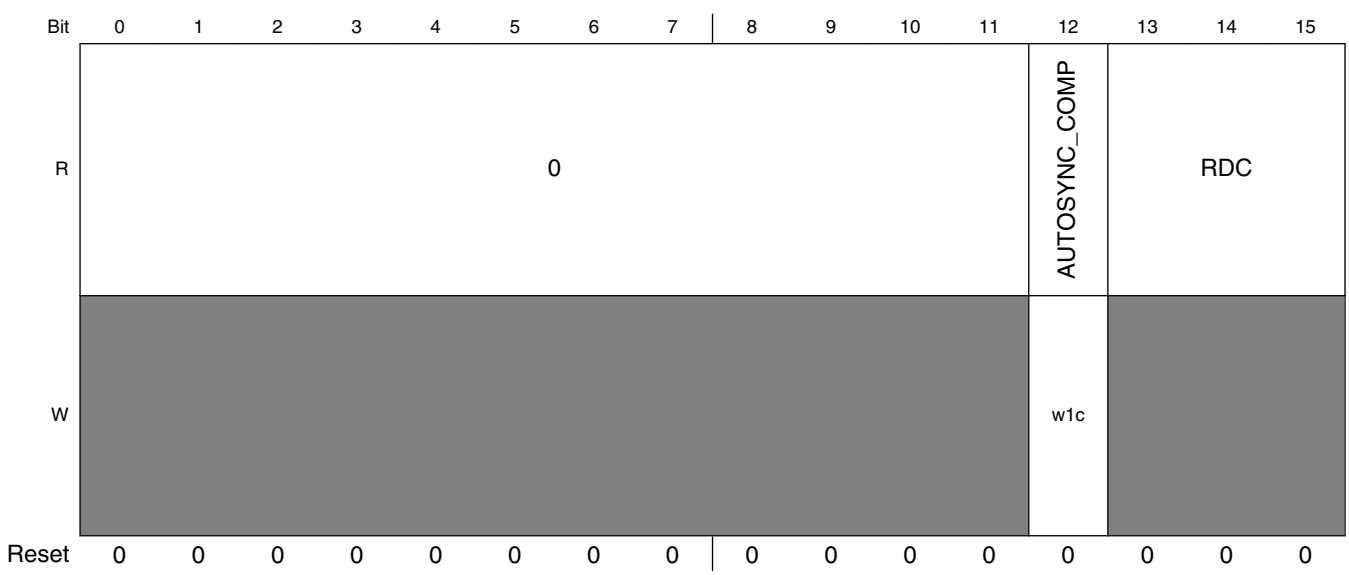
LINFlexD_LINIER field descriptions (continued)

Field	Description
28 TOIE	Timeout Interrupt Enable An interrupt is generated if this bit is set and UARTSR[TO] status bit is set (in UART mode). 0 No interrupt 1 Interrupt enabled
29 DRIE	Data Reception complete Interrupt enable An interrupt is generated when this bit is set and Data Received flag (DRF) in LINSR or UARTSR is set. 0 No interrupt 1 Interrupt enabled
30 DTIE	Data Transmitted Interrupt enable An interrupt is generated when this bit is set and Data Transmitted flag (DTF) in LINSR or UARTSR is set. 0 No interrupt 1 Interrupt enabled
31 HRIE	Header Received Interrupt An interrupt is generated when this bit is set and the Header Received flag (HRF) in LINSR is set. **NOTE:** If generic slave = 0, then this bit will always read a 0, and cannot be programmed. 0 No interrupt 1 Interrupt enabled

58.5.3 LIN Status Register (LINFlexD_LINSR)

This register consists of status bits indicating the state of the LINFlexD hardware.

Address: 0h base + 8h offset = 8h



Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	LINS				0		RMB	DRBNE	RXbusy	RDI	WUF	0		DRF	DTF	HRF
W	1						w1c	w1c			w1c			w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0	0	*	0	0	0	0	0	0

* Notes:
- RDI field: Reset value of RDI reflects the RX pin state

LINFlexD_LINSR field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 AUTOSYNC_ COMP	AUTOSYNC_COMP This bit is set after autosynchronization is complete and when the LASE bit in LINCR1 register is enabled. Only after this bit is set, the contents of LINIBRR and LINFBRR registers can be read in autosynchronization mode. **NOTE:** If autosynchronization is disabled, this bit is reserved.
13–15 RDC	Receive Data Byte Count RDC contains the number of entries (bytes) in the Receive data buffer in LIN mode. RDCx is a read-only field available for debug purposes. 000 1 byte 001 2 bytes 010 3 bytes 011 4 bytes 100 5 bytes 101 6 bytes 110 7 bytes 111 8 bytes

Table continues on the next page...

LINFlexD_LINSR field descriptions (continued)

Field	Description
16–19 LINS	LIN state In UART mode Idle, Init, Sleep, and Data Transmission/Reception states are flagged by the LIN status bits. **NOTE:** The value of this bit field doesn't change by any write operation to it. Writing 0xF to this bit field clears the Rx interrupt, only when set due to the LIN state event. 0000 Sleep mode: LINFlexD is in Sleep mode, to save power consumption. 0001 Init mode: LINFlexD is in Initialization mode. 0010 Idle mode: This mode is entered when: SLEEP bit and INIT bit are reset by software; Wakeup pulse has been received on RX pin (AUTOWU set); Previous frame transmission/reception has been completed/aborted 0011 Sync break: In slave mode, a falling edge followed by a dominant state has been detected. Receiving sync break. In slave mode, a falling edge followed by a dominant state has been detected. Receiving sync break. In master mode, sync break transmission ongoing. Note: In slave mode upon any error LIN state could be either Idle or Rec Break, depending on last bit detected on LIN_RX. If last bit detected is dominant then Rec_Break, otherwise Idle. 0100 Sync Del: In Slave mode, valid Sync break has been detected (10 bit or 11 bit). Waiting for a rising edge. In Master mode, Sync break transmission has been completed, sync delimiter transmission is ongoing. 0101 Sync Field: In Slave mode, a valid sync Del has been detected (recessive state for at least one bit time). Receiving sync field. In Master mode, sync field transmission ongoing. 0110 Identifier Field: In Slave mode, a valid sync field has been received. Receiving ID field. In Master mode, identifier transmission is ongoing. 0111 Header Reception/Transmission: In Slave mode, a valid header has been received and Identifier field is available in the BIDR. In Master mode, header transmitted. 1000 Data Reception/Data Transmission: In Receiver mode, reception ongoing. In Transmitter mode, response transmission ongoing. 1001 Checksum: Data transmission/reception completed, checksum transmission/reception ongoing.
20–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 RMB	Release Message Buffer 0 Buffer data is free. Reset by hardware in when in Initialization mode 1 Buffer data ready to be read by software. This bit should be cleared by software after reading the data received in the buffer.
23 DRBNE	Data Reception Buffer Not Empty Flag This bit is set by hardware as soon as the first byte of response has been received and stored in BDRL (when there is at least one data byte in reception buffer). Software should clear it after reading all the buffers. This bit is also reset by hardware in Initialization mode. This flag could be checked by software in case of a response timeout event.
24 RXbusy	Receiver Busy flag In Slave mode after header reception, if DIR bit is reset and reception starts, then this bit is set. In this case user cannot set the DTRQ bit. 0 Receiver is idle 1 Reception ongoing

Table continues on the next page...

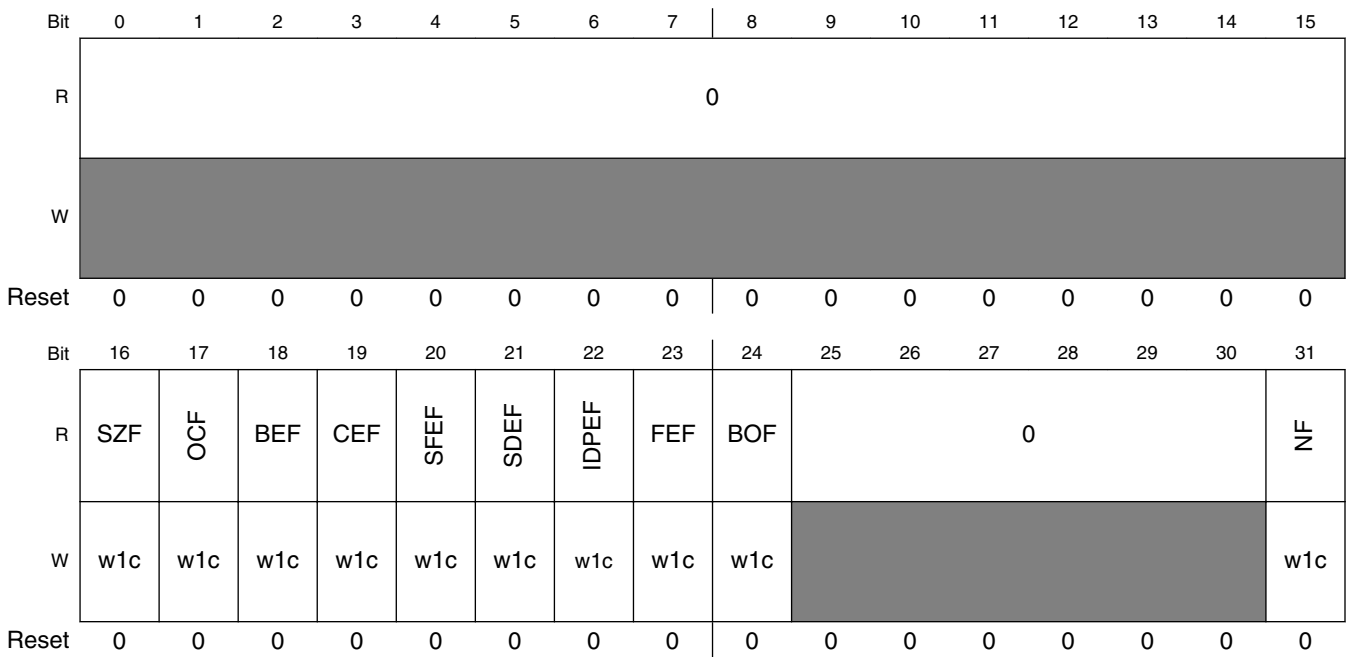
LINFlexD_LINSR field descriptions (continued)

Field	Description
25 RDI	LIN Receive signal This bit reflects the current status of the Rx pin. **NOTE:** After reset is released, RDI reflects the actual value of Rx pin.
26 WUF	Wakeup flag This bit is set by hardware when a falling edge is detected on the Rx pin. 1. When slave is in Sleep mode 2. When master is in Sleep mode or Idle mode It can be cleared by software. It gets reset by hardware in Initialization mode.
27–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29 DRF	Data Reception Completed flag This bit is set by hardware and indicates that data reception has been completed. This flag should be cleared by software. This bit is also reset by hardware in Initialization mode. **NOTE:** In case framing error or checksum error occurs then this flag is not set.
30 DTF	Data Transmission Completed flag This bit is set by hardware and indicates that data transmission is completed. This flag should be cleared by software. This bit is also reset by hardware in Initialization mode. **NOTE:** For LIN mode, in case a bit error occurs (and IOBE is 1) then this flag is not set.
31 HRF	Header Received flag This bit is set when the header reception is completed. It should be cleared by software. This bit is set only when: a) All filters are inactive and Bypass filter (BF) bit is set b) No match in any filter and Bypass filter (BF) bit is set c) TX filter match At end of frame or frame aborted, if HRF is still set, it gets reset by hardware. This bit is also reset by hardware in Initialization mode. **NOTE:** If generic slave = 0, then this bit will always read a 0, and cannot be programmed.

58.5.4 LIN Error Status Register (LINFlexD_LINESR)

Refer to Errors for detailed description of all errors.

Address: 0h base + Ch offset = Ch



LINFlexD_LINESR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 SZF	Stuck at Zero flag This bit is set when there is a stuck-at-zero timeout error. It should be reset by software.
17 OCF	Output Compare Flag 0: No output compare event occurred 1: In master mode, LINESR[OCF] flag is set when counter LINTCSR[CNT] has matched the content of LINOCR[OC2]. In slave mode, LINESR[OCF] is set when the content of the counter LINTCSR[CNT] has matched the content of LINOCR[OC1] or LINOCR[OC2]. This bit should be cleared by software. If this bit is set, MODE bit in LINTCSR is cleared, and the IOT bit of LINTCSR is set, then LINFlexD moves to Idle state. If the MODE bit in LINTCSR is clear, then OCF gets reset by hardware in Initialization mode; if the MODE bit is set, then OCF maintains its status irrespective of the LIN state.
18 BEF	Bit Error flag This bit is set by hardware when there is a bit error. It should be cleared by software. Reset by hardware in Initialization mode.

Table continues on the next page...

LINFlexD_LINESR field descriptions (continued)

Field	Description
19 CEF	Checksum Error flag This bit is set by hardware if the received checksum does not match the hardware-calculated checksum. It should be cleared by software. This error will never occur if CCD or CFD bit of LINCR1 is set. Reset by hardware in Initialization mode.
20 SFEF	Sync Field Error flag This bit is set by hardware when the received Sync Field is inconsistent. It should be cleared by software. Reset by hardware in Initialization mode. If generic slave = 0, then this bit will always read a 0, and cannot be programmed.
21 SDEF	Sync Delimiter Error flag This bit is set by hardware when the delimiter is too short (in other words, less than one bit time). It should be cleared by software. Reset by hardware in Initialization mode. **NOTE:** If generic slave = 0, then this bit will always read a 0, and cannot be programmed.
22 IDPEF	ID Parity Error flag This bit is set by hardware when there is an error in the ID parity. It should be cleared by software. **NOTE:** Header Error Interrupt is triggered for SFEF or SDEF or IDPEF flag is set and HEIE is set. If generic slave = 0, then this bit will always read a 0, and cannot be programmed. For generic slave = 1,this bit is reset by hardware in Initialization mode.
23 FEF	Framing Error flag This bit is set by hardware when there is a framing error (invalid stop bit). It should be cleared by software. Reset by hardware in initialization mode.
24 BOF	Buffer overrun flag This bit is set by hardware when there is a new byte received and RMB bit is not cleared. It can be cleared by software. Reset by hardware in initialization mode.
25–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 NF	Noise flag This bit is set by hardware when noise is detected in the received character. It should be cleared by software. Reset by hardware in Initialization mode.

58.5.5 UART Mode Control Register (LINFlexD_UARTCR)

NOTE

When accessing the UARTCR register, reserved bits should always be written to zero.

NOTE

- The LINFlexD module in UART mode does not support communication with Special Word Length (UARTCR[WLS] = 1) in buffer mode.
- The LINFlexD module in UART mode supports communication with Special Word Length (UARTCR[WLS] = 1) in FIFO mode only with UARTCR[WL1, WL0] = 1,1.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	MIS	CSP			OSR				ROSE	NEF			DTU_PCETX	SBUR		WLS
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	TDFL_TFC			RDFL_RFC			RFBM	TFBM	WL1	PC1	RxEn	TxEn	PC0	PCE	WL0	UART
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LINFlexD_UARTCR field descriptions

Field	Description
0 MIS	Monitor Idle State Register bit can be read in any mode, written only in initialization mode. 0 UARTCTO monitors the number of bits to be received. 1 UARTCTO monitors the idle state of the reception line.
1–3 CSP	Configurable Sample Point (i) These bits will decide the sample point during reduced over sampling. CSP can take the following range of values for a certain over sampling rate: **OSR / CSP** 4 / 2,3 5 / 2, 3, 4 6 / 3, 4, 5 8 / NA Register bit can be read in any mode, written only in initialization mode.

Table continues on the next page...

LINFlexD_UARTCR field descriptions (continued)

Field	Description
4–7 OSR	Over Sampling Rate These bits are programmable by the user to configure the number of samples taken for a bit when reduced over sampling is enabled. Allowed values are: 4, 5, 6 and 84 and 8 . Register bit can be read in any mode, written only in initialization mode.
8 ROSE	Reduced Over Sampling EnableRegister bit can be read in any mode, written only in initialization mode. 0 Each bit is over sampled sixteen times. 1 OSR bits decide the over sampling rate.
9–11 NEF	Number of expected frame These bits are used to configure the number of expected frames in UART reception mode. If the DTU bit is set, then the UART timeout counter will be reset after the configured number of frames have been received. Register bit can be read in any mode, written only in Initialization mode. Register bit is a read/write field.
12 DTU_PCETX	Disable Timeout in UART mode This bit can be programmed in Initialization mode only when the UART bit is set. There is an internal counter that gives the number of frames received. **In Buffer mode:** This timer gets reset whenever the number of bytes received (rec_byte_cnt) is equal to RDFL. At this point the DRF bit is also set and num_of_frames (number of frames received), rec_byte_cnt are reset. When num_of_frames equals NEF, Disable Timeout is generated. But this clears num_of_frames also. Thus the timer restarts again. The value of counter is 0 when it restarts. **In FIFO mode:** When num_of_frames equals NEF, Disable Timeout is generated which clears num_of_frames and causes the timer to restart again. The value of counter is 0 when it restarts. Notes: • Disable Timeout causes only the Timer to restart which enables Timeout again. • Timer reset means it resets and starts counting again and the Timeout is enabled. 0 Timeout has to be handled by software 1 Timeout in UART mode is disabled after the configured number of data frames are received
13–14 SBUR	Stop bits in UART reception mode When the UART is used for transmission and reception we have to set the same number of stop bits in GCR and SBUR. When the UART is used only as receiver, it is enough to set SBUR bits only. This bit can be programmed in the initialization mode only, when the UART bit is set. Register bit can be read in any mode, written only in Initialization mode. 00 1 stop bit 01 2 stop bits 10 3 stop bits 11 reserved
15 WLS	Special Word Length in UART mode

Table continues on the next page...

LINFlexD_UARTCR field descriptions (continued)

Field	Description
	This bit can be programmed in initialization mode only when the UART bit is set. If this bit is set, setting WL and PCE bits has no effect in UART reception although parity check is enabled by default in this mode and PC0/1 bits can be used to select the parity control. This bit is given the highest priority in UART reception mode. Register bit can be read in any mode, written only in Initialization mode. 0 This bit is disabled. 1 This bit enables 12-bit + parity bit in reception (UART mode) for MSC (Micro Second Channel upstream frame) support.
16–18 TDFL_TFC	Transmitter Data Field Length/TX FIFO Counter TDFL defines the number of bytes to be transmitted in UART buffer mode (TFBM = 0). TDFL is a read/write field. Bit 16 is reserved and not implemented. When the UART data length is configured as halfword (WL = 10 or WL = 11), only the configurations TDFL = x01 or TDFL = x11 are allowed. x00 : 1 byte x01 : 2 bytes x10 : 3 bytes x11 : 4 bytes Register bit is a read/write field. TFC contains the number of entries (bytes) of the Tx FIFO in UART FIFO mode (TFBM = 1). TFCx is a read-only field available for debug purposes. 000 : empty 001 : 1 byte 010 : 2 bytes 011 : 3 bytes 100 : 4 bytes Others : reserved TDFLTFC can be programmed and are significative only when the UART bit is set. Register bit can be read in any mode, written only in Initialization mode. **NOTE:** When a debugger is connected, this counter will decrement if TxFIFO is being read through the debugger. **NOTE:** In case of data path is functioning normally, RFC/TFC counters will be cleared internally by HW.
19–21 RDFL_RFC	Reception Data Field Length /RX FIFO Counter RDFL defines the number of bytes to be received in UART buffer mode (RFBM = 0). RDFL is a read/write field. Bit 19 is reserved and not implemented. When the UART data length is configured as halfword (WL = 10 or WL = 11), only the configurations RDFL = x01 or RDFL = x11 are allowed. x00 : 1 byte x01 : 2 bytes x10 : 3 bytes x11 : 4 bytes RFC contains the number of entries (bytes) of the Rx FIFO in UART FIFO mode (RFBM = 1). RFCx is a read-only field available for debug purposes. 000 : Empty

Table continues on the next page...

LINFlexD_UARTCR field descriptions (continued)

Field	Description
	001 : 1 byte 010 : 2 bytes/1.5 byte in case of WLS bit setting 011 : 3 bytes 100 : 4 bytes/2x1.5 byte in case of WLS bit setting Others - Reserved RDFLRFC can be programmed and are significative only when the UART bit is set. **NOTE:** In buffer mode, RDFL should be programmed to be greater than or equal to NEF (number of expected frames). In FIFO mode, there is no such constraint. **NOTE:** When a debugger is connected, this counter will decrement if RxFIFO is being read through the debugger. **NOTE:** In case of data path is functioning normally, RFC/TFC counters will be cleared internally by HW.
22 RFBM	RFBM Rx Fifo/Buffer mode This bit can be programmed in Initialization mode, only when the UART bit is set. Register bit can be read in any mode, written only in initialization mode. 0 Rx Buffer mode enabled 1 Rx Fifo mode enabled (mandatory in DMA Rx mode)
23 TFBM	Tx Fifo/Buffer mode This bit can be programmed in initialization mode, only when the UART bit is set. Register bit can be read in any mode, written only in initialization mode. 0 Tx Buffer mode enabled 1 Tx Fifo mode enabled (mandatory in DMA Tx mode)
24 WL1	Word Length in UART mode This bit can be programmed in Initialization mode only, when the UART bit is set. Register bit can be read in any mode, written only in initialization mode.

WL1	WL0	Description
0	0	7 bits data + parity
0	1	8 bits data when PCE = 0 or 8 bits data + parity when PCE = 1
1	0	15 bits data + parity
1	1	16 bits data when PCE = 0 or 16 bits data + parity when PCE = 1

25 PC1	Parity Control This bit can be programmed in Initialization mode, only when UART bit is set. Register bit can be read in any mode, written only in initialization mode.

PC1	PC0	Description
0	0	Parity sent is Even

LINFlexD_UARTSR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 SZF	Stuck at Zero flag This bit is set by hardware when 100 dominant bits are detected. It should be cleared by software. An interrupt will be generated if the SZIE bit in LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.
17 OCF	Output Compare Flag An interrupt will be generated if the OCIE bit in LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set. **NOTE:** For Baud rate above 1 Mbit/s, this flag is not usable. 0 No output compare event occurred 1 The content of the counter has matched the content of LINOCR
18–21 PE	Parity Error flag These bits indicate if there is a Parity Error in the corresponding byte. No interrupt is generated if this error occurs. This bit will reflect the same value as in LINESR, when in initialization mode and UART bit set. **NOTE:** Parity is checked only after complete frame is received. Following are the conditions when WL bits = 01 or 11 (either PE0 or PE2 is only set). • When PE0 is set, it indicates Parity error in either first or second byte received • When PE2 is set, it indicates Parity error in either third or fourth byte received 0 No parity error 1 Parity error in the corresponding received byte
22 RMB	Release Message Buffer This bit should be cleared by software. This bit will reflect the same value as in LINSR, when in Initialization mode and the UART bit is set. 0 Buffer data is free 1 Buffer data ready to be read by software
23 FEF	Framing Error flag This bit is set by hardware when there is a framing error (invalid stop bit). It should be cleared by software. It will generate an interrupt if the FEIE bit of LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.
24 BOF	FIFO/Buffer overrun flag This bit is set by hardware when there is a new byte received and the RMB bit is not cleared in UART buffer mode. In UART FIFO mode this bit is set when there is a new byte and the Rx FIFO is full. In UART FIFO mode, once Rx FIFO is full, the new received message will be discarded irrespective of the new value of the RBLM bit. In UART Rx Buffer mode, if RBLM is set then the new message received will be discarded; if RBLM is reset then the new message will overwrite the buffer. It can be cleared by software writing a 1. An interrupt is generated if the BOIE bit of LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.
25 RDI	Receiver Data Input signal This bit reflects the current status of the RX pin.

Table continues on the next page...

LINFlexD_UARTSR field descriptions (continued)

Field	Description
26 WUF	Wakeup flag This bit is set by hardware when a falling edge is detected on the RX pin in sleep mode. It should be cleared by software. An interrupt will be generated if the WUIE bit in LINIER is set. This bit will reflect the same value as in LINESR when in Initialization mode and the UART bit is set.
27 RFNE	Receive FIFO Not Empty RFNE bit is set by hardware in UART FIFO mode (RFBM = 1), when there is at least one data byte present in the receive FIFO. RFNE is a read-only bit for debugging purposes. This flag can be used by software in case of a timeout event.
28 TO	Timeout This bit is set by hardware when a UART timeout occurs — in other words, the value of UARTCTO becomes equal to the preset value of the timeout (UARTPTO register setting). TO should be cleared by software. The SR bit should be used to reset the receiver fsm to Idle state in case of UART TIMEOUT for UART reception, depending on the application, in both buffer and FIFO mode. An interrupt will be generated when LINIER.TOIE bit is set on the Error interrupt line in UART mode.
29 DRFRFE	Data Reception Completed Flag /Rx FIFO Empty Flag DRF is set by hardware in UART buffer mode (RFBM = 0) and indicates that the number of bytes programmed in RDFL have been received. DRF should be cleared by software. An interrupt will be generated if the DRIE bit in LINIER is set. DRF bit is set when the configured number of valid stop bits are received for the last frame (number of frames is configurable by RDFL bits). DRF is set irrespective of framing error in case framing error is in the last STOP bit configured, parity error or overrun error. This bit will reflect the same value as in LINSR when in Initialization mode and the UART bit is set. Register bit can be read/cleared by software. Writing 1 clears contents. RFE is set by hardware in UART FIFO mode (RFBM = 1) when the RX FIFO is empty. RFE is a read-only bit for debugging purposes. It is internally used by the DMA RX interface.
30 DTFTFF	Data Transmission Completed Flag/ TX FIFO Full Flag DTF is set by hardware in UART buffer mode (TFBM = 0) and indicates that data transmission is completed. DTF should be cleared by software. An interrupt will be generated if the DTIE bit in LINIER is set. This bit will reflect the same value as in LINSR when in Initialization mode and the UART bit is set. Register bit can be read/cleared by software. Writing 1 clears contents. TFF is set by hardware in UART FIFO mode (TFBM = 1) when TX FIFO is full. TFF is a read-only bit for debugging purposes. It is internally used by the DMA TX interface.
31 NF	Noise flag This bit is set by hardware when noise is detected in the received character. It should be cleared by software. This bit will reflect the same value as in LINESR when in Initialization mode and the UART bit is set. During reduced oversampling (ROSE bit = 1), it is enabled only when OSR = 8.

58.5.7 LIN Time-Out Control Status Register (LINFlexD_LINTCSR)

This register contains control and status bits for timeout feature.

NOTE

When the MODE bit is 0, any activity on the transmit or receive pins will cause an unwanted change in the value of the 8-bit field Output Compare Value 2 (OC2) of the LIN Output Compare register (LINOCR). The LINFlexD module is enabled in LIN mode and the value of the MODE bit of the LIN Timeout Control Status register (LINTCSR) is changed from ‘1’ to ‘0’, then the old value of the Output Compare Value 1 (OC1) and Output Compare Value 2 (OC2) of the LIN Output Compare register (LINOCR) is retained. As a consequence, if the module is reconfigured from UART to LIN mode, or LINTCSR MODE bit is changed from ‘1’ to ‘0’, an incorrect timeout exception is generated when a LIN communication starts. To avoid this, set mode bit to '1', then reconfigure the LINFlexD in LIN mode and then reset the MODE bit. Before switching LINTCSR[MODE] from 1 to 0 in between frames, load LINOCR with 0xFFFF.

Address: 0h base + 18h offset = 18h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	0					MODE	IOT	TOCE	CNT							
W																
Reset	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0

LINFlexD_LINTCSR field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 MODE	Time-out counter mode This bit can be configured only during initialization. Register bit can be read in any mode, written only in initialization mode. **NOTE:** Always set LINTCSR[MODE] to 1 when UARTCR[UART] is 1. **NOTE:** Before switching LINTCSR[MODE] from 1 to 0 in between frames, load LINOCR to 0xFFFF. 0 LIN mode 1 Output compare mode
22 IOT	Idle on timeout Register bit can be read in any mode, written only in initialization mode. This feature is applicable only when MODE bit in LINTCSR is cleared. 0 LIN state machine does not reset to Idle on timeout 1 LIN state machine resets to Idle on timeout event
23 TOCE	Time-out counter enable TOCE is always configurable by software in Initialization mode. If LIN state is other than INIT and if timer is configured in LIN mode, then hardware takes control of TOCE. 0 Time-out counter disable. OCF flag is not set on an output compare event. 1 Time-out counter enable. OCF flag is set if an output compare event occurs.
24–31 CNT	Counter Value These bits reflect the value of a counter used for timeout. **NOTE:** For proper functionality of this counter, LINIBRR should be >= 5.

58.5.8 LIN Output Compare Register (LINFlexD_LINOCR)

This register contains the value to be compared to the LINTCSR:CNT value. This register is writable by software only in Output Compare Mode.

Address: 0h base + 1Ch offset = 1Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

R	0				RTO				0	HTO						
W																
Reset	0	0	0	0	1	1	1	0	0	*	*	*	*	*	*	*

* Notes:

- HTO field: HTO reset values:

  HTO resets to 0011100b in Master only mode, if generic slave = 0.

  HTO resets to 0101100b in Master/Slave mode, if generic slave = 1.

LINFlexD_LINTOCR field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–23 RTO	Response timeout value This is the response timeout duration (in bit time) for 1 byte. The reset value is 0Eh = 14, corresponding to $T_{Response\_Maximum} = 1.4 \times T_{Response\_Nominal}$
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–31 HTO	Header timeout value This register contains the header timeout duration (in bit time). This register can be written only for Slave mode. If Master mode is enabled then these bits will always reflect 28 (1.4 x 10 bits of sync + 1.4 x 10 bits of ID). For slave, these bits should be programmed without considering 11 bits of break.

58.5.10 LIN Fractional Baud Rate Register (LINFlexD_LINFBRR)

This register consists of bits that decide the fractional part of the LIN Baud Rate. It can be programmed only in Initialization mode.

NOTE

When LASE bit is set, this register should be read only after AUTOSYNC_COMP bit in LINSR register is set to obtain the correct value.

NOTE

This register cannot be used when reduced oversampling is enabled (ROSE bit = 1)

Address: 0h base + 24h offset = 24h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																												FBR

LINFlexD_LINFBRR field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 FBR	Fractional Baud rates Register bit can be read in any mode, written only in initialization mode. 0000 Fraction(LDIV) = 0 0001 Fraction(LDIV) = 1/16 0010 Fraction(LDIV) = 2/16 0011 Fraction(LDIV) = 3/16 0100 Fraction(LDIV) = 4/16 0101 Fraction(LDIV) = 5/16 0110 Fraction(LDIV) = 6/16 0111 Fraction(LDIV) = 7/16 1000 Fraction(LDIV) = 8/16 1001 Fraction(LDIV) = 9/16 1010 Fraction(LDIV) = 10/16 1011 Fraction(LDIV) = 11/16 1100 Fraction(LDIV) = 12/16 1101 Fraction(LDIV) = 13/16 1110 Fraction(LDIV) = 14/16 1111 Fraction(LDIV) = 15/16

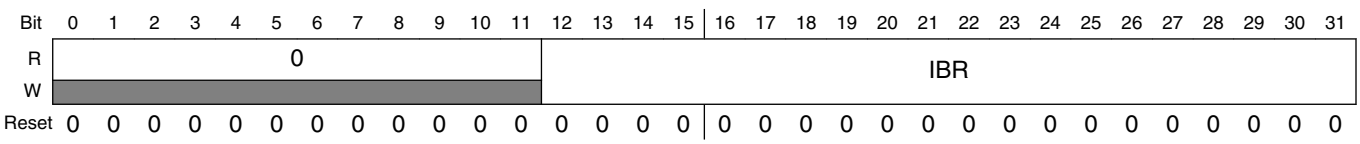
58.5.11 LIN Integer Baud Rate Register (LINFlexD_LINIBRR)

This register consists of control bits that decide the baud rate along with the LINFBRR. It can be programmed only in Initialization mode.

NOTE

When LASE bit is set, this register should be read only after AUTOSYNC_COMP bit in LINSR register is set to obtain the correct value.

Address: 0h base + 28h offset = 28h



LINFlexD_LINIBRR field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–31 IBR	Integer Baud rates These bits along with the fractional baud rate bits decide the LIN baud rate. IBR = 0h: LIN clock disabled IBR = 1h: Mantissa (LDIV) = 1 ... IBR = FFFFEh: Mantissa (LDIV) = 1048574 IBR = FFFFFh: Mantissa (LDIV) = 1048575 Register bit can be read in any mode, written only in initialization mode.

58.5.12 LIN Checksum Field Register (LINFlexD_LINCFR)

NOTE

There is a delay between 4 to 6 clock cycles of PBRIDGEx_CLK for the internal checksum's value (which is clocked with LIN_CLK/16 * LDIV) to reflect on LINCFR.

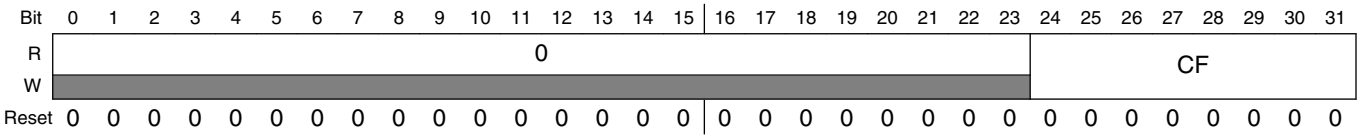
This register consists of checksum bits.

CFD	CCD	LINCHKSUM Read/write	Checksum sent
1	1	read/write	None

Table continues on the next page...

CFD	CCD	LINCHKSUM Read/write	Checksum sent
1	0	read-only	None
0	1	read/write	Programmed checksum
0	0	read-only	Calculated checksum

Address: 0h base + 2Ch offset = 2Ch



LINFlexD_LINCFR field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 CF	Checksum bits When the CCD bit is reset these bits are read-only and are calculated by hardware. When the CCD bit is set, these bits can be written by software.

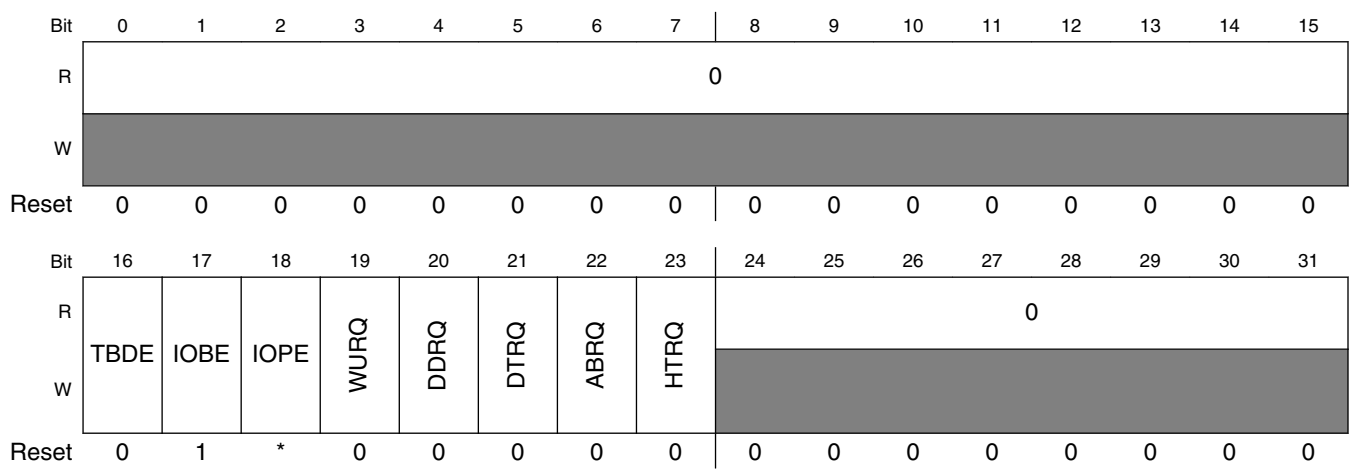
58.5.13 LIN Control Register 2 (LINFlexD_LINCR2)

This register includes control status bits related to buffer operations.

NOTE

When accessing the LINCR2 register, each reserved bit should be written to its original reset value.

Address: 0h base + 30h offset = 30h



* Notes:

- IOPE field: When slave = 0, this field always reads ‘0’ and cannot be programmed else this bit is programmable and reset value is 1.

LINFlexD_LINCR2 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 TBDE	Two Bit delimiter bit This bit can be set in Initialization mode only. Register bit can be read in any mode, written only in initialization mode. 0 Delimiter length in break field is 1 bit 1 Delimiter length in break field is 2 bits
17 IOBE	Idle on Bit Error This bit can be set in Initialization mode only. Register bit can be read in any mode, written only in initialization mode. 0 Bit Error does not reset LIN state machine 1 Bit Error resets LIN state machine
18 IOPE	Idle on Identifier Parity Error This bit can be set in Initialization mode only. Register bit can be read in any mode, written only in initialization mode. 0 Parity Error does not reset LIN state machine 1 Parity Error resets LIN state machine
19 WURQ	Wakeup Generate Request Setting this bit will generate a wakeup pulse. It is reset by hardware when the wakeup character has been transmitted. The character sent during wakeup is copied from BDRL (DATA0). Note that this bit cannot be set in Sleep mode — software has to exit Sleep mode before setting this bit. Bit Error is not checked when transmitting the wakeup request. Register bit can be read/set by software
20 DDRQ	Data Discard request Set by software to stop data reception if the frame does not concern the node. This bit is reset by hardware once LINFlexD ignores the response and moves to Idle state. For LIN slave this bit can be set only when HRF bit is set and Identifier is software-filtered. Register bit can be read/set by software
21 DTRQ	Data Transmission Request Set by software in slave mode to request the transmission of the LIN Data field stored in the Buffer data register. This bit can be set only when the HRF bit is set (to ensure that data transmission is requested only after a header reception). Cleared by hardware when the request has been completed, or on abort request or error condition. In Master mode, this bit is set by hardware when the DIR bit is set and header transmission is complete. Register bit can be read/set by software
22 ABRQ	Abort Request Set by software to abort the current transmission.

Table continues on the next page...

LINFlexD_LINCR2 field descriptions (continued)

Field	Description
	Cleared by hardware when the transmission has been aborted. LINFlexD aborts the transmission at the end of the current bit. This bit can abort a wakeup request also and can be used in UART mode also. Register bit can be read/set by software
23 HTRQ	Header Transmission Request Set by software to request the transmission of the LIN Header. Cleared by hardware when the request has been completed or on abort request. This bit has no effect in UART mode. **NOTE:** In master mode, if both HTRQ and ABRQ are set at the same time then ABRQ has no effect. Similarly, in slave mode after header reception, if DTRQ and ABRQ are simultaneously set then ABRQ has no effect.
24–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

58.5.14 Buffer Identifier Register (LINFlexD_BIDR)

This register contains the bits which provide information about the identifier of the transaction and other related information.

NOTE

All the fields (ID, CSS, DIR, DFL) of the BIDR register must be updated when an ID filter (enabled) in Slave mode (Tx or Rx) matches the ID received.

Address: 0h base + 34h offset = 34h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0

LINFlexD_BIDR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–18 Reserved	This field is reserved.
19–21 DFL	Data Field Length Number of data bytes in the response part of the frame.

Table continues on the next page...

LINFlexD_BIDR field descriptions (continued)

Field	Description
	DFL = Number of data bytes - 1
22 DIR	Direction This bit controls the direction of the data field. 0 LINFlexD receives the data and copy them in the BDR registers 1 LINFlexD transmits the data from the BDR registers
23 CCS	Classic Checksum This bit controls the type of checksum applied on the current message. 0 Enhanced Checksum covering Identifier and Data fields. This is compatible with LIN specification rev. 2.0 and higher. 1 Classic Checksum covering Data filed only. This is compatible with LIN specification 1.3 and lower.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 ID	Identifier Identifier part of the identifier field without the identifier parity. This field can be written only in Master mode (MME = '1').

58.5.15 Buffer Data Register Least Significant (LINFlexD_BDRL)

This register is a part of an 8-byte data buffer.

Address: 0h base + 38h offset = 38h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

LINFlexD_BDRL field descriptions

Field	Description
0–7 DATA3	Data Byte 3 Data byte 3 of the data field.
8–15 DATA2	Data Byte 2 Data byte 2 of the data field.
16–23 DATA1	Data Byte 1 Data byte 1of the data field.
24–31 DATA0	Data Byte 0 Data byte 0 of the data field.

58.5.16 Buffer Data Register Most Significant (LINFlexD_BDRM)

This register is a part of an 8-byte data buffer.

Address: 0h base + 3Ch offset = 3Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

LINFlexD_BDRM field descriptions

Field	Description
0–7 DATA7	Data Byte 7 Data byte 7 of the data field.
8–15 DATA6	Data Byte 6 Data byte 6 of the data field.
16–23 DATA5	Data Byte 5 Data byte 5of the data field.
24–31 DATA4	Data Byte 4 Data byte 4 of the data field.

58.5.17 Identifier Filter Enable Register (LINFlexD_IFER)

This register enables/disables a particular filter.

Address: 0h base + 40h offset = 40h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

LINFlexD_IFER field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 FACT	Filter active The software sets the bit FACT[x] to activate the filter x in Identifier list mode. Register bit can be read in any mode, written only in initialization mode.

Table continues on the next page...

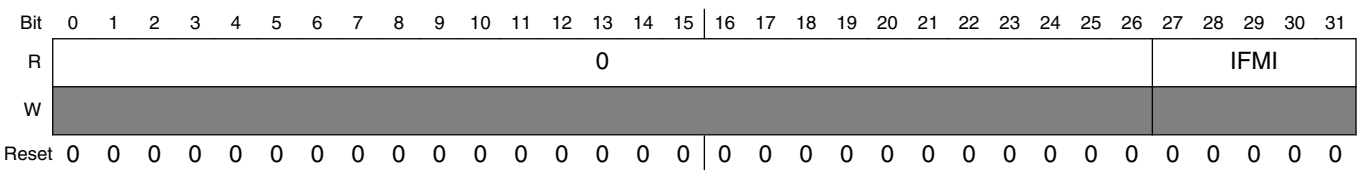
LINFlexD_IFER field descriptions (continued)

Field	Description
	1. In Identifier mask mode, FACT (2n+1) have no effect on the corresponding filters as they act as mask for the Identifier 2n. 2. The length of this field depends on the value of no_of_filters. 3. The register diagram depicts the maximum no_of_filters, which can be up to 16. **NOTE:** Refer to chip configuration details to see the number of filters used in the device.

58.5.18 Identifier Filter Match Index (LINFlexD_IFMI)

This register contains the index corresponding to the received ID. It can be used to read or write the data directly in RAM.

Address: 0h base + 44h offset = 44h



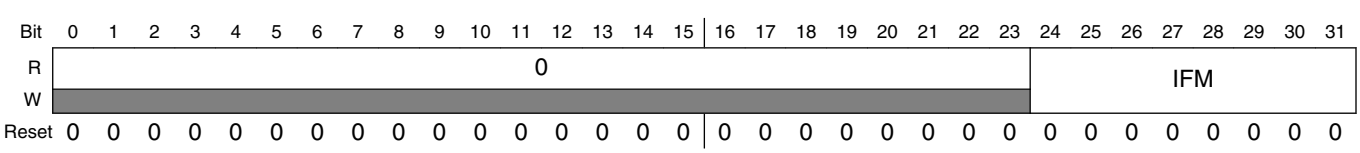
LINFlexD_IFMI field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 IFMI	Filter match index Upon a filter match with xth filter – IFMI[4:0] = x+1. On no match IFMI is equal to 00h. This register contains the index corresponding to the received identifier. It can be used to directly write or read the data in SRAM (see Slave mode for more details).

58.5.19 Identifier Filter Mode Register (LINFlexD_IFMR)

This register configures the modes of filters.

Address: 0h base + 48h offset = 48h



LINFlexD_IFMR field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 IFM	Filter mode Register bit can be read in any mode, written only in initialization mode. 0 Filters 2n and 2n+1 are in identifier list mode 1 Filters 2n and 2n+1 are in mask mode, where filter 2n+1 is the mask for filter 2n

58.5.20 Identifier Filter Control Register (LINFlexD_IFCR*n*)

This register is read-only in normal mode and can be programmed only in Initialization mode.

Even-numbered instances (IFCR0, IFCR2, IFCR4, ...) of this register act as filters in both Identifier list and Identifier mask modes.

Odd-numbered instances (IFCR1, IFCR3, IFCR5, ...) of this register act:

- As filters in Identifier list mode
- As a mask for the preceding-numbered register in identifier mask mode

Refer to chip configuration details to see the number of filters used in the device.

Address: 0h base + 4Ch offset + (4d × i), where i=0d to 15d

LINFlexD_IFCR*n* field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–18 Reserved	This field is reserved.
19–21 DFL	Data Field Length Number of data bytes in the response part of the frame. DFL = Number of data bytes - 1

Table continues on the next page...

LINFlexD_IFCR*n* field descriptions (continued)

Field	Description
	Register bit can be read in any mode, written only in initialization mode.
22 DIR	Direction This bit controls the direction of the data field. Register bit can be read in any mode, written only in initialization mode. 0 LINFlexD receives data and copies to the BDR registers 1 LINFlexD transmits data from the BDR registers
23 CCS	Classic Checksum This bit controls the type of checksum applied on the current message. Register bit can be read in any mode, written only in initialization mode. 0 Enhanced Checksum covering Identifier and Data fields. This is compatible with LIN specification rev. 2.0 and higher. 1 Classic Checksum covering Data field only. This is compatible with LIN specification 1.3 and lower.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 ID	Identifier Identifier part of the identifier field without the identifier parity. Register bit can be read in any mode, written only in initialization mode.

58.5.21 Global Control Register (LINFlexD_GCR)

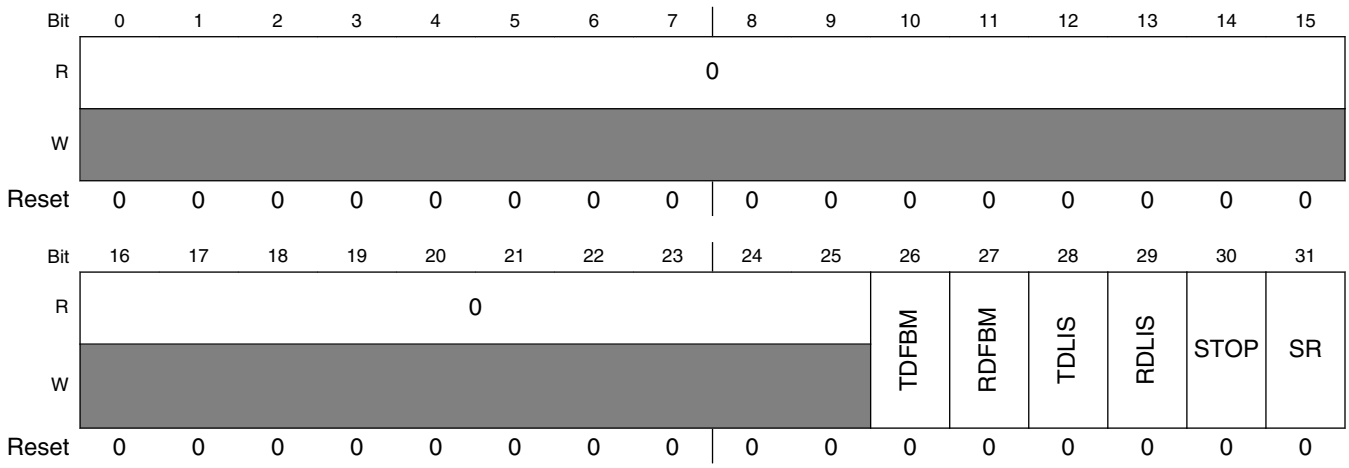
This register is read-only in Normal mode and can be programmed only in Initialization mode. This is a global control register — in other words, the register configuration will be applied in LIN mode as well as in UART mode.

The address offset depends on the no_of_filters. Refer to the chip configuration details for the number of filters used in this device.

Table 58-18. Register fields reset by SR

Register	Comment
LINSR	All fields except RXbusy and AUTOSYNC_COMP are reset
LINESR	All fields are reset
LINTCSR	Only CNT[0:7] is reset
UARTSR	All fields except RFE & TFF are reset
UARTCR	Only TFC & RFC are reset
UARTCTO	All fields are reset

Address: 0h base + 8Ch offset = 8Ch



LINFlexD_GCR field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 TDFBM	Transmit data first bit MSB This bit controls the first bit of transmit data (payload only) as MSB/LSB in both UART and LIN modes. Register bit can be read in any mode, written only in initialization mode. 0 The first bit of transmitted data is LSB — in other words, the first bit transmitted is mapped on LSB bit (BDR (0), BDR (8), BDR (16), BDR (24)) 1 The first bit of transmitted data is MSB — in other words, the first bit transmitted is mapped on MSB bit (BDR (7), BDR (15), BDR (23), BDR (31))
27 RDFBM	Received data first bit MSB This bit controls the first bit of received data (payload only) as MSB/LSB both in UART and LIN modes. Register bit can be read in any mode, written only in initialization mode. 0 The first bit of received data is LSB — in other words, the first bit received is mapped on LSB bit (BDR (0), BDR (8), BDR (16), BDR (24)) 1 The first bit of received data is MSB — in other words, the first bit received is mapped on MSB bit (BDR (7), BDR (15), BDR (23), BDR (31))
28 TDLIS	Transmit data level inversion selection This bit controls the data inversion of transmitted data (payload only) in both UART and LIN modes. Register bit can be read in any mode, written only in initialization mode. 0 Transmitted data is not inverted 1 Transmitted data is inverted
29 RDLIS	Received data level inversion selection This bit controls the data inversion of received data (payload only) in both UART and LIN modes. Register bit can be read in any mode, written only in initialization mode. 0 Received data is not inverted 1 Received data is inverted

Table continues on the next page...

LINFlexD_GCR field descriptions (continued)

Field	Description
30 STOP	1/2 stop bit configuration This bit controls the number of stop bit transmitted data in both UART and LIN modes. The stop bit is configured for all the fields (Delimiter, Sync, ID, Checksum, Payload). Register bit can be read in any mode, written only in initialization mode. 0 1 stop bit 1 2 stop bits
31 SR	Soft reset SR executes a soft reset of the LINFlexD controller (FSMs, FIFO pointers, counters, timers, status and error registers) without modifying the configuration registers when a 1 write operation is performed. This bit should be cleared by software to perform further operations (this bit is not cleared by hardware). Register bit can be written only be software in initialization mode. Bit is always read 0 by software. Table 58-18 describes the register fields reset by SR.

58.5.22 UART Preset Timeout Register (LINFlexD_UARTPTO)

This register contains the preset value of the timeout register in UART mode and is programmed according to the number of bits to be received or to monitor the idle state of the reception line. This register can be written by software any time.

The address offset depends on no_of_filters. Refer to the chip configuration details to see the number of filters used in the device.

Address: 0h base + 90h offset = 90h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																PTO															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1

LINFlexD_UARTPTO field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 PTO	Preset Timeout PTO defines the preset value of timeout counter. A zero-value is forbidden, otherwise the UARTSR[TO] status bit is immediately set. Refer also to register UARTCTO.

58.5.23 UART Current Timeout Register (LINFlexD_UARTCTO)

This register contains the current timeout value in UART mode, and is used in conjunction with the UARTPTO register (see UART Preset Timeout Register (LINFlexD_UARTPTO) to monitor the number of bits received by UART or to monitor the idle state of the reception line. UART timeout works in both CPU and DMA modes.

The timeout counter:

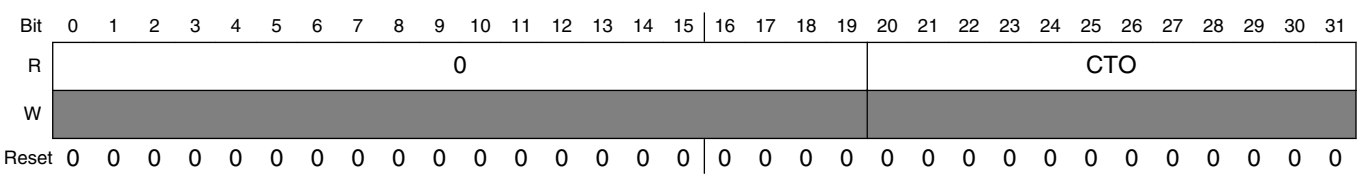
- Starts at zero and counts upward
- Is clocked with LIN_CLK / (16 * LDIV) synchronized to PBRIDGEx_CLK (when ROSE = 0)
- Is clocked with LIN_CLK / (OSR * IBRR) synchronized to PBRIDGEx_CLK (when ROSE = 1)
- Is automatically enabled when UARTCR[RXEN] = 1

It is reset when:

- Number of frames received is equal to NEF bits
- UARTCTO becomes equal to UARTPTO
- Whenever UARTPTO is written
- When DRF is set and DTU bit = 1

The address offset depends on no_of_filters. Refer to chip configuration details to see the number of filters used in the device.

Address: 0h base + 94h offset = 94h



LINFlexD_UARTCTO field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 CTO	Current Timeout

Table continues on the next page...

LINFlexD_UARTCTO field descriptions (continued)

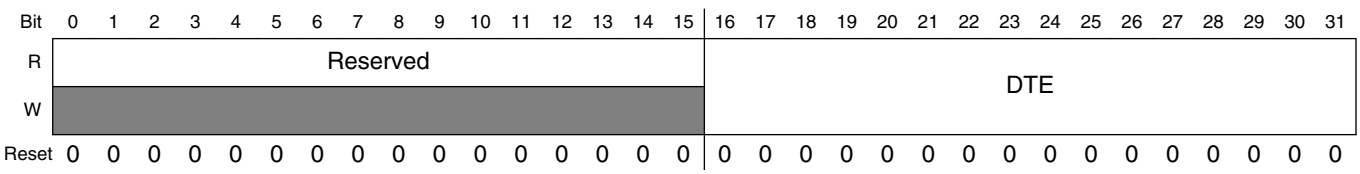
Field	Description
	CTO defines the current value of the timeout counter. CTO is a read-only field. CTO is reset every time UARTPTO is re-initialized, or UARTCTO = UARTPTO, or by hard/soft reset. When the CTO value matches the preset value (UARTPTO), the status bit UARTSR[TO] is set.

58.5.24 DMA Tx Enable Register (LINFlexD_DMATXE)

This register enables the DMA TX interface. This register can be written and read by software anytime.

The address offset depends on no_of_filters. Refer to chip configuration details to see the number of filters used in the device.

Address: 0h base + 98h offset = 98h



LINFlexD_DMATXE field descriptions

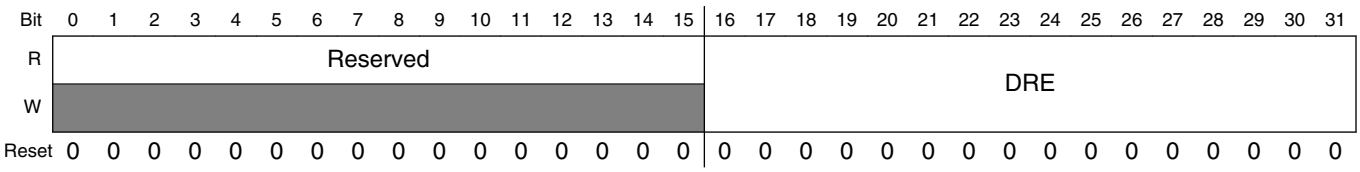
Field	Description
0–15 Reserved	This field is reserved. Reserved **NOTE:** The number of reserved bits varies, and is equal to 32 - $2^{TX\_CH\_NUM}$. These lies from 0 to (31 - $2^{TX\_CH\_NUM}$). Refer to the chip configuration details for the value of TX_CH_NUM used in this device.
16–31 DTE	DMA Tx channel Y enable **NOTE:** The actual size of the register DMATXE depends on the value of the static parameter TX_CH_NUM. The size is [$2^{TX\_CH\_NUM}$ - 1 : 0]. The position of these bits are (32 - $2^{TX\_CH\_NUM}$) to 31. When DMATXE = 0x00000000, the DMA TX interface FSM is forced (soft reset) in Idle state. **NOTE:** Refer to the chip configuration details for the value of TX_CH_NUM used in this device. 0 DMA Tx channel Y disabled 1 DMA Tx channel Y enabled

58.5.25 DMA Rx Enable Register (LINFlexD_DMARXE)

This register enables the DMA RX interface. This register can be written and read by software any time.

The address offset depends on no_of_filters. Refer to device configuration chapter to see the number of filters used in the device.

Address: 0h base + 9Ch offset = 9Ch



LINFlexD_DMARXE field descriptions

Field	Description
0–15 Reserved	This field is reserved. Reserved **NOTE:** The number of reserved bits varies, and is equal to 32 - $2^{RX\_CH\_NUM}$. These lies from 0 to (31 - $2^{RX\_CH\_NUM}$). Refer to the chip configuration details for the value of RX_CH_NUM used in this device.
16–31 DRE	DMA Rx channel Y enable **NOTE:** The actual size of the register DMARXE depends on the value of the static parameter RX_CH_NUM. The size is [$2^{RX\_CH\_NUM}$ -1 : 0]. The position of these bits are (32 - $2^{RX\_CH\_NUM}$) to 31. When DMARXE = 0x00000000, the DMA RX interface FSM is forced (soft reset) in Idle state. **NOTE:** Refer to the chip configuration details for the value of RX_CH_NUM used in this device. 0 DMA Rx channel Y disabled 1 DMA Rx channel Y enabled

58.6 Programming considerations

The next subsections describe the various configurations in which the LINFlexD module can be used.

58.6.1 Master node

LINFlexD acts as Master when the MME bit is set.

58.6.1.1 Transmitter

Transmitter Master Node - Transmitter configuration.

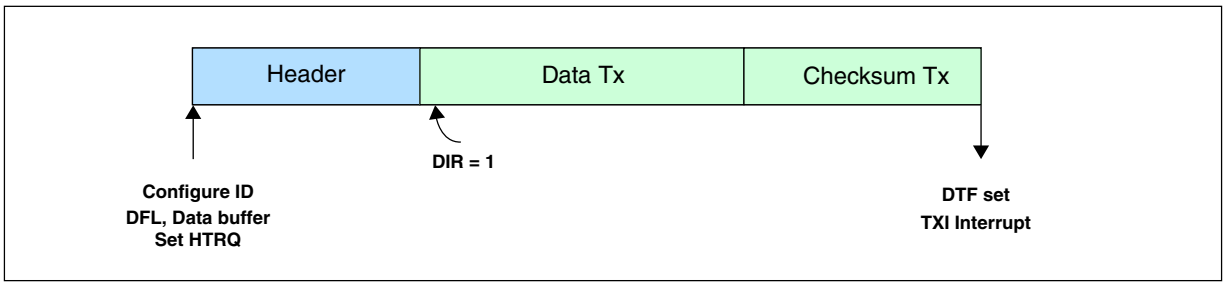


Figure 58-39. Master node – Transmitter configuration

58.6.1.2 Receiver

Receiver Master Mode - RX Configuration

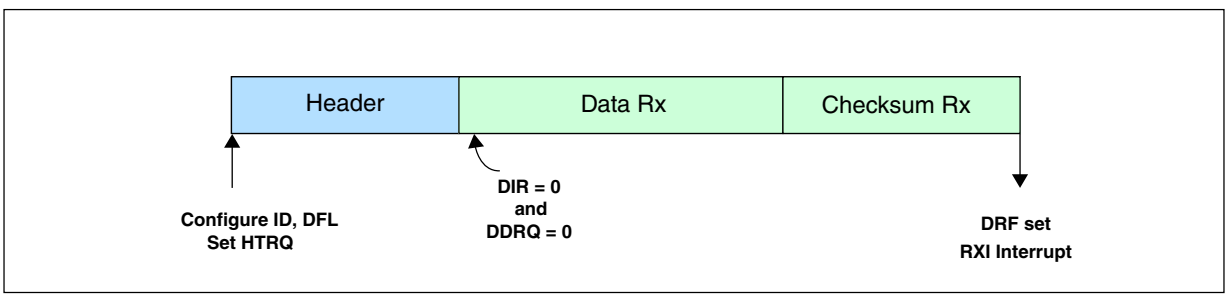

Figure 58-40. Master node – Receiver configuration

58.6.1.3 Transmitter, Bit Error

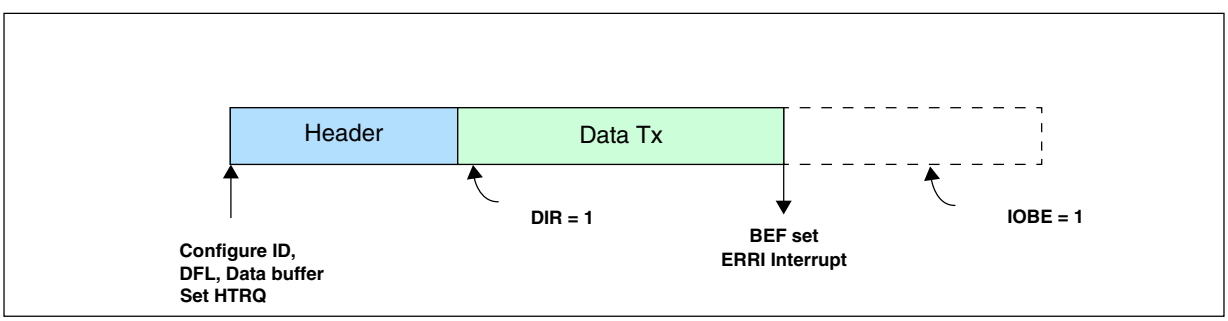

Figure 58-41. Master node – Transmitter, Bit Error configuration

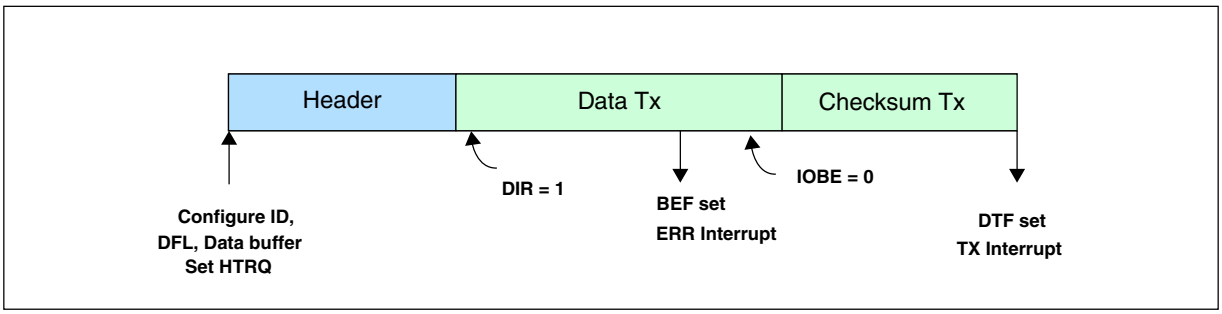

Figure 58-42. Master node – Transmitter, Checksum Error configuration

58.6.1.4 Receiver, Checksum Error

Checksum Error for Receiver.

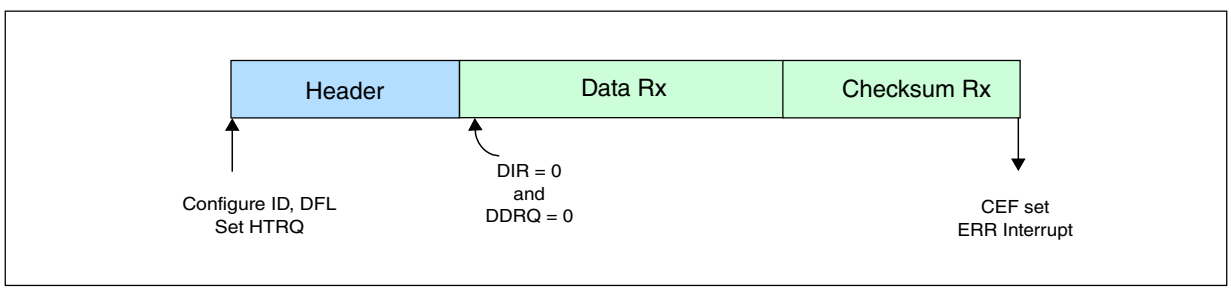

Figure 58-43. Master node – Receiver, Checksum Error configuration

58.6.2 Slave node

Slave node (transmitter).

58.6.2.1 Transmitter (no identifier filters)

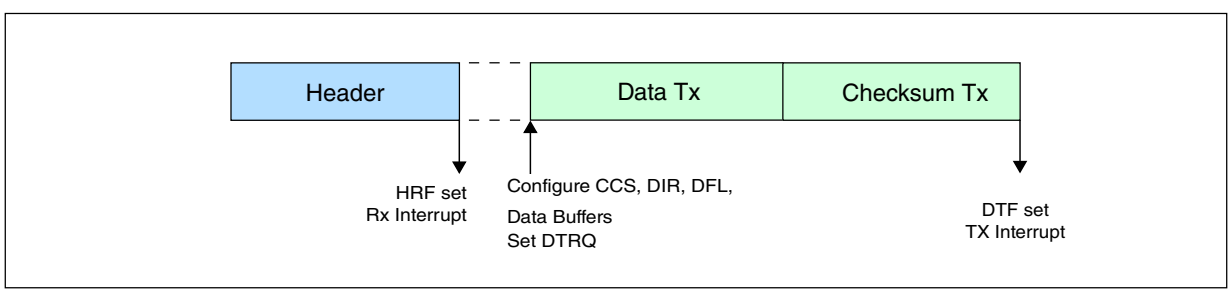

Figure 58-44. Slave node – Transmitter (no identifier filters) configuration

58.6.2.2 Receiver (no identifier filters)

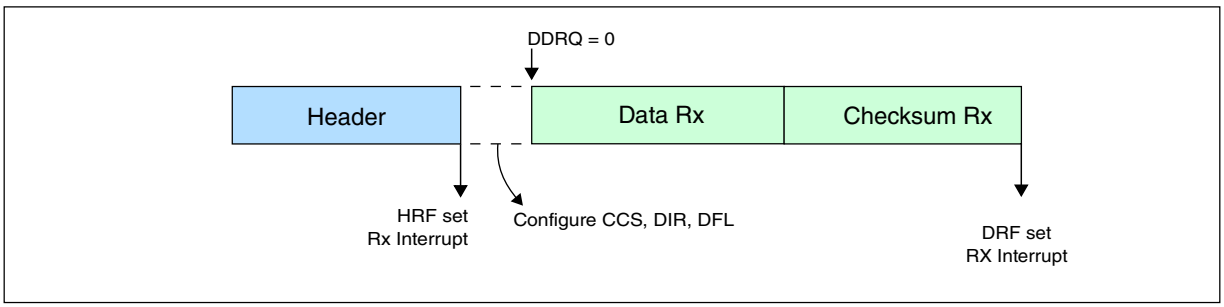

Figure 58-45. Slave node – Receiver (no identifier filters) configuration

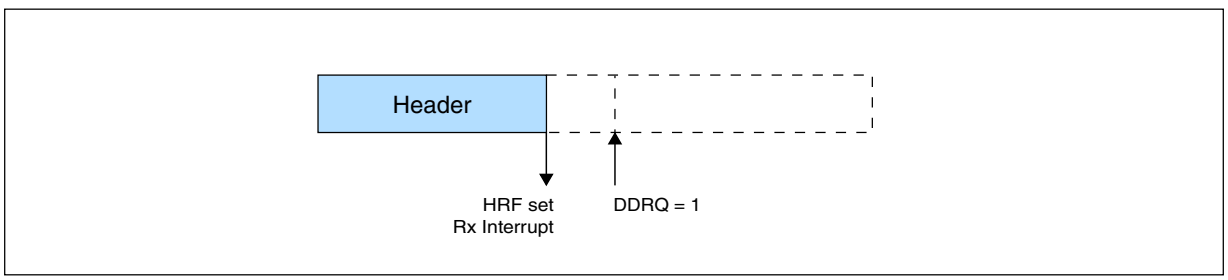

Figure 58-46. Slave node – Receiver (no identifier filters) configuration

58.6.2.3 No filters, Transmitter, Bit error

The following figure shows Slave node - No filters, Transmitter, Bit error configuration.

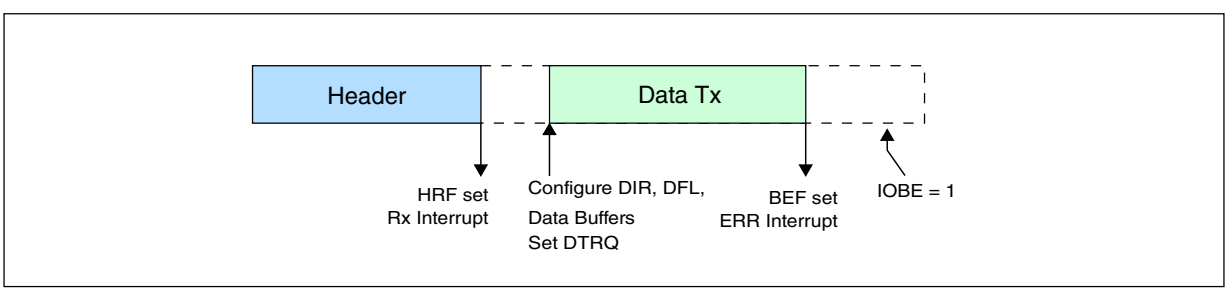

Figure 58-47. Slave node – No filters, Transmitter, Bit error configuration

58.6.2.4 No filters, Receiver, Checksum Error

The following figure shows Slave node - No filters, Receiver, Checksum error configuration.

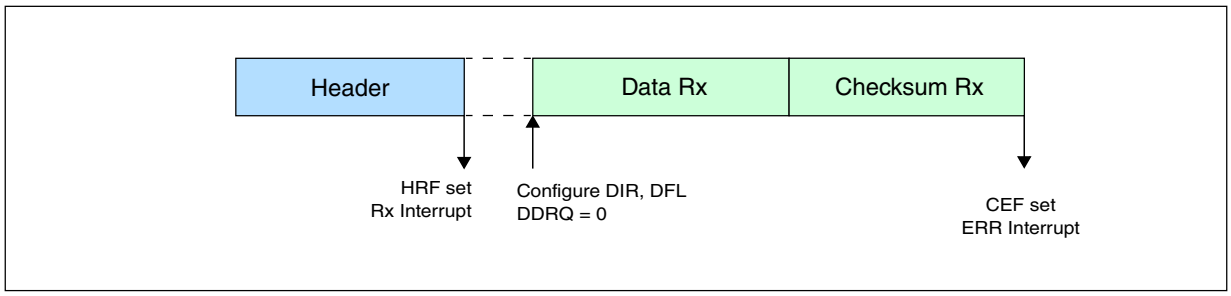

Figure 58-48. Slave node – No filters, Receiver, Checksum error configuration

58.6.2.5 At least one TX filter, BF is reset, ID matches filter

This configuration can be used in case slave never receives data, for example, sensor.

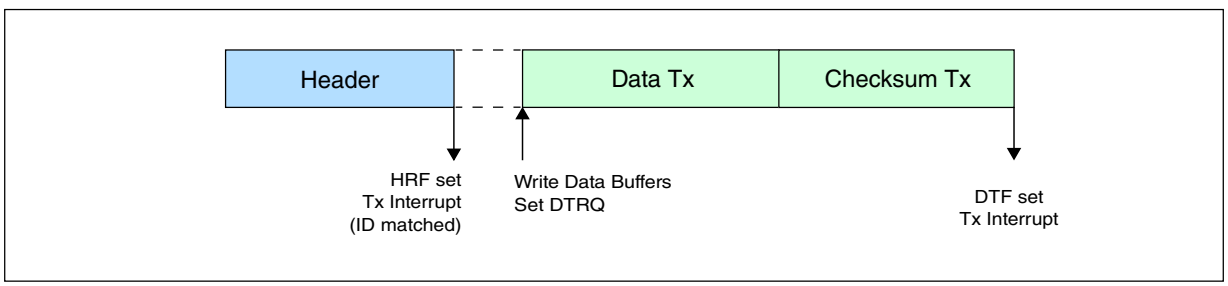

Figure 58-49. Slave node – one TX filter configuration

58.6.2.6 At least one RX filter, BF reset, ID matches filter

The following figure shows Slave node - one RX filter configuration.

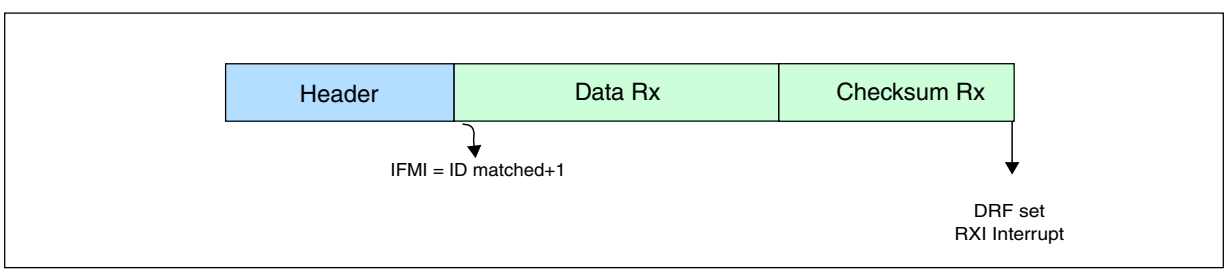

Figure 58-50. Slave node – one RX filter configuration

58.6.2.7 RX only, TX only, RX & TX filters, ID not matching filter, BF reset

The following figure shows RX only, TX only, RX and TX filters configuration.

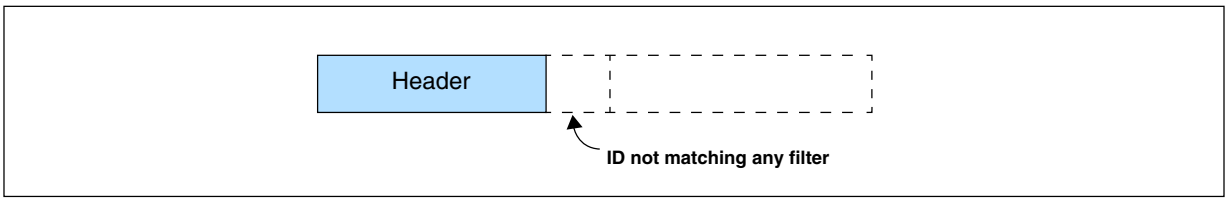

Figure 58-51. RX only, TX only, RX & TX filters configuration

58.6.2.8 TX filter, BF is set

This configuration is used when:

- All TX IDs are handled by filters.
- There are not enough other filters to handle all reception IDs.

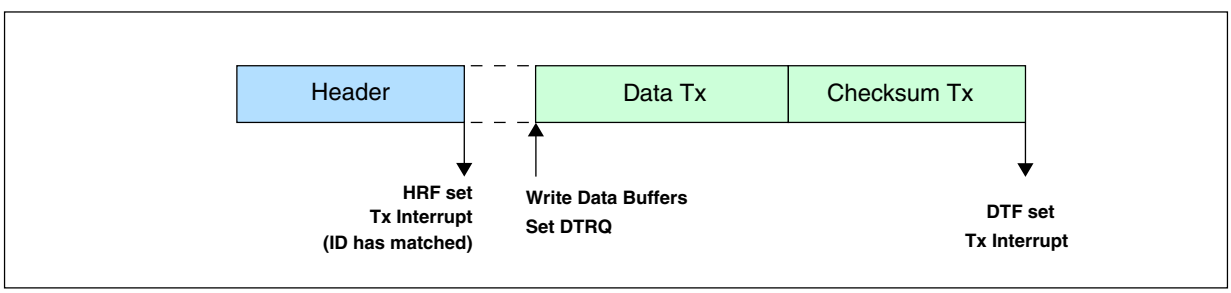

Figure 58-52. TX filter, BF is set configuration – ID has matched

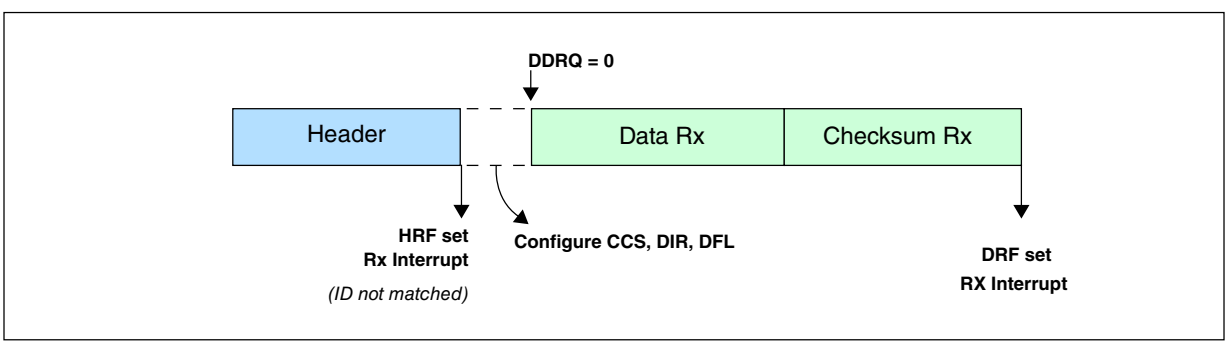

Figure 58-53. TX filter, BF is set configuration – ID not matched

58.6.2.9 RX filter, BF is set

The following figures show RX filter configurations.

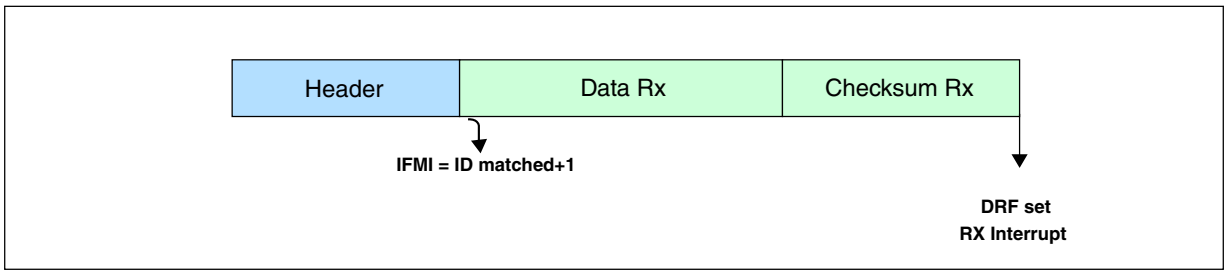

Figure 58-54. RX filter, BF is set configuration – ID matched

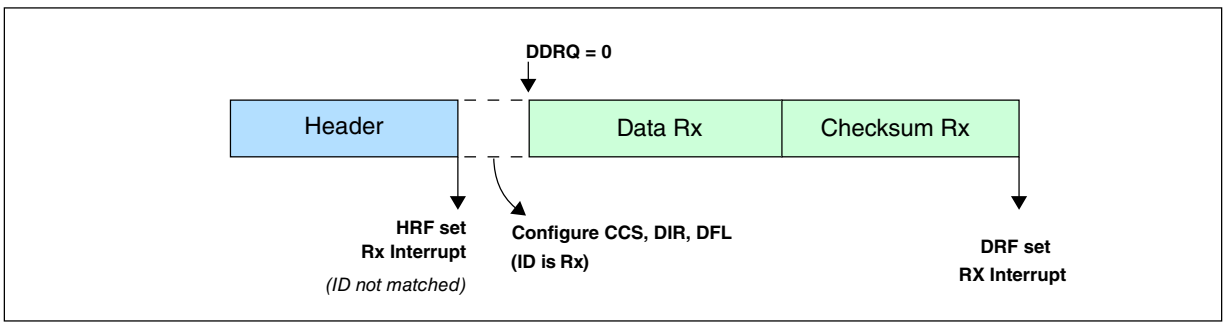

Figure 58-55. RX filter, BF is set configuration – ID not matched (ID is Rx)

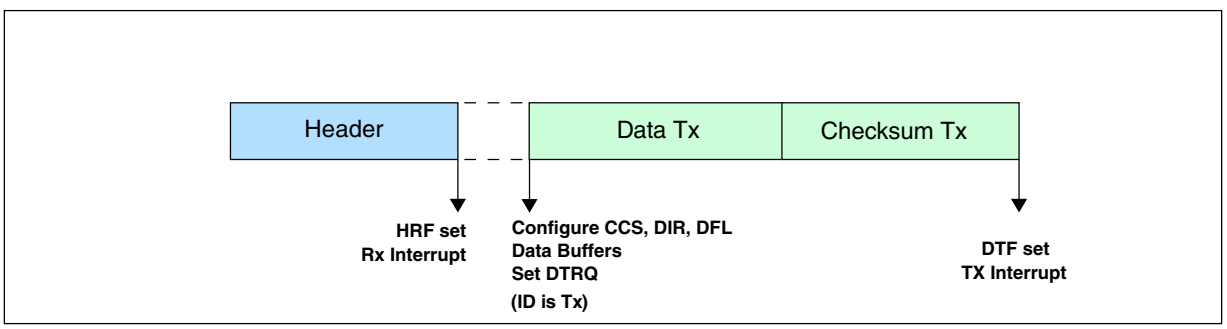

Figure 58-56. RX filter, BF is set configuration – (ID is Tx)

58.6.2.10 TX filter, RX filter, BF set

This configuration is used when:

- There are not enough filters.
- The filters are used for most frequently used IDs to reduce CPU usage.

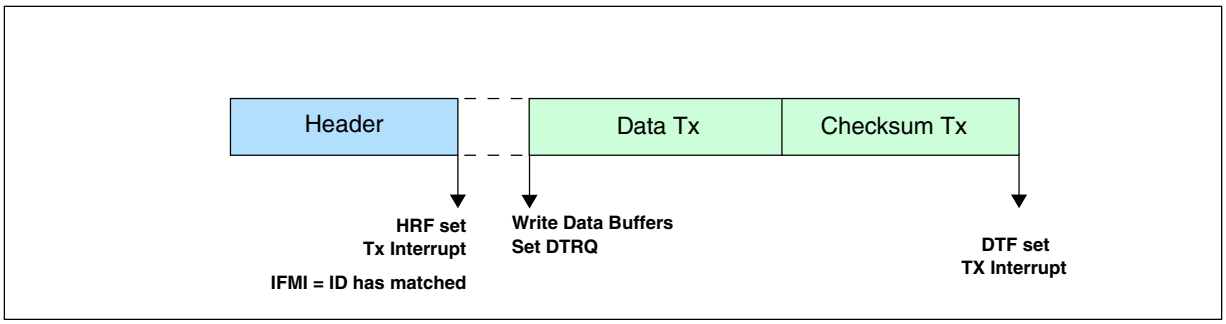

Figure 58-57. TX filter, RX filter, BF set configuration – (ID matched)

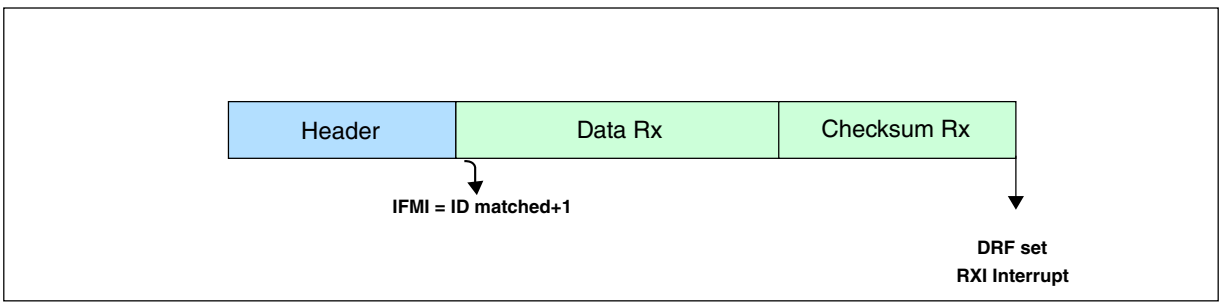

Figure 58-58. TX filter, RX filter, BF set configuration – (ID matched + 1)

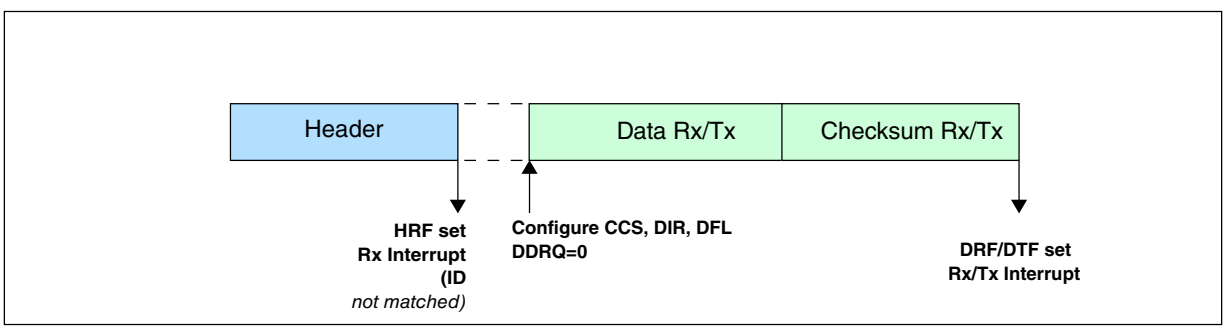

Figure 58-59. TX filter, RX filter, BF set configuration – (ID not matched, RX/TX Interrupt)

58.6.3 Timeout

Master Node: Response (during reception only) and frame timeout are checked.

Slave Node: Header, Response (during reception only), and frame timeout are checked.

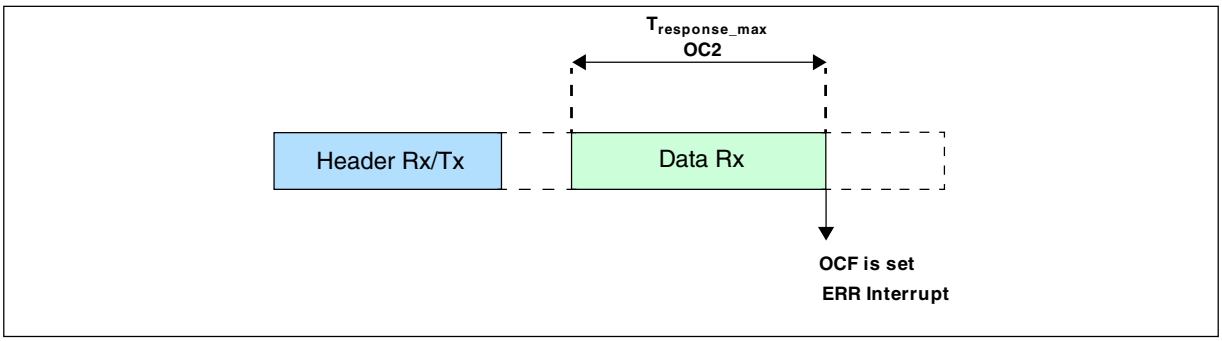

Figure 58-60. Response timeout

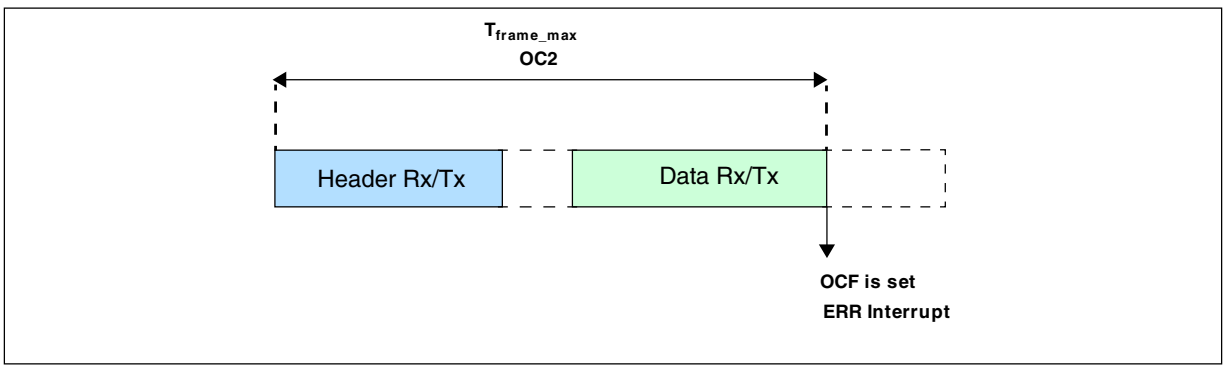

Figure 58-61. Frame timeout

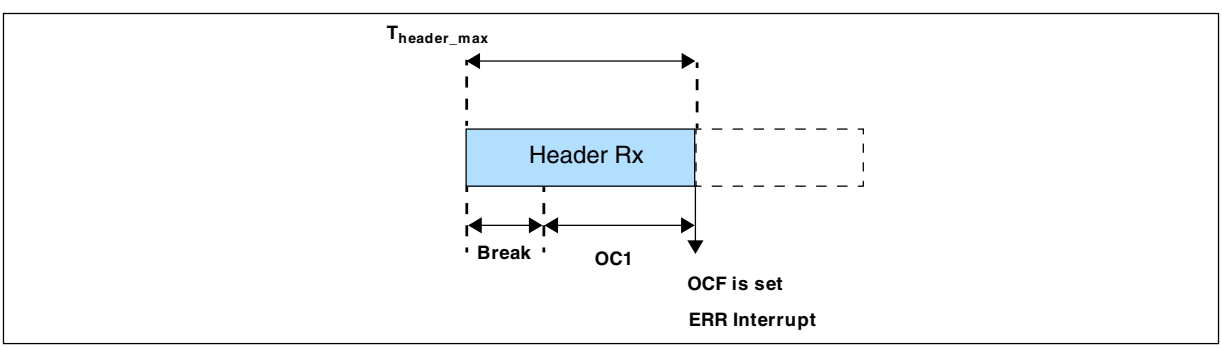

Figure 58-62. Header timeout

58.6.4 UART mode

The following figure shows UART mode configuration.

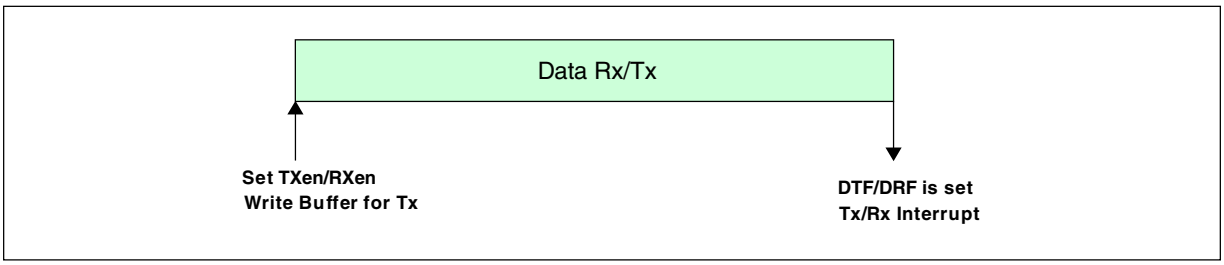

Figure 58-63. UART mode configuration

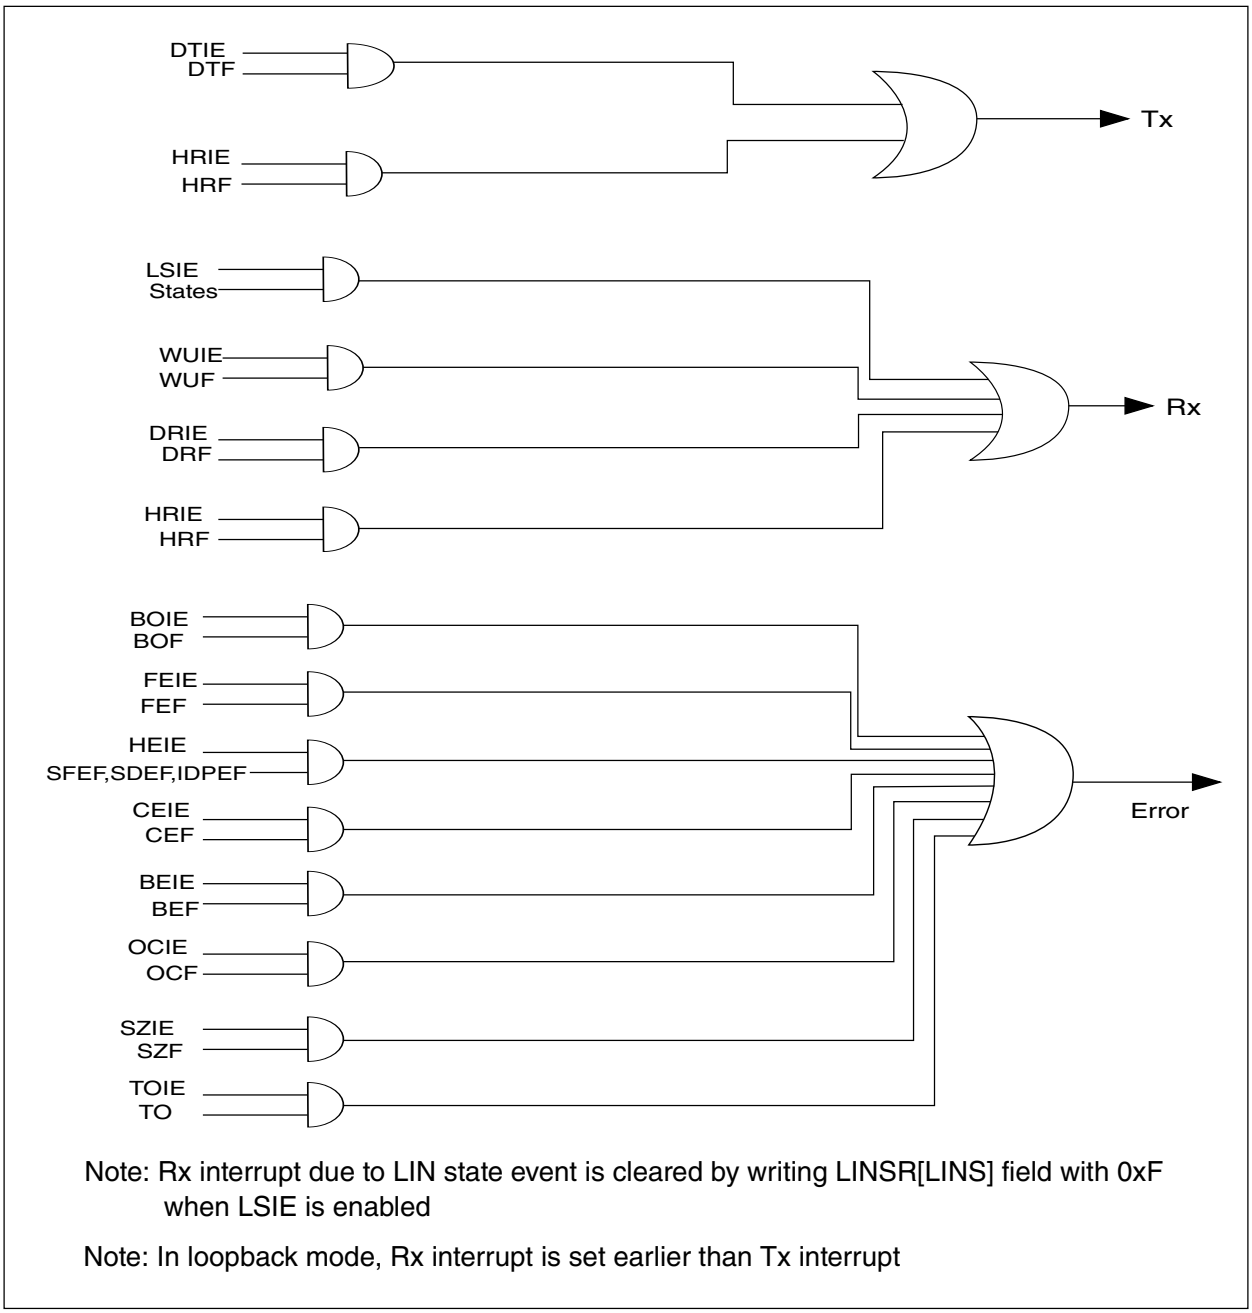
58.6.5 Interrupts

Interrupt section.

Table 58-19. Interrupts

Interrupt Event	Event flag	Enable control bit	Interrupt vector
Stuck at zero	SZF	SZIE	Error
Output compare	OCF	OCIE	Error
Bit error	BEF	BEIE	Error
Checksum error	CEF	CEIE	Error
Header error	SFEF orSDEF orIDPEF	HEIE	Error
Frame error	FEF	FEIE	Error
Buffer Overrun error	BOF	BOIE	Error
UART Timeout error	TO	TOIE	Error
Lin state	Sync Del, Sync Field,Identifier field or Checksum Field	LSIE	Rx
Wakeup	WUF	WUIE	Rx
Data Reception Complete	DRF	DRIE	Rx
Data transmitted	DTF	DTIE	Tx
Header received	HRF	HRIE	Rx
Header received	HRF	HRIE	Tx (if there is a filter match for Tx identifier)

The following figure shows an Interrupt Flow Diagram.



Note: Rx interrupt due to LIN state event is cleared by writing LINSR[LINS] field with 0xF when LSIE is enabled

Note: In loopback mode, Rx interrupt is set earlier than Tx interrupt

Figure 58-64. Interrupt diagram

58.6.6 LINFlexD Clock Tolerance

1. **Faster receiver tolerance:**
   In this case the receiver has a higher baud rate than the transmitter, thus the stop bit sampling starts already in the last transmitted payload bit. To ensure the correct noise and framing error free reception bit, the samples RS8, RS9, and RS10 must be located in the transmitted stop bit as shown in the following figure.

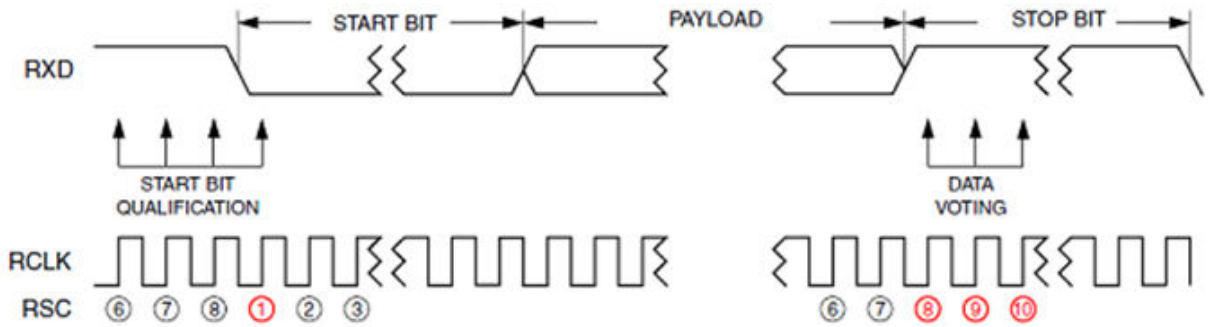


Figure 58-65. Faster receiver

2. **Slower receiver tolerance:**
   In this case the receiver has a slower baud rate than the transmitter, thus the stop bit sampling is still running while the next start bit is already transmitted. To ensure the correct noise and framing error free reception bit , the samples RS8, RS9, and RS10 must be located in the transmitted stop bit as shown in the following figure.

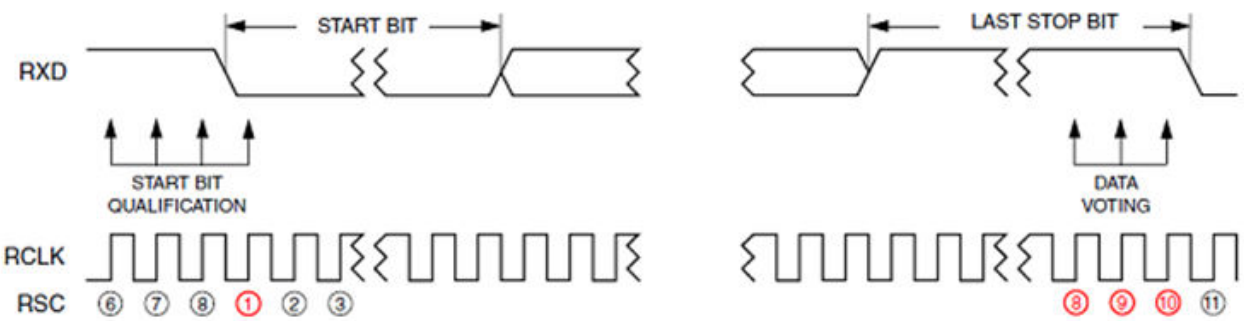

Figure 58-66. Slower receiver

Chapter 59
Inter-Integrated Circuit (I2C)

59.1 Overview

This chapter describes the Inter-Integrated Circuit (I^2C) bus module implemented on this chip and presents the following topics:

- Introduction to I^2C
- External signal descriptions
- Memory map and register definition
- Functional description
- Initialization/application information

59.2 Introduction to I^2C

This section presents the following topics:

- Definition: I^2C module
- Advantages of the I^2C bus
- Module block diagram
- Features
- Modes of operation
- Definition: I^2C conditions

59.2.1 Definition: I2C module

The I2C module is a functional unit that provides a two-wire— serial data (SDA) and serial clock (SCL) — bidirectional serial bus that provides a simple and efficient method of data exchange between this chip and other devices, such as microcontrollers, EEPROMs, real-time clock devices, analog-to-digital converters, and LCDs.

59.2.2 Advantages of the I2C bus

The synchronous, multiple-master two-wire I2C bus:

- Minimizes interconnections between devices
- Allows the connection of additional devices to the bus for expansion and system development
- Does not require an external address decoder

59.2.3 Module block diagram

The following figure shows a block diagram of the I2C module.

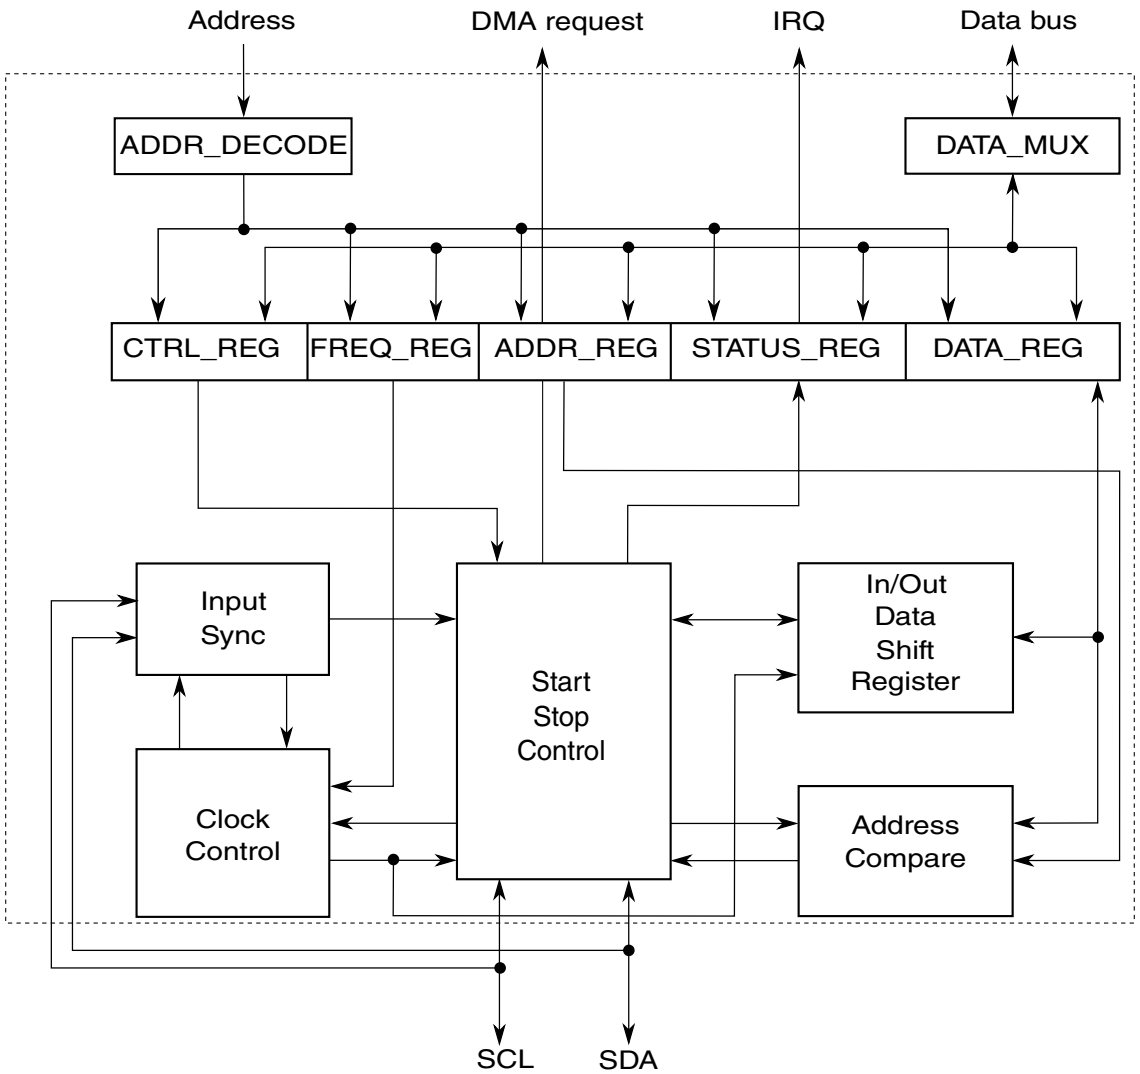

Figure 59-1. I²C block diagram

59.2.4 Features

The I²C module has the following key features:

- Compatible with I²C bus standard[1]
- Operating speeds
  - Up to 100 kbps in Standard Mode
  - Up to 400 kbps in Fast Mode

1. Compliant with I²C 2.0 standard with the exception that HS (high speed) mode is not supported

  - Operation at higher baud rates (up to a maximum of module clock/20) with reduced bus loading
  - Actual baud rate dependent on the SCL rise time (which depends on external pull-up resistor values and bus loading)
- Software programmable for one of 256 different serial clock frequencies
- Software selectable acknowledge bit
- Interrupt driven byte-by-byte data transfer
- Calling address identification interrupt
- Start and stop signal generation/detection
- Repeated start signal generation
- Acknowledge bit generation/detection
- Bus busy detection
- Basic DMA interface
- Maximum communication length and the number of devices that can be connected are limited by a maximum bus capacitance of 400 pF

59.2.5 Modes of operation

The I^2C module supports the chip modes described in the following table.

Table 59-1. Chip modes supported by the I^2C module

Chip mode	Description	Important notes
RUN	Basic mode of operation	—
STOP	The lowest-power mode that allows the chip to turn off all the clocks to the I^2C module	The I^2C module can enter this mode when there are no active transfers (active data between valid START and STOP conditions) on the bus. See STOP mode.
DEBUG	Allows the chip to freeze all ongoing activities (such as an ongoing transaction, counter values, and register status) for debugging	See DEBUG mode.

In addition to chip modes, the I^2C module has several module-specific modes. These are described in the following table.

Table 59-2. Module-specific modes supported by the I²C module

Module mode	Description	Important notes
Master mode	The I²C module is the driver of the SDA line.	• Do not use the I²C module's slave address as a calling address. • The I²C module cannot be a master and a slave simultaneously.
Slave mode	The I²C module is not the driver of the SDA line.	• Enable the I²C module before a START condition from a non-I²C master is detected. • By default the I²C module performs as a slave receiver.

59.2.6 Definition: I²C conditions

The following table shows the I²C-specific conditions defined for the I²C module.

Table 59-3. I²C Conditions

Condition	Description
START	A condition that denotes the beginning of a new data transfer and awakens all slaves. Each data transfer contains several bytes of data. It is defined as a high-to-low transition of SDA while SCL is high, as shown in the following figure.
STOP	A condition generated by the master to terminate a transfer and free the bus. It is defined as a low-to-high transition of SDA while SCL is high, as shown in the following figure.
Repeated START	A START condition that is generated without a STOP condition to terminate the previous transfer.

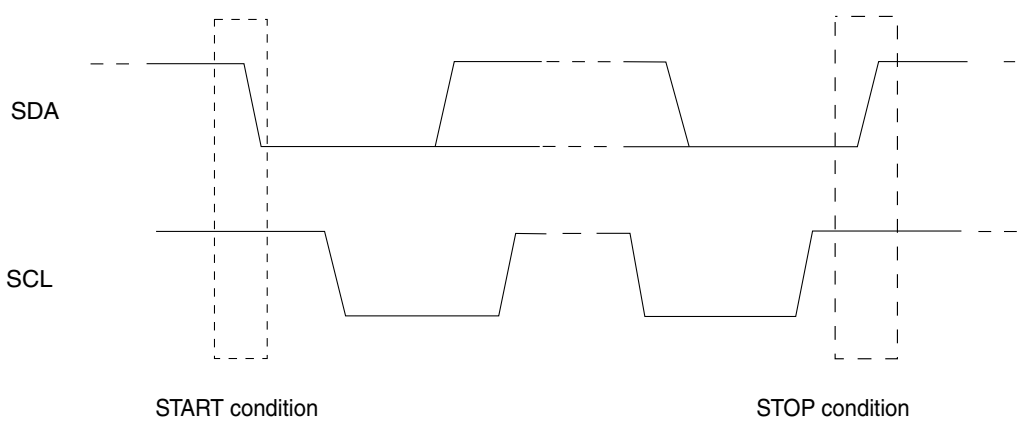

Figure 59-2. START and STOP conditions

59.3 External signal descriptions

This section presents the following topics:

- Signal overview
- Detailed external signal descriptions

59.3.1 Signal overview

The I^2C module uses the Serial Data (SDA) and Serial Clock (SCL) signals as a communication interconnect with other devices. The signal patterns driven on the SDA signal represent address, data, or read/write information at different stages of the protocol.

All devices connected to the SDA and SCL signals must have open-drain or open-collector outputs. The logical AND function is performed on both signals with external pull-up resistors. For the electrical characteristics of these signals, see the data sheet for this chip.

59.3.2 Detailed external signal descriptions

The SDA and SCL signals are described in the following table.

Table 59-4. External signal descriptions

Signal	Description
SCL	Bidirectional serial clock line of the module, compatible with the I^2C bus specification
SDA	Bidirectional serial data line of the module, compatible with the I^2C bus specification

59.4 Memory map and register definition

This section provides a detailed description of all memory-mapped registers in the I^2C module. It presents the following topics:

- Register accessibility
- Register figure conventions

- I2C Bus Address Register (I2C_IBAD)
- I2C Bus Frequency Divider Register (I2C_IBFD)
- I2C Bus Control Register (I2C_IBCR)
- I2C Bus Status Register (I2C_IBSR)
- I2C Bus Data I/O Register (I2C_IBDR)
- I2C Bus Interrupt Config Register (I2C_IBIC)
- I2C Bus Debug Register (I2C_IBDBG)

59.4.1 Register accessibility

Address location 0x0007 is a reserved location, but access to this location will not generate any bus error.

All registers are accessible via 8-bit, 16-bit, or 32-bit accesses. However, 16-bit accesses must be aligned to 16-bit boundaries, and 32-bit accesses must be aligned to 32-bit boundaries.

As an example, the IBFD is at address offset 0x01, and can be accessed in any of the following ways:

- 8-bit R/W access of address offset 0x0001
- Second byte of 16-bit R/W access of address offset 0x0000
- Second byte of 32-bit R/W access of address offset 0x0000

The IBFD register cannot be accessed by a 16- or 32-bit RW operation at address offset 0x0001 because those operations require an address aligned to a 16- or 32-bit boundary.

59.4.2 Register figure conventions

The register figures show the field structure using the conventions in the following figure.

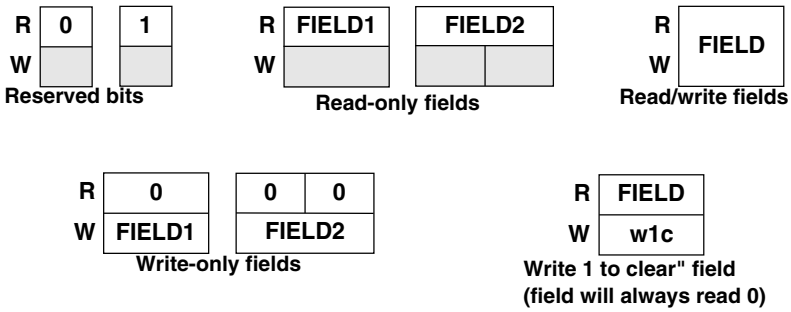

Figure 59-3. Register figure convention

The memory map for the I^{2}C module is given below. The total address for each register is the sum of the base address for the I^{2}C module and the address offset for each register.

I2C memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	I2C Bus Address Register (I2C_IBAD)	8	R/W	00h	59.4.3/2846
1	I2C Bus Frequency Divider Register (I2C_IBFD)	8	R/W	00h	59.4.4/2847
2	I2C Bus Control Register (I2C_IBCR)	8	R/W	80h	59.4.5/2847
3	I2C Bus Status Register (I2C_IBSR)	8	R/W	80h	59.4.6/2849
4	I2C Bus Data I/O Register (I2C_IBDR)	8	R/W	00h	59.4.7/2850
5	I2C Bus Interrupt Config Register (I2C_IBIC)	8	R/W	00h	59.4.8/2851
6	I2C Bus Debug Register (I2C_IBDBG)	8	R/W	00h	59.4.9/2852

59.4.3 I2C Bus Address Register (I2C_IBAD)

This register contains the address the I^{2}C Bus will respond to when addressed as a slave. This is not the address sent on the bus during the address transfer.

Access: Supervisor mode only (user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7
Read	ADR							0
Write								
Reset	0	0	0	0	0	0	0	0

I2C_IBAD field descriptions

Field	Description
0–6 ADR	Slave Address. Specific slave address to be used by the I^{2}C Bus module.

Table continues on the next page...

I2C_IBAD field descriptions (continued)

Field	Description
	NOTE: The default mode of I^2C Bus is slave mode for an address match on the bus.
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

59.4.4 I2C Bus Frequency Divider Register (I2C_IBFD)

Access: Supervisor mode only (user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

Address: 0h base + 1h offset = 1h

Bit	0	1	2	3	4	5	6	7
Read Write	IBC							
Reset	0	0	0	0	0	0	0	0

I2C_IBFD field descriptions

Field	Description
0–7 IBC	I-Bus Clock Rate. This field is used to prescale the bus clock for bit rate selection. See Clock rate and IBFD settings.

59.4.5 I2C Bus Control Register (I2C_IBCR)

Access: Supervisor mode only (user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

Address: 0h base + 2h offset = 2h

Bit	0	1	2	3	4	5	6	7
Read	MDIS	IBIE	MSSL	TXRX	NOACK	0	DMAEN	Reserved
Write						RSTA		
Reset	1	0	0	0	0	0	0	0

I2C_IBCR field descriptions

Field	Description
0 MDIS	Module disable. This bit controls the software reset of the entire I^2C Bus module.

Table continues on the next page...

I2C_IBCR field descriptions (continued)

Field	Description
	0 The I²C Bus module is enabled. This bit must be cleared before any other IBCR bits have any effect 1 The module is reset and disabled. This is the power-on reset situation. When high, the interface is held in reset, but registers can still be accessed. Status register bits (IBSR) are not valid when module is disabled.
1 IBIE	I-Bus Interrupt Enable. 0 Interrupts from the I²C Bus module are disabled. This does not clear any currently pending interrupt condition. 1 Interrupts from the I²C Bus module are enabled. An I²C Bus interrupt occurs provided the IBIF bit in the status register is also set.
2 MSSL	Master/Slave mode select. When this bit is changed from 0 to 1, a START signal is generated on the bus and the master mode is selected. When this bit is changed from 1 to 0, a STOP signal is generated and the operation mode changes from master to slave. A STOP signal should be generated only if the IBIF flag is set. 0 Slave Mode 1 Master Mode
3 TXRX	Transmit/Receive mode select. This bit selects the direction of master and slave transfers. When addressed as a slave this bit should be set by software according to the SRW bit in the status register. In master mode this bit should be set according to the type of transfer required. Therefore, for address cycles, this bit will always be high. 0 Receive 1 Transmit
4 NOACK	Data Acknowledge disable. This bit specifies the value driven onto SDA during data acknowledge cycles for both master and slave receivers. The I²C module will always acknowledge address matches, provided it is enabled, regardless of the value of NOACK. **NOTE:** Values written to this bit are only used when the I²C Bus is a receiver, not a transmitter. 0 An acknowledge signal will be sent out to the bus at the 9th clock bit after receiving one byte of data 1 No acknowledge signal response is sent (i.e., acknowledge bit = 1)
5 RSTA	Repeat Start. Writing a one to this bit will generate a repeated START condition on the bus, provided it is the current bus master. This bit will always be read as a low. The I²C module should not attempt a repeated start when the bus is owned by another master. 0 No effect 1 Generate repeat start cycle
6 DMAEN	DMA Enable. When this bit is set, the DMA Tx and Rx lines will be asserted when the I²C module requires data to be read or written to the data register. No Transfer Done interrupts will be generated when this bit is set, however an interrupt will be generated if addressed as slave conditions occur. The DMA mode is only valid when the I²C module is configured as a Master and the DMA transfer still requires CPU intervention at the start and the end of each frame of data. See the DMA Application Information section for more details. 0 Disable the DMA TX/RX request signals 1 Enable the DMA TX/RX request signals
7 Reserved	This field is reserved. Although this bit supports read/write access, writing to this bit is not recommended, and can produce unexpected results.

59.4.6 I2C Bus Status Register (I2C_IBSR)

Access: Supervisor mode only (user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

Address: 0h base + 3h offset = 3h

Bit	0	1	2	3	4	5	6	7
Read	TCF	IAAS	IBB	0		SRW	IBIF	RXAK
Write							w1c	
Reset	1	0	0	0	0	0	0	0

I2C_IBSR field descriptions

Field	Description
0 TCF	Transfer complete. While one byte of data is being transferred, this bit is cleared. It is set by the falling edge of the 9th clock of a byte transfer. **NOTE:** This bit is only valid during or immediately following a transfer to the I^2C module or from the I^2C module. 0 Transfer in progress 1 Transfer complete
1 IAAS	Addressed as a slave. When its own specific address (I-Bus Address Register) is matched with the calling address, this bit is set. The CPU is interrupted provided the IBIE is set. Then the CPU needs to check the SRW bit and set the TXRX field accordingly. Writing to the I-Bus Control Register clears this bit. 0 Not addressed 1 Addressed as a slave
2 IBB	Bus busy. This bit indicates the status of the bus. When a START signal is detected, IBB is set. If a STOP signal is detected, IBB is cleared and the bus enters idle state. **NOTE:** Software must ensure that the I^2C bus is idle by checking the IBSR[IBB] field (bus busy) before switching to master mode and attempting a START cycle. 0 Bus is Idle 1 Bus is busy
3–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 SRW	Slave Read/Write. When the IAAS bit is set, this bit indicates the value of the R/W command bit of the calling address sent from the master. This bit is only valid when the I-Bus is in slave mode, a complete address transfer has occurred with an address match and no other transfers have been initiated. By reading this field, the CPU can detect slave transmit/receive mode according to the command of the master.

Table continues on the next page...

I2C_IBSR field descriptions (continued)

Field	Description
	0 Slave receive, master writing to slave 1 Slave transmit, master reading from slave
6 IBIF	I-Bus Interrupt Flag. The IBIF bit is set when one of the following conditions occurs: • Byte transfer complete (TCF bit set and DMAEN bit not set) • Addressed as slave (IAAS bit set) • NoAck from Slave (MS & Tx bits set) • I^2C Bus going idle (IBB high-low transition and enabled by BIIE) A processor interrupt request will be caused if the IBIE bit is set. This bit must be cleared by software, by writing a one to it. A write of zero has no effect on this bit. In DMA mode (DMAEN set) a byte transfer complete condition will not trigger the setting of IBIF. All other conditions still apply.
7 RXAK	Received Acknowledge. This is the value of SDA during the acknowledge bit of a bus cycle. If the received acknowledge bit (RXAK) is low, it indicates an acknowledge signal has been received after the completion of 8 bits data transmission on the bus. If RXAK is high, it means no acknowledge signal is detected at the 9th clock. This bit is valid only after transfer is complete. 0 Acknowledge received 1 No acknowledge received

59.4.7 I2C Bus Data I/O Register (I2C_IBDR)

In master transmit mode, when data is written to the IBDR, a data transfer is initiated. The most significant bit is sent first. In master receive mode, reading this register initiates next byte data receiving. In slave mode, the same functions are available after an address match has occurred.

NOTE

The IBCR[TXRX] field must correctly reflect the desired direction of transfer in master and slave modes for the transmission to begin. For instance, if the I^2C is configured for master transmit but a master receive is desired, then reading the IBDR will not initiate the receive.

Reading the IBDR will return the most recent byte received while the I^2C is configured in either master receive or slave receive modes. The IBDR does not reflect every byte that is transmitted on the I^2C bus, nor can software verify that a byte has been written to the IBDR correctly by reading it back.

In master transmit mode, the first byte of data written to IBDR following assertion of MSSL is used for the address transfer and should comprise the calling address (in position DATA[7:1]) concatenated with the required R/ $\overline{W}$ bit (in position D0).

NOTE

When the I^2C is configured in master mode and receiving data from a slave that is transmitting data bytes on an irregular basis, the master cannot know whether the data received in the IBDR is the old latched data or the new data received from the slave. To avoid this, 2 consecutive intermittent data bytes from slave should be different.

Access: Supervisor mode only (user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7
Read Write	DATA							
Reset	0	0	0	0	0	0	0	0

I2C_IBDR field descriptions

Field	Description
0–7 DATA	Data transmitted or received

59.4.8 I2C Bus Interrupt Config Register (I2C_IBIC)

To program BIIE = 1, you must ensure that IBCR[MDIS] = 0.

Access: Supervisor mode only (user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

Address: 0h base + 5h offset = 5h

Bit	0	1	2	3	4	5	6	7
Read	BIIE	0	0					
Write								
Reset	0	0	0	0	0	0	0	0

I2C_IBIC field descriptions

Field	Description
0 BIIE	Bus Idle Interrupt Enable bit. This config bit can be used to enable the generation of an interrupt once the I^2C bus becomes idle. Once this bit is set, an IBB high-low transition will set the IBIF bit. This feature can be used to signal to the CPU the completion of a STOP on the I^2C bus. 0 Bus Idle Interrupts disabled 1 Bus Idle Interrupts enabled
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

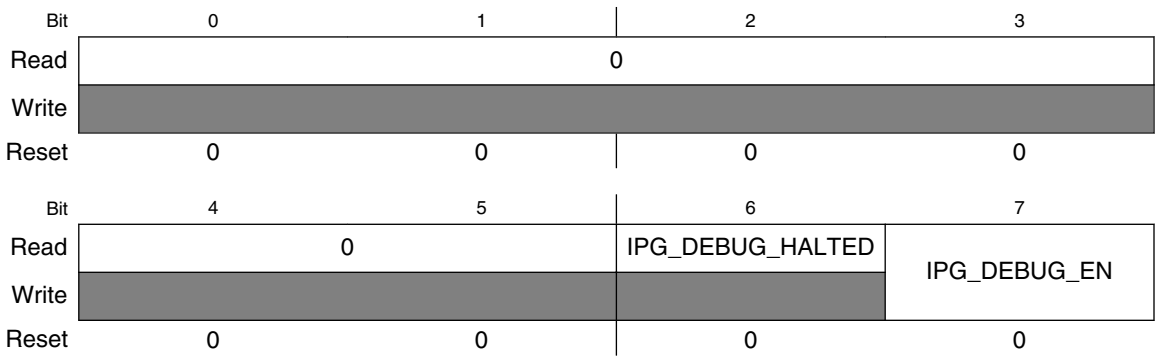
I2C_IBIC field descriptions (continued)

Field	Description
2–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

59.4.9 I2C Bus Debug Register (I2C_IBDBG)

Access: Supervisor mode only (user mode accesses are ignored, and no error response is asserted while accessing this register in user mode)

Address: 0h base + 6h offset = 6h



I2C_IBDBG field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 IPG_DEBUG_ HALTED	Debug Halted Bit: This is s status bit which can be read back after asserting the debug enable signal so as to know if the IP has entered the debug mode or not. 0 IP is still executing a transaction 1 IP has entered the debug mode
7 IPG_DEBUG_EN	Debug enable bit. This bit is used to enable IP enter the debug mode provided the IPG DEBUG signal is high. All the registers, counter values and status bits are frozen and can be accessed by the CPU. **NOTE:** If the assertion of this bit along with the IPG DEBUG signal happens in the middle of a transaction, IP enters the debug mode only after successful completion of the current transaction after which no further transaction can take place until the debug mode is exited. 0 Normal operation, Bus Idle Interrupts disabled 1 IP is in debug mode

59.5 Functional description

This section presents the following topics:

- Notes about module operation
- Transactions
- Clock behavior
- Interrupts
- DEBUG mode
- DMA interface

59.5.1 Notes about module operation

- The I^2C module always performs as a slave receiver by default, unless explicitly programmed to be a master or slave transmitter.
- When the I^2C module is acting as a master, it must not try to call its own slave address.

59.5.2 Transactions

This section presents the following topics:

- Protocol overview
- Transaction protocol definitions
- High-level protocol steps
- START condition
- Slave address transmission
- Data transmission
- STOP condition
- Repeated START condition

59.5.2.1 Protocol overview

The following figure shows the behavior of SCL and SDA during a typical I²C transaction.

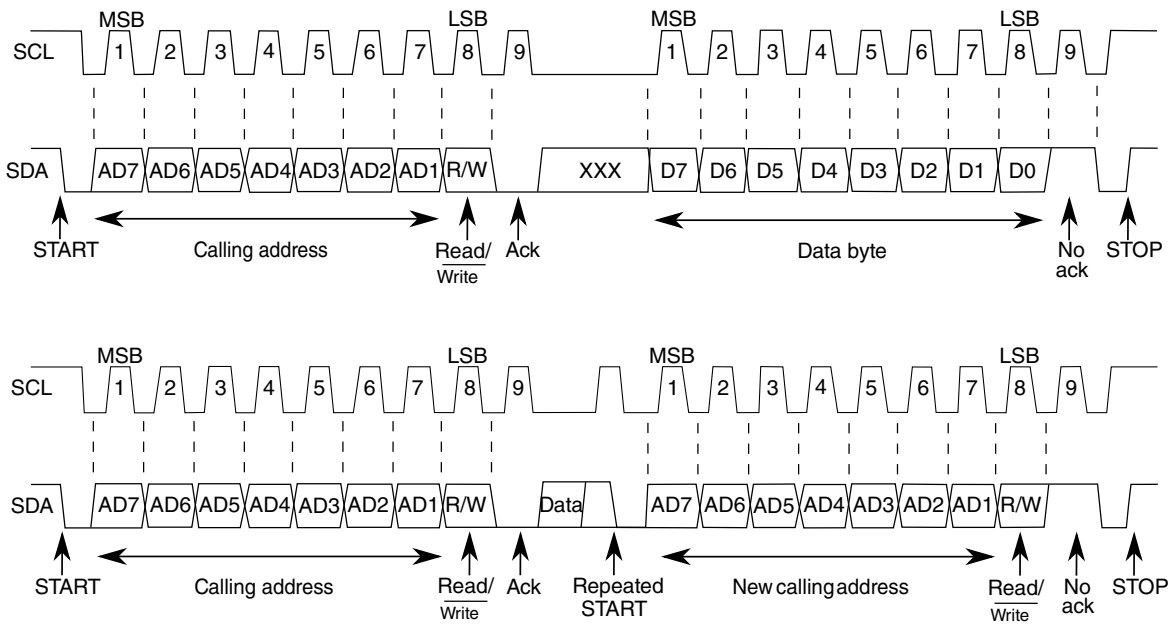


Figure 59-4. I²C transaction protocol

59.5.2.2 Transaction protocol definitions

This section defines several important terms presented in Figure 59-4.

Table 59-5. I²C definitions

Term	Definition
START	A START condition, as defined in Section 1.2.6, Definition: I²C conditions"
STOP	A STOP condition, as defined in Section 1.2.6, Definition: I²C conditions"
Calling (slave) address	A seven-bit address used to identify a slave on the I²C bus. The requirements for specifying this address are presented in Section 1.5.2.3, I²C calling address requirements."
Read/write (R/W)	A bit that specifies the direction of the data transfer to the slave as follows: • 0=The data is being transferred from the master to the slave ("write") • 1=The data is being transferred from the slave to the master ("read")
Ack	A bit that specifies the acknowledgement of a calling address, indicated by pulling SDA low.

59.5.2.3 I²C calling address requirements

The calling addresses of the devices used on an I²C network are subject to the following requirements:

- Each slave must have a unique calling address.
- A master must not transmit a calling address that is the same as its own slave address.

59.5.2.4 High-level protocol steps

The I²C protocol conceptually supports two types of transfers, which are illustrated in Figure 59-4. The significant steps in these transfers are presented in the following table. Details of each of these steps are presented in subsequent sections.

Table 59-6. I²C high-level protocol steps

Standard Transfer	Repeated START Transfer
1. START condition	1. START condition
2. Slave target or general call address transmission	2. Slave target or general call address transmission
3. Acknowledgment from slave	3. Acknowledgment from slave
4. Data transfer	4. Data transfer
5. STOP condition	5. Repeated START condition
6. (repeat Steps 1–4)	6. (repeat Steps 2–4 as needed)
	7. STOP condition.
	8. (repeat Steps 1–7)

59.5.2.5 START condition

When the bus is free, that is, no master device is engaging the bus (both SCL and SDA lines are at logical high), a master may initiate communication by sending a START condition (see Definition: I²C conditions). This signal denotes the beginning of a new data transfer (each data transfer may contain several bytes of data) and brings all slaves out of their idle states.

See Clock rate and IBFD settings and I2C Bus Frequency Divider Register (I2C_IBFD) for the associated timing requirements.

59.5.2.6 Slave address transmission

The master transmits the slave address on the next clock cycle after the START condition (see START condition). The process of slave address transmission is presented in the following table.

Table 59-7. Slave address transmission process

Step	Action
1	The master transmits the seven-bit slave address.
2	The master transmits the R/W bit.
3	Each slave examines the transmitted address and compares it to its own. If the addresses match, the slave device returns the acknowledge bit on the ninth SCL clock cycle.
4	The master waits for the acknowledge bit and determines the next step as follows: • The acknowledge bit is set: The master must initiate a data transfer followed by either a STOP condition or a repeated START condition. • The acknowledge bit is cleared: The master must wait for SCL to return to logic zero.

59.5.2.7 Data transmission

A data transfer session has the following characteristics:

- Can transmit one or more bytes of data
- Awakens all slaves
- Proceeds on a byte-by-byte basis in the direction specified by the R/W bit sent by the calling master

The transmitted data is subject to the following requirements:

- Each data byte must consist of 8 bits.
- Data bits can be changed only while SCL is low and must be held stable while SCL is high.
- One data bit is transmitted during one SCL clock pulse.
- The most significant bit (msb) must be transmitted first.
- Each data byte must be followed by an acknowledge bit on the ninth SCL clock pulse.

If the slave receiver does not acknowledge the master, the SDA line must be left high by the slave. The master can then generate a stop condition to abort the data transfer or a START condition (repeated START) to begin a new calling.

If the master receiver does not acknowledge the slave transmitter after a byte of transmission, the slave interprets that the end-of-data has been reached. Then the slave releases the SDA line for the master to generate a STOP or a START condition.

59.5.2.8 STOP condition

The master can terminate the communication by generating a STOP condition (see Definition: I^2C conditions). It can do so even if the slave has generated an acknowledge, at which point the slave must release the bus.

A master is not required to send a STOP condition at the end of every transfer. For more information, see Repeated START condition.

See Clock rate and IBFD settings and I2C Bus Frequency Divider Register (I2C_IBFD) for the associated timing requirements.

59.5.2.9 Repeated START condition

The I^2C protocol also supports a repeated START condition, which can be generated without a preceding STOP condition. A master device can use this condition to communicate with another slave or with the same slave in a different mode without releasing the bus. This condition is illustrated in the second timing diagram of Figure 59-4.

59.5.3 Clock behavior

This section presents the following topics:

- Clock synchronization
- Clock stretching
- Handshaking
- Clock rate and IBFD settings

59.5.3.1 Clock synchronization

Due to the wired-AND logic on the SCL line, a high-to-low transition on the SCL line affects all devices connected on the bus. The devices begin counting their low period when the master drives the SCL line low. After a device has driven SCL low, it holds the SCL line low until the clock high state is reached.

However, the change of low-to-high in a device clock may not change the state of the SCL line if another device is still within its low period. Therefore, the synchronized clock signal, SCL, is held low by the device with the longest low period. Devices with shorter low periods enter a high wait state during this time (see the following figure). When all devices concerned have counted off their low period, the synchronized SCL line is released and pulled high. Then there is no difference between the devices' clocks and the state of the SCL line, and all the devices begin counting their high periods. The first device to complete its high period pulls the SCL line low again.

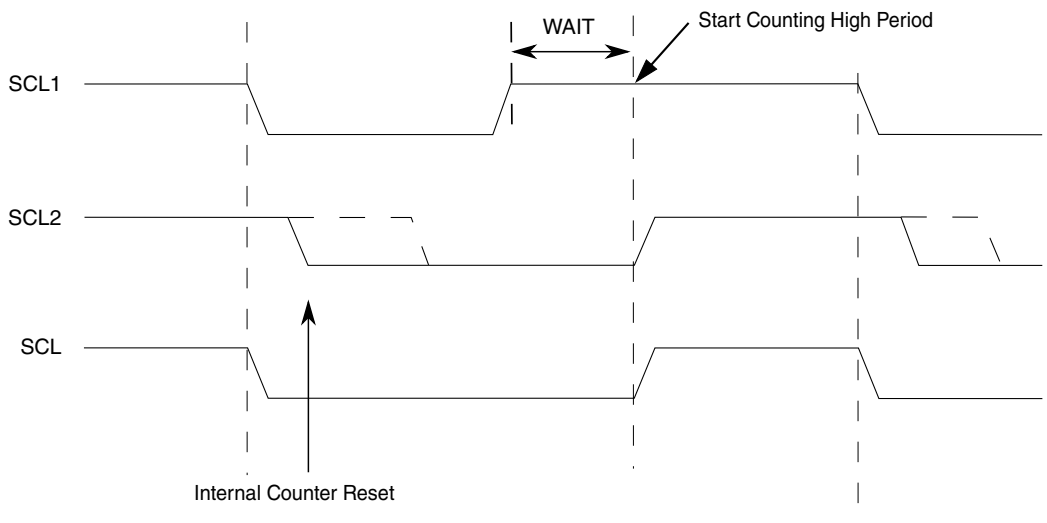

Figure 59-5. I²C bus clock synchronization

59.5.3.2 Clock stretching

The clock synchronization mechanism can be used by slaves to slow down the bit rate of a transfer. After the master has driven SCL low, the slave can drive SCL low for the required period and then release it. If the slave SCL low period is greater than the master SCL low period then the resulting SCL bus signal low period is stretched.

59.5.3.3 Handshaking

The clock synchronization mechanism can be used as a handshake in data transfer. Slave devices may hold the SCL low after completion of one byte transfer (9 bits). In such cases, it halts the bus clock and forces the master clock into wait state until the slave releases the SCL line.

59.5.3.4 Clock rate and IBFD settings

59.5.3.4.1 Timing definitions

Table 59-8. Timing definitions relevant to clock rate and IBFD settings

Term	Definition
SCL Divider	The factor used to prescale the CPU clock for bit rate selection (see Figure 59-6 and Table 59-9)
SCL period	(CPU clock period) × (SCL Divider)
SCL Hold	The required number of CPU clocks to generate a START or STOP condition (see Figure 59-6 and Table 59-9)
SDA Hold	See Figure 59-7 and Table 59-9

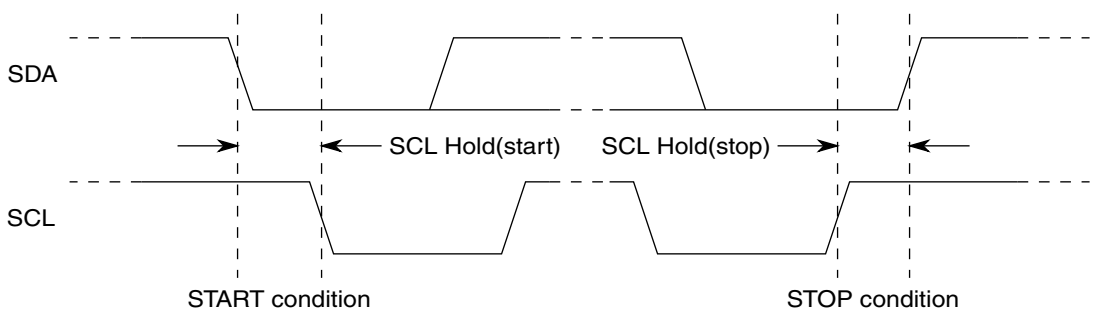

Figure 59-6. SCL Divider and SDA Hold

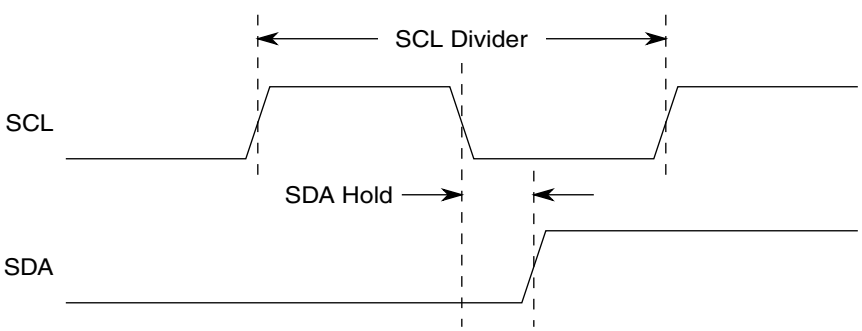

Figure 59-7. SDA Hold time

59.5.3.4.2 Divider and hold values

59.5.4 Interrupts

This section presents the following topics:

- Interrupt vector
- Interrupt description

59.5.4.1 Interrupt vector

The I²C module uses only one interrupt vector.

Table 59-10. Interrupt summary

Interrupt	Offset	Vector	Priority	Source	Description
I²C Interrupt	—	—	—	TCF, IAAS, IBB bits in IBSR register	When TCF or IAAS bits is set, an interrupt may be caused based on Transfer Complete or Address Detect conditions. If enabled by BIIE, the de-assertion of IBB can also cause an interrupt, indicating that the bus is idle.

59.5.4.2 Interrupt description

There are five types of internal interrupts in the I²C. The interrupt service routine can determine the interrupt type by reading the Status register.

I²C Interrupt can be generated on the following events:

- Byte Transfer condition (TCF bit set and DMAEN bit not set)
- Address Detect condition (IAAS bit set)

- No Acknowledge from slave received when expected
- Bus Going Idle (IBB bit not set)

The I2C interrupt is enabled by the IBCR[IBIE] bit. It must be cleared by writing '1' to the IBIF bit in the interrupt service routine. The Bus Going Idle interrupt needs to be additionally enabled by the IBIC[BIIE] bit.

59.5.5 STOP mode

This mode allows the software to put the I2C module in power-down state. Once the STOP request is asserted, the I2C module comes to a graceful halt after completing all the ongoing transactions.

As soon as the I2C module enters STOP mode:

- The I2C clock is disabled.
- No transaction can take place.
- All registers are inaccessible.

The I2C module enters this mode only after successfully completing the current ongoing transaction, hence the low-power request is acknowledged once the STOP condition occurs. The user must ensure that the bus is free when STOP is requested. To request STOP for ongoing transmission the user must wait until the transmission is complete, followed by clearing of the IBCR[TXRX] field. See the figure below for more details.

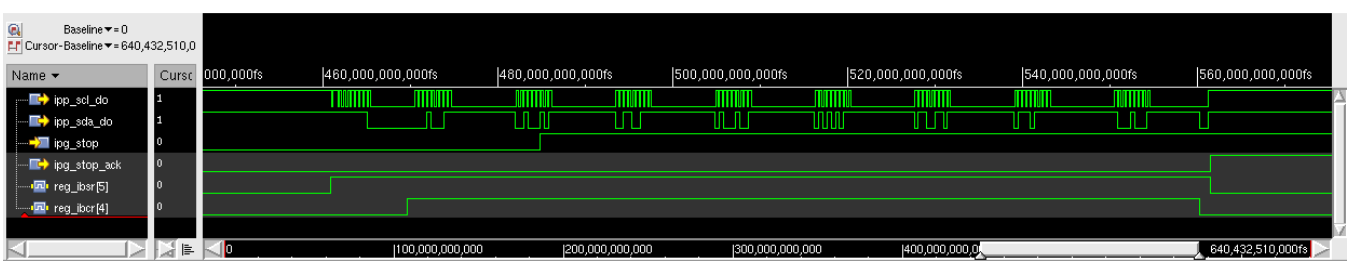

Figure 59-8. I2C stop mode behavior when master is receiving and slave is transmitting

59.5.6 DEBUG mode

This mode allows CPU to debug the I2C by freezing all the counters, registers and status bits. Once the Debug request is asserted along with IBDBG[IPG_DEBUG_EN] bit, I2C comes to a graceful halt after completing all the ongoing transactions. A Debug halted

signal IBDBG[IPG_DEBUG_HALTED] is also asserted to indicate that the debug request has been successfully serviced and is de-asserted when the Debug request is de-asserted.

As soon as the I^{2}C module enters DEBUG mode:

- No transaction can take place.
- All the registers, counters and status bits are frozen. They all can be accessed by the CPU to enable the debugging.

The I^{2}C module enters this mode only after successfully completing the current ongoing transaction. For example, if the current transaction consists of 8 bytes and the debug mode was initiated by user at the time of the second byte, the IPG Debug Halted signal will be asserted after the 8th byte is transmitted/received. See the simulation result in Figure 59-9 for more details.

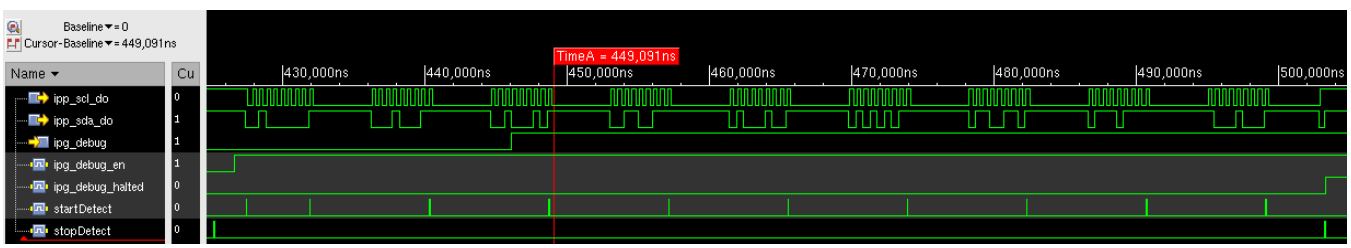

Figure 59-9. Simulation result of IPG Debug Halted in case of frame transmission

If any DMA transaction (transmit or receive) is in progress, and if the debug mode is requested while a byte is being transmitted or received, the I^{2}C module enters DEBUG mode after completing the transmission or reception of the current byte. As soon as the module exits DEBUG mode, transmission or reception of the remaining bytes resumes. Please see the simulation snapshot shown in Figure 59-10 for details where the I^{2}C is transmitting 8 bytes using DMA and DEBUG mode is requested while a second byte is being transmitted. DEBUG mode is entered after successfully transmitting the second byte (IPG Debug Halted signal asserted). As soon as the module exits DEBUG mode (IPG Debug Halted signal de-asserted), transmission resumes successfully.

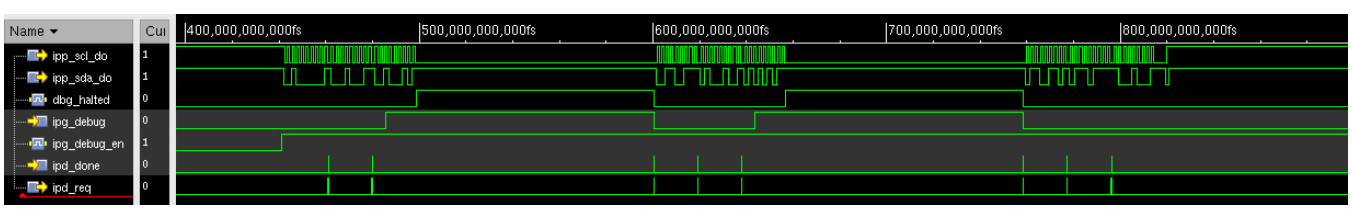

Figure 59-10. Simulation result of IPG Debug Halted in case of frame transmission using DMA

No more transaction can take place until the debug signal is de-asserted after which the I^2C module starts functioning normally. There is a status halted signal IBDBG[IPG_DEBUG_HALTED] to indicate to the user that the I^2C module has entered the DEBUG mode. See the following figure for more details.

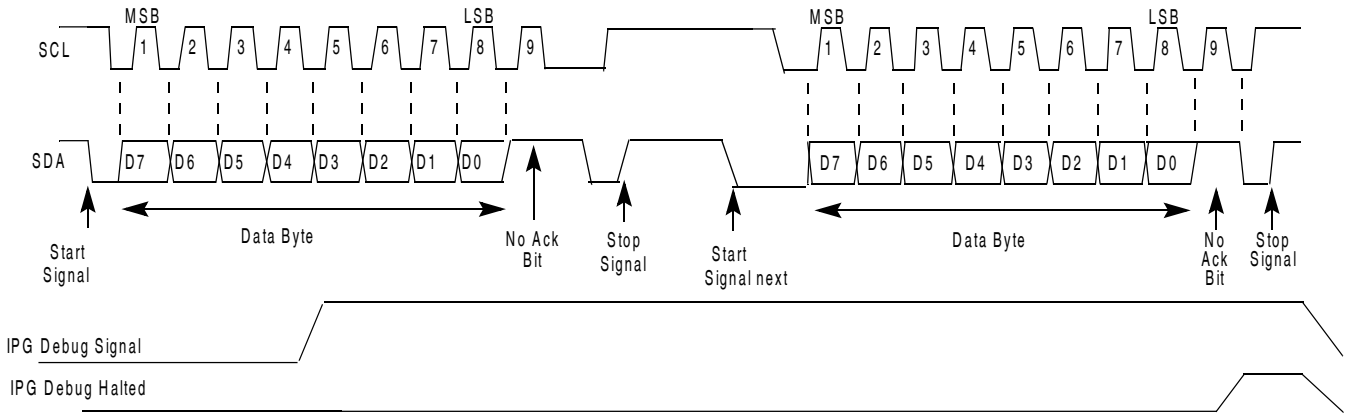

Figure 59-11. DEBUG mode

The following figure shows a case of DEBUG mode with repeated START transaction. In this case, if the debug signal is asserted in between the transaction, the entire transaction with multiple repeated start will be completed before the I^2C module enters DEBUG mode.

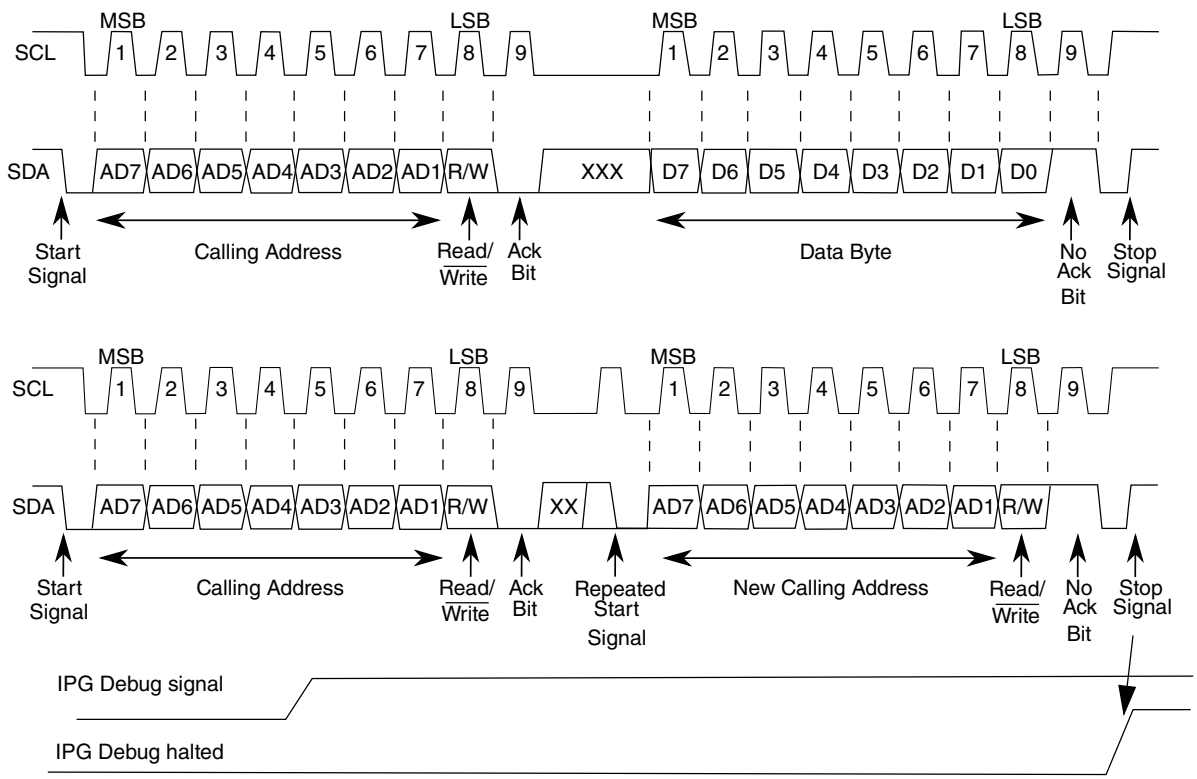

Figure 59-12. DEBUG mode with repeated start

59.5.7 DMA interface

A simple DMA interface is implemented so that the I^2C can request data transfers with minimal support from the CPU (see DMA application information). DMA mode is enabled by setting bit 1 in the Control Register (IBCR).

The DMA interface is operational when the I^2C module is configured for Master mode.

At least three bytes of data per frame must be transferred from/to the slave when using DMA mode, although in practice it will only be worthwhile using the DMA mode when there is a large number of data bytes to transfer per frame.

Two internal signals, TX request and RX request, are used to signal the DMA controller when the I^2C module requires data to be written or read from the data register.

Further details of the DMA interface can be found in the Initialization/application information, of this document.

59.6 Initialization/application information

This section presents the following topics:

- Recommended interrupt service flow
- General programming guidelines (for both master and slave mode)
- Programming guidelines specific to master mode
- Programming guidelines specific to slave mode
- DMA application information

59.6.1 Recommended interrupt service flow

The following figure shows a flowchart for the recommended I^2C interrupt service routine. Deviation from the flowchart may result in unpredictable I^2C bus behavior.

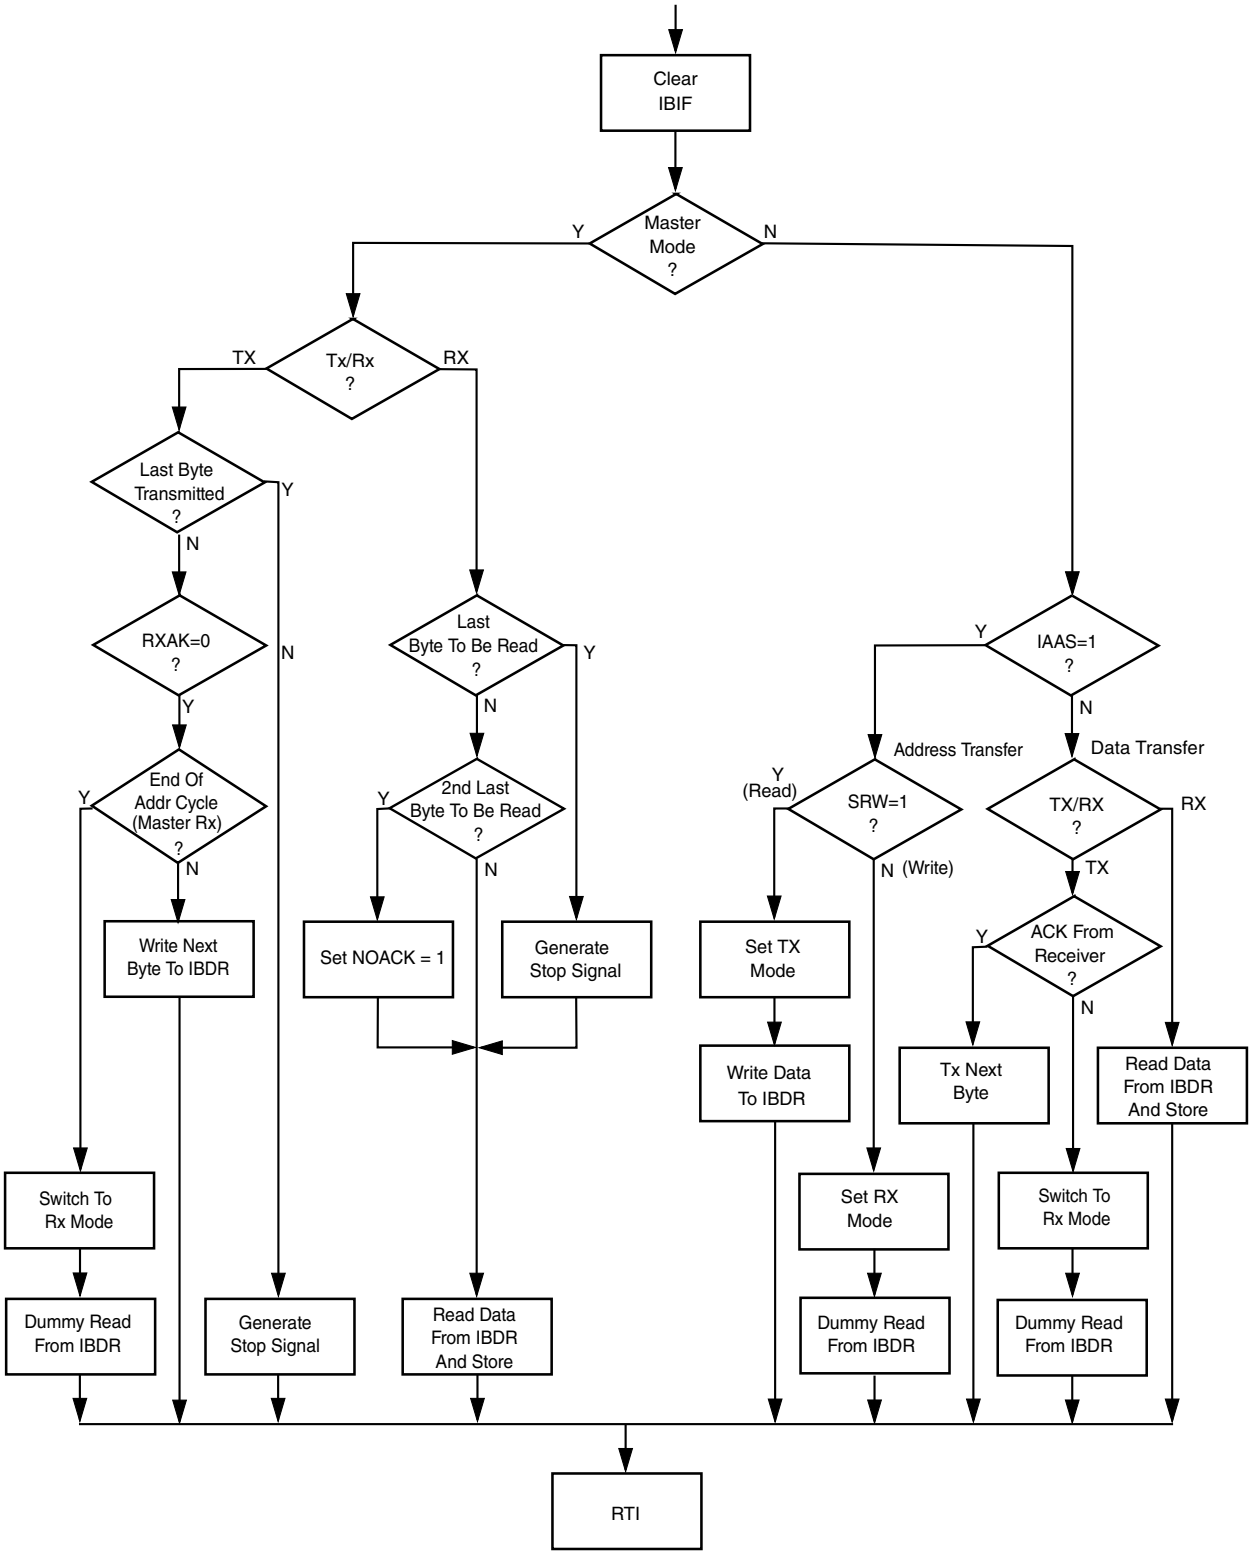

Figure 59-13. Recommended I²C interrupt service routine flowchart

59.6.2 General programming guidelines (for both master and slave mode)

This section provides programming guidelines recommended for the I^{2}C module in both master and slave mode. It presents the following topics:

- Initializing the I^{2}C module
- Software response after a transfer

59.6.2.1 Initializing the I^{2}C module

The following table describes how to initialize the I^{2}C module.

Table 59-11. I^{2}C initialization procedure

Step	Action
1	Use I2C Bus Frequency Divider Register (I2C_IBFD) to select the required division ratio to obtain SCL frequency from the system clock.
2	Use I2C Bus Address Register (I2C_IBAD) to define the slave address.
3	Clear the MDIS field in I2C Bus Control Register (I2C_IBCR) to enable the I^{2}C interface system.
4	Use I2C Bus Control Register (I2C_IBCR) to select Master/Slave mode, Transmit/Receive mode, and whether interrupts are enabled or disabled.
5	(Optional) Use I2C Bus Interrupt Config Register (I2C_IBIC) to further refine the interrupt behavior.

59.6.2.2 Software response after a transfer

Transmission or reception of a byte will set the data transferring bit (TCF) to 1, which indicates one byte communication is finished. The I^{2}C Bus interrupt bit (IBIF) is set also; an interrupt will be generated if the interrupt function is enabled during initialization by setting the IBIE bit. The IBIF (interrupt flag) can be cleared by writing one (in the interrupt service routine, if interrupts are used).

The TCF bit will be cleared to indicate data transfer in progress whenever data register is written to in transmit mode, or during reading out from data register in receive mode. The TCF bit should not be used as a data transfer complete flag as the flag timing is dependent on a number of factors including the I^{2}C bus frequency. This bit may not conclusively provide an indication of a transfer complete situation. It is recommended that transfer complete situations are detected using the IBIF flag.

Software may service the I^{2}C I/O in the main program by monitoring the IBIF bit if the interrupt function is disabled.

When a "Transfer Complete" interrupt occurs at the end of the address cycle, the master will always be in transmit mode, i.e. the address is transmitted. If master receive mode is required, indicated by R/W bit sent with slave calling address, then the Tx/Rx bit at Master side should be toggled at this stage. If Master does not receive an ACK from Slave, then transmission must be re-initiated or terminated.

In slave mode, IAAS bit will get set in IBSR if Slave address (IBAD) matches the Master calling address. This is an indication that Master-Slave data communication can now start. During address cycles (IBSR[IAAS]=1), the SRW bit in the status register is read to determine the direction of the subsequent transfer and the Tx/Rx bit is programmed accordingly. For slave mode data cycles (IBSR[IAAS]=0), the SRW bit is not valid. The Tx/Rx bit in the control register should be read to determine the direction of the current transfer.

59.6.3 Programming guidelines specific to master mode

This section presents the following topics:

- Generating START
- Transmit/receive sequence
- Generating STOP
- Generating repeated START

59.6.3.1 Generating START

After completion of the initialization procedure, serial data can be transmitted by selecting the 'master transmitter' mode. If the device is connected to a multi-master bus system, the state of the I^2C Bus Busy bit (IBB) must be tested to check whether the serial bus is free.

If the bus is free (IBB=0), the start condition and the first byte (the slave address) can be sent. The data written to the data register comprises the slave calling address and the LSB, which is set to indicate the direction of transfer required from the slave.

The bus free time (i.e., the time between a STOP condition and the following START condition) is built into the hardware that generates the START cycle. Depending on the relative frequencies of the system clock and the SCL period, it may be necessary to wait until the I^2C is busy after writing the calling address to the IBDR before proceeding with the following instructions. This is illustrated in the following example.

An example of the sequence of events which generates the START signal and transmits the first byte of data (slave address) is shown below:

```
while (IBSR[IBB]==1)                // wait in loop for IBB flag to clear
IBCR[MS/MSL] and IBCR[]Tx/Rx] = 1    // master and transmit mode, that is,
                                    // generate start condition
IBDR = calling_address              // send the calling address to the data register
while (bit 5, IBSR ==0)             // wait in loop for IBB flag to be set
```

59.6.3.2 Transmit/receive sequence

The following tables present the sequences for:

- Master transmit
- Master receive
- Slave transmit
- Slave receive

Table 59-12. Master transmit sequence

Step	Action
a	Use I2C Bus Frequency Divider Register (I2C_IBFD) to select the required division ratio to obtain SCL frequency from Platform clock/2.
b	Write 0 to the IBDIS field in I2C Bus Control Register (I2C_IBCR) to enable the I^2C interface system.
c	Use I2C Bus Control Register (I2C_IBCR) to select Master mode, Transmit mode, and interrupt enable.
d	Write 0 to the IBIF field in I2C Bus Status Register (I2C_IBSR).
e	Write data to I2C Bus Data I/O Register (I2C_IBDR).
f	Observe changes in the TCF field of I2C Bus Status Register (I2C_IBSR) : • When IBSR[TCF] becomes 0, the transfer is in progress. • When IBSR[TCF] becomes 1, the transfer is complete.
g	Wait until the IBIF field in I2C Bus Status Register (I2C_IBSR) becomes 1.
h	Read the fields in I2C Bus Status Register (I2C_IBSR) to determine what happened: • If TCF = 1, the transfer completed. • If RXAK = 1, a No Acknowledge condition occurred. • If IBB = 0, the bus transitioned from Busy to Idle state. **NOTE:** You can ignore Address Detect (IAAS = 1) for master mode (it is valid only for slave mode).
i	Examine the RXAK field in I2C Bus Status Register (I2C_IBSR) for an acknowledgment from the slave.
j	Repeat steps d through i to transfer the next consecutive bytes of data.

Table 59-13. Master receive sequence

Step	Action
a	Follow steps a through i in Table 59-12 for address dispatch.
b	Write 0 to the IBIF field in I2C Bus Status Register (I2C_IBSR).
c	Write 0 to the TXRX field in I2C Bus Control Register (I2C_IBCR) to select Receive mode.

Table continues on the next page...

Table 59-13. Master receive sequence (continued)

Step	Action
d	Perform a dummy read of I2C Bus Data I/O Register (I2C_IBDR) to initiate the receive operation.
e	Wait until the TCF field in I2C Bus Status Register (I2C_IBSR) becomes 1. (This proves that the transfer is complete.)
f	Wait until the IBIF field in I2C Bus Status Register (I2C_IBSR) becomes 1.
g	Read the fields in I2C Bus Status Register (I2C_IBSR) to determine what happened: • If TCF = 1, the reception completed. • If IBB = 0, the bus transitioned from Busy to Idle state. **NOTE:** You can ignore the No Acknowledge condition (RXAK = 1) for receive mode.
h	Read I2C Bus Data I/O Register (I2C_IBDR) to determine the data received from the slave.

Table 59-14. Slave transmit sequence

Step	Action
a	Use I2C Bus Address Register (I2C_IBAD) to define the slave address.
b	Write 0 to the IBDIS field in I2C Bus Control Register (I2C_IBCR) to enable the I^2C interface system.
c	Examine fields in I2C Bus Status Register (I2C_IBSR) as follows: • If IAAS = 1, examine IBSR[SRW]. • If IAAS = 1 and SRW = 1, write 1 to IBCR[TXRX] to select Transmit mode.
d	Write data to I2C Bus Data I/O Register (I2C_IBDR).
e	Wait until the IBIF field in I2C Bus Status Register (I2C_IBSR) becomes 1.
f	Wait until the RXAK field in I2C Bus Status Register (I2C_IBSR) becomes 0.
g	Write 0 to the IBIF field in I2C Bus Status Register (I2C_IBSR).
h	Repeat steps d through g for the next consecutive data transfers.

Table 59-15. Slave receive sequence

Step	Action
a	Use I2C Bus Address Register (I2C_IBAD) to define the slave address.
b	Write 0 to the IBDIS field of I2C Bus Control Register (I2C_IBCR) to enable the I^2C interface system.
c	Examine fields in I2C Bus Status Register (I2C_IBSR) as follows: • If IAAS = 1, examine IBSR[SRW]. • If IAAS = 1 and SRW = 0, write 0 to IBCR[TXRX] to select Receive mode.
d	Write 0 to the IBIF field of I2C Bus Status Register (I2C_IBSR).
e	Perform a dummy read of I2C Bus Data I/O Register (I2C_IBDR) to initiate the receive operation.
f	Wait until the TCF field of I2C Bus Status Register (I2C_IBSR) becomes 1. (This proves that the transfer is complete.)
g	Wait until the IBIF field of I2C Bus Status Register (I2C_IBSR) becomes 1.
h	Read the fields in I2C Bus Status Register (I2C_IBSR) to determine what happened: • If TCF = 1, the reception completed. • If IBB = 0, the bus transitioned from Busy to Idle state. **NOTE:** You can ignore the No Acknowledge condition (RXAK = 1) for receive mode.
i	Read I2C Bus Data I/O Register (I2C_IBDR) to determine the data received from the master.

59.6.3.3 Generating STOP

A data transfer ends with a STOP signal generated by the 'master' device. A master transmitter can simply generate a STOP signal after all the data has been transmitted. The following is an example showing how a STOP condition is generated by a master transmitter.

```
if (tx_count == 0) or     // check to see if all data bytes have been transmitted
  (bit 0, IBSR == 1) {    // or if no ACK generated
    clear bit 5, IBCR     // generate stop condition
  }
else {
 IBDR = data_to_transmit  // write byte of data to DATA register
   tx_count --            // decrement counter
 }                        // return from interrupt
```

If a master receiver wants to terminate a data transfer, it must inform the slave transmitter by not acknowledging the last byte of data which can be done by setting the NOACK bit in IBCR before reading the 2nd last byte of data. Before reading the last byte of data, a STOP signal must first be generated. The following is an example showing how a STOP signal is generated by a master receiver.

```
rx_count --             // decrease the rx counter
if (rx_count ==1)       // 2nd last byte to be read ?
 bit 3, IBCR = 1        // disable ACK
 if (rx_count == 0)     // last byte to be read ?
 bit 5, IBCR = 0        // generate stop signal
else
data_received = IBDR    // read RX data and store
```

59.6.3.4 Generating repeated START

At the end of data transfer, if the master still wants to communicate on the bus, it can generate another START signal followed by another slave address without first generating a STOP signal. A program example is as shown.

```
bit 2, IBCR = 1             // generate another start (restart)
IBDR == calling_address     // transmit the calling address
```

59.6.4 Programming guidelines specific to slave mode

In the slave interrupt service routine, the module addressed as slave bit (IAAS) should be tested to check if a calling of its own address has just been received. If IAAS is set, software should set the transmit/receive mode select bit (Tx/Rx bit of IBCR) according to

the R/W command bit (SRW). Writing to the IBCR clears IAAS automatically. Note that the only time IAAS is read as set is from the interrupt at the end of the address cycle where an address match occurred. Interrupts resulting from subsequent data transfers will have IAAS cleared. A data transfer may now be initiated by writing information to IBDR for slave transmits or dummy reading from IBDR in slave receive mode. The slave will drive SCL low in-between byte transfers, SCL is released when the IBDR is accessed in the required mode.

In slave transmitter routine, the received acknowledge bit (RXAK) must be tested before transmitting the next byte of data. Setting RXAK means an "end of data" signal from the master receiver, after which it must be switched from transmitter mode to receiver mode by software. A dummy read then releases the SCL line so that the master can generate a STOP signal.

59.6.5 DMA application information

The DMA interface on the I^2C is not completely autonomous and requires intervention from the CPU to start and to terminate the frame transfer. DMA mode is only valid for Master transmit and Master receive modes. Software must ensure that the DMAEN field in I2C Bus Control Register (I2C_IBCR) is not set when the I^2C module is configured in slave mode.

The DMA controller must only transfer one byte of data per Tx/Rx request. This is because there is no FIFO on the I^2C block.

The CPU should also keep the I^2C interrupt enabled during a DMA transfer. The DMAEN field in I2C Bus Control Register (I2C_IBCR) works as a disable for the transfer complete interrupt. This means that during normal transfers (no errors) there will always be either an interrupt or a request to the DMA controller, depending on the setting of the DMAEN field. All error conditions will trigger an interrupt and require CPU intervention. The address match condition will not occur in DMA mode as the I^2C should never be configured for slave operation.

The following sections detail how to set up a DMA transfer and what intervention is required from the CPU. It is assumed that the system DMA controller is capable of generating an interrupt after a certain number of DMA transfers have taken place.

The sections present the following topics:

- DMA mode, master transmit
- DMA mode, master reception
- Exiting DMA mode, system requirement considerations

59.6.5.1 DMA mode, master transmit

The following flow diagram details exactly the operation for using a DMA controller to transmit "n" data bytes to a slave. The first byte (the slave calling address) is always transmitted by the CPU. All subsequent data bytes (apart from the last data byte) can be transferred by the DMA controller. The last data byte must be transferred by the CPU.

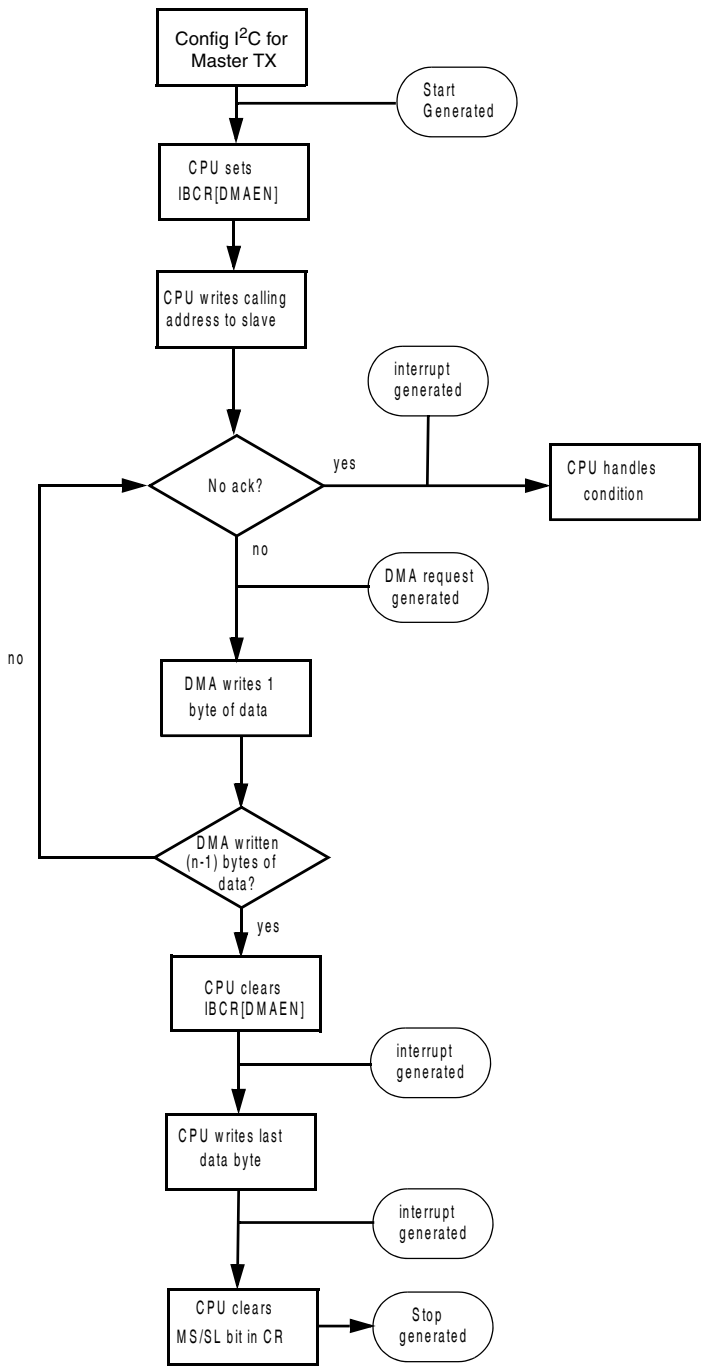

Figure 59-14. Flow-Chart of DMA mode master transmit

59.6.5.2 DMA mode, master reception

The following flow diagram details the exact operation for using a DMA controller to receive "n" data bytes from a slave. The first byte (the slave calling address) is always transmitted by the CPU. All subsequent data bytes (apart from the two last data bytes) can be read by the DMA controller. The last two data bytes must be transferred by the CPU.

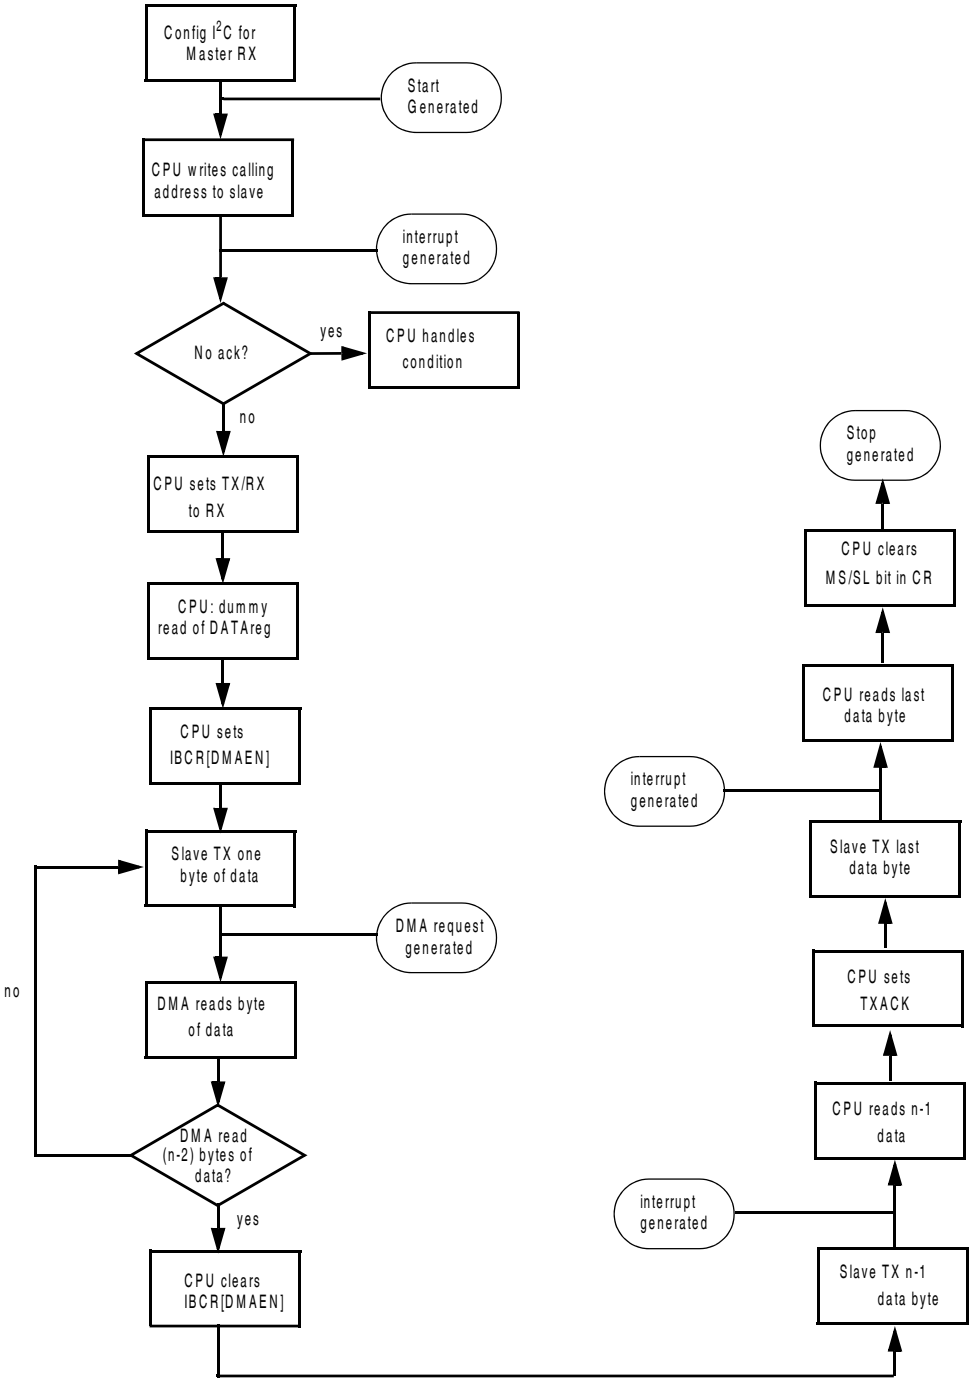

Figure 59-15. Flow-Chart of DMA mode master receive

59.6.5.3 Exiting DMA mode, system requirement considerations

As described above, the final transfers of both TX and RX transfers need to be handled via interrupt by the CPU. To change from DMA to interrupt driven transfers in the I^2C module, you have to disable the DMAEN bit in the IBCR register. The trigger to exit the DMA mode is that the programmed DMA Transfer Control Descriptor (TCD) has completed all its transfers to/from the I^2C module.

After the last DMA write (TX mode) to the I^2C the module will immediately start the next I^2C-bus transfer. The same is true for receive mode. After the DMA read from the IBDR register the module initiates the next I^2C-bus transfer. This results in two possible scenarios in the DMA mode exiting scheme.

1. Fast reaction

   The DMAEN bit is cleared before the next I^2C-bus transfer completes. In this case the module will raise an interrupt request to the CPU which can be serviced normally.

2. Slow reaction

   The DMAEN bit is cleared after the next I^2C-bus transfer has already completed. In this case, the module will not raise an interrupt request to the CPU. Instead the TCF bit can be read to determine that the transfer completed and the module is ready for further transfer.

What is fast/slow reaction?

The reaction time T_R for the system to disable DMAEN after the last DMA controller access to the I^2C is the time required for one byte transfer over the I^2C. For 'fast reaction' the disabling has to occur before the 9^{th} bit of the data transfer which is the ACK bit. So the time available is eight times the SCL period.

$$T_R = 8 \times T_{SCL}$$

In fast mode, with 400kbit/s, T_{SCL} is 2.5µs, so T_R is 20µs.

Depending on the system and DMA controller there are different possibilities for the de-assertion of DMAEN. Three options are:

1. CPU intervention via Interrupt

   The DMA controller is programmed to signal an interrupt to the CPU which is then responsible for the de-assertion of DMAEN. This scheme should be supported by most systems but it can result in a slow reaction time if other higher priority interrupts interfere. Therefore the interrupt handling routine can become complicated as it has to check which of the two cases happened (check TCF bit) and act

accordingly. In case of slow reaction you can force an interrupt for the I^2C in the interrupt controller to have the further transfer handled by the normal I^2C interrupt routine.

Note

The use of nested interrupts can still cause potential issues in this scenario, if someone tries to stall the DMA interrupt between the de-assertion and DMAEN bit and checks the TCF bit.

2. DMA channel linking

   If the Transfer control descriptor in the DMA controller that performs the data transfer is linked to another channel that does a write to IBCR to disable the DMAEN field, this might probably be the fastest system solution, but it uses two DMA channels.

   Note

   Here you have to make sure on system level that no higher priority DMA requests occur between the two linked TCDs as those could again create a scenario of slow reaction.

3. DMA scatter/gather process

   If the Transfer control descriptor in the DMA controller that performs the data transfer has the scatter/gather feature activated, this feature will initiate a reload of another TCD from system RAM after the completion of the first TCD. The new TCD will have its start bit already set and immediately start the required write to the IBCR to disable the DMAEN field. This TCD also has scatter/gather activated and is programmed to reload the initial TCD upon completion, bringing the system back into a "ready-for-I^2C-transfer" state. The advantage over the two other solutions is that this requires neither CPU intervention nor a second DMA channel. This comes at the cost of 64 bytes RAM (two TCDs), some system bus transfer overhead and a little increase in application code complexity.

Note

Here you have to make sure at system level that no higher priority DMA requests occur during the scatter/gather process, as those could again create a scenario of slow reaction.

Example latencies for a 32 MHz system with a full speed 32-bit AHB bus and an I^2C connected via half speed IPI bus:

- Accessing the I^2C from the DMA controller via IPI bus typically requires four cycles (consecutive accesses to the I^2C could be faster):

  $4 \times T_{IPI}$ = 4/16 MHz = 250 ns

- Reloading a new TCD (8 x 32-bit) via AHB to the DMA controller (scatter/gather process):

  $8 \times T_{AHD}$ = 8/32 MHz = 250 ns

Example latencies for a 150 MHz system with a full speed 32-bit AHB bus and an I^2C connected via half speed IPI bus:

- Accessing the I^2C from the DMA controller via IPI bus typically requires four cycles (consecutive accesses to the I^2C could be faster):

  $4 \times T_{IPI}$ = 4/150 MHz = 26.6 ns

- Reloading a new TCD (4 x 64-bit) via AHB to the DMA controller (scatter/gather process):

  $4 \times T_{AHD}$ = 4/150 MHz = 26.6 ns

With the DMA scatter/gather process the required IBCR access can be done in 0.5 µs, leaving a large margin of 19.5 µs for additional system delays. In this way, the slow reaction case can be prevented. The system user needs to decide which usage model best suits his overall requirement.

Chapter 60
FlexRay Communication Controller (FlexRay)

60.1 Chip-specific FlexRay information

60.1.1 FlexRay Configuration

The FlexRay communications system is designed to provide high-speed deterministic distributed control for advanced automotive applications. Its dual-channel architecture supporting data rates up to 10 Mbit/s per channel offers system-wide redundancy that supports the reliability requirements of enhanced availability and safety system.

60.1.1.1 FlexRay signals pin assignment

This table lists the pin names for the FlexRay signals that are connected to pins on the boundary of the chip.

Table 60-1. Flexray pin names

Signal description	Pin name
FR_A_RX (Receive Data Channel A)	CA_RX
FR_A_TX (Transmit Data Channel A)	TXD_A
$\overline{\text{FR\_A\_TX\_EN}}$ (Transmit Enable Channel A)	$\overline{\text{TXEN\_A}}$
FR_B_RX (Receive Data Channel B)	CB_RX
FR_B_TX (Transmit Data Channel B)	CB_TX
$\overline{\text{FR\_B\_TX\_EN}}$ (Transmit Enable Channel B)	$\overline{\text{TXEN\_B}}$
FR_DBG[0] (Debug Strobe Signal 0)	DEBUG_0
FR_DBG[1] (Debug Strobe Signal 1)	DEBUG_1
FR_DBG[2] (Debug Strobe Signal 2)	DEBUG_2
FR_DBG[3] (Debug Strobe Signal 3)	DEBUG_3

60.2 Introduction

This section provides a high-level summary of module features.

60.2.1 Reference

The following documents are referenced.

- *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*[1]
  - Refer to this document for the all of the FlexRay related informaton including the configuration parameters and the allowed parameter ranges.
- *FlexRay Communications System Electrical Physical Layer Specification, Version 3.0*

60.2.2 Glossary

This section provides a list of terms used in this chapter.

Table 60-2. List of terms

Term	Definition
BCU	Buffer Control Unit. Handles message buffer access.
BMIF	Bus Master Interface. Provides master access to FlexRay memory area.
CC	Communication Controller
CDC	Clock Domain Crosser
CHI	Controller Host Interface
Cycle length in µT	The actual length of a cycle in µT for the ideal controller (+/- 0 ppm)
EBI	External Bus Interface
FlexRay Memory Area	Memory area to store the physical message buffer payload data, frame header, frame and slot status, and synchronization frame related tables.
FSS	Frame Start Sequence
HIF	Host Interface. Provides host access to controller.
Host	The FlexRay CC host MCU
Keyslot	Key slot is used to transmit the startup frame, sync frame, or designated single slot frame.

Table continues on the next page...

1. The FlexRay Specifications have been developed for automotive applications.The FlexRay Specifications have been neither developed nor tested for non-automotive applications.

Table 60-2. List of terms (continued)

Term	Definition
LUT	Look Up Table. Stores message buffer header index value.
LRAM	Look Up Table RAM. Module internal memory to store message buffer configuration data and data field offsets for individual message buffers and receive shadow buffers.
MB	Message Buffer
Mini-slot	An interval of time within the dynamic segment of the communication cycle that is of constant duration (in terms of macroticks) and that is used by the synchronized FTDMA media access scheme to manage media arbitration
MBIDX	Message Buffer Index: the position of a header field entry within the header area. If the header area is accessed as an array, this is the same as the array index of the entry.
MBNum	Message Buffer Number: Position of message buffer configuration registers within the register map. For example, Message Buffer Number 5 corresponds to the MBCCS5 register.
MCU	Microcontroller Unit
µT	Microtick
MT	Macrotick
MTS	Media Access Test Symbol
message frame	Frame with *Null Frame Indicator* set to 1
normal frame	null frame or message frame with both *Sync Frame Indicator* and *Startup Frame Indicator* set to 0
null frame	frame with *Null Frame Indicator* set to 0
NIT	Network Idle Time
PE	Protocol Engine
POC	Protocol Operation Control. Each state of the POC is denoted by POC:state
Rx	Reception
Slot	An interval of time during which access to a communication channel is granted exclusively to a specific node for the transmission of a frame with a frame ID corresponding to the slot.
SEQ	Sequencer Engine
SU	Status update
SECDED	Single-bit error correction, double-bit error detection
System Memory	Memory that contains the FlexRay Memory Area.
System Bus	Bus that connects the controller and System Memory
sync frame	null frame or message frame with *Sync Frame Indicator* set to 1
startup frame	null frame or message frame with both *Sync Frame Indicator* and *Startup Frame Indicator* set to 1
TCU	Time Control Unit
Tx	Transmission

60.2.3 Overview

The CC is a FlexRay communication controller that implements the FlexRay Communications System Protocol Specification, Version 2.1 Rev A.

The CC has three main components:

- *Controller host interface (CHI)*
- *Protocol engine (PE)*
- *Clock domain crossing unit (CDC)*

A block diagram of the CC with its surrounding modules is given in the below figure.

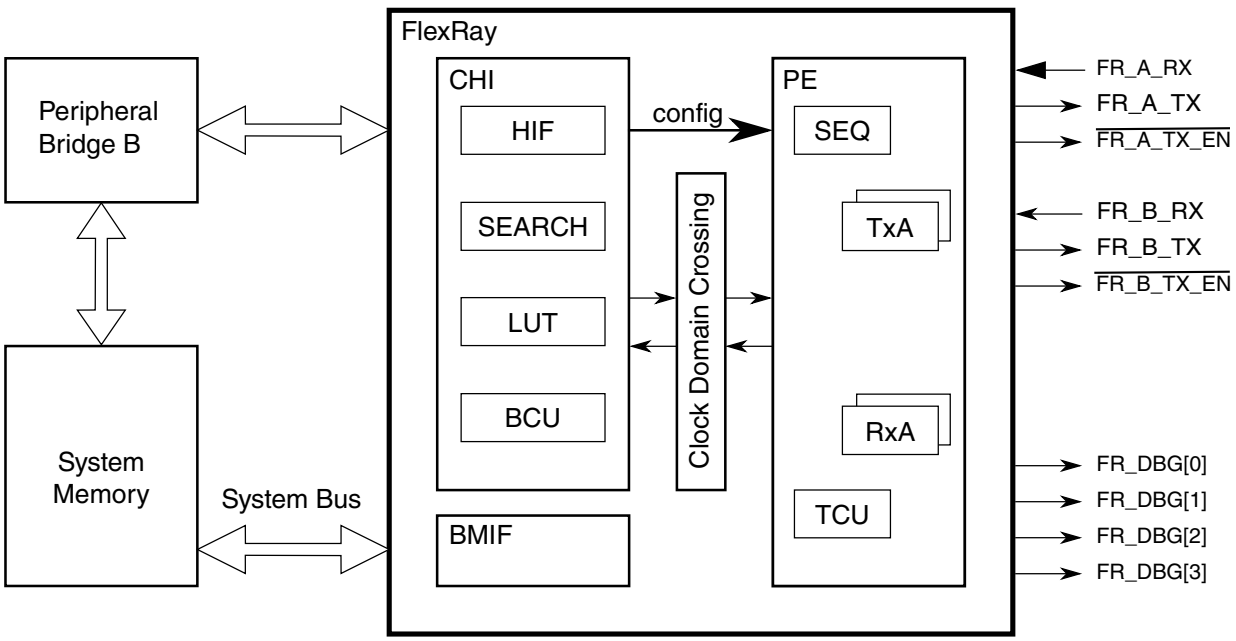

Figure 60-1. FlexRay block diagram

The protocol engine has two transmitter units TxA and TxB and two receiver units RxA and RxB for sending and receiving frames through the two FlexRay channels. The time control unit (TCU) is responsible for maintaining global clock synchronization to the FlexRay network. The overall activity of the PE is controlled by the sequencer engine (SEQ).

The controller host interface provides host access to the module's configuration, control, and status registers, as well as to the message buffer configuration, control, and status registers. The message buffers themselves, which contain the frame header and payload data received or to be transmitted, and the slot status information, are stored in the FlexRay memory area.

The clock domain crossing unit implements signal crossing from the CHI clock domain to the PE clock domain and vice versa, to allow for asynchronous PE and CHI clock domains.

The CC stores the frame header and payload data of frames received or of frames to be transmitted in the FlexRay memory area. The application accesses the FlexRay memory area to retrieve and provide the frames to be processed by the CC. In addition to the frame header and payload data, the CC stores the synchronization frame related tables in the FlexRay memory area for application processing.

The FlexRay memory area is located in the system memory of the MCU. The CC has access to the FlexRay memory area via its bus master interface (BMIF). The host provides the start address of the FlexRay memory area within the system memory by programming the System Memory Base Address Register (FR_SYMBADHR and FR_SYMBADLR). All FlexRay memory area related offsets are stored in offset registers. The physical address pointer into the FlexRay memory area is calculated using the offset values the FlexRay memory base address.

Note

The CC does not provide a memory protection scheme for the FlexRay memory area.

60.2.4 Features

The CC provides the following features:

- *FlexRay Communications System Protocol Specification, Version 2.1 Rev A compliant protocol implementation*
- *FlexRay Communications System Electrical Physical Layer Specification, Version 3.0 compliant bus driver interface*
- Single channel support
  - FlexRay Port A can be configured to be connected either to physical FlexRay channel A or physical FlexRay channel B.
- Dual channel support
- FlexRay bus data rates of 10 Mbit/s, 8 Mbit/s, 5 Mbit/s, and 2.5 Mbit/s supported
- 128 configurable message buffers with
  - individual frame ID filtering

    - individual channel ID filtering
    - individual cycle counter filtering
- Message buffer header, status and payload data stored in dedicated FlexRay memory area
    - allows for flexible and efficient message buffer implementation
    - consistent data access ensured by means of buffer locking scheme
    - application can lock multiple buffers at the same time
- Size of message buffer payload data section configurable from 0 up to 254 bytes
- Two independent message buffer segments with configurable size of payload data section
    - each segment can contain message buffers assigned to the static segment and message buffers assigned to the dynamic segment at the same time
- Zero padding for transmit message buffers in static segment
    - applied when the frame payload length exceeds the size of the message buffer data section
- Transmit message buffers configurable with state/event semantics
- Message buffers can be configured as
    - receive message buffer
    - transmit message buffer
- Individual message buffer reconfiguration supported
    - means provided to safely disable individual message buffers
    - disabled message buffers can be reconfigured
- Two independent receive FIFOs
    - one receive FIFO per channel
    - up to 255 entries for each FIFO
    - global frame ID filtering, based on both value/mask filters and range filters
    - global channel ID filtering
    - global message ID filtering for the dynamic segment

- 4 configurable slot error counters
- 4 dedicated slot status indicators
  - used to observe slots without using receive message buffers
- Measured value indicators for the clock synchronization
  - internal synchronization frame ID and synchronization frame measurement tables can be copied into the FlexRay memory area
- Fractional macroticks are supported for clock correction
- Maskable interrupt sources provided via individual and combined interrupt lines
- 1 absolute timer
- 1 timer that can be configured to absolute or relative
- Error correction and error detection (SECDED ECC) for protocol engine data RAM
- Error detection (SECDED ECC) for CHI lookup table RAM

60.2.5 Modes of Operation

This section describes the basic operational power modes of the CC.

60.2.5.1 Disabled Mode

The CC enters the Disabled Mode during hard reset or when the host clears the ‘MEN’ field in the Module Configuration Register (FR_MCR). The host can clear this field by writing ‘0’ and only when the module is in POC:default config mode. The Disabled mode can be checked by reading the module enable field, MEN, in the Module Configuration Register (FR_MCR).

No communication is performed on the FlexRay bus.

All registers with the write access conditions *Any Time* and *Disabled Mode* can be accessed for writing as stated in the Memory Map and Register Description section.

The application configures the CC by accessing the configuration bits and fields in the Module Configuration Register (FR_MCR) as described in Module Initialization .

60.2.5.1.1 Leave Disabled Mode

The CC leaves the Disabled Mode and enters the Normal Mode, when the application writes 1 to the module enable bit MEN in the Module Configuration Register (FR_MCR)

Note

Once the CC is enabled, it can only be disabled during POC: default config.

60.2.5.2 Normal Mode

In this mode the CC is fully functional. The CC indicates that it is in Normal Mode by asserting the module enable bit MEN in the Module Configuration Register (FR_MCR).

60.2.5.2.1 Enter Normal Mode

This mode is entered when the application requests the CC to leave the Disabled Mode. If the Normal Mode was entered by leaving the Disabled Mode, the application has to perform the protocol initialization described in Protocol Initialization to achieve full FlexRay functionality.

Depending on the values of the SCM, CHA, and CHB bits in the Module Configuration Register (FR_MCR), the corresponding FlexRay bus driver ports are enabled and driven.

60.3 External Signal Description

This section lists and describes the CC signals connected to external pins. These signals are summarized in the following table and described in detail in the Detailed Signal Descriptions section below.

NOTE

Please refer the device configuration of the reference manual for the exact module pin names.

NOTE

The off chip signals FR_A_RX, FR_A_TX, and $\overline{\text{FR\_A\_TX\_EN}}$ are available on each package option. The availability of the other off-chip signals depends on the package option and is chip-specific.

Table 60-3. External Signal Properties

Name	Direction	Active	Reset	Function
FR_A_RX	Input	—	—	Receive Data Channel A
FR_A_TX	Output	—	1	Transmit Data Channel A
$\overline{\text{FR\_A\_TX\_EN}}$	Output	Low	1	Transmit Enable Channel A
FR_B_RX	Input	—	—	Receive Data Channel B
FR_B_TX	Output	—	1	Transmit Data Channel B
$\overline{\text{FR\_B\_TX\_EN}}$	Output	Low	1	Transmit Enable Channel B
FR_DBG[0]	Output	—	0	Debug Strobe Signal 0
FR_DBG[1]	Output	—	0	Debug Strobe Signal 1
FR_DBG[2]	Output	—	0	Debug Strobe Signal 2
FR_DBG[3]	Output	—	0	Debug Strobe Signal 3

60.3.1 Detailed Signal Descriptions

This section provides a detailed description of the CC signals, connected to external pins.

60.3.1.1 FR_A_RX — Receive Data Channel A

The FR_A_RX signal carries the receive data for channel A from the corresponding FlexRay bus driver.

60.3.1.2 FR_A_TX — Transmit Data Channel A

The FR_A_TX signal carries the transmit data for channel A to the corresponding FlexRay bus driver.

60.3.1.3 $\overline{\text{FR\_A\_TX\_EN}}$ — Transmit Enable Channel A

The $\overline{\text{FR\_A\_TX\_EN}}$ signal indicates to the FlexRay bus driver that the CC is attempting to transmit data on channel A.

60.3.1.4 FR_B_RX — Receive Data Channel B

The FR_B_RX signal carries the receive data for channel B from the corresponding FlexRay bus driver.

60.3.1.5 FR_B_TX — Transmit Data Channel B

The FR_B_TX signal carries the transmit data for channel B to the corresponding FlexRay bus driver

60.3.1.6 $\overline{\text{FR\_B\_TX\_EN}}$ — Transmit Enable Channel B

The $\overline{\text{FR\_B\_TX\_EN}}$ signal indicates to the FlexRay bus driver that the CC is attempting to transmit data on channel B.

60.3.1.7 FR_DBG[3], FR_DBG[2], FR_DBG[1], FR_DBG[0] — Strobe Signals

These signals provide the selected debug strobe signals. For details on the debug strobe signal selection refer to the Strobe Signal Support.

60.4 Controller Host Interface Clocking

The clock for the CHI is derived from the system bus clock and has the same phase and frequency as the system bus clock. There are two constraints for the minimum CHI clock frequency.

The first constraint corresponds to the number of utilized message buffers and is specified in Number of Usable Message Buffers.

The second constraint corresponds to the value of the TIMEOUT field in the System Memory Access Time-Out Register (FR_SYMATOR) and is specified in Configure System Memory Access Time-Out Register (FR_SYMATOR).

60.5 Protocol Engine Clocking

The clock for the protocol engine can be generated by two sources. The first source is the internal crystal oscillator and the second source is an internal PLL. The clock source to be used is selected by the clock source select bit CLKSEL in the Module Configuration Register (FR_MCR).

Note

See the Device clocking details for the exact clock sources used.

60.5.1 Oscillator Clocking

If the protocol engine is clocked by the internal crystal oscillator, a crystal or CMOS compatible clock must be connected to the oscillator pins. The crystal or clock must fulfill the requirements given by the *FlexRay Communications System Protocol Specification, Version* 2.1 Rev A.

60.5.2 PLL Clocking

If the protocol engine is clocked by the internal PLL, the PLL clock should be divided down appropriately and provided to the PE.

For more details, see the clocking chapter of the device reference manual.

60.6 Register Descriptions

This section provides detailed descriptions of all registers in ascending address order, presented as 16-bit wide entities.

Table 60-4. Register Access Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writeable.
R*	Reserved bit or field, will not be changed. Application must not write any value different from the reset value.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.

Table 60-5. Register Field Types

Convention	Description
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A flag bit that can be read, is cleared by writing a one, writing 0 has no effect.

Table continues on the next page...

Table 60-5. Register Field Types (continued)

Convention	Description
Reset Value	
0	Resets to zero.
1	Resets to one.
-	Not defined after reset and not affected by reset.

60.6.1 Register Reset

All registers except the Message Buffer Cycle Counter Filter Register (FR_MBCCFR*n*), Message Buffer Frame ID Register (FR_MBFIDR*n*), and Message Buffer Index Register (FR_MBIDXR*n*) are reset to their reset value on system reset. The registers mentioned above are located in physical memory blocks and, thus, they are not affected by reset. For some register fields, additional reset conditions exist. These additional reset conditions are mentioned in the detailed description of the register. The additional reset conditions are explained in the table below.

Table 60-6. Additional Register Reset Conditions

Condition	Description
Protocol RUN Command	The register field is reset when the application writes to RUN command "0101" to the POCCMD field in the Protocol Operation Control Register (FR_POCR).
Message Buffer Disable	The register field is reset when the application has disabled the message buffer. This happens when the application writes 1 to the message buffer disable trigger bit FR_MBCCSRn[EDT] while the message buffer is enabled (FR_MBCCSRn[EDS] = 1) and the CC grants the disable to the application by clearing the FR_MBCCSRn[EDS] bit.

60.6.2 Register Write Access

This section describes the write access restriction terms that apply to all registers.

60.6.2.1 Register Write Access Restriction

For each register bit and register field, the write access conditions are specified in the detailed register description. A description of the write access conditions is given in the table below. If, for a specific register bit or field, none of the given write access conditions is fulfilled, any write attempt to this register bit or field is ignored without any

notification. The values of the bits or fields are not changed. The condition term [A or B] indicates that the register or field can be written to if at least one of the conditions is fulfilled. The condition term [A and B] indicates that the register or field can be written to if both conditions are fulfilled.

Table 60-7. Register Write Access Restrictions

Condition	Indication	Description
Any Time	-	No write access restriction.
Disabled Mode	FR_MCR[MEN] = 0	Write access only when CC is in Disabled Mode.
Normal Mode	FR_MCR[MEN] = 1	Write access only when CC is in Normal Mode.
POC:config	FR_PSR0[PROTSTATE] = *POC:config*	Write access only when Protocol is in the *POC:config* state.
MB_DIS	FR_MBCCSR[EDS] = 0	Write access only when related Message Buffer is disabled.
MB_LCK	FR_MBCCSRn[LCKS] = 1	Write access only when related Message Buffer is locked.
IDL	FR_EEIRICR[BSY] = 0	Write access only when ECC configuration is idle.

60.6.2.2 Register Write Access Requirements

All registers can be accessed with 8-bit, 16-bit and 32-bit wide operations.

For some of the registers, at least a 16-bit wide write access is required to ensure correct operation. This write access requirement is described in the Memory map and register definition section. If an 8-bit wide write access is performed to any of these registers, this access is ignored without notification.

60.6.2.3 Internal Register Access

The following memory mapped registers are used to access multiple internal registers.

- *Strobe Signal Control Register (FR_STBSCR)*
- *Slot Status Selection Register (FR_SSSR)*
- *Slot Status Counter Condition Register (FR_SSCCR)*
- *Receive Shadow Buffer Configuration Data*

Each of these memory mapped registers provides a SEL field and a WMD bit. The SEL field is used to select the internal register. The WMD bit controls the write mode. If the WMD bit is set to 0 during the write access, all fields of the internal register are updated.

If the WMD bit set to 1, only the SEL field is changed. All other fields of the internal register remain unchanged. This allows for reading back the values of the selected internal register in a subsequent read access.

60.7 Memory map and register definition

The CC occupies 8 KB (8192 bytes) of address space starting at the CC base address defined by the memory map of the MCU. Address offset - 0x0Ah,0xDEh-0xE0hand 0xE2h-0xE4hshould not be accessed by application as corresponding feature/s are not available. Therefore, transfer error will not be generated at these offset/s.

NOTE

The following registers are 16-bit write accessible only.

Strobe Signal Control Register (FR_STBSCR)

PE DRAM Access Register (FR_PEDRAR)

PE DRAM Data Register (FR_PEDRDR)

Sync Frame ID Rejection Filter Register (FR_SFIDRFR)

Slot Status Selection Register (FR_SSSR)

Slot Status Counter Condition Register (FR_SSCCR)

Receive Shadow Buffer Index Register (FR_RSBIR)

Receive FIFO Range Filter Configuration Register (FR_RFRFCFR)

Message Buffer Cycle Counter Filter Register (FR_MBCCFRn)

Message Buffer Frame ID Register (FR_MBFIDRn)

Message Buffer Index Register (FR_MBIDXRn)

Message Buffer Data Field Offset Register (FR_MBDORn)

LRAM ECC Error Test Register (FR_LEETRn)

FR memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Module Version Register (FR_MVR)	16	R	A568h	60.7.1/2932

60.7.1 Module Version Register (FR_MVR)

This register provides the CC version number. The module version number is derived from the CHI version number and the PE version number.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	CHIVER								PEVER							
Write																
Reset	1	0	1	0	0	1	0	1	0	1	1	0	1	0	0	0

FR_MVR field descriptions

Field	Description
0–7 CHIVER	CHI Version Number. This field provides the version number of the controller host interface.
8–15 PEVER	PE Version Number. This field provides the version number of the protocol engine.

60.7.2 Module Configuration Register (FR_MCR)

This register defines the global configuration of the CC.

Write: SBFF, SCM, CHB, CHA, ECCE, FUM, FAM , CLKSEL , BITRATE: Disabled Mode and SFFE, MEN: Disabled Mode or POC: config

Address: 0h base + 2h offset = 2h

Bit	0	1	2	3	4	5	6	7
Read Write	MEN	SBFF	SCM	CHB	CHA	SFFE	ECCE	Reserved
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read	FUM	FAM	0	CLKSEL	BITRATE			0
Write								
Reset	0	0	0	0	0	0	0	0

FR_MCR field descriptions

Field	Description
0 MEN	Module Enable. This bit indicates whether or not the CC is in the Disabled Mode. The application requests the CC to leave the Disabled Mode by writing 1 to this bit Before leaving the Disabled Mode, the application must configure the SCM, SBFF, CHB, CHA, TMODE, BITRATE values. For details see Modes of Operation. **NOTE:** If the CC is enabled it can only be disabled during mode: POC:default config. 0 Write: only during POC:default config, CC disable Read: CC disabled 1 Write: enable CC Read: CC enabled
1 SBFF	System Bus Failure Freeze This bit controls the behavior of the CC in case of a system bus failure. 0 Continue normal operation 1 Transition to freeze mode
2 SCM	Single Channel Device Mode. This control bit defines the channel device mode of the CC as described in Channel Device Modes. 0 CC works in dual channel device mode 1 CC works in single channel device mode
3 CHB	Channel B Enable. protocol related parameter: pChannels The semantic of these control bits depends on the channel device mode controlled by the SCM bit and is given in the following table.

Table 60-8. FlexRay channel selection

SCM	CHB	CHA	Description
Dual Channel Device Modes			
0	0	0	ports FR_A_RX, FR_A_TX, and $\overline{\text{FR\_A\_TX\_EN}}$ not driven by CC ports FR_B_RX, FR_B_TX, and $\overline{\text{FR\_A\_TX\_EN}}$ not driven by CC
	0	1	ports FR_A_RX, FR_A_TX, and $\overline{\text{FR\_A\_TX\_EN}}$ driven by CC - connected to FlexRay channel A ports FR_B_RX, FR_B_TX, and $\overline{\text{FR\_A\_TX\_EN}}$ not driven by CC
	1	0	reserved
	1	1	ports FR_A_RX, FR_A_TX, and $\overline{\text{FR\_A\_TX\_EN}}$ driven by CC - connected to FlexRay channel A ports FR_B_RX, FR_B_TX, and $\overline{\text{FR\_A\_TX\_EN}}$ driven by CC - connected to FlexRay channel B
Single Channel Device Mode			
1	0	0	ports FR_A_RX, FR_A_TX, and $\overline{\text{FR\_A\_TX\_EN}}$ not driven by CC ports FR_B_RX, FR_B_TX, and $\overline{\text{FR\_A\_TX\_EN}}$ not driven by CC
	0	1	ports FR_A_RX, FR_A_TX, and $\overline{\text{FR\_A\_TX\_EN}}$ driven by CC - connected to FlexRay channel A

60.7.3 System Memory Base Address High Register (FR_SYMBADHR)

NOTE

The system memory base address must be set before the CC is enabled.

The system memory base address registers (FR_SYMBADHR) define the base address of the FlexRay memory area within the system memory. The base address is used by the BMIF to calculate the physical memory address for system memory accesses.

The FR_SYMBADHR register contains the most significant bits of the base address.

Write: Disabled Mode

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	SMBA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_SYMBADHR field descriptions

Field	Description
0–15 SMBA	System Memory Base Address high. This is the value of the system memory base address for the individual message buffers and sync frame table. This is the value of the system memory base address for the receive FIFO if the FIFO address mode bit FR_MCR[FAM] is set to 1. It is defines as a byte address.

60.7.4 System Memory Base Address Low Register (FR_SYMBADLR)

NOTE

The system memory base address must be set before the CC is enabled.

The system memory base address registers (FR_SYMBADLR) define the base address of the FlexRay memory area within the system memory. The base address is used by the BMIF to calculate the physical memory address for system memory accesses.

The FR_SYMBADLR register contains the least significant bits of the base address.

Write: Disabled Mode

Address: 0h base + 6h offset = 6h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	SMBA												0			
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_SYMBADLR field descriptions

Field	Description
0–11 SMBA	System Memory Base Address low. This is the value of the system memory base address for the individual message buffers and sync frame table. This is the value of the system memory base address for the receive FIFO if the FIFO address mode bit FR_MCR[FAM] is set to 1. It is defines as a byte address.
12–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

60.7.5 Strobe Signal Control Register (FR_STBSCR)

Write: Anytime

This register is used to assign the individual protocol timing related strobe signals given in Table 60-9 to the external strobe ports. Each strobe signal can be assigned to at most one strobe port . Each write access to registers overwrites the previously written ENB and STBPSEL values for the signal indicated by SEL . If more than one strobe signal is assigned to one strobe port, the current values of the strobe signals are combined with a binary OR and presented at the strobe port . If no strobe signal is assigned to a strobe port, the strobe port carries logic 0 . For more detailed and timing information refer to Strobe Signal Support .

NOTE

In single channel device mode, channel B related strobe signals are undefined and should not be assigned to the strobe ports.

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0	0			SEL				0			ENB	0		STBPSEL	
Write	WMD															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_STBSCR field descriptions

Field	Description
0 WMD	Write Mode. This control bit defines the write mode of this register. 0 Write to all fields in this register on write access. 1 Write to SEL field only on write access.
1–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–7 SEL	Strobe Signal Select. This control field selects one of the strobe signals given in Table 60-9 to be enabled or disabled and assigned to one of the four strobe ports given in the following table.

Table 60-9. Strobe Signal Mapping

SEL		Description	Channel	Type	Offset (Given in PE clock cycles)	Reference
dec	hex					
0	0x0	arm	-	value	+1	MT start
1	0x1	mt	-	value	+1	MT start
2	0x2	cycle start	-	pulse	0	MT start
3	0x3	minislot start	-	pulse	0	MT start
4	0x4	slot start	A	pulse	0	MT start
5	0x5		B			
6	0x6	receive data after glitch filtering	A	value	+4	FR_A_RX
7	0x7		B			FR_B_RX
8	0x8	channel idle indicator	A	level	+5	FR_A_RX
9	0x9		B			FR_B_RX
10	0xA	syntax error detected	A	pulse	+4	FR_A_RX
11	0xB		B			FR_B_RX
12	0xC	content error detected	A	level	+4	FR_A_RX
13	0xD		B			FR_B_RX
14	0xE	receive FIFO almost-full interrupt signals	A	value	n.a.	RX FIFO A Almost Full Interrupt
15	0xF		B			RX FIFO B Almost Full Interrupt

Write: Disabled Mode

Table continues on the next page...

FR_STBSCR field descriptions (continued)

Field	Description
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 ENB	Strobe Signal Enable. The control bit is used to enable and to disable the strobe signal selected by STBSSEL. 0 Strobe signal is disabled and not assigned to any strobe port. 1 Strobe signal is enabled and assigned to the strobe port selected by STBPSEL.
12–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–15 STBPSEL	Strobe Port Select. This field selects the strobe port that the strobe signal selected by the SEL is assigned to. All strobe signals that are enabled and assigned to the same strobe port are combined with a binary OR operation. 00 assign selected signal to FR_DBG[0] 01 assign selected signal to FR_DBG[1] 10 assign selected signal to FR_DBG[2] 11 assign selected signal to FR_DBG[3]

60.7.6 Message Buffer Data Size Register (FR_MBDSR)

Write: POC:config

This register defines the size of the message buffer data section for the two message buffer segments in a number of two-byte entities.

The CC provides two independent segments for the individual message buffers. All individual message buffers within one segment have to have the same size for the message buffer data section. This size can be different for the two message buffer segments.

Address: 0h base + Ch offset = Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0	MBSEG2DS							0	MBSEG1DS						
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_MBDSR field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–7 MBSEG2DS	Message Buffer Segment 2 Data Size. The field defines the size of the message buffer data section in two-byte entities for message buffers within the second message buffer segment.

Table continues on the next page...

FR_MBDSR field descriptions (continued)

Field	Description
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–15 MBSEG1DS	Message Buffer Segment 1 Data Size. The field defines the size of the message buffer data section in two-byte entities for message buffers within the first message buffer segment.

60.7.7 Message Buffer Segment Size and Utilization Register (FR_MBSSUTR)

Write: POC:config

This register is used to define the last individual message buffer that belongs to the first message buffer segment and the number of the last used individual message buffer.

Address: 0h base + Eh offset = Eh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0	LAST_MB_SEG1							0	LAST_MB_UTIL						
Write																
Reset	0	1	1	1	1	1	1	1	0	1	1	1	1	1	1	1

FR_MBSSUTR field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–7 LAST_MB_SEG1	Last Message Buffer In Segment 1. This field defines the message buffer number of the last individual message buffer that is assigned to the first message buffer segment. The individual message buffers in the first segment correspond to the message buffer control registers FR_MBCCSRn, FR_MBCCFRn, FR_MBFIDRn, FR_MBIDXRn with n <= LAST_MB_SEG1. The first message buffer segment contains LAST_MB_SEG1+1 individual message buffers. **NOTE:** The first message buffer segment contains at least one individual message buffer. The individual message buffers in the second message buffer segment correspond to the message buffer control registers FR_MBCCSRn, FR_MBCCFRn, FR_MBFIDRn, FR_MBIDXRn with LAST_MB_SEG1 < n < 128 . **NOTE:** If LAST_MB_SEG1 = 127 all individual message buffers belong to the first message buffer segment and the second message buffer segment is empty.
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–15 LAST_MB_UTIL	Last Message Buffer Utilized. This field defines the message buffer number of last utilized individual message buffer. The message buffer search engine examines all individual message buffer with a message buffer number n <= LAST_MB_UTIL. **NOTE:** If LAST_MB_UTIL=LAST_MB_SEG1 all individual message buffers belong to the first message buffer segment and the second message buffer segment is empty.

60.7.8 PE DRAM Access Register (FR_PEDRAR)

The PEDRAR register is used to trigger write and read operations on the PE data memory (PE DRAM). These operations are used for memory error injection and memory error observation.

Each write access to this registers initiates a read or write operation on the PE DRAM. The access done status bit DAD is cleared after the write access and is set if the PE DRAM access has been finished.

In case of an PE DRAM write access, the data provided in FR_PEDRDR are written into the PE DRAM, read back from the PE DRAM and are stored into the FR_PEDRDR.

In case of an PE DRAM read access, the requested data are read from PE DRAM and stored into the FR_PEDRDR.

For a detailed description refer to Memory Content Fault Detection

Address: 0h base + 10h offset = 10h

Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_PEDRAR field descriptions

Field	Description
0–3 INST	PE DRAM Access Instruction. This field defines the operation to be executed on the PE DRAM. 0011 PE DRAM write: Write FR_PEDRDR[DATA] to PE DRAM address ADDR (16 bit) 0101 PE DRAM read: Read Data from PE DRAM address ADDR (16 bit) into FR_PEDRDR[DATA] other reserved
4–14 ADDR	PE DRAM Access Address. This field defines the address in the PE DRAM to be written to or read from.
15 DAD	PE DRAM Access Done. This status bit is cleared when the application has written to this register and is set when the PE DRAM access has finished. 0 PE DRAM access running 1 PE DRAM access done

60.7.9 PE DRAM Data Register (FR_PEDRDR)

This register provides the data to be written to or read from the PE DRAM by the access initiated by write access to the FR_PEDRAR.

Address: 0h base + 12h offset = 12h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	DATA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_PEDRDR field descriptions

Field	Description
0–15 DATA	Data to be written to or read from the PE DRAM by the access initiated by write access to the FR_PEDRAR.

60.7.10 Protocol Operation Control Register (FR_POCR)

The application uses this register to issue

- protocol control commands
- external clock correction commands

Protocol control commands are issued by writing to the POCCMD field. For more information on protocol control commands, see Protocol Control Command Execution .

External clock correction commands are issued by writing to the EOC_AP and ERC_AP fields. For more information on external clock correction, refer to External Clock Synchronization .

Write: Normal Mode

Address: 0h base + 14h offset = 14h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0	0			EOC_AP		ERC_AP		BSY_ WMC	0			POCCMD			
Write	WME															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_POCR field descriptions

Field	Description
0 WME	Write Mode External Correction. This bit controls the write mode of the EOC_AP and ERC_AP fields. 0 Write to EOC_AP and ERC_AP fields on register write. 1 No write to EOC_AP and ERC_AP fields on register write.
1–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–5 EOC_AP	External Offset Correction Application. This field is used to trigger the application of the external offset correction value defined in the Protocol Configuration Register 29 (FR_PCR29). 00 do not apply external offset correction value 01 reserved 10 subtract external offset correction value 11 add external offset correction value
6–7 ERC_AP	External Rate Correction Application. This field is used to trigger application of the external rate correction value defined in the Protocol Configuration Register 21 (FR_PCR21) 00 do not apply external rate correction value 01 reserved 10 subtract external rate correction value 11 add external rate correction value
8 BSY_WMC	**NOTE:** The name and function of this field varies depending on whether it is being read or written. BSY (Read-Only). Protocol Control Command Busy. This status bit indicates the acceptance of the protocol control command issued by the application via the POCCMD field. The CC sets this status bit when the application has issued a protocol control command via the POCCMD field. The CC clears this status bit when protocol control command was accepted by the PE. When the application issues a protocol control command while the BSY bit is asserted, the CC ignores this command, sets the protocol command ignored error flag PCMI_EF in the CHI Error Flag Register (FR_CHIERFR) , and will not change the value of the POCCMD field. WMC (Write-Only) Protocol Control Command Write. This status bit indicates the acceptance of the protocol control command issued by the application via the POCCMD field. The CC sets this status bit when the application has issued a protocol control command via the POCCMD field. The CC clears this status bit when protocol control command was accepted by the PE. When the application issues a protocol control command while the BSY bit is asserted, the CC ignores this command, sets the protocol command ignored error flag PCMI_EF in the CHI Error Flag Register (FR_CHIERFR) , and will not change the value of the POCCMD field. 0 (Write-Only) Write to POCCMD field on register write. 1 (Write-Only) Do not write to POCCMD field on register write. 0 (Read-Only) Command write idle, command accepted and ready to receive new protocol command. 1 (Read-Only) Command write busy, command not yet accepted, not ready to receive new protocol command.
9–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 POCCMD	Protocol Control Command. The application writes to this field to issue a protocol control command to the PE. The CC sends the protocol command to the PE immediately. While the transfer is running, the BSY bit is set. 0000 ALLOW_COLDSTART. Immediately activate capability of node to cold start cluster.

Immediately transition to the POC:startup start state. 0110 DEFAULT_CONFIG. Immediately transition to the POC:default config state. 0111 HALT. Delayed transition to the POC:halt state 1000 WAKEUP. Immediately initiate the wakeup procedure. 1001 Reserved 1010 Reserved 1011 Reserved 1100 Reserved 1101 Reserved 1110 Reserved 1111 Reserved

60.7.11 Global Interrupt Flag and Enable Register (FR_GIFER)

Write: Normal Mode

This register provides the means to control some of the interrupt request lines and provides the corresponding interrupt flags. The interrupt flags MIF, PRIF, CHIF, RBIF, and TBIF are the outcome of a binary OR of the related individual interrupt flags and interrupt enables . The generation scheme for these flags is depicted in Figure 60-33 . For more details on interrupt generation, see Interrupt Support . These flags are cleared automatically when all of the corresponding interrupt flags or interrupt enables in the related interrupt flag and enable registers are cleared by the application.

Address: 0h base + 16h offset = 16h

Bit	0	1	2	3	4	5	6	7
Read	MIF	PRIF	CHIF	WUPIF	FAFBIF	FAFAIF	RBIF	TBIF
Write				w1c	w1c	w1c		
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read Write	MIE	PRIE	CHIE	WUPIE	FAFBIE	FAFAIE	RBIE	TBIE
Reset	0	0	0	0	0	0	0	0

FR_GIFER field descriptions

Field	Description
0 MIF	Module Interrupt Flag. This interrupt flag is set if at least one of the other interrupt flags in this register and the related interrupt enable bit are set. 0 No interrupt flag and related interrupt enable bit are set 1 At least one of the other interrupt flags in this register and the related interrupt bit are set.
1 PRIF	Protocol Interrupt Flag. This interrupt flag is set if at least one of the individual flags in the Protocol Interrupt Flag Register 0 (FR_PIFR0) and Protocol Interrupt Flag Register 1 (FR_PIFR1) and the related interrupt enable bit are set. 0 No individual protocol interrupt flag and related interrupt enable bit are set. 1 At least one of the individual protocol interrupt flags and the related interrupt enable bit are set.
2 CHIF	CHI Interrupt Flag. This interrupt flag is set if at least one of the error flags in the CHI Error Flag Register (FR_CHIERFR) and the chi error interrupt enable bit FR_GIFER[CHIE] are set . 0 All CHI error flags are equal to 0 or the chi error interrupt is disabled. 1 At least one CHI error flag and the chi error interrupt enable are is set.
3 WUPIF	Wakeup Interrupt Flag. This interrupt flag is set when the CC has received a wakeup symbol on the FlexRay bus. The application can determine on which channel the wakeup symbol was received by reading the related wakeup flags WUB and WUA in the Protocol Status Register 3 (FR_PSR3). 0 No Wakeup symbol received on FlexRay bus 1 Wakeup symbol received on FlexRay bus
4 FAFBIF	Receive FIFO Channel B Almost Full Interrupt Flag. This interrupt flag is set when one of the following events occurs a) the current number of FIFO B entries is equal to or greater than the watermark defined by the WM field in the Receive FIFO Watermark and Selection Register (FR_RFWMSR), and the CC writes a received message into the FIFO B, or b) the current number of FIFO B entries is at least 1 and the periodic timer as defined by Receive FIFO Periodic Timer Register (FR_RFPTR) expires. 0 no such event 1 FIFO B almost full event has occurred
5 FAFAIF	Receive FIFO Channel A Almost Full Interrupt Flag. This interrupt flag is set when one of the following events occurs a) the current number of FIFO A entries is equal to or greater than the watermark defined by the WM field in the Receive FIFO Watermark and Selection Register (FR_RFWMSR), and the CC writes a received message into the FIFO A, or b) the current number of FIFO B entries is at least 1 and the periodic timer as defined by Receive FIFO Periodic Timer Register (FR_RFPTR) expires. 0 no such event 1 FIFO A almost full event has occurred
6 RBIF	Receive Message Buffer Interrupt Flag. This interrupt flag is set if for at least one of the individual receive message buffers (FR_MBCCSRn[MTD] = 0) both the interrupt flag MBIF and the interrupt enable bit MBIE in the corresponding Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn) are asserted. The application can not clear this interrupt flag directly, instead it is cleared by the CC when all of the interrupt flags MBIF of the individual receive message buffers are cleared by the application or if the application has cleared the related interrupt enables bit MBIE.

Table continues on the next page...

FR_GIFER field descriptions (continued)

Field	Description
	0 None of the individual receive message buffers has the MBIF and MBIE flag set. 1 At least one individual receive message buffer has the MBIF and MBIE flag set.
7 TBIF	Transmit Message Buffer Interrupt Flag. This flag is set if for at least one of the individual message buffers (FR_MBCCSRn[MTD] = 1) both the interrupt flag MBIF and the interrupt enable bit MBIE in the corresponding Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn) are equal to 1. The application can not clear this interrupt flag directly, instead, this interrupt flag is cleared by the CC when either all of the individual interrupt flags MBIF of the individual transmit message buffers are cleared by the application or the application has cleared the related interrupt enables bit MBIE. 0 None of the individual transmit message buffers has the MBIF and MBIE flag set. 1 At least one individual transmit message buffer has the MBIF and MBIE flag set.
8 MIE	Module Interrupt Enable. This bit controls if the Module Interrupt line is asserted when the MIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
9 PRIE	Protocol Interrupt Enable. This bit controls if the Protocol Interrupt line is asserted when the PRIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
10 CHIE	CHI Interrupt Enable. This bit controls if the CHI Interrupt line is asserted when the CHIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
11 WUPIE	Wakeup Interrupt Enable. This bit controls if the Wakeup Interrupt line is asserted when the WUPIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
12 FAFBIE	Receive FIFO Channel B Almost Full Interrupt Enable. This bit controls if the RX FIFO B Almost Full Interrupt line is asserted when the FAFBIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
13 FAFAIE	Receive FIFO Channel A Almost Full Interrupt Enable. This bit controls if the RX FIFO A Almost Full Interrupt line is asserted when the FAFAIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
14 RBIE	Receive Message Buffer Interrupt Enable. This bit controls if the Receive Message Buffer Interrupt line is asserted when the RBIF flag is set. 0 Disable interrupt line 1 Enable interrupt line
15 TBIE	Transmit Message Buffer Interrupt Enable. This bit controls if the Transmit Message Buffer Interrupt line is asserted when the TBIF flag is set. 0 Disable interrupt line 1 Enable interrupt line

60.7.12 Protocol Interrupt Flag Register 0 (FR_PIFR0)

Write: Normal Mode

The register holds one set of the protocol-related individual interrupt flags.

Address: 0h base + 18h offset = 18h

Bit	0	1	2	3	4	5	6	7
Read	FATL_IF	INTL_IF	ILCF_IF	CSA_IF	MRC_IF	MOC_IF	CCL_IF	MXS_IF
Write	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read	MTX_IF	LTXB_IF	LTXA_IF	TBVB_IF	TBVA_IF	TI2_IF	TI1_IF	CYS_IF
Write	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0

FR_PIFR0 field descriptions

Field	Description
0 FATL_IF	Fatal Protocol Error Interrupt Flag. This flag is set when the protocol engine has detected a fatal protocol error. In this case, the protocol engine goes into the POC:halt state immediately. The fatal protocol errors are: 1) pLatestTx violation, as described in the MAC process of the FlexRay protocol 2) transmission across slot boundary violation, as described in the FSP process of the FlexRay protocol 0 No such event. 1 Fatal protocol error detected.
1 INTL_IF	Internal Protocol Error Interrupt Flag. This flag is set when the protocol engine has detected an internal protocol error. In this case, the protocol engine goes into the POC:halt state immediately. An internal protocol error occurs when the protocol engine has not finished a calculation and a new calculation is requested. This can be caused by a hardware error. 0 No such event. 1 Internal protocol error detected.
2 ILCF_IF	Illegal Protocol Configuration Interrupt Flag. This flag is set when the protocol engine has detected an illegal protocol configuration parameter setting. In this case, the protocol engine goes into the POC:halt state immediately. The protocol engine checks the listen_timeout value programmed into the Protocol Configuration Register 14 (FR_PCR14) and Protocol Configuration Register 15 (FR_PCR15) when the CONFIG_COMPLETE command was sent by the application via the Protocol Operation Control Register (FR_POCR). If the value of listen_timeout is equal to zero, the protocol configuration setting is considered as illegal. 0 No such event. 1 Illegal protocol configuration detected.
3 CSA_IF	Cold Start Abort Interrupt Flag. This flag is set when the configured number of allowed cold start attempts is reached and none of these attempts was successful. The number of allowed cold start attempts is configured by the coldstart_attempts field in the Protocol Configuration Register 3 (FR_PCR3).

Table continues on the next page...

FR_PIFR0 field descriptions (continued)

Field	Description
	0 No such event. 1 Cold start aborted and no more coldstart attempts allowed.
4 MRC_IF	Missing Rate Correction Interrupt Flag. This flag is set when an insufficient number of measurements is available for rate correction at the end of the communication cycle. 0 No such event 1 Insufficient number of measurements for rate correction detected
5 MOC_IF	Missing Offset Correction Interrupt Flag. This flag is set when an insufficient number of measurements is available for offset correction. This is related to the MISSING_TERM event in the CSP process for offset correction in the FlexRay protocol. 0 No such event. 1 Insufficient number of measurements for offset correction detected.
6 CCL_IF	Clock Correction Limit Reached Interrupt Flag. This flag is set when the internal calculated offset or rate calculation values have reached or exceeded its configured thresholds as given by the offset_coorection_out field in the Protocol Configuration Register 9 (FR_PCR9) and the rate_correction_out field in the Protocol Configuration Register 14 (FR_PCR14). 0 No such event. 1 Offset or rate correction limit reached.
7 MXS_IF	Max Sync Frames Detected Interrupt Flag. This flag is set when the number of synchronization frames detected in the current communication cycle exceeds the value of the node_sync_max field in the Protocol Configuration Register 30 (FR_PCR30). **NOTE:** Only synchronization frames that have passed the synchronization frame acceptance and rejection filters are taken into account. 0 No such event. 1 More than node_sync_max sync frames detected.
8 MTX_IF	Media Access Test Symbol Received Interrupt Flag. This flag is set when the MTS symbol was received on channel A or channel B. 0 No such event. 1 MTS symbol received.
9 LTXB_IF	pLatestTx Violation on Channel B Interrupt Flag. This flag is set when the frame transmission on channel B in the dynamic segment exceeds the dynamic segment boundary. This is related to the pLatestTx violation, as described in the MAC process of the FlexRay protocol. 0 No such event. 1 pLatestTx violation occurred on channel B.
10 LTXA_IF	pLatestTx Violation on Channel A Interrupt Flag. This flag is set when the frame transmission on channel A in the dynamic segment exceeds the dynamic segment boundary. This is related to the pLatestTx violation as described in the MAC process of the FlexRay protocol. 0 No such event. 1 pLatestTx violation occurred on channel A.
11 TBVB_IF	Transmission across boundary on channel B Interrupt Flag. This flag is set when the frame transmission on channel B crosses the slot boundary. This is related to the transmission across slot boundary violation as described in the FSP process of the FlexRay protocol.

Table continues on the next page...

FR_PIFR0 field descriptions (continued)

Field	Description
	0 No such event. 1 Transmission across boundary violation occurred on channel B.
12 TBVA_IF	Transmission across boundary on channel A Interrupt Flag. This flag is set when the frame transmission on channel A crosses the slot boundary. This is related to the transmission across slot boundary violation as described in the FSP process of the FlexRay protocol. 0 No such event. 1 Transmission across boundary violation occurred on channel A.
13 TI2_IF	Timer 2 Expired Interrupt Flag. This flag is set whenever timer 2 expires. 0 No such event. 1 Timer 2 has reached its time limit.
14 TI1_IF	Timer 1 Expired Interrupt Flag. This flag is set whenever timer 1 expires. 0 No such event 1 Timer 1 has reached its time limit
15 CYS_IF	Cycle Start Interrupt Flag. This flag is set when a communication cycle starts. 0 No such event 1 Communication cycle started.

60.7.13 Protocol Interrupt Flag Register 1 (FR_PIFR1)

Write: Normal Mode

The register holds one set of the protocol-related individual interrupt flags.

Address: 0h base + 1Ah offset = 1Ah

Bit	0	1	2	3	4	5	6	7
Read	EMC_IF	IPC_IF	PECF_IF	PSC_IF	SSI3_IF	SSI2_IF	SSI1_IF	SSI0_IF
Write	w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read	0		EVT_IF	ODT_IF	0			
Write			w1c	w1c				
Reset	0	0	0	0	0	0	0	0

FR_PIFR1 field descriptions

Field	Description
0 EMC_IF	Error Mode Changed Interrupt Flag. This flag is set when the value of the ERRMODE bit field in the Protocol Status Register 0 (FR_PSR0) is changed by the CC.

Table continues on the next page...

FR_PIFR1 field descriptions (continued)

Field	Description
	0 No such event. 1 ERRMODE field changed.
1 IPC_IF	Illegal Protocol Control Command Interrupt Flag. This flag is set when the PE tries to execute a protocol control command, which was issued via the POCCMD field of the Protocol Operation Control Register (FR_POCR), and detects that this protocol control command is not allowed in the current protocol state. In this case the command is not executed. For more details, see Protocol Control Command Execution . 0 No such event. 1 Illegal protocol control command detected.
2 PECF_IF	Protocol Engine Communication Failure Interrupt Flag. This flag is set if the CC has detected a communication failure between the PE and the CHI. 0 No such event. 1 Protocol Engine Communication Failure detected.
3 PSC_IF	Protocol State Changed Interrupt Flag. This flag is set when the protocol state in the PROTSTATE field in the Protocol Status Register 0 (FR_PSR0) has changed. 0 No such event. 1 Protocol state changed.
4 SSI3_IF	Slot Status Counter Incremented Interrupt Flag. Each of these flags is set when the SLOTSTATUSCNT field in the corresponding Slot Status Counter Registers (FR_SSCRn) is incremented. 0 No such event. 1 The corresponding slot status counter has incremented.
5 SSI2_IF	Slot Status Counter Incremented Interrupt Flag. Each of these flags is set when the SLOTSTATUSCNT field in the corresponding Slot Status Counter Registers (FR_SSCRn) is incremented. 0 No such event. 1 The corresponding slot status counter has incremented.
6 SSI1_IF	Slot Status Counter Incremented Interrupt Flag. Each of these flags is set when the SLOTSTATUSCNT field in the corresponding Slot Status Counter Registers (FR_SSCRn) is incremented. 0 No such event. 1 The corresponding slot status counter has incremented.
7 SSI0_IF	Slot Status Counter Incremented Interrupt Flag. Each of these flags is set when the SLOTSTATUSCNT field in the corresponding Slot Status Counter Registers (FR_SSCRn) is incremented. 0 No such event. 1 The corresponding slot status counter has incremented.
8–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 EVT_IF	Even Cycle Table Written Interrupt Flag. This flag is set if the CC has written the sync frame measurement / ID tables into the FlexRay memory area for the even cycle. 0 No such event. 1 Sync frame measurement table written
11 ODT_IF	Odd Cycle Table Written Interrupt Flag. This flag is set if the CC has written the sync frame measurement / ID tables into the FlexRay memory area for the odd cycle.

Table continues on the next page...

FR_PIFR1 field descriptions (continued)

Field	Description
	0 No such event. 1 Sync frame measurement table written
12–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

60.7.14 Protocol Interrupt Enable Register 0 (FR_PIER0)

Write: Anytime

This register defines whether or not the individual interrupt flags defined in the Protocol Interrupt Flag Register 0 (FR_PIFR0) can generate a protocol interrupt request.

Address: 0h base + 1Ch offset = 1Ch

Bit	0	1	2	3	4	5	6	7

FR_CHIERFR field descriptions

Field	Description
0 FRLB_EF	Frame Lost Channel B Error Flag. This flag is set if a complete frame was received on channel B but could not be stored in the selected individual message buffer because this message buffer is currently locked by the application. In this case, the frame and the related slot status information are lost.

Table continues on the next page...

FR_CHIERFR field descriptions (continued)

Field	Description
	0 No such event 1 Frame lost on channel B detected
1 FRLA_EF	Frame Lost Channel A Error Flag. This flag is set if a complete frame was received on channel A but could not be stored in the selected individual message buffer because this message buffer is currently locked by the application. In this case, the frame and the related slot status information are lost. 0 No such error 1 Frame lost on channel A detected
2 PCMI_EF	Protocol Command Ignored Error Flag. This flag is set if the application has issued a POC command by writing to the POCCMD field in the Protocol Operation Control Register (FR_POCR) while the BSY flag is equal to 1. In this case the command is ignored by the CC and is lost. 0 No such error 1 POC command ignored
3 FOVB_EF	Receive FIFO Overrun Channel B Error Flag. This flag is set when an overrun of the FIFO for channel B occurred. This error occurs if a semantically valid frame was received on channel B and matches the all criteria to be appended to the FIFO for channel B but the FIFO is full. In this case, the received frame and its related slot status information is lost. 0 No such error 1 FIFO overrun on channel B has been detected
4 FOVA_EF	Receive FIFO Overrun Channel A Error Flag. This flag is set when an overrun of the FIFO for channel A occurred. This error occurs if a semantically valid frame was received on channel A and matches the all criteria to be appended to the FIFO for channel A but the FIFO is full. In this case, the received frame and its related slot status information is lost. 0 No such error 1 FIFO overrun on channel B has been detected
5 MBS_EF	Message Buffer Search Error Flag. This flag is set if at least one of the following events occurs: a) The message buffer search engine is still running while the next search must be started due to the FlexRay protocol timing. b) A message buffer index greater than 131 is detected in the FR_MBIDXR[MBIDX] field of an found message buffer or in one of the FR_RSBIR[RSBIDX] fields. Refer to Message Buffer Search Error for details. 0 No such event 1 Search engine active while search start appears or illegal message buffer index detected
6 MBU_EF	Message Buffer Utilization Error Flag. This flag is asserted if the application writes to a message buffer control field that is beyond the number of utilized message buffers programmed in the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR). If the application writes to a FR_MBCCSRn register with n > LAST_MB_UTIL, the CC ignores the write attempt and asserts the message buffer utilization error flag MBU_EF in the CHI Error Flag Register (FR_CHIERFR). 0 No such event 1 Non-utilized message buffer enabled
7 LCK_EF	Lock Error Flag. This flag is set if the application tries to lock a message buffer that is already locked by the CC due to internal operations. In that case, the CC does not grant the lock to the application. The application must issue the lock request again.

Table continues on the next page...

FR_CHIERFR field descriptions (continued)

Field	Description
	0 No such error 1 Lock error detected
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9 SBCF_EF	System Bus Communication Failure Error Flag. This flag is set if a system bus access was not finished within the required amount of time (see System Bus Access Timeout). 0 No such event 1 System bus access not finished in time
10 FID_EF	Frame ID Error Flag. This flag is set if the frame ID stored in the message buffer header area differs from the frame ID stored in the message buffer control register and "also an illegal CHI command RUN is issued in POC:normal active state". 0 No such error occurred 1 Frame ID error occurred
11 DPL_EF	Dynamic Payload Length Error Flag. This flag is set if the payload length written into the message buffer header field of a transmit message buffer assigned to the dynamic segment is greater than the maximum payload length for the dynamic segment as it is configured in the corresponding protocol configuration register field max_payload_length_dynamic in the Protocol Configuration Register 24 (FR_PCR24). 0 No such error occurred 1 Dynamic payload length error occurred
12 SPL_EF	Static Payload Length Error Flag. This flag is set if the payload length written into the message buffer header field of a transmit message buffer assigned to the static segment is different from the payload length for the static segment as it is configured in the corresponding protocol configuration register field payload_length_static in the Protocol Configuration Register 19 (FR_PCR19). 0 No such error occurred 1 Static payload length error occurred
13 NML_EF	Network Management Length Error Flag. This flag is set if the payload length written into the header structure of a receive message buffer assigned to the static segment is less than the configured length of the Network Management Vector as configured in the Network Management Vector Length Register (FR_NMVLR). In this case the received part of the Network Management Vector will be used to update the Network Management Vector. 0 No such error occurred 1 Network management length error occurred
14 NMF_EF	Network Management Frame Error Flag. This flag is set if a received message in the static segment with a Preamble Indicator flag PP asserted has its Null Frame indicator flag NF asserted as well. In this case, the Global Network Management Registers (see Network Management Vector Registers (FR_NMVR0-FR_NMVR5)) are not updated. 0 No such error occurred 1 Network management frame error occurred
15 ILSA_EF	Illegal System Bus Address Error Flag. This flag is set if the external system bus subsystem has detected an access to an illegal system bus address from the CC (see System Bus Illegal Address Access). 0 No such event 1 Illegal system bus address accessed

60.7.17 Message Buffer Interrupt Vector Register (FR_MBIVEC)

This register indicates the lowest numbered receive message buffer and the lowest numbered transmit message buffer that have their interrupt status flag MBIF and interrupt enable MBIE bits asserted. This means that message buffers with lower message buffer numbers have higher priority.

Address: 0h base + 22h offset = 22h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0	TBIVEC							0	RBIVEC						
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_MBIVEC field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–7 TBIVEC	Transmit Buffer Interrupt Vector. This field provides the number of the lowest numbered enabled transmit message buffer that has its interrupt status flag MBIF and its interrupt enable bit MBIE set. If there is no transmit message buffer with the interrupt status flag MBIF and the interrupt enable MBIE bits asserted, the value in this field is set to 0.
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–15 RBIVEC	Receive Buffer Interrupt Vector. This field provides the message buffer number of the lowest numbered receive message buffer which has its interrupt flag MBIF and its interrupt enable bit MBIE asserted. If there is no receive message buffer with the interrupt status flag MBIF and the interrupt enable MBIE bits asserted, the value in this field is set to 0.

60.7.18 Channel A Status Error Counter Register (FR_CASERCR)

This register provides the channel status error counter for channel A. The protocol engine generates a slot status vector for each static slot, each dynamic slot, the symbol window, and the NIT. The slot status vector contains the four protocol related error indicator bits vSS!SyntaxError, vSS!ContentError, vSS!BViolation, and vSS!TxConflict. The CC increments the status error counter by 1 if, for a slot or segment, at least one error indicator bit is set to 1. The counter wraps around after it has reached the maximum value. For more information on slot status monitoring, see Slot Status Monitoring.

Address: 0h base + 24h offset = 24h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	CHAERSCNT															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_CASERCR field descriptions

Field	Description
0–15 CHAERSCNT	Channel A Status Error Counter. This field provides the current value channel status error counter. The counter value is updated within the first macrotick of the following slot or segment.

60.7.19 Channel B Status Error Counter Register (FR_CBSERCR)

This register provides the channel status error counter for channel B. The protocol engine generates a slot status vector for each static slot, each dynamic slot, the symbol window, and the NIT. The slot status vector contains the four protocol related error indicator bits vSS!SyntaxError, vSS!ContentError, vSS!BViolation, and vSS!TxConflict. The CC increments the status error counter by 1 if, for a slot or segment, at least one error indicator bit is set to 1. The counter wraps around after it has reached the maximum value. For more information on slot status monitoring see Slot Status Monitoring.

Address: 0h base + 26h offset = 26h

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_CBSERCR field descriptions

Field	Description
0–15 CHBERSCNT	Channel B Status Error Counter. This field provides the current channel status error count. The counter value is updated within the first macrotick of the following slot or segment.

60.7.20 Protocol Status Register 0 (FR_PSR0)

This register provides information about the current protocol status.

Address: 0h base + 28h offset = 28h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	ERRMODE		SLOTMODE		0	PROTSTATE			STARTUPSTATE				0	WAKEUPSTATUS		
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_PSR0 field descriptions

Field	Description
0–1 ERRMODE	Error Mode. protocol related variable: vPOC!ErrorMode. This field indicates the error mode of the protocol. 00 ACTIVE 01 PASSIVE 10 COMM_HALT 11 reserved
2–3 SLOTMODE	Slot Mode. protocol related variable: vPOC!SlotMode. This field indicates the slot mode of the protocol. 00 SINGLE 01 ALL_PENDING 10 ALL 11 reserved
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–7 PROTSTATE	Protocol State. protocol related variable: vPOC!State. This field indicates the state of the protocol. 000 POC:default config 001 POC:config 010 POC:wakeup 011 POC:ready 100 POC:normal passive 101 POC:normal active 110 POC:halt 111 POC:startup

Table continues on the next page...

FR_PSR0 field descriptions (continued)

Field	Description
8–11 STARTUPSTATE	Startup State. protocol related variable: vPOC!StartupState. This field indicates the current sub-state of the startup procedure. 0000 reserved 0001 reserved 0010 POC:coldstart collision resolution 0011 POC:coldstart listen 0100 POC:integration consistency check 0101 POC:integration listen 0110 reserved 0111 POC:initialize schedule 1000 reserved 1001 reserved 1010 POC:coldstart consistency check 1011 reserved 1100 reserved 1101 POC:integration coldstart check 1110 POC:coldstart gap 1111 POC:coldstart join
12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–15 WAKEUPSTATUS	Wakeup Status. protocol related variable: vPOC!WakeupStatus. This field provides the outcome of the execution of the wakeup mechanism. 000 UNDEFINED 001 RECEIVED_HEADER 010 RECEIVED_WUP 011 COLLISION_ HEADER 100 COLLISION_WUP 101 COLLISION_UNKNOWN 110 TRANSMITTED 111 reserved

60.7.21 Protocol Status Register 1 (FR_PSR1)

FR_PSR1 field descriptions

Field	Description
0 CSAA	Cold Start Attempt Aborted Flag. protocol related event: 'set coldstart abort indicator in CHI' This flag is set when the CC has aborted a cold start attempt. 0 No such event 1 Cold start attempt aborted
1 CSP	Leading Cold Start Path. This status bit is set when the CC has reached the POC:normal active state via the leading cold start path. This indicates that this node has started the network 0 No such event 1 POC:normal active reached from POC:startup state via leading cold start path
2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–7 REMCSAT	Remaining Coldstart Attempts. protocol related variable: vRemainingColdstartAttempts This field provides the number of remaining cold start attempts that the CC will execute.
8 CPN	Leading Cold Start Path Noise. protocol related variable: vPOC!ColdstartNoise This status bit is set if the CC has reached the POC:normal active state via the leading cold start path under noise conditions. This indicates there was some activity on the FlexRay bus while the CC was starting up the cluster. 0 No such event 1 POC:normal active state was reached from POC:startup state via noisy leading cold start path
9 HHR	Host Halt Request Pending. protocol related variable: vPOC!CHIHaltRequest This status bit is set when CC receives the HALT command from the application via the Protocol Operation Control Register (FR_POCR). The CC clears this status bit after a hard reset condition or when the protocol is in the POC:default config state. 0 No such event 1 HALT command received

Table continues on the next page...

FR_PSR1 field descriptions (continued)

Field	Description
10 FRZ	Freeze Occurred. protocol related variable: vPOC!Freeze This status bit is set when the CC has reached the POC:halt state due to the host FREEZE command or due to an internal error condition requiring immediate halt. The CC clears this status bit after a hard reset condition or when the protocol is in the POC:default config state. 0 No such event 1 Immediate halt due to FREEZE or internal error condition
11–15 APTAC	Allow Passive to Active Counter. protocol related variable: vPOC!vAllowPassivetoActive This field provides the number of consecutive even/odd communication cycle pairs that have passed with valid rate and offset correction terms, but the protocol is still in the POC:normal passive state due to an application configured delay to enter POC:normal active state. This delay is defined by the allow_passive_to_active field in the Protocol Configuration Register 12 (FR_PCR12).

60.7.22 Protocol Status Register 2 (FR_PSR2)

This register provides a snapshot of status information about the Network Idle Time NIT, the Symbol Window and the clock synchronization. The NIT related status bits NBVB, NSEB, NBVA, and NSEA are updated by the CC after the end of the NIT and before the end of the first slot of the next communication cycle. The Symbol Window related status bits STCB, SBVB, SSEB, MTB, STCA, SBVA, SSEB, and MTA are updated by the CC after the end of the symbol window and before the end of the current communication cycle. If no symbol window is configured, the symbol window related status bits remain in their reset state. The clock synchronization related CLKCORRFAILCNT is updated by the CC after the end of the static segment and before the end of the current communication cycle.

Address: 0h base + 2Ch offset = 2Ch

Write								
Reset	0	0	0	0	0	0	0	0

FR_PSR2 field descriptions

Field	Description
0 NBVB	NIT Boundary Violation on Channel B. protocol related variable: vSS!BViolation for NIT on channel B This status bit is set when there was some media activity on the FlexRay bus channel B at the end of the NIT. 0 No such event 1 Media activity at boundaries detected
1 NSEB	NIT Syntax Error on Channel B. protocol related variable: vSS!SyntaxError for NIT on channel B This status bit is set when a syntax error was detected during NIT on channel B. 0 No such event 1 Syntax error detected
2 STCB	Symbol Window Transmit Conflict on Channel B. protocol related variable: vSS!TxConflict for symbol window on channel B This status bit is set if there was a transmission conflict during the symbol window on channel B. 0 No such event 1 Transmission conflict detected
3 SBVB	Symbol Window Boundary Violation on Channel B. protocol related variable: vSS!BViolation for symbol window on channel B This status bit is set if there was some media activity on the FlexRay bus channel B at the start or at the end of the symbol window. 0 No such event 1 Media activity at boundaries detected
4 SSEB	Symbol Window Syntax Error on Channel B. protocol related variable: vSS!SyntaxError for symbol window on channel B This status bit is set when a syntax error was detected during the symbol window on channel B. 0 No such event 1 Syntax error detected
5 MTB	Media Access Test Symbol MTS Received on Channel B. protocol related variable: vSS!ValidMTS for Symbol Window on channel B This status bit is set if the Media Access Test Symbol MTS was received in the symbol window on channel B. 0 No such event 1 MTS symbol received
6 NBVA	NIT Boundary Violation on Channel A. protocol related variable: vSS!BViolation for NIT on channel A This status bit is set when there was some media activity on the FlexRay bus channel A at the end of the NIT. 0 No such event 1 Media activity at boundaries detected
7 NSEA	NIT Syntax Error on Channel A. protocol related variable: vSS!SyntaxError for NIT on channel A This status bit is set when a syntax error was detected during NIT on channel A. 0 No such event 1 Syntax error detected

Table continues on the next page...

FR_PSR2 field descriptions (continued)

Field	Description
8 STCA	Symbol Window Transmit Conflict on Channel A. protocol related variable: vSS!TxConflict for symbol window on channel A This status bit is set if there was a transmission conflicts during the symbol window on channel A. 0 No such event 1 Transmission conflict detected
9 SBVA	Symbol Window Boundary Violation on Channel A. protocol related variable: vSS!BViolation for symbol window on channel A This status bit is set if there was some media activity on the FlexRay bus channel A at the start or at the end of the symbol window. 0 No such event 1 Media activity at boundaries detected
10 SSEA	Symbol Window Syntax Error on Channel A. protocol related variable: vSS!SyntaxError for symbol window on channel A This status bit is set when a syntax error was detected during the symbol window on channel A. 0 No such event 1 Syntax error detected
11 MTA	Media Access Test Symbol MTS Received on Channel A. protocol related variable: vSS!ValidMTS for symbol window on channel A This status bit is set if the Media Access Test Symbol MTS was received in the symbol window on channel A. 1 MTS symbol received 0 No such event
12–15 CKCORFCNT	Clock Correction Failed Counter. protocol related variable: vClockCorrectionFailed This field provides the number of consecutive even/odd communication cycle pairs that have passed without clock synchronization having performed an offset or a rate correction due to lack of synchronization frames. It is not incremented when it has reached the configured value of either max_without_clock_correction_fatal or max_without_clock_correction_passive as defined in the Protocol Configuration Register 8 (FR_PCR8). The CC resets this counter on a hard reset condition, when the protocol enters the POC:normal active state, or when both the rate and offset correction terms have been calculated successfully.

60.7.23 Protocol Status Register 3 (FR_PSR3)

Write: Normal Mode

This register provides aggregated channel status information as an accrued status of channel activity for all communication slots, regardless of whether they are assigned for transmission or subscribed for reception. It provides accrued information for the symbol window, the NIT, and the wakeup status.

Address: 0h base + 2Eh offset = 2Eh

FR_PSR3 field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 WUB	Wakeup Symbol Received on Channel B. This flag is set when a wakeup symbol was received on channel B. 0 No wakeup symbol received 1 Wakeup symbol received
3 ABVB	Aggregated Boundary Violation on Channel B. This flag is set when a boundary violation has been detected on channel B. Boundary violations are detected in the communication slots, the symbol window, and the NIT. 0 No boundary violation detected 1 Boundary violation detected
4 AACB	Aggregated Additional Communication on Channel B. This flag is set when at least one valid frame was received on channel B in a slot that also contained an additional communication with either syntax error, content error, or boundary violations. 0 No additional communication detected 1 Additional communication detected
5 ACEB	Aggregated Content Error on Channel B. This flag is set when a content error has been detected on channel B. Content errors are detected in the communication slots, the symbol window, and the NIT. 0 No content error detected 1 Content error detected
6 ASEB	Aggregated Syntax Error on Channel B. This flag is set when a syntax error has been detected on channel B. Syntax errors are detected in the communication slots, the symbol window and the NIT. 0 No syntax error detected 1 Syntax errors detected
7 AVFB	Aggregated Valid Frame on Channel B. This flag is set when a syntactically correct valid frame has been received in any static or dynamic slot through channel B. 1 At least one syntactically valid frame received 0 No syntactically valid frames received
8–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

FR_PSR3 field descriptions (continued)

Field	Description
10 WUA	Wakeup Symbol Received on Channel A. This flag is set when a wakeup symbol was received on channel A. 0 No wakeup symbol received 1 Wakeup symbol received
11 ABVA	Aggregated Boundary Violation on Channel A. This flag is set when a boundary violation has been detected on channel A. Boundary violations are detected in the communication slots, the symbol window, and the NIT. 0 No boundary violation detected 1 Boundary violation detected
12 AACA	Aggregated Additional Communication on Channel A. This flag is set when a valid frame was received in a slot on channel A that also contained an additional communication with either syntax error, content error, or boundary violations. 0 No additional communication detected 1 Additional communication detected
13 ACEA	Aggregated Content Error on Channel A. This flag is set when a content error has been detected on channel A. Content errors are detected in the communication slots, the symbol window, and the NIT. 0 No content error detected 1 Content error detected
14 ASEA	Aggregated Syntax Error on Channel A. This flag is set when a syntax error has been detected on channel A. Syntax errors are detected in the communication slots, the symbol window, and the NIT. 0 No syntax error detected 1 Syntax errors detected
15 AVFA	Aggregated Valid Frame on Channel A. This flag is set when a syntactically correct valid frame has been received in any static or dynamic slot through channel A. 0 No syntactically valid frames received 1 At least one syntactically valid frame received

60.7.24 Macrotick Counter Register (FR_MTCTR)

This register provides the macrotick count of the current communication cycle.

Address: 0h base + 30h offset = 30h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0		MTCT													
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

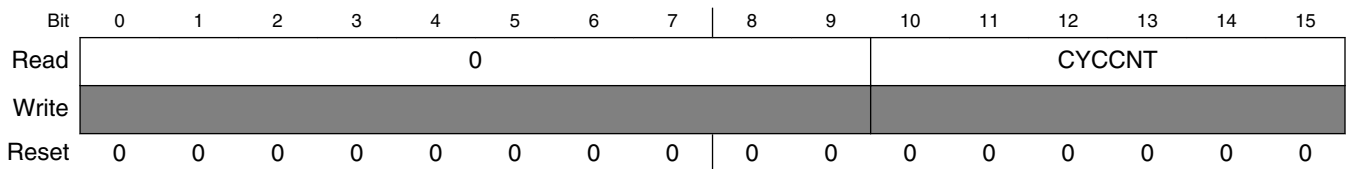
FR_MTCTR field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–15 MTCT	Macrotick Counter. protocol related variable: vMacrotick This field provides the macrotick count of the current communication cycle.

60.7.25 Cycle Counter Register (FR_CYCTR)

This register provides the number of the current communication cycle.

Address: 0h base + 32h offset = 32h



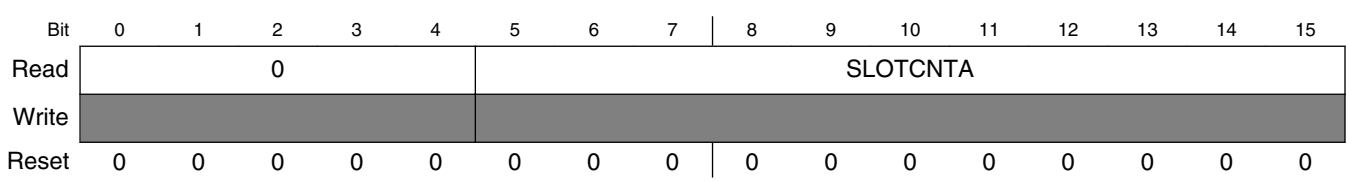
FR_CYCTR field descriptions

Field	Description
0–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–15 CYCCNT	Cycle Counter. protocol related variable: vCycleCounter This field provides the number of the current communication cycle. If the counter reaches the maximum value of 63, the counter wraps and starts from zero again.

60.7.26 Slot Counter Channel A Register (FR_SLTCTAR)

This register provides the number of the current slot in the current communication cycle for channel A.

Address: 0h base + 34h offset = 34h



FR_SLTCTAR field descriptions

Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–15 SLOTCNTA	Slot Counter Value for Channel A. protocol related variable: vSlotCounter for channel A This field provides the number of the current slot in the current communication cycle.

60.7.27 Slot Counter Channel B Register (FR_SLTCTBR)

This register provides the number of the current slot in the current communication cycle for channel B.

Address: 0h base + 36h offset = 36h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0					SLOTCNTB										
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_SLTCTBR field descriptions

Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–15 SLOTCNTB	Slot Counter Value for Channel B. protocol related variable: vSlotCounter for channel B This field provides the number of the current slot in the current communication cycle.

60.7.28 Rate Correction Value Register (FR_RTCORVR)

This register provides the sign extended rate correction value in microticks as it was calculated by the clock synchronization algorithm. The CC updates this register during the NIT of each odd numbered communication cycle.

Address: 0h base + 38h offset = 38h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	RATECORR															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RTCORVR field descriptions

Field	Description
0–15 RATECORR	Rate Correction Value. protocol related variable: vRateCorrection (before value limitation and external rate correction) This field provides the sign extended rate correction value in microticks as it was calculated by the clock synchronization algorithm. The value is represented in 2's complement format. This value does not include the value limitation and the application of the external rate correction. If the magnitude of the internally calculated rate correction value exceeds the limit given by rate_correction_out in the Protocol Configuration Register 13 (FR_PCR13), the clock correction reached limit interrupt flag CCL_IF is set in the Protocol Interrupt Flag Register 0 (FR_PIFR0). **NOTE:** If the CC was not able to calculate a new rate correction term due to a lack of synchronization frames, the RATECORR value is not updated.

60.7.29 Offset Correction Value Register (FR_OFCORVR)

This register provides the sign extended offset correction value in microticks as it was calculated by the clock synchronization algorithm. The CC updates this register during the NIT.

Address: 0h base + 3Ah offset = 3Ah

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	OFFSETCORR															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_OFCORVR field descriptions

Field	Description
0–15 OFFSETCORR	Offset Correction Value. protocol related variable: vOffsetCorrection (before value limitation and external offset correction) This field provides the sign extended offset correction value in microticks as it was calculated by the clock synchronization algorithm. The value is represented in 2's complement format. This value does not include the value limitation and the application of the external offset correction. If the magnitude of the internally calculated rate correction value exceeds the limit given by offset_correction_out field in the Protocol Configuration Register 29 (FR_PCR29), the clock correction reached limit interrupt flag CCL_IF is set in the Protocol Interrupt Flag Register 0 (FR_PIFR0). **NOTE:** If the CC was not able to calculate an new offset correction term due to a lack of synchronization frames, the OFFSETCORR value is not updated.

60.7.30 Combined Interrupt Flag Register (FR_CIFR)

This register provides five combined interrupt flags and a copy of three individual interrupt flags. The combined interrupt flags are the result of a binary OR of the values of other interrupt flags regardless of the state of the interrupt enable bits. The generation scheme for the combined interrupt flags is depicted in Figure 60-35 . The individual interrupt flags WUPIF, FAFBIF, and FAFAIF are copies of corresponding flags in the Global Interrupt Flag and Enable Register (FR_GIFER) and are provided here to simplify the application interrupt flag check. To clear the individual interrupt flags, the application must use the Global Interrupt Flag and Enable Register (FR_GIFER).

NOTE

The meanings of the combined status bits MIF, PRIF, CHIF, RBIF, and TBIF are different from those mentioned in the Global Interrupt Flag and Enable Register (FR_GIFER).

Address: 0h base + 3Ch offset = 3Ch

Reset	0	0	0	0	0	0	0	0

FR_CIFR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 MIF	Module Interrupt Flag. This flag is set if there is at least one interrupt source that has its interrupt flag asserted. 0 No interrupt source has its interrupt flag asserted 1 At least one interrupt source has its interrupt flag asserted
9 PRIF	Protocol Interrupt Flag. This flag is set if at least one of the individual protocol interrupt flags in the Protocol Interrupt Flag Register 0 (FR_PIFR0) or Protocol Interrupt Flag Register 1 (FR_PIFR1) is equal to 1. 0 All individual protocol interrupt flags are equal to 0 1 At least one of the individual protocol interrupt flags is equal to 1
10 CHIF	CHI Interrupt Flag. This flag is set if at least one of the individual CHI error flags in the CHI Error Flag Register (FR_CHIERFR) is equal to 1.

Table continues on the next page...

FR_CIFR field descriptions (continued)

Field	Description
	0 All CHI error flags are equal to 0 1 At least one CHI error flag is equal to 1
11 WUPIF	Wakeup Interrupt Flag. Provides the same value as FR_GIFER[WUPIF]
12 FAFBIF	Receive FIFO Channel B Almost Full Interrupt Flag. Provides the same value as FR_GIFER[FAFBIF]
13 FAFAIF	Receive FIFO Channel A Almost Full Interrupt Flag. Provides the same value as FR_GIFER[FAFAIF]
14 RBIF	Receive Message Buffer Interrupt Flag. This flag is set if for at least one of the individual receive message buffers (FR_MBCCSRn[MTD] = 0) the interrupt flag MBIF in the corresponding Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn) is equal to 1. 0 None of the individual receive message buffers has the MBIF flag asserted. 1 At least one individual receive message buffers has the MBIF flag asserted.
15 TBIF	Transmit Message Buffer Interrupt Flag. This flag is set if for at least one of the individual transmit message buffers (FR_MBCCSRn[MTD] = 1) the interrupt flag MBIF in the corresponding Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn) is equal to 1. 0 None of the individual transmit message buffers has the MBIF flag asserted. 1 At least one individual transmit message buffers has the MBIF flag asserted.

60.7.31 System Memory Access Time-Out Register (FR_SYMATOR)

Write: Disabled Mode

Address: 0h base + 3Eh offset = 3Eh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0								TIMEOUT							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0

FR_SYMATOR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–15 TIMEOUT	System Memory Access Time-Out. This value defines when a system bus access timout is detected. For a detailed description see Configure System Memory Access Time-Out Register (FR_SYMATOR) and System Bus Access Timeout .

60.7.32 Sync Frame Counter Register (FR_SFCNTR)

This register provides the number of synchronization frames that are used for clock synchronization in the last even and in the last odd numbered communication cycle. This register is updated after the start of the NIT and before 10 MT after offset correction start.

NOTE

If the application has locked the even synchronization table at the end of the static segment of an even communication cycle, the CC will not update the fields SFEVB and SFEVA.

NOTE

If the application has locked the odd synchronization table at the end of the static segment of an odd communication cycle, the CC will not update the values SFODB and SFODA.

Address: 0h base + 40h offset = 40h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	SFEVB				SFEVA				SFODB				SFODA			
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_SFCNTR field descriptions

Field	Description
0–3 SFEVB	Sync Frames Channel B, even cycle. protocol related variable: size of (vsSyncIdListB for even cycle) This field provides the size of the internal list of frame IDs of received synchronization frames used for clock synchronization.
4–7 SFEVA	Sync Frames Channel A, even cycle. protocol related variable: size of (vsSyncIdListA for even cycle) This field provides the size of the internal list of frame IDs of received synchronization frames used for clock synchronization.
8–11 SFODB	Sync Frames Channel B, odd cycle. protocol related variable: size of (vsSyncIdListB for odd cycle) This field provides the size of the internal list of frame IDs of received synchronization frames used for clock synchronization .
12–15 SFODA	Sync Frames Channel A, odd cycle. protocol related variable: size of (vsSyncIdListA for odd cycle) This field provides the size of the internal list of frame IDs of received synchronization frames used for clock synchronization .

60.7.33 Sync Frame Table Offset Register (FR_SFTOR)

Write: POC:config

This register defines the FlexRay memory area related offset for sync frame tables. For more details, see Sync Frame ID and Sync Frame Deviation Tables .

Address: 0h base + 42h offset = 42h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	SFT_OFFSET															0
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_SFTOR field descriptions

Field	Description
0–14 SFT_OFFSET	Sync Frame Table Offset. The offset of the Sync Frame Tables in the FlexRay memory area. This offset is required to be 16-bit aligned. Thus STF_OFFSET[0] is always 0.
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

60.7.34 Sync Frame Table Configuration, Control, Status Register (FR_SFTCCSR)

Write: Normal Mode

This register provides configuration, control, and status information related to the generation and access of the clock sync ID tables and clock sync measurement tables. For a detailed description, see Sync Frame ID and Sync Frame Deviation Tables .

Address: 0h base + 44h offset = 44h

Bit	0	1	2	3	4	5	6	7
Read	0	0	CYCNUM					
Write	ELKT	OLKT						
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read	ELKS	OLKS	EVAL	OVAL	0	0	SDVEN	SIDEN
Write						OPT		
Reset	0	0	0	0	0	0	0	0

FR_SFTCCSR field descriptions

Field	Description
0 ELKT	Even Cycle Tables Lock/Unlock Trigger. This trigger bit is used to lock and unlock the even cycle tables. 0 No effect 1 Triggers lock/unlock of the even cycle tables.
1 OLKT	Odd Cycle Tables Lock/Unlock Trigger. This trigger bit is used to lock and unlock the odd cycle tables. 0 No effect 1 Triggers lock/unlock of the odd cycle tables.

Table continues on the next page...

FR_SFTCCSR field descriptions (continued)

Field	Description
2–7 CYCNUM	Cycle Number. This field provides the number of the cycle in which the currently locked table was recorded. If none or both tables are locked, this value is related to the even cycle table.
8 ELKS	Even Cycle Tables Lock Status. This status bit indicates whether the application has locked the even cycle tables. 0 Application has not locked the even cycle tables. 1 Application has locked the even cycle tables.
9 OLKS	Odd Cycle Tables Lock Status. This status bit indicates whether the application has locked the odd cycle tables. 0 Application has not locked the odd cycle tables. 1 Application has locked the odd cycle tables.
10 EVAL	Even Cycle Tables Valid. This status bit indicates whether the Sync Frame ID and Sync Frame Deviation Tables for the even cycle are valid. The CC clears this status bit when it starts updating the tables, and sets this bit when it has finished the table update. 0 Tables are not valid (update is ongoing) 1 Tables are valid (consistent).
11 OVAL	Odd Cycle Tables Valid. This status bit indicates whether the Sync Frame ID and Sync Frame Deviation Tables for the odd cycle are valid. The CC clears this status bit when it starts updating the tables, and sets this bit when it has finished the table update. 0 Tables are not valid (update is ongoing) 1 Tables are valid (consistent).
12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 OPT	One Pair Trigger. This trigger bit controls whether the CC writes continuously or only one pair of Sync Frame Tables into the FlexRay memory area. If this trigger is set to 1 while SDVEN or SIDEN is set to 1, the CC writes only one pair of the enabled Sync Frame Tables corresponding to the next even-odd-cycle pair into the FlexRay memory area. In this case, the CC clears the SDVEN or SIDEN bits immediately. If this trigger is set to 0 while SDVEN or SIDEN is set to 1, the CC writes continuously the enabled Sync Frame Tables into the FlexRay memory area. 0 Write continuously pairs of enabled Sync Frame Tables into FlexRay memory area. 1 Write only one pair of enabled Sync Frame Tables into FlexRay memory area.
14 SDVEN	Sync Frame Deviation Table Enable. This bit controls the generation of the Sync Frame Deviation Tables. The application must set this bit to request the CC to write the Sync Frame Deviation Tables into the FlexRay memory area. **NOTE:** If SDVEN is set to 1, then SIDEN must also be set to 1. 0 Do not write Sync Frame Deviation Tables 1 Write Sync Frame Deviation Tables into FlexRay memory area
15 SIDEN	Sync Frame ID Table Enable. This bit controls the generation of the Sync Frame ID Tables. The application must set this bit to 1 to request the CC to write the Sync Frame ID Tables into the FlexRay memory area. 0 Do not write Sync Frame ID Tables 1 Write Sync Frame ID Tables into FlexRay memory area

60.7.35 Sync Frame ID Rejection Filter Register (FR_SFIDRFR)

Write: Normal Mode

This register defines the Sync Frame Rejection Filter ID. The application must update this register outside of the static segment. If the application updates this register in the static segment, it can appear that the CC accepts the sync frame in the current cycle.

Address: 0h base + 46h offset = 46h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0								SYNFRID							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_SFIDRFR field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–15 SYNFRID	Sync Frame Rejection ID. This field defines the frame ID of a frame that must not be used for clock synchronization. For details see Sync Frame Rejection Filtering .

60.7.36 Sync Frame ID Acceptance Filter Value Register (FR_SFIDAFVR)

Write: POC:config

This register defines the sync frame acceptance filter value. For details on filtering, see Sync Frame Filtering .

Address: 0h base + 48h offset = 48h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0								FVAL							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_SFIDAFVR field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–15 FVAL	Filter Value. This field defines the value for the sync frame acceptance filtering.

60.7.37 Sync Frame ID Acceptance Filter Mask Register (FR_SFIDAFMR)

Write: POC:config

This register defines the sync frame acceptance filter mask. For details on filtering see Sync Frame Acceptance Filtering .

Address: 0h base + 4Ah offset = 4Ah

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0						FMSK									
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_SFIDAFMR field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–15 FMSK	Filter Mask. This field defines the mask for the sync frame acceptance filtering.

60.7.38 Network Management Vector Register (FR_NMVR*n*)

Each of these six registers holds one part of the Network Management Vector. The length of the Network Management Vector is configured in the Network Management Vector Length Register (FR_NMVLR). If FR_NMVLR is programmed with a value that is less than 12 bytes, the remaining bytes of the Network Management Vector Registers (FR_NMVR0-FR_NMVR5), which are not used for the Network Management Vector accumulating, will remain 0.

The NMVR provides accrued information over all received NMVs in the last communication cycle. All NMVs received in one cycle are ORed into the NMVR. The NMVR is updated at the end of the communication cycle.

Address: 0h base + 4Ch offset + (2d × i), where i=0d to 5d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	NMVP															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_NMVR*n* field descriptions

Field	Description
0–15 NMVP	Network Management Vector Part. The mapping between the Network Management Vector Registers (FR_NMVR0-FR_NMVR5) and the receive message buffer payload bytes in NMV[0:11] is depicted in the following table.

Table 60-10. Mapping of NMVRn to the Received Payload Bytes NMVn

NMVRn Register	NMVn Received Payload
FR_NMVR0[NMVP[15:8]]	NMV0
FR_NMVR0[NMVP[7:0]]	NMV1
FR_NMVR1[NMVP[15:8]]	NMV2
FR_NMVR1[NMVP[7:0]]	NMV3
...	
FR_NMVR5[NMVP[15:8]]	NMV10
FR_NMVR5[NMVP[7:0]]	NMV11

60.7.39 Network Management Vector Length Register (FR_NMVLR)

Write: POC:config

This register defines the length of the network management vector in bytes.

Address: 0h base + 58h offset = 58h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0												NMVL			
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_NMVLR field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 NMVL	Network Management Vector Length. protocol related variable: gNetworkManagementVectorLength This field defines the length of the Network Management Vector in bytes. Legal values are between 0 and 12.

60.7.40 Timer Configuration and Control Register (FR_TICCR)

Write: T2_CFG: POC:config T2_REP, T1_REP, T1SP, T2SP, T1TR, T2TR: Normal Mode

This register is used to configure and control the two timers T1 and T2. For timer details, see Timer Support . The Timer T1 is an absolute timer. The Timer T2 can be configured as an absolute or relative timer.

NOTE

Both timers are deactivated immediately when the protocol enters a state different from POC:normal active or POC:normal passive.

Address: 0h base + 5Ah offset = 5Ah

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0		T2_CFG	T2_REP	0	0	0	T2ST	0			T1_REP	0	0	0	T1ST
Write						T2SP	T2TR							T1SP	T1TR	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_TICCR field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 T2_CFG	Timer T2 Configuration. This bit configures the timebase mode of Timer T2. 0 T2 is absolute timer. 1 T2 is relative timer.
3 T2_REP	Timer T2 Repetitive Mode. This bit configures the repetition mode of Timer T2. 0 T2 is non repetitive 1 T2 is repetitive
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5 T2SP	Timer T2 Stop. This trigger bit is used to stop timer T2. 0 no effect 1 stop timer T2
6 T2TR	Timer T2 Trigger. This trigger bit is used to start timer T2. 0 no effect 1 start timer T2
7 T2ST	Timer T2 State. This status bit provides the current state of timer T2. 0 timer T2 is idle 1 timer T2 is running
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 T1_REP	Timer T1 Repetitive Mode. This bit configures the repetition mode of timer T1. 0 T1 is non repetitive 1 T1 is repetitive

Table continues on the next page...

FR_TICCR field descriptions (continued)

Field	Description
12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 T1SP	Timer T1 Stop. This trigger bit is used to stop timer T1. 0 no effect 1 stop timer T1
14 T1TR	Timer T1 Trigger. This trigger bit is used to start timer T1. 0 no effect 1 start timer T1
15 T1ST	Timer T1 State. This status bit provides the current state of timer T1. 0 timer T1 is idle 1 timer T1 is running

60.7.41 Timer 1 Cycle Set Register (FR_TI1CYSR)

Write: Anytime

This register defines the cycle filter value and the cycle filter mask for timer T1. For a detailed description of timer T1, refer to Absolute Timer T1 .

NOTE

If the application modifies the value in this register while the timer is running, the change becomes effective immediately and timer T1 will expire according to the changed value.

Address: 0h base + 5Ch offset = 5Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0		T1_CYC_VAL						0		T1_CYC_MSK					
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_TI1CYSR field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–7 T1_CYC_VAL	Timer T1 Cycle Filter Value. This field defines the cycle filter value for timer T1.
8–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–15 T1_CYC_MSK	Timer T1 Cycle Filter Mask. This field defines the cycle filter mask for timer T1.

60.7.42 Timer 1 Macrotick Offset Register (FR_TI1MTOR)

Write: Anytime

This register holds the macrotick offset value for timer T1. For a detailed description of timer T1, refer to Absolute Timer T1 .

NOTE

If the application modifies the value in this register while the timer is running, the change becomes effective immediately and timer T1 will expire according to the changed value.

Address: 0h base + 5Eh offset = 5Eh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0		T1_MTOFFSET													
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_TI1MTOR field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–15 T1_MTOFFSET	Timer 1 Macrotick Offset. This field defines the macrotick offset value for timer 1.

60.7.43 Timer 2 Configuration Register 0 (Absolute Timer Configuration) (FR_TI2CR0_ABS)

The content of this register depends on the value of the T2_CFG bit in the Timer Configuration and Control Register (FR_TICCR). For a detailed description of timer T2, .

NOTE

If timer T2 is configured as an absolute timer and the application modifies the values in this register while the timer is running, the change becomes effective immediately and timer T2 will expire according to the changed values.

Address: 0h base + 60h offset = 60h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0		T2CYCVAL						0		T2CYCMSK					
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_TI2CR0_ABS field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–7 T2CYCVAL	Timer T2 Cycle Filter Mask
8–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–15 T2CYCMSK	Timer T2 Cycle Filter Mask

60.7.44 Timer 2 Configuration Register 0 (Relative Timer Configuration) (FR_TI2CR0_REL)

Write: Anytime

The content of this register depends on the value of the T2_CFG bit in the Timer Configuration and Control Register (FR_TICCR). For a detailed description of timer T2, refer to Relative Timer T2.

NOTE

If timer T2 is configured as a relative timer and the application changes the values in this register while the timer is running, the change becomes effective when the timer has expired according to the old values.

Address: 0h base + 60h offset = 60h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	T2MTCNT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_TI2CR0_REL field descriptions

Field	Description
0–15 T2MTCNT	Timer T2 Macrotick High Word

60.7.45 Timer 2 Configuration Register 1 (Absolute Timer Configuration) (FR_TI2CR1_ABS)

Write: Anytime

The content of this register depends on the value of the T2_CFG bit in the Timer Configuration and Control Register (FR_TICCR). For a detailed description of timer T2, refer to Absolute Timer T2

NOTE

If timer T2 is configured as an absolute timer and the application modifies the values in this register while the timer is running, the change becomes effective immediately and the timer T2 will expire according to the changed values.

Address: 0h base + 62h offset = 62h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_TI2CR1_REL field descriptions

Field	Description
0–15 T2MTCNT	Timer T2 Macrotick Low Word

60.7.47 Slot Status Selection Register (FR_SSSR)

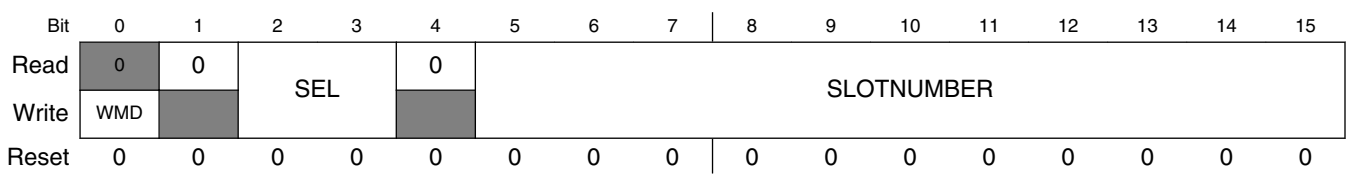
Write: Anytime

This register is used to access the four internal non-memory mapped slot status selection registers FR_SSSR0 to FR_SSSR3. Each internal register selects a slot, or symbol window/NIT, whose status vector will be saved in the corresponding Slot Status Registers (FR_SSR0-FR_SSR7) according to Slot Status Selection Register (FR_SSSR) . For a detailed description of slot status monitoring, refer to Slot Status Monitoring .

Table 60-11. Mapping Between FR_SSSRn and FR_SSRn

Internal Slot Status Selection Register	Write the Slot Status of the Slot Selected by FR_SSSRn for each			
	Even Communication Cycle		Odd Communication Cycle	
	For Channel B to	For Channel A to	For Channel B to	For Channel A to
FR_SSSR0	FR_SSR0[15:8]	FR_SSR0[7:0]	FR_SSR1[15:8]	FR_SSR1[7:0]
FR_SSSR1	FR_SSR2[15:8]	FR_SSR2[7:0]	FR_SSR3[15:8]	FR_SSR3[7:0]
FR_SSSR2	FR_SSR4[15:8]	FR_SSR4[7:0]	FR_SSR5[15:8]	FR_SSR5[7:0]
FR_SSSR3	FR_SSR6[15:8]	FR_SSR6[7:0]	FR_SSR7[15:8]	FR_SSR7[7:0]

Address: 0h base + 64h offset = 64h



FR_SSSR field descriptions

Field	Description
0 WMD	Write Mode. This control bit defines the write mode of this register. 0 Write to all fields in this register on write access. 1 Write to SEL field only on write access.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

FR_SSSR field descriptions (continued)

Field	Description
2–3 SEL	Selector. This field selects one of the four internal slot status selection registers for access. 00 select FR_SSSR0. 01 select FR_SSSR1. 10 select FR_SSSR2. 11 select FR_SSSR3.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–15 SLOTNUMBER	Slot Number. This field specifies the number of the slot whose status will be saved in the corresponding slot status registers. **NOTE:** If this value is set to 0, the related slot status register provides the status of the symbol window after the NIT start, and provides the status of the NIT after the cycle start.

60.7.48 Slot Status Counter Condition Register (FR_SSCCR)

Write: Anytime

This register is used to access and program the four internal non-memory mapped Slot Status Counter Condition Registers FR_SSCCR0 to FR_SSCCR3. Each of these four internal slot status counter condition registers defines the mode and the conditions for incrementing the counter in the corresponding Slot Status Counter Registers (FR_SSCR0-FR_SSCR3). The correspondence is given in Slot Status Counter Condition Register (FR_SSCCR) . For a detailed description of slot status counters, refer to Slot Status Counter Registers .

Table 60-12. Mapping between internal FR_SSCCRn and FR_SSCRn

Condition Register	Condition Defined for Register
FR_SSCCR0	FR_SSCR0
FR_SSCCR1	FR_SSCR1
FR_SSCCR2	FR_SSCR2
FR_SSCCR3	FR_SSCR3

Address: 0h base + 66h offset = 66h

FR_SSCCR field descriptions

Field	Description
0 WMD	Write Mode. This control bit defines the write mode of this register. 0 Write to all fields in this register on write access. 1 Write to SEL field only on write access.
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–3 SEL	Selector. This field selects one of the four internal slot counter condition registers for access. 00 select FR_SSCCR0. 01 select FR_SSCCR1. 10 select FR_SSCCR2. 11 select FR_SSCCR3.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–6 CNTCFG	Counter Configuration. These bit field controls the channel related incrementing of the slot status counter. 00 increment by 1 if condition is fulfilled on channel A. 01 increment by 1 if condition is fulfilled on channel B. 10 increment by 1 if condition is fulfilled on at least one channel. 11 increment by 2 if condition is fulfilled on both channels channel; increment by 1 if condition is fulfilled on only one channel.
7 MCY	Multi Cycle Selection. This bit defines whether the slot status counter accumulates over multiple communication cycles or provides information for the previous communication cycle only. 0 The Slot Status Counter provides information for the previous communication cycle only. 1 The Slot Status Counter accumulates over multiple communication cycles.
8 VFR	Valid Frame Restriction. This bit is used to restrict the counter to received valid frames. 0 The counter is not restricted to valid frames only. 1 The counter is restricted to valid frames only.
9 SYF	Sync Frame Restriction. This bit is used to restrict the counter to received frames with the sync frame indicator bit set to 1. 0 The counter is not restricted with respect to the sync frame indicator bit. 1 The counter is restricted to frames with the sync frame indicator bit set to 1.
10 NUF	Null Frame Restriction. This bit is used to restrict the counter to received frames with the null frame indicator bit set to 0. 0 The counter is not restricted with respect to the null frame indicator bit. 1 The counter is restricted to frames with the null frame indicator bit set to 0.
11 SUF	Startup Frame Restriction. This bit is used to restrict the counter to received frames with the startup frame indicator bit set to 1. 0 The counter is not restricted with respect to the startup frame indicator bit. 1 The counter is restricted to received frames with the startup frame indicator bit set to 1.
12–15 STATUSMASK	Slot Status Mask. This bit field is used to enable the counter with respect to the four slot status error indicator bits. STATUSMASK[3] - This bit enables the counting for slots with the syntax error indicator bit set to 1. STATUSMASK[2] - This bit enables the counting for slots with the content error indicator bit set to 1.

Table continues on the next page...

FR_SSCCR field descriptions (continued)

Field	Description
	STATUSMASK[1] - This bit enables the counting for slots with the boundary violation indicator bit set to 1. STATUSMASK[0] - This bit enables the counting for slots with the transmission conflict indicator bit set to 1.

60.7.49 Slot Status Register (FR_SSR*n*)

Each Slot Status Register (SSR) holds the status vector of the slot specified in the corresponding internal slot status selection register, which can be programmed using the Slot Status Selection Register (FR_SSSR). Each register is updated after the end of the corresponding slot as shown in Figure 60-31 . The register bits are directly related to the protocol variables and described in more detail in Slot Status Monitoring .

Address: 0h base + 68h offset + (2d × i), where i=0d to 7d

60.7.50 Slot Status Counter Register (FR_SSCR*n*)

Each of these four registers provides the slot status counter value for the previous communication cycle(s) and is updated at the cycle start. The provided value depends on the control bits and fields in the related internal slot status counter condition register FR_SSCCRn, which can be programmed by using the Slot Status Counter Condition Register (FR_SSCCR). For more details, see Slot Status Counter Registers .

NOTE

If the counter has reached its maximum value 0xFFFF and is in the multicycle mode, i.e. FR_SSCCRn[MCY] = 1, the counter is not reset to 0x0000. The application can reset the counter by clearing the FR_SSCCRn[MCY] bit and waiting for the next cycle start, when the CC clears the counter. Subsequently, the counter can be set into the multicycle mode again.

NOTE

Address: 0h base + 78h offset + (2d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	SLOTSTATUSCNT															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_SSCR*n* field descriptions

Field	Description
0–15 SLOTSTATUSCNT	Slot Status Counter. This field provides the current value of the Slot Status Counter.

60.7.51 MTS A Configuration Register (FR_MTSACFR)

Write: MTE: Anytime; CYCCNTMSK,CYCCNTVAL: POC:config

This register controls the transmission of the Media Access Test Symbol MTS on channel A. For more details, see MTS Generation .

Address: 0h base + 80h offset = 80h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	MTE	0	CYCCNTMSK						0		CYCCNTVAL					
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_MTSACFR field descriptions

Field	Description
0 MTE	Media Access Test Symbol Transmission Enable. This control bit is used to enable and disable the transmission of the Media Access Test Symbol in the selected set of cycles. 0 MTS transmission disabled 1 MTS transmission enabled
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–7 CYCCNTMSK	Cycle Counter Mask. This field provides the filter mask for the MTS cycle count filter.
8–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–15 CYCCNTVAL	Cycle Counter Value. This field provides the filter value for the MTS cycle count filter.

60.7.52 MTS B Configuration Register (FR_MTSBCFR)

Write: MTE: Anytime; CYCCNTMSK,CYCCNTVAL: POC:config

This register controls the transmission of the Media Access Test Symbol MTS on channel B. For more details, see MTS Generation .

Address: 0h base + 82h offset = 82h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	MTE	0	CYCCNTMSK						0		CYCCNTVAL					
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_MTSBCFR field descriptions

Field	Description
0 MTE	Media Access Test Symbol Transmission Enable. This control bit is used to enable and disable the transmission of the Media Access Test Symbol in the selected set of cycles. 0 MTS transmission disabled 1 MTS transmission enabled
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–7 CYCCNTMSK	Cycle Counter Mask. This field provides the filter mask for the MTS cycle count filter.
8–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–15 CYCCNTVAL	Cycle Counter Value. This field provides the filter value for the MTS cycle count filter.

60.7.53 Receive Shadow Buffer Index Register (FR_RSBIR)

Write: WMD, SEL: Any Time; RSBIDX: POC:config

This register is used to provide and retrieve the indices of the message buffer header fields currently associated with the receive shadow buffers . For more details on the receive shadow buffer concept, refer to Receive Shadow Buffers Concept .

Address: 0h base + 84h offset = 84h

Bit	0	1	2	3	4	5	6	7
Read Write	WMD	Reserved	SEL		Reserved			
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read Write	RSBIDX							
Reset	0	0	0	0	0	0	0	0

FR_RSBIR field descriptions

Field	Description
0 WMD	Write Mode. This bit controls the write mode for this register. 0 update SEL and RSBIDX field on register write 1 update only SEL field on register write
1 Reserved	This field is reserved.
2–3 SEL	Selector. This field is used to select the internal receive shadow buffer index register for access. 00 FR_RSBIR_A1. receive shadow buffer index register for channel A, segment 1 01 FR_RSBIR_A2. receive shadow buffer index register for channel A, segment 2 10 FR_RSBIR_B1. receive shadow buffer index register for channel B, segment 1 11 FR_RSBIR_B2. receive shadow buffer index register for channel B, segment 2
4–7 Reserved	This field is reserved.
8–15 RSBIDX	RSBIDXA1/RSBIDXA2/RSBIDXB1/RSBIDXB2- Receive Shadow Buffer Index Receive Shadow Buffer Index. This field contains the current index of the message buffer header field of the receive shadow message buffer selected by the SEL field. The CC uses this index to determine the physical location of the shadow buffer header field in the FlexRay memory area. The CC will update this field during receive operation.The application provides initial message buffer header index value in the configuration phase. CC: Updates the message buffer header index after successful reception. Application: Provides initial message buffer header index. Legal Values are 0 <= i <= 131 . Illegal values will be detected during the message buffer search.

60.7.54 Receive FIFO Watermark and Selection Register (FR_RFWMSR)

Write: WMA/WMB: POC:config, SEL: Anytime

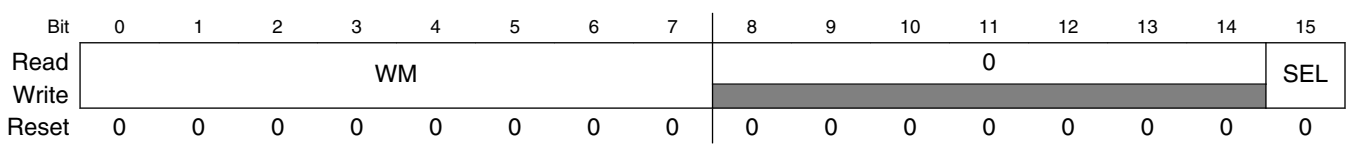
This register is used to

- select a receiver FIFO for subsequent programming access through the receiver FIFO configuration registers summarized in Receive FIFO Watermark and Selection Register (FR_RFWMSR) .
- to define the watermark for the selected FIFO.

Table 60-13. SEL Controlled Receiver FIFO Registers

Register
Receive FIFO Start Index Register (FR_RFSIR)
Receive FIFO Depth and Size Register (FR_RFDSR)
Receive FIFO Message ID Acceptance Filter Value Register (FR_RFMIDAFVR)
Receive FIFO Message ID Acceptance Filter Mask Register (FR_RFMIDAFMR)
Receive FIFO Frame ID Rejection Filter Value Register (FR_RFFIDRFVR)
Receive FIFO Frame ID Rejection Filter Mask Register (FR_RFFIDRFMR)
Receive FIFO Range Filter Configuration Register (FR_RFRFCFR)
Receive FIFO Range Filter Control Register (FR_RFRFCTR)

Address: 0h base + 86h offset = 86h



FR_RFWMSR field descriptions

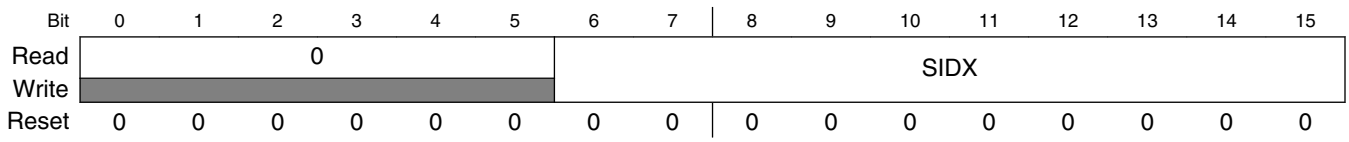
Field	Description
0–7 WM	WMA/WMB - Watermark This field defines the watermark value for the selected FIFO. This value is used to control the generation of the almost full interrupt flags.
8–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15 SEL	Select. This control bit selects the receiver FIFO for subsequent programming. 0 Receiver FIFO for channel A selected 1 Receiver FIFO for channel B selected

60.7.55 Receive FIFO Start Index Register (FR_RFSIR)

Write: POC:config

This register defines the message buffer header index of the first message buffer of the selected FIFO.

Address: 0h base + 88h offset = 88h



FR_RFSIR field descriptions

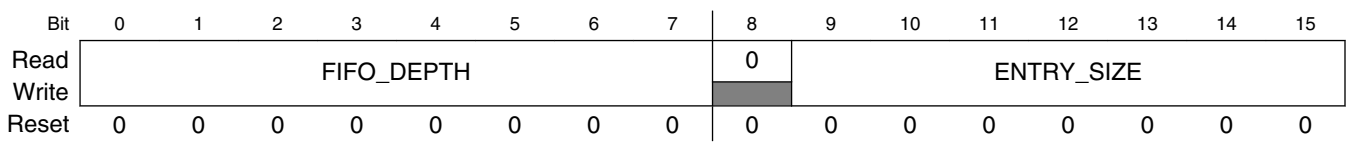
Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–15 SIDX	SIDXA/SIDXB - Start Index This field defines the number of the message buffer header field of the first message buffer of the selected FIFO. The CC uses the value of the SIDX field to determine the physical location of the receiver FIFO's first message buffer header field.

60.7.56 Receive FIFO Depth and Size Register (FR_RFDSR)

Write: POC:config

This register defines the structure of the selected FIFO, i.e. the number of entries and the size of each entry .

Address: 0h base + 8Ah offset = 8Ah



FR_RFDSR field descriptions

Field	Description
0–7 FIFO_DEPTH	FIFO_DEPTHA/FIFO_DEPTHB - FIFO Depth FIFO Depth. This field defines the depth of the selected FIFO, i.e. the number of entries. Note: If the FIFO_DEPTH is configured to 0, FR_RFFIDRFMR[FIDRFMSK] must be configured to 0 too, to ensure that no frames are received into the FIFO.

Table continues on the next page...

FR_RFDSR field descriptions (continued)

Field	Description
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–15 ENTRY_SIZE	ENTRY_SIZEA/ENTRY_SIZEB - Entry Size This field defines the size of the frame data sections for the selected FIFO in 2 byte entities.

60.7.57 Receive FIFO A Read Index Register (FR_RFARIR)

This register provides the message buffer header index of the next available FIFO A entry that the application can read.

NOTE

If the FIFO is empty, the RDIDX field points to an physical message buffer with invalid content.

Address: 0h base + 8Ch offset = 8Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0						RDIDX									
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RFARIR field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–15 RDIDX	Read Index. This field provides the message buffer header index of the next available FIFO message buffer that the application can read.

60.7.58 Receive FIFO B Read Index Register (FR_RFBRIR)

This register provides the message buffer header index of the next available FIFO B entry that the application can read.

NOTE

If the FIFO is empty, the RDIDX field points to an physical message buffer with invalid content.

Address: 0h base + 8Eh offset = 8Eh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0								RDIDX							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RFBRIR field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–15 RDIDX	Read Index. This field provides the message buffer header index of the next available FIFO message buffer that the application can read.

60.7.59 Receive FIFO Message ID Acceptance Filter Value Register (FR_RFMIDAFVR)

Write: POC:config

This register defines the filter value for the message ID acceptance filter of the selected FIFO. For details on message ID filtering see FIFO Filtering .

Address: 0h base + 90h offset = 90h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	MIDAFVAL															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RFMIDAFVR field descriptions

Field	Description
0–15 MIDAFVAL	MIDAFVALA/MIDAFVALB - Message ID Acceptance Filter Value Filter value for the message ID acceptance filter.

60.7.60 Receive FIFO Message ID Acceptance Filter Mask Register (FR_RFMIDAFMR)

Write: POC:config

This register defines the filter mask for the message ID acceptance filter of the selected FIFO. For details on message ID filtering see FIFO Filtering .

Address: 0h base + 92h offset = 92h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	MIDAFMSK															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RFMIDAFMR field descriptions

Field	Description
0–15 MIDAFMSK	MIDAFMSKA/MIDAFMSKB - Message ID Acceptance Filter Mask Filter mask for the message ID acceptance filter.

60.7.61 Receive FIFO Frame ID Rejection Filter Value Register (FR_RFFIDRFVR)

Write: POC:config

This register defines the filter value for the frame ID rejection filter of the selected FIFO. For details on frame ID filtering see FIFO Filtering .

Address: 0h base + 94h offset = 94h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0					FIDRFVAL										
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RFFIDRFVR field descriptions

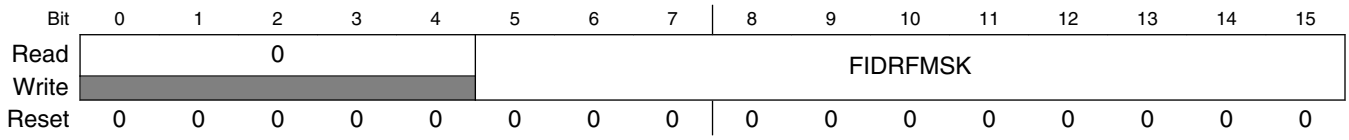
Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–15 FIDRFVAL	FIDRFVALA/FIDRFVALB - Frame ID Rejection Filter Value Filter value for the frame ID rejection filter.

60.7.62 Receive FIFO Frame ID Rejection Filter Mask Register (FR_RFFIDRFMR)

Write: POC:config

This register defines the filter mask for the frame ID rejection filter of the selected FIFO. For details on frame ID filtering see FIFO Filtering .

Address: 0h base + 96h offset = 96h



FR_RFFIDRFMR field descriptions

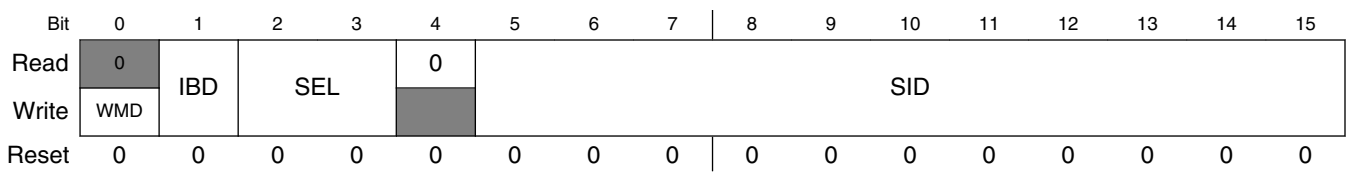
Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–15 FIDRFMSK	Frame ID Rejection Filter Mask. Filter mask for the frame ID rejection filter.

60.7.63 Receive FIFO Range Filter Configuration Register (FR_RFRFCFR)

Write: WMD, IBD, SEL: Any Time; SID: POC:config

This register provides access to the four internal frame ID range filter boundary registers of the selected FIFO. For details on frame ID range filter see FIFO Filtering .

Address: 0h base + 98h offset = 98h



FR_RFRFCFR field descriptions

Field	Description
0 WMD	Write Mode. This control bit defines the write mode of this register. 0 Write to all fields in this register on write access. 1 Write to SEL and IBD field only on write access.
1 IBD	Interval Boundary. This control bit selects the interval boundary to be programmed with the SID value. 0 program lower interval boundary 1 program upper interval boundary
2–3 SEL	Filter Selector. This control field selects the frame ID range filter to be accessed. 00 select frame ID range filter 0. 01 select frame ID range filter 1. 10 select frame ID range filter 2. 11 select frame ID range filter 3.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

FR_RFRFCFR field descriptions (continued)

Field	Description
5–15 SID	Slot ID Defines the IBD-selected frame ID boundary value for the SEL-selected range filter.

60.7.64 Receive FIFO Range Filter Control Register (FR_RFRFCTR)

Write: Anytime

This register is used to enable and disable each frame ID range filter and to define whether it is running as acceptance or rejection filter.

Address: 0h base + 9Ah offset = 9Ah

Bit	0	1	2	3	4	5	6	7
Read	0				F3MD	F2MD	F1MD	F0MD
Write								
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read	0				F3EN	F2EN	F1EN	F0EN
Write								
Reset	0	0	0	0	0	0	0	0

FR_RFRFCTR field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 F3MD	Range Filter 3 Mode. This control bit defines the filter mode of the frame ID range filter 3. 0 range filter 3 runs as acceptance filter 1 range filter 3 runs as rejection filter
5 F2MD	Range Filter 2 Mode. This control bit defines the filter mode of the frame ID range filter 2. 0 range filter 2 runs as acceptance filter 1 range filter 2 runs as rejection filter
6 F1MD	Range Filter 1 Mode. This control bit defines the filter mode of the frame ID range filter 1. 0 range filter 1 runs as acceptance filter 1 range filter 1 runs as rejection filter
7 F0MD	Range Filter 0 Mode. This control bit defines the filter mode of the frame ID range filter 0. 0 range filter 0 runs as acceptance filter 1 range filter 0 runs as rejection filter
8–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

FR_RFRFCTR field descriptions (continued)

Field	Description
12 F3EN	Range Filter 3 Enable. This control bit is used to enable and disable the frame ID range filter 3. 0 range filter 3 disabled 1 range filter 3 enabled
13 F2EN	Range Filter 2 Enable. This control bit is used to enable and disable the frame ID range filter 2. 0 range filter 2 disabled 1 range filter 2 enabled
14 F1EN	Range Filter 1 Enable. This control bit is used to enable and disable the frame ID range filter 1. 0 range filter 1 disabled 1 range filter 1 enabled
15 F0EN	Range Filter 0 Enable. This control bit is used to enable and disable the frame ID range filter 0. 0 range filter 0 disabled 1 range filter 0 enabled

60.7.65 Last Dynamic Transmit Slot Channel A Register (FR_LDTXSLAR)

This register provides the number of the last transmission slot in the dynamic segment for channel A. This register is updated after the end of the dynamic segment and before the start of the next communication cycle.

Address: 0h base + 9Ch offset = 9Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0					LDYNTXSLOTA										
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_LDTXSLAR field descriptions

Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–15 LDYNTXSLOTA	Last Dynamic Transmission Slot Channel A. protocol related variable: zLastDynTxSlot channel A Number of the last transmission slot in the dynamic segment for channel A. If no frame was transmitted during the dynamic segment on channel A, the value of this field is set to 0.

60.7.66 Last Dynamic Transmit Slot Channel B Register (FR_LDTXSLBR)

This register provides the number of the last transmission slot in the dynamic segment for channel B. This register is updated after the end of the dynamic segment and before the start of the next communication cycle.

Address: 0h base + 9Eh offset = 9Eh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0					LDYNTXSLOTB										
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_LDTXSLBR field descriptions

Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–15 LDYNTXSLOTB	Last Dynamic Transmission Slot Channel B. protocol related variable: zLastDynTxSlot channel B Number of the last transmission slot in the dynamic segment for channel B. If no frame was transmitted during the dynamic segment on channel B the value of this field is set to 0.

60.7.67 Protocol Configuration Register 0 (FR_PCR0)

Write: POC:config

The protocol configuration registers (FR_PCRn) provide the necessary configuration information to the protocol engine. The individual values in the registers are described in Protocol Configuration Register 0 (FR_PCR0) .

Table 60-14. Protocol Configuration Register (PCR0-30) Fields

Name	Description	Min	Max	Unit	FR_PCR
coldstart_attempts	gColdstartAttempts			number	3
action_point_offset	gdActionPointOffset - 1			MT	0
cas_rx_low_max	gdCASRxLowMax - 1			gdBit	4
dynamic_slot_idle_phase	gdDynamicSlotIdlePhase			minislot	28
minislot_action_point_offset	gdMinislotActionPointOffset - 1			MT	3

Table 60-14. Protocol Configuration Register (PCR0-30) Fields (continued)

Name	Description	Min	Max	Unit	FR_PCR
micro_initial_offset_b	pMicroInitialOffset[B]			µT	20
micro_per_cycle	pMicroPerCycle			µT	22/23
micro_per_cycle_min	pMicroPerCycle - pdMaxDrift			µT	24/25
micro_per_cycle_max	pMicroPerCycle + pdMaxDrift			µT	26/27
micro_per_macro_nom_half	round(pMicroPerMacroNom / 2)			µT	7
offset_correction_out	pOffsetCorrectionOut			µT	9
rate_correction_out	pRateCorrectionOut			µT	14
single_slot_enabled	pSingleSlotEnabled			bool	10
wakeup_channel	pWakeupChannel	see Protocol Configuration Register 0 (FR_PCR0)			10
wakeup_pattern	pWakeupPattern			number	18
decoding_correction_a	pDecodingCorrection + pDelayCompensation[A] + 2			µT	19
decoding_correction_b	pDecodingCorrection + pDelayCompensation[B] + 2			µT	7
key_slot_header_crc	header CRC for key slot	0x000	0x7FF	number	12
extern_offset_correction	pExternOffsetCorrection			µT	29
extern_rate_correction	pExternRateCorrection			µT	21

Table 60-15. Wakeup Channel Selection

wakeup_channel	Wakeup Channel
0	A
1	B

Address: 0h base + A0h offset = A0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	action_point_offset								static_slot_length							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_PCR0 field descriptions

Field	Description
0–5 action_point_offset	gdActionPointOffset - 1
6–15 static_slot_length	gdStaticSlot

60.7.68 Protocol Configuration Register 1 (FR_PCR1)

Write: POC:config

The protocol configuration registers (FR_PCRn) provide the necessary configuration information to the protocol engine. The individual values in the registers are described in Protocol Configuration Register 0 (FR_PCR0) .

Address: 0h base + A2h offset = A2h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0		macro_after_first_static_slot													
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_PCR1 field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–15 macro_after_ first_static_slot	gMacroPerCycle - gdStaticSlot

60.7.69 Protocol Configuration Register 2 (FR_PCR2)

Write: POC:config

The protocol configuration registers (FR_PCRn) provide the necessary configuration information to the protocol engine. The individual values in the registers are described in Protocol Configuration Register 0 (FR_PCR0) .

Address: 0h base + A4h offset = A4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	minislot_after_action_point						number_of_static_slots									
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_PCR2 field descriptions

Field	Description
0–5 minislot_after_ action_point	gdMinislot - gdMinislotActionPointOffset - 1
6–15 number_of_ static_slots	gNumberOfStaticSlots

60.7.70 Protocol Configuration Register 3 (FR_PCR3)

Write: POC:config

The protocol configuration registers (FR_PCRn) provide the necessary configuration information to the protocol engine. The individual values in the registers are described in Protocol Configuration Register 0 (FR_PCR0) .

Address: 0h base + A6h offset = A6h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	wakeup_symbol_rx_low						minislot_action_point_offset					coldstart_attempts				
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_PCR3 field descriptions

Field	Description
0–5 wakeup_symbol_rx_low	gdWakeupSymbolRxLow
6–10 minislot_action_point_offset	gdMinislotActionPointOffset - 1
11–15 coldstart_attempts	gColdstartAttempts

60.7.71 Protocol Configuration Register 4 (FR_PCR4)

Write: POC:config

The protocol configuration registers (FR_PCRn) provide the necessary configuration information to the protocol engine. The individual values in the registers are described in Protocol Configuration Register 0 (FR_PCR0) .

Address: 0h base + A8h offset = A8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	cas_rx_low_max							wakeup_symbol_rx_window								
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_PCR4 field descriptions

Field	Description
0–6 cas_rx_low_max	gdCASRxLowMax - 1

Table continues on the next page...

FR_PCR4 field descriptions (continued)

Field	Description
7–15 wakeup_symbol_ rx_window	gdWakeupSymbolRxWindow

60.7.72 Protocol Configuration Register 5 (FR_PCR5)

Write: POC:config

The protocol configuration registers (FR_PCRn) provide the necessary configuration information to the protocol engine. The individual values in the registers are described in Protocol Configuration Register 0 (FR_PCR0) .

Address: 0h base + AAh offset = AAh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	tss_transmitter				wakeup_symbol_tx_low						wakeup_symbol_rx_idle					
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_PCR5 field descriptions

Field	Description
0–3 tss_transmitter	gdTSSTransmitter
4–9 wakeup_symbol_ tx_low	gdWakeupSymbolTxLow
10–15 wakeup_symbol_ rx_idle	gdWakeupSymbolRxIdle

60.7.73 Protocol Configuration Register 6 (FR_PCR6)

Write: POC:config

The protocol configuration registers (FR_PCRn) provide the necessary configuration information to the protocol engine. The individual values in the registers are described in Protocol Configuration Register 0 (FR_PCR0) .

Address: 0h base + ACh offset = ACh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0	symbol_window_after_action_point							macro_initial_offset_a							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 sync_node_max	gSyncNodeMax

60.7.98 Receive FIFO Start Data Offset Register (FR_RFSDOR)

Write: POC:config

NOTE

Since all data fields of the FIFO are of equal length and are located at subsequent system memory addresses the content of the FR_RFSDOR corresponds to the start address of payload area of the selected FIFO.

Address: 0h base + E6h offset = E6h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	SDO															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RFSDOR field descriptions

Field	Description
0–15 SDO	SDOA/SDOB - Start Data Field Offset Start Data Field Offset. This field defines the data field offset of the header field of the first message buffer of the selected FIFO. The CC uses the value of the SDO field to determine the physical location of the receiver FIFO's first message buffer header field. For configuration constraints see Configure Data Field Offsets .

60.7.99 Receive FIFO System Memory Base Address High Register (FR_RFSYMBADHR)

These registers define the system memory base address for the receive FIFO if the FIFO address mode bit FR_MCR[FAM] is set to 1. The system memory base address is used by the BMIF to calculate the physical memory address for system memory accesses for the FIFOs.

Write: Disabled Mode

Address: 0h base + E8h offset = E8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	SMBA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RFSYMBADHR field descriptions

Field	Description
0–15 SMBA	System Memory Base Address. This is the value of the system memory base address for the receive FIFO if the FIFO address mode bit FR_MCR[FAM] is set to 1. It is defines as a byte address.

60.7.100 Receive FIFO System Memory Base Address Low Register (FR_RFSYMBADLR)

These registers define the system memory base address for the receive FIFO if the FIFO address mode bit FR_MCR[FAM] is set to 1. The system memory base address is used by the BMIF to calculate the physical memory address for system memory accesses for the FIFOs.

Write: Disabled Mode

Address: 0h base + EAh offset = EAh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	SMBA												0			
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RFSYMBADLR field descriptions

Field	Description
0–11 SMBA	System Memory Base Address. This is the value of the system memory base address for the receive FIFO if the FIFO address mode bit FR_MCR[FAM] is set to 1. It is defines as a byte address.
12–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

60.7.101 Receive FIFO Periodic Timer Register (FR_RFPTR)

Write: POC:config

This register holds periodic timer duration for the periodic FIFO timer. The periodic timer applies to both FIFOs (see FIFO Periodic Timer).

Address: 0h base + ECh offset = ECh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0								PTD							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_RFPTR field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–15 PTD	Periodic Timer Duration. This value defines the periodic timer duration in terms of macroticks. 0000 timer stays expired 3FFF timer never expires other timer expires after specified number of macroticks, expires and is restarted at each cycle start

60.7.102 Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR)

This register provides the current fill level of the two receiver FIFOs and is used to pop a number of entries from the FIFOs

If the pop count value PCA/PCB is greater than the current FIFO fill level FLB/FLA, than the FIFO is empty after the update. No notification is given that not the required number of entries was removed.

.

Address: 0h base + EEh offset = EEh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	FLB_or_PCB								FLA_or_PCA							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

60.7.103 ECC Error Interrupt Flag and Enable Register (FR_EEIFER)

This register provides the means to control the ECC related interrupt request lines and provides the corresponding interrupt flags. The interrupt flags are cleared by writing 1, which resets the corresponding report registers. For a detailed description see Memory Error Reporting .

Address: 0h base + F0h offset = F0h

Bit	0	1	2	3	4	5	6	7

Field	Description
	0 Disable interrupt line 1 Enable interrupt line

60.7.104 ECC Error Report and Injection Control Register (FR_EERICR)

This register configures the error injection and error reporting and provides the selector for the content of the report registers.

Address: 0h base + F2h offset = F2h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	BSY	0					ERS		0			ERM	0		EIM	EIE
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_EERICR field descriptions

Field	Description
0 BSY	Register Update Busy- This field indicates the current state of the ECC configuration update and controls the register write access condition IDL specified in " Register Write Access 0 ECC configuration is idle 1 ECC configuration is running
1–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–7 ERS	Error Report Select. This field selects the content of the ECC Error reporting registers. 00 show PE DRAM non-corrected error information 01 show PE DRAM corrected error information 10 show CHI LRAM non-corrected error information 11 show CHI LRAM corrected error information
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 ERM	Error Report Mode. This bit configures the type of data written into the internal error report registers on the detection of a memory error. 0 store data and code as delivered by ecc decoding logic. 1 store data and code as read from the memory.
12–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 EIM	Error Injection Mode. This bit configures the ECC error injection mode.

Table continues on the next page...

FR_EERICR field descriptions (continued)

Field	Description
	0 use FR_EEIDR[DATA] and FR_EEICR[CODE] as XOR distortion pattern for error injection. 1 use FR_EEIDR[DATA] and FR_EEICR[CODE] as write value for error injection.
15 EIE	Error Injection Enable. This bit configures the ECC error injection on the memories. 0 Error injection disabled 1 Error injection enabled

60.7.105 ECC Error Report Address Register (FR_EERAR)

This register provides the memory identifier, bank, and address for which the memory error is reported.

Address: 0h base + F4h offset = F4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	MID	BANK			ADDR											
Write																
Reset	0	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0

FR_EERAR field descriptions

Field	Description
0 MID	Memory Identifier. This flag provides the memory instance for which the memory error is reported. 0 PE DRAM 1 CHI LRAM
1–3 BANK	Memory Bank. This field provides the BANK for which the memory error is reported. 111 reset value, indicates no error found after reset. For MID=0: 000 PE DRAM [7:0] 001 PE DRAM [15:8] others - not used For MID=1: Refer to the following table for the assignment of the LRAM banks.

Table 60-16. LRAM Bank Value for MID = 1

BANK	Register		
000	FR_MBCCFR(2n)	FR_MBDOR(6n)	FR_LEETR0
001	FR_MBFIDR(2n)	FR_MBDOR(6n + 1)	FR_LEETR1
010	FR_MBIDXR(2n)	FR_MBDOR(6n + 2)	FR_LEETR2

Read	DATA															
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_EERDR field descriptions

Field	Description
0–15 DATA	Data. The content of this field depends on the report mode selected by FR_EERICR[ERM] ERM=0: Ecc Data, shows data as generated by the ecc decoding logic. ERM=1: Memory Data, shows data as read from the memory.

60.7.107 ECC Error Report Code Register (FR_EERCR)

This register provides the ECC related information of the reported memory read access.

Address: 0h base + F8h offset = F8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0											CODE				
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_EERCR field descriptions

Field	Description
0–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–15 CODE	Code. The content of this field depends on the report mode selected by FR_EERICR[ERM] ERM=0: Syndrome. Shows the ecc syndrome generated by the ecc decoding logic. The coding of the PE DRAM syndrome is shown in PE DRAM Syndrome . The coding of the CHI LRAM syndrome is shown in CHI LRAM Syndrome . ERM=1: Checkbits. Shows the ecc checkbits read from the memory.

60.7.108 ECC Error Injection Address Register (FR_EEIAR)

This register defines the memory module, bank, and address where the ECC error has to be injected.

Address: 0h base + FAh offset = FAh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	MID	BANK			ADDR											
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_EEIAR field descriptions

Field	Description
0 MID	Memory Identifier. This flag defines the memory instance for ECC error injection. 0 PE DRAM 1 CHI LRAM
1–3 BANK	Memory Bank. This field defines the memory bank for ECC error injection. For MID=0: 000 BANK0: PE DRAM [7:0] 001 BANK1: PE DRAM [15:8] others reserved For MID=1: Refer to ECC Error Report Address Register (FR_EERAR) for the assignment of the LRAM banks.
4–15 ADDR	Memory Address. This flag defines the memory address for ECC error injection.

60.7.109 ECC Error Injection Data Register (FR_EEIDR)

This register defines the data distortion pattern for the error injection write. The number of valid bits depends on the selected memory and memory bank as shown in ECC Error Report Data Register (FR_EERDR) .

NOTE

The effect of the error injected depends from the LRAM content at the address accessed and from the module internal usage of the data. Refer to Memory Error Response for details.

Address: 0h base + FCh offset = FCh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	DATA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_EEIDR field descriptions

Field	Description
0–15 DATA	Data. The content of this field depends on the error injection mode selected by FR_EERICR[EIM]. EIM=0: This field defines the XOR distortion pattern for the data written into the memory. EIM=1: This field defines the data to be written into the memory.

60.7.110 ECC Error Injection Code Register (FR_EEICR)

This register defines the ECC code distortion pattern for the error injection write.

Address: 0h base + FEh offset = FEh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0											CODE				
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FR_EEICR field descriptions

Field	Description
0–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–15 CODE	Code. The content of this field depends on the error injection mode selected by FR_EERICR[EIM]. EIM=0: This field defines the XOR distortion pattern for the ecc checkbits written into the memory. EIM=1: This field defines the ecc checkbits written into the memory.

60.7.111 Message Buffer Configuration, Control, Status Register (FR_MBCCSR*n*)

Write: MTD: POC:config or MB_DIS CMT: MB_LCK or MB_DIS EDT, LCKT, MBIE, MBIF: Normal Mode

The content of these registers is composed of message buffer configuration data, message buffer control data, message buffer status information, and message buffer interrupt flags. A detailed description of all flags can be found in Individual Message Buffer Functional Description.

If the application writes 1 to the EDT bit, no write access to the other register bits is performed.

If the application writes 0 to the EDT bit and 1 to the LCKT bit, no write access to the other bits is performed.

Address: 0h base + 800h offset + (8d × i), where i=0d to 127d

Bit	0	1	2	3	4	5	6	7
Read	0			MTD	CMT		0	MBIE
Write						EDT	LCKT	
Reset	0	0	0	0	0	0	0	0

Bit	8	9	10	11	12	13	14	15
Read	0			DUP	DVAL	EDS	LCKS	MBIF
Write								w1c
Reset	0	0	0	0	0	0	0	0

FR_MBCCSR*n* field descriptions

Field	Description
0–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 MTD	Message Buffer Transfer Direction. This bit configures the transfer direction of a message buffer. 0 Receive message buffer 1 Transmit message buffer
4 CMT	Commit for Transmission. This bit indicates if the transmit message buffer data are ready for transmission. **NOTE:** This bit is read/write but may be modified by hardware other than by a reset. 0 Message buffer data not ready for transmission 1 Message buffer data ready for transmission
5 EDT	Enable/Disable Trigger. If the application writes 1 to this bit, a message buffer enable or disable is triggered, depending on the current value of the EDS status bit. 0 No effect 1 Message buffer enable or disable is triggered
6 LCKT	Lock/Unlock Trigger. If the application writes 1 to this bit and writes 0 to the EDT bit, a message buffer lock or unlock is triggered, depending on the current value of the LCKS status bit. 0 No effect 1 Message buffer lock or unlock is triggered
7 MBIE	Message Buffer Interrupt Enable. This control bit defines whether the message buffer will generate an interrupt request when its MBIF flag is set. 0 Interrupt request generation disabled 1 Interrupt request generation enabled
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

FR_MBCCSR*n* field descriptions (continued)

Field	Description
11 DUP	Data Updated. This status bit indicates whether the frame header in the message buffer header field and the data in the message buffer data field were updated after a frame reception. 0 Frame Header and Message buffer data field not updated 1 Frame Header and Message buffer data field updated
12 DVAL	Data Valid. For receive message buffers this status bit indicates whether the message buffer data field contains valid frame data. For transmit message buffers the status bit indicates if a message is transferred again due to the state transmission mode of the message buffer. 0 receive message buffer contains no valid frame data / message is transmitted for the first time 1 receive message buffer contains valid frame data / message will be transferred again
13 EDS	Enable/Disable Status. This status bit indicates whether the message buffer is enabled or disabled. 0 Message buffer is disabled. 1 Message buffer is enabled.
14 LCKS	Lock Status. This status bit indicates the current lock status of the message buffer. 0 Message buffer is not locked by the application. 1 Message buffer is locked by the application.
15 MBIF	Message Buffer Interrupt Flag. This flag is set when the slot status field of the message buffer was updated after frame transmission or reception, or when a transmit message buffer was just enabled by the application. 0 No such event 1 Slot status field updated or transmit message buffer just enabled

60.7.112 Message Buffer Cycle Counter Filter Register (FR_MBCCFR*n*)

NOTE

After Phase3 reset, LRAM is not initialized. LRAM is initialized when CC leaves the Disabled Mode (For details, refer CHI LRAM Initialization section).

Write: POC:config or MB_DIS

This register contains message buffer configuration data for the transmission mode, the channel assignment, and for the cycle counter filtering. For detailed information on cycle counter filtering, refer to Message Buffer Cycle Counter Filtering .

NOTE

If at least one message buffer assigned to a certain slot is assigned to both channels, then all message buffers assigned to this slot have to be assigned to both channels. Otherwise, the

message buffer configuration is illegal and the result of the message buffer search is not defined.

Table 60-18. Channel Assignment Description

CHA	CHB	Transmit Message Buffer		Receive Message Buffer	
		static segment	dynamic segment	static segment	dynamic segment
1	1	transmit on both channel A and channel B	transmit on channel A only	store first valid frame received on either channel A or channel B	store first valid frame received on channel A, ignore channel B
0	1	transmit on channel B	transmit on channel B	store first valid frame received on channel B	store first valid frame received on channel B
1	0	transmit on channel A	transmit on channel A	store first valid frame received on channel A	store first valid frame received on channel A
0	0	no frame transmission	no frame transmission	no frame stored	no frame stored

Address: 0h base + 802h offset + (8d × i), where i=0d to 127d

Bit	0	1	2	3	4	5	6	7
Read Write	MTM	CHA	CHB	CCFE	CCFMSK			
Reset	0*	0*	0*	0*	0*	0*	0*	0*

Bit	8	9	10	11	12	13	14	15
Read Write	CCFMSK		CCFVAL					
Reset	0*	0*	0*	0*	0*	0*	0*	0*

* Notes:
- After Phase3 reset, LRAM is not initialized. LRAM is initialized when CC leaves the Disabled Mode (For details, refer CHI LRAM Initialization section).

FR_MBCCFR*n* field descriptions

Field	Description
0 MTM	Message Buffer Transmission Mode. This control bit applies only to transmit message buffers and defines the transmission mode. 0 Event transmission mode 1 State transmission mode
1 CHA	Channel Assignment. In conjunction with the CHB field, defines the channel assignment and control the receive and transmit behavior of the message buffer according to Message Buffer Cycle Counter Filter Register (FR_MBCCFR*n*) .
2 CHB	Channel Assignment. In conjunction with the CHB field, defines the channel assignment and control the receive and transmit behavior of the message buffer according to Message Buffer Cycle Counter Filter Register (FR_MBCCFR*n*) .
3 CCFE	Cycle Counter Filtering Enable. This control bit is used to enable and disable the cycle counter filtering. 0 Cycle counter filtering disabled 1 Cycle counter filtering enabled

Table continues on the next page...

FR_MBCCFR*n* field descriptions (continued)

Field	Description
4–9 CCFMSK	Cycle Counter Filtering Mask. This field defines the filter mask for the cycle counter filtering.
10–15 CCFVAL	Cycle Counter Filtering Value. This field defines the filter value for the cycle counter filtering.

60.7.113 Message Buffer Frame ID Register (FR_MBFIDR*n*)

NOTE

After Phase3 reset, LRAM is not initialized. LRAM is initialized when CC leaves the Disabled Mode (For details, refer CHI LRAM Initialization section).

Write: POC:config or MB_DIS

Address: 0h base + 804h offset + (8d × i), where i=0d to 127d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0					FID										
Write																
Reset	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*

* Notes:
- After Phase3 reset, LRAM is not initialized. LRAM is initialized when CC leaves the Disabled Mode (For details, refer CHI LRAM Initialization section).

FR_MBFIDR*n* field descriptions

Field	Description
0–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–15 FID	Frame ID. The semantic of this field depends on the message buffer transfer type. • Receive Message Buffer: This field is used as a filter value to determine if the message buffer is used for reception of a message received in a slot with the slot ID equal to FID. • Transmit Message Buffer: This field is used to determine the slot in which the message in this message buffer should be transmitted.

60.7.114 Message Buffer Index Register (FR_MBIDXR*n*)

NOTE

After Phase3 reset, LRAM is not initialized. LRAM is initialized when CC leaves the Disabled Mode (For details, refer CHI LRAM Initialization section).

Write: POC:config or MB_DIS

Address: 0h base + 806h offset + (8d × i), where i=0d to 127d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0								MBIDX							
Write																
Reset	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*

* Notes:
- After Phase3 reset, LRAM is not initialized. LRAM is initialized when CC leaves the Disabled Mode (For details, refer CHI LRAM Initialization section).

FR_MBIDXR*n* field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–15 MBIDX	Message Buffer Index. This field provides the index of the message buffer header field of the physical message buffer that is currently associated with this message buffer. The application writes the index of the initially associated message buffer header field into this register. The CC updates this register after frame reception or transmission. Legal Values are 0 <= i <= 131 . Illegal values will be detected during the message buffer search.

60.7.115 Message Buffer Data Field Offset Register (FR_MBDOR*n*)

NOTE

After Phase3 reset, LRAM is not initialized. LRAM is initialized when CC leaves the Disabled Mode (For details, refer CHI LRAM Initialization section).

Write: POC:config

Address: 0h base + 1000h offset + (2d × i), where i=0d to 131d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	MBDO															
Write																
Reset	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*

* Notes:
- After Phase3 reset, LRAM is not initialized. LRAM is initialized when CC leaves the Disabled Mode (For details, refer CHI LRAM Initialization section).

FR_MBDOR*n* field descriptions

Field	Description
0–15 MBDO	Message Buffer Data Field Offset. This field provides the data field offset belonging to a particular Message Buffer Index. For configuration constraints see Configure Data Field Offsets .

60.7.116 LRAM ECC Error Test Register (FR_LEETR*n*)

NOTE

After Phase3 reset, LRAM is not initialized. LRAM is initialized when CC leaves the Disabled Mode (For details, refer CHI LRAM Initialization section).

Address: 0h base + 1108h offset + (2d × i), where i=0d to 5d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read Write	LEETD															
Reset	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*	0*

* Notes:
- After Phase3 reset, LRAM is not initialized. LRAM is initialized when CC leaves the Disabled Mode (For details, refer CHI LRAM Initialization section).

FR_LEETR*n* field descriptions

Field	Description
0–15 LEETD	LRAM ECC Error Test Data. This field contains the LRAM data belonging to the test register located in LRAM Bank n.

60.8 Functional Description

This section provides a detailed description of the functionality implemented in the CC.

60.8.1 Message Buffer Concept

The CC uses a data structure called a *message buffer* to store frame data, configuration, control, and status data. Each message buffer consists of two parts, the *message buffer control data* and the *physical message buffer*. The message buffer control data are located in dedicated registers. The structure of the message buffer control data depends on the message buffer type and is described in the Message Buffer Types section. The physical message buffer is located in the FlexRay memory area and is described in the next section.

60.8.2 Physical Message Buffer

All FlexRay messages and related frame and slot status information of received frames and of frames to be transmitted to the FlexRay bus are stored in data structures called *physical message buffers*. The physical message buffers are located in the FlexRay memory area.The structure of a physical message buffer is depicted in the figure below.

A physical message buffer consists of two fields, the *message buffer header field* and the *message buffer data field*. The message buffer header field contains the *frame header* and the *slot status*. The message buffer data field contains the *frame data*.

The connection between the two fields is established by the *data field offset*.

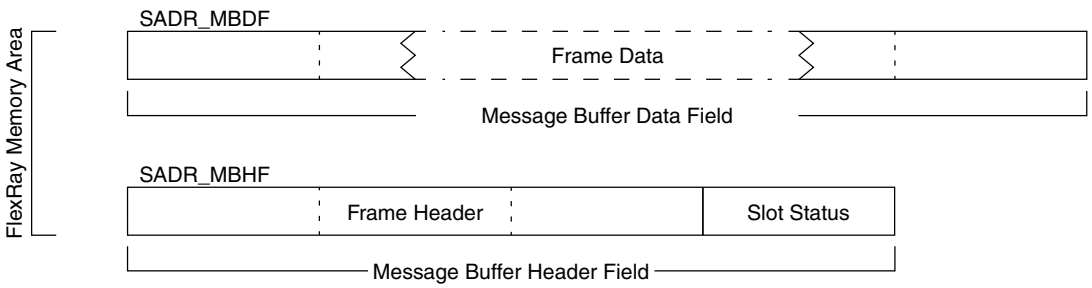

Figure 60-2. Physical Message Buffer Structure

60.8.2.1 Message Buffer Header Field

The message buffer header field is a contiguous region in the FlexRay memory area and occupies eight bytes. It contains the frame header, and the slot status. Its structure is shown in the above figure. The physical start address *SADR_MBHF* of the message buffer header field must be 16-bit aligned.

60.8.2.1.1 Frame Header

The frame header occupies the first six bytes in the message buffer header field. It contains all FlexRay frame header related information according to the *FlexRay Communications System Protocol Specification, Version*2.1 Rev A. A detailed description of the usage and the content of the frame header is provided in Frame Header Description section.

60.8.2.1.2 Slot Status

The slot status occupies the last two bytes of the message buffer header field. It provides the slot and frame status related information according to the *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*. A detailed description of the content and usage of the slot status is provided in the Slot Status Description section.

60.8.2.2 Message Buffer Data Field

The message buffer data field is a contiguous area of 2-byte entities. This field contains the frame payload data, or a part of it, of the frame to be transmitted to or received from the FlexRay bus. The minimum length of this field depends on the specific message buffer configuration and is specified in the message buffer descriptions given in the following section.

60.8.3 Message Buffer Types

The CC provides three different types of message buffers.

- *Individual Message Buffers*
- *Receive Shadow Buffers*
- *Receive FIFO Buffers*

For each message buffer type the structure of the physical message buffer is identical. The message buffer types differ only in the structure and content of message buffer control data, which control the related physical message buffer. The message buffer control data are described in the following sections.

60.8.3.1 Individual Message Buffers

The individual message buffers are used for all types of frame transmission and for dedicated frame reception based on individual filter settings for each message buffer. The CC supports three types of individual message buffers, which are described in the Individual Message Buffer Functional Description section.

Each individual message buffer consists of two parts, the physical message buffer, which is located in the FlexRay memory area, and the message buffer control data, which are located in dedicated registers. The structure of an individual message buffer is given in the figure below.

Each individual message buffer has a message buffer number n assigned, which determines the set of message buffer control registers associated to this individual message buffer. The individual message buffer with message buffer number *n* is controlled by the registers FR_MBCCSRn, FR_MBCCFRn, FR_MBFIDRn, and FR_MBIDXRn.

The connection between the message buffer control registers and the physical message buffer is established by the message buffer index field MBIDX in the Message Buffer Index Registers (FR_MBIDXRn). The start address SADR_MBHF of the related message buffer header field in the FlexRay memory area is determined according to this equation:

$$SADR\_MBHF = (FR\_MBIDXRn[MBIDX] \times 8) + SMBA$$

Equation 14

The data field belonging to a particular physical message buffer is characterized by the data field offset. For each physical message buffer with MBIDX i the FR_MBDORi contains the offset of the corresponding message buffer data field with respect to the CC FlexRay memory area base address as provided by SMBA field in the System Memory Base Address Register (FR_SYMBADR).

The data field offset is used to determine the start address SADR_MBDF of the corresponding message buffer data field in the FlexRay memory area according to this equation:

$$SADR\_MBDF = [DataFieldOffset] + SMBA$$

Equation 15

The FR_MBDORn are stored in the module internal memory LRAM. Refer to CHI LRAM Initialization for the setup of the data field offset values.

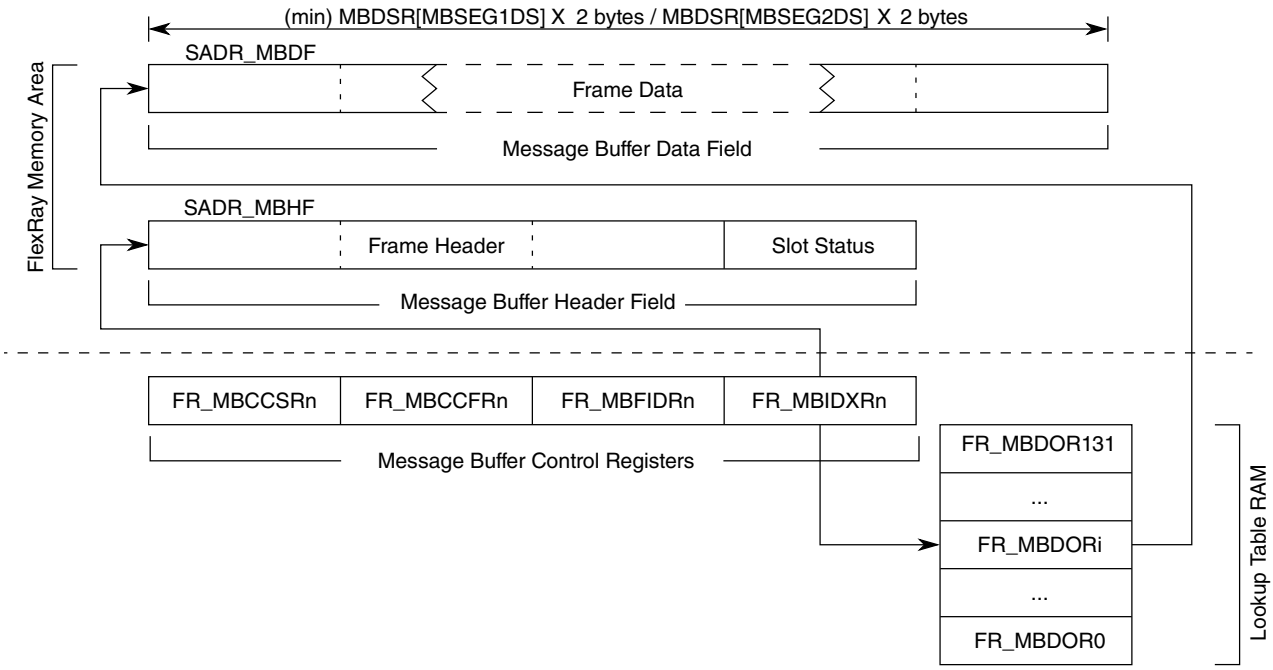

Figure 60-3. Individual Message Buffer Structure

60.8.3.1.1 Individual Message Buffer Segments

The set of the individual message buffers can be split up into two message buffer segments using the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR). All individual message buffers with a message buffer number n ≤ FR_MBSSUTR[LAST_MB_SEG1] belong to the first message buffer segment. All individual message buffers with a message buffer number n > FR_MBSSUTR[LAST_MB_SEG1] belong to the second message buffer segment. The following rules apply to the length of the message buffer data field:

- *all physical message buffers associated to individual message buffers that belong to the same message buffer segment must have message buffer data fields of the same length*
- *the minimum length of the message buffer data field for individual message buffers in the first message buffer segment is 2 × FR_MBDSR[MBSEG1DS] bytes*
- *the minimum length of the message buffer data field for individual message buffers assigned to the second segment is 2 × FR_MBDSR[MBSEG2DS] bytes.*

60.8.3.2 Receive Shadow Buffers

The receive shadow buffers are required for the frame reception process for individual message buffers. The CC provides four receive shadow buffers, one receive shadow buffer per channel and per message buffer segment.

Each receive shadow buffer consists of two parts, the physical message buffer located in the FlexRay memory area and the receive shadow buffer control registers located in dedicated registers. The structure of a receive shadow buffer is shown in the figure below. The four internal shadow buffer control registers can be accessed by the Receive Shadow Buffer Index Register (FR_RSBIR).

The connection between the receive shadow buffer control register and the physical message buffer for the selected receive shadow buffer is established by the receive shadow buffer index field RSBIDX in the Receive Shadow Buffer Index Register (FR_RSBIR). The start address SADR_MBHF of the related message buffer header field in the FlexRay memory area is determined according to this equation:

$$SADR\_MBHF = (FR\_RSBIR[RSBIDX] \times 8) + SMBA$$

Equation 16

The length required for the message buffer data field depends on the message buffer segment that the receive shadow buffer is assigned to. For the receive shadow buffers assigned to the first message buffer segment, the length must be the same as for the individual message buffers assigned to the first message buffer segment. For the receive shadow buffers assigned to the second message buffer segment, the length must be the same as for the individual message buffers assigned to the second message buffer segment. The receive shadow buffer assignment is described in Receive Shadow Buffer Index Register (FR_RSBIR).

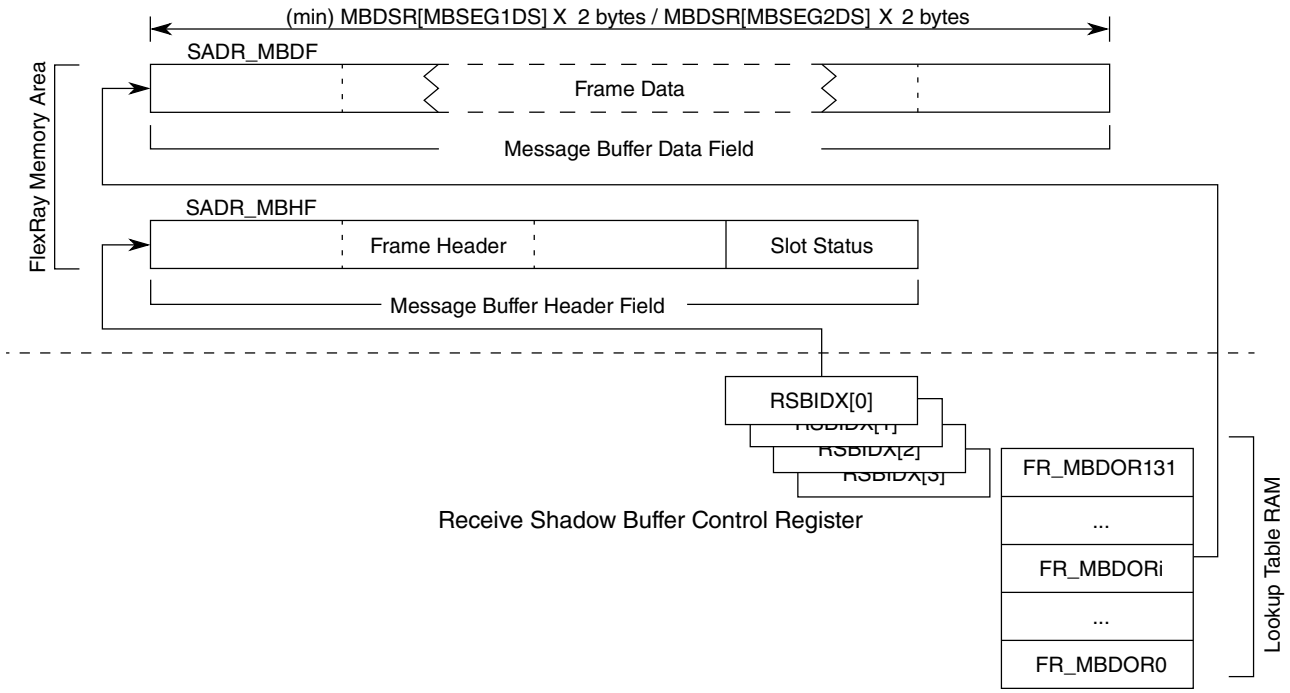

Figure 60-4. Receive Shadow Buffer Structure

60.8.3.3 Receive FIFO

The receive FIFO implements a frame reception system based on the FIFO concept. The CC provides two independent receive FIFOs, one per channel.

A receive FIFO consists of a set of physical message buffers in the FlexRay memory area and a set of receive FIFO control registers located in dedicated registers. The structure of a receive FIFO is given in the Receive FIFO Structure figure, later in this section.

The connection between the receive FIFO control registers and the set of physical message buffers is established by the Receive FIFO Start Index Register (FR_RFSIR), the Receive FIFO Depth and Size Register (FR_RFDSR), and the Receive FIFO A Read Index Register (FR_RFARIR) / Receive FIFO B Read Index Register (FR_RFBRIR).

The system memory base address SMBA valid for the receive FIFOs is defined by the system memory base address register selected by the FIFO address mode bit FR_MCR[FAM] in the Module Configuration Register.

The start byte address SADR_MBHF[1] of the first message buffer header field that belongs to the receive FIFO is determined according to Equation 17 on page 3040.

$$SADR\_MBHF[1] = (8 \times FR\_RFSIR[SIDX]) + SMBA$$

Equation 17

The start byte address SADR_MBHF[n] of the last message buffer header field that belongs to the receive FIFO in the FlexRay memory area is determined according Equation 18 on page 3041 .

$$SADR\_MBHF[n] = (8 \times (FR\_RFSIR[SIDX] + FR\_RFDSR[FIFO\_DEPTH])) + SMBA$$

Equation 18

The required information to access the current entry of the FIFO is given in the following registers:

- *The registers Receive FIFO A Read Index Register (FR_RFARIR) and Receive FIFO B Read Index Register (FR_RFBRIR) provide the index of the physical message buffer belonging to the current entry.*

  The data field offset belonging to the current FIFO entry RF_DFO[X] must be calculated using the current read index i according to the following formula:

$$RF\_DFO[X] = FR\_RFSDOR[X] + (FR\_RFDSR[X][ENTRY\_SIZE] \times 2) \times i - FR\_RFSIDX[X])$$

Equation 19

Note

The current read index loops up starting at the number given in the FR_RD[A/B]RDIDX register for the required number of entries.

Refer to FIFO Update for details about updating the FIFO read pointer.

All message buffer header fields assigned to a receive FIFO are within a contiguous region defined by FR_RFSIR[SIDX] and FR_RFDSR[FIFO_DEPTH].

The data sections of all FIFO entries within on receive FIFO are of the same length defined by FR_RFDSR[FIFO_SIZE].

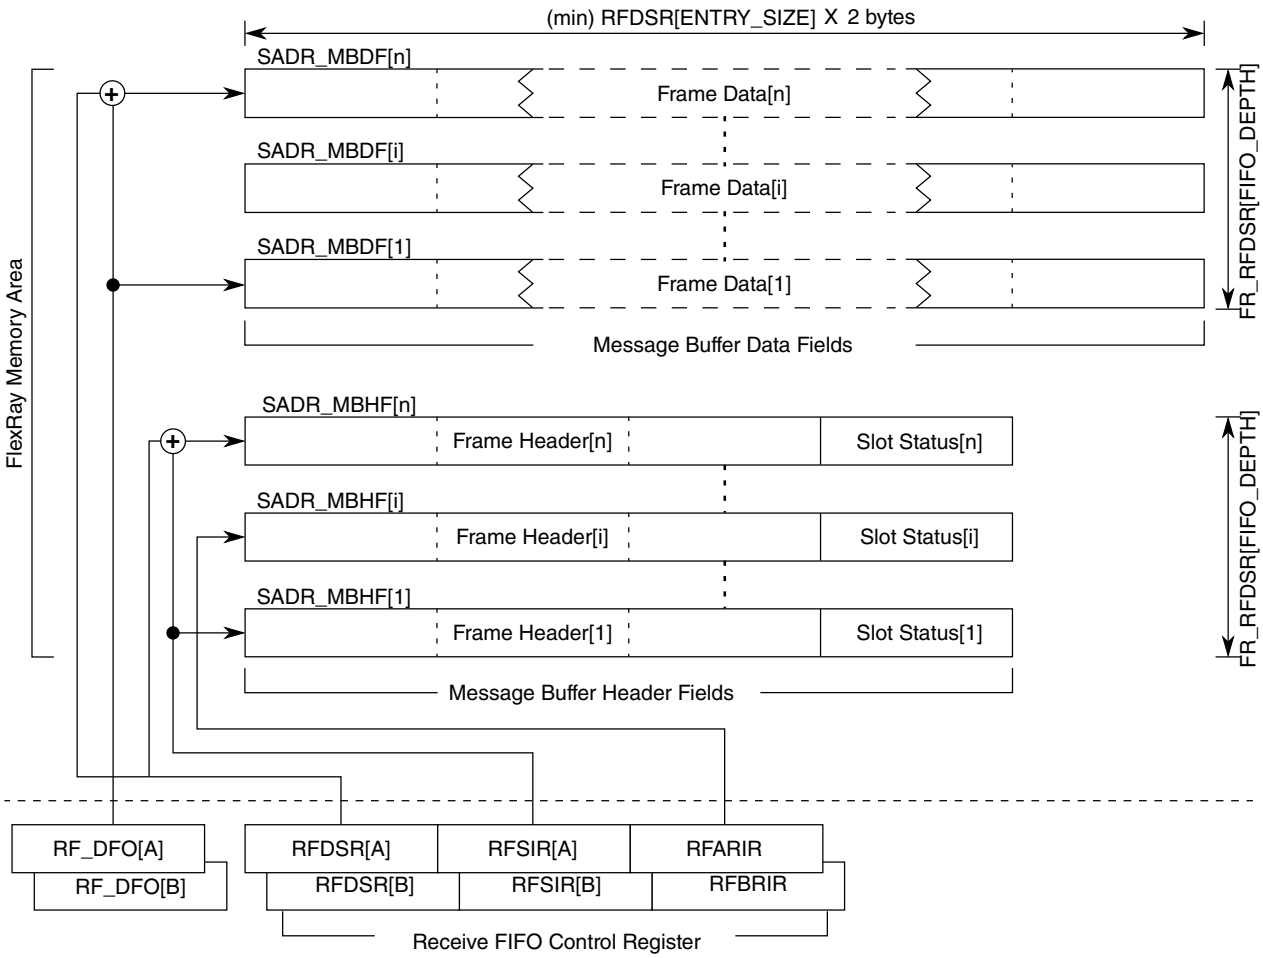

Figure 60-5. Receive FIFO Structure

Note

The actual values of the data field offsets RF_DFO[A/B] need to be calculated according to Equation 19 on page 3041. They are not stored in a register.

60.8.3.4 Message Buffer Configuration and Control Data

This section describes the configuration and control data for each message buffer type.

60.8.3.4.1 Individual Message Buffer Configuration Data

Before an individual message buffer can be used for transmission or reception, it must be configured. There is a set of common configuration parameters that applies to all individual message buffers and a set of configuration parameters that applies to each message buffer individually.

60.8.3.4.1.1 Common Configuration Data

The set of common configuration data for individual message buffers is located in the following registers.

- *Message Buffer Data Size Register (FR_MBDSR)*

  The MBSEG2DS and MBSEG1DS fields define the minimum length of the message buffer data field with respect to the message buffer segment.

- *Message Buffer Segment Size and Utilization Register (FR_MBSSUTR)*

  The LAST_MB_SEG1 and LAST_MB_UTIL fields define the segmentation of the individual message buffers and the number of individual message buffers that are used. For more details, see Individual Message Buffer Segments.

60.8.3.4.1.2 Specific Configuration Data

The set of message buffer specific configuration data for individual message buffers is located in the following registers.

- *Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn)*

  The MTD bit configures the message buffer type.

- *Message Buffer Cycle Counter Filter Registers (FR_MBCCFRn)*

  The MTM, CHA, CHB bits configure the transmission mode and the channel assignment. The CCFE, CCFMSK, and CCFVAL bits and fields configure the cycle counter filter.

- *Message Buffer Frame ID Registers (FR_MBFIDRn)*

  For a transmit message buffer, the FID field is used to determine the slot in which the message in this message buffer will be transmitted.

- *Message Buffer Index Registers (FR_MBIDXRn)This MBIDX field provides the index of the message buffer header field of the physical message buffer that is currently associated with this message buffer.*

60.8.3.5 Individual Message Buffer Control Data

During normal operation, each individual message buffer can be controlled by the control and trigger bits CMT, LCKT, EDT, and MBIE in the Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn).

60.8.3.6 Receive Shadow Buffer Configuration Data

Before frame reception into the individual message buffers can be performed, the receive shadow buffers must be configured. The configuration data are provided by the Receive Shadow Buffer Index Register (FR_RSBIR). For each receive shadow buffer, the application provides the message buffer header index. When the protocol is in the *POC:normal active* or *POC:normal passive* state, the receive shadow buffers are under full CC control.

60.8.3.7 Receive FIFO Control and Configuration Data

This section describes the configuration and control data for the two receive FIFOs.

60.8.3.7.1 Receive FIFO Configuration Data

The CC provides two functional independent receive FIFOs, one per channel. The FIFOs have a common subset of configuration data:

- *Receive FIFO Periodic Timer Register (FR_RFPTR)*

Each FIFO has its own set of configuration data. The configuration data are located in the following registers:

- *Receive FIFO Watermark and Selection Register (FR_RFWMSR)*
- *Receive FIFO Start Index Register (FR_RFSIR)*
- *Receive FIFO Start Data Offset Register (FR_RFSDOR)*
- *Receive FIFO Depth and Size Register (FR_RFDSR)*
- *Receive FIFO Message ID Acceptance Filter Value Register (FR_RFMIDAFVR)*
- *Receive FIFO Message ID Acceptance Filter Mask Register (FR_RFMIDAFMR)*
- *Receive FIFO Frame ID Rejection Filter Value Register (FR_RFFIDRFVR)*

- *Receive FIFO Frame ID Rejection Filter Mask Register (FR_RFFIDRFMR)*
- *Receive FIFO Range Filter Configuration Register (FR_RFRFCFR)*

60.8.3.7.2 Receive FIFO Control Data

The application can access the FIFOs at any time using the control bits in the following registers:

- *Global Interrupt Flag and Enable Register (FR_GIFER)*
- *Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR)*

60.8.3.7.3 Receive FIFO Status Data

The current status of the receive fifo is provided in the following register:

- *Global Interrupt Flag and Enable Register (FR_GIFER)*
- *Receive FIFO A Read Index Register (FR_RFARIR)*
- *Receive FIFO B Read Index Register (FR_RFBRIR)*
- *Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR)*

60.8.4 FlexRay Memory Area Layout

The CC supports a wide range of possible layouts for the FlexRay memory area. Two basic layout modes can be selected by the FIFO address mode bit FR_MCR[FAM].

60.8.4.1 FlexRay Memory Area Layout (FR_MCR[FAM] = 0)

In the figure given below, shows an example layout for the FIFO address mode FR_MCR[FAM]=0. In this mode, the following set of rules applies to the layout of the FlexRay memory area:

- The FlexRay memory area is one contiguous region.
- The FlexRay memory area size is maximum 64 KB.
- The FlexRay memory area starts at a 16 byte boundary

The FlexRay memory area contains three areas: the *message buffer header area*, the *message buffer data area*, and the *sync frame table area*.

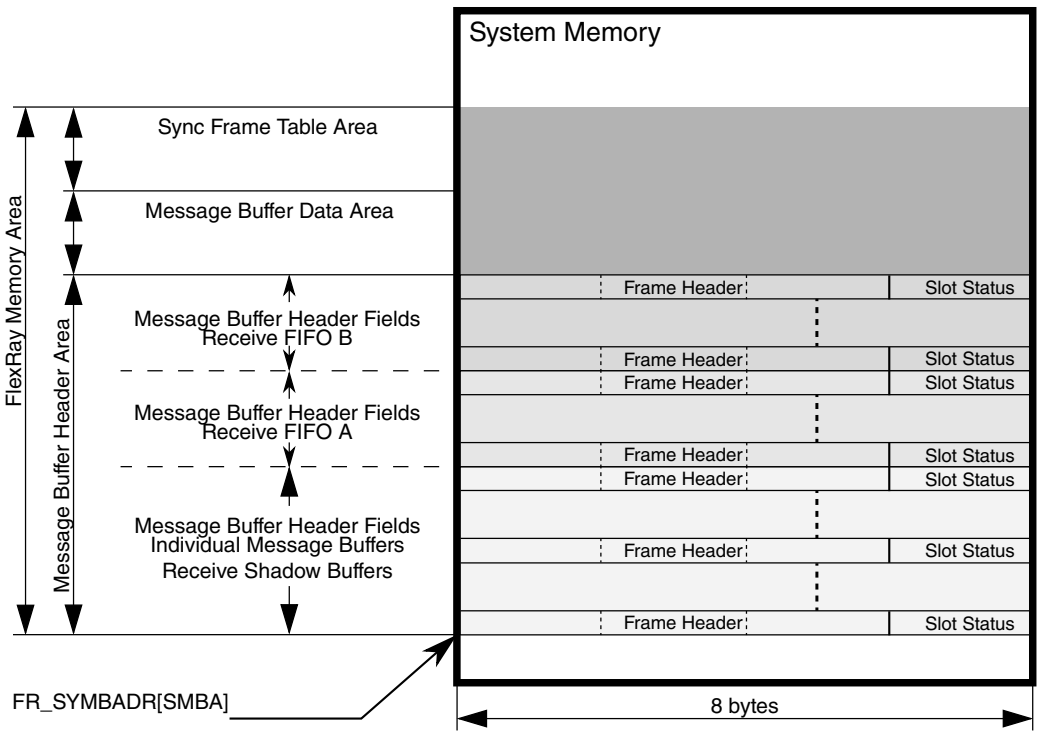

Figure 60-6. Example of FlexRay Memory Area Layout (FR_MCR[FAM] = 0)

60.8.4.2 FlexRay Memory Area Layout (FR_MCR[FAM] = 1)

The following figure shows an example layout for the FIFO address mode FR_MCR[FAM]=1. The following set of rules applies to the layout of the FlexRay memory area:

- The FlexRay memory area consists of two contiguous regions.
- The size of each region is maximum 64 KB.
- Each region start at a 16 byte boundary.

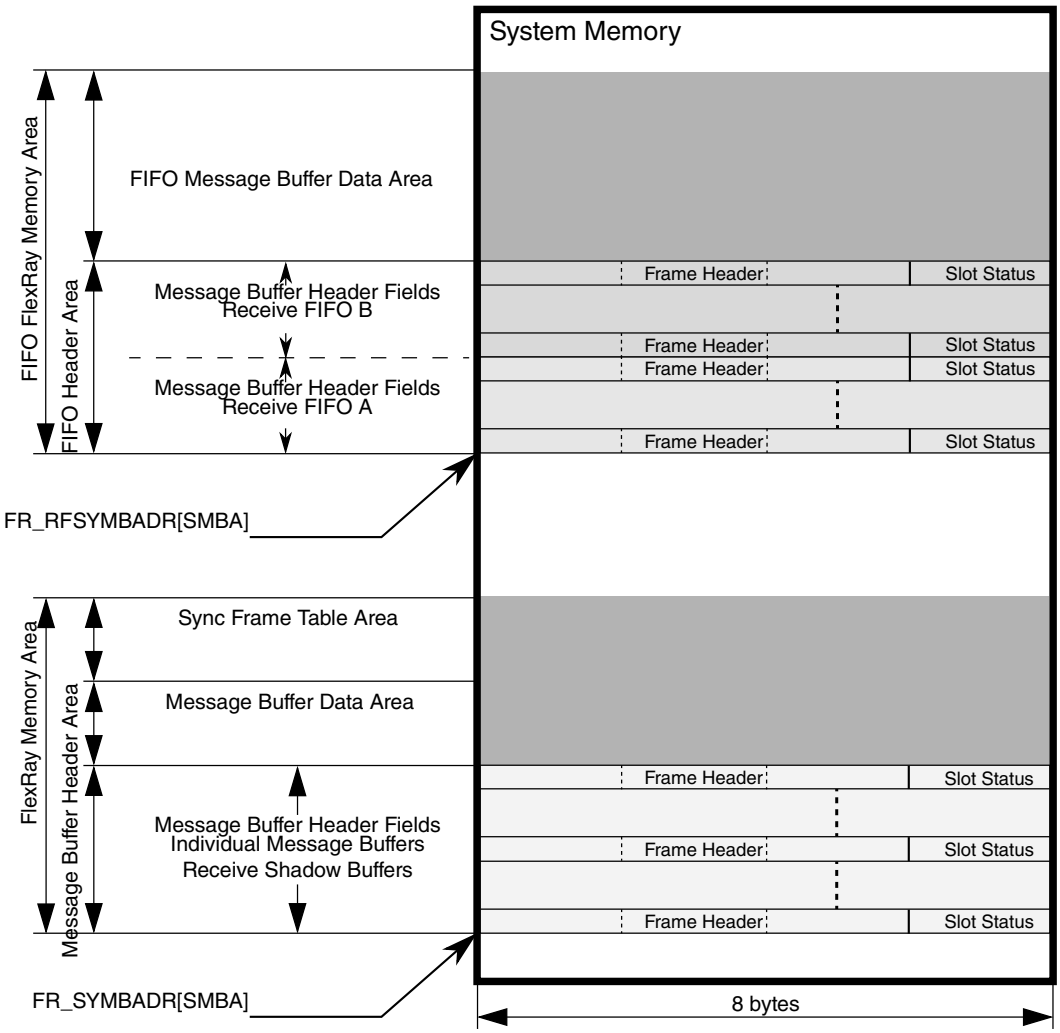

Figure 60-7. Example of FlexRay Memory Area Layout (FR_MCR[FAM] = 1)

60.8.4.3 Message Buffer Header Area (FR_MCR[FAM] = 0)

The message buffer header area contains all message buffer header fields of the physical message buffers for all message buffer types. The following rules apply to the message buffer header fields for the three type of message buffers.

1. The start byte address SADR_MBHF of each message buffer header field for *individual message buffers* and *receive shadow buffers* must fulfill Equation 20 on page 3047.

$$SADR\_MBHF = (i \times 8) + FR\_SYMBADR[SMBA]; (0 \le i \le 131)$$

Equation 20

2. The start byte address SADR_MBHF of each message buffer header field for the *FIFO* must fulfill Equation 20 on page 3047.

$$SADR\_MBHF = (i \times 8) + FR\_SYMBADR[SMBA]; (0 \le i \le 1023)$$

Equation 21

$$SADR\_MBHF = (i \times 8) + FR\_SYMBADR[SMBA]; (0 \le i \le 1023)$$

Equation 22

3. The message buffer header fields for each FIFO have to be a contiguous area.

60.8.4.4 Message Buffer Header Area (FR_MCR[FAM] = 1)

The message buffer header area contains all message buffer header fields of the physical message buffers for the individual message buffers and receiver shadow buffers. The following rules apply to the message buffer header fields for the two type of message buffers.

1. The start address SADR_MBHF of each message buffer header field for individual message buffers and receive shadow buffers must fulfill Equation 23 on page 3048.

$$SADR\_MBHF = (i \times 8) + FR\_SYMBADR[SMBA]; (0 \le i \le 131)$$

Equation 23

60.8.4.5 FIFO Message Buffer Header Area (FR_MCR[FAM] = 1)

The FIFO message buffer header area contains all message buffer header fields of the physical message buffers for the FIFO. The following rules apply to the FIFO message buffer header fields.

1. The start byte address SADR_MBHF of each message buffer header field for the FIFO must fulfill the following equation:Equation 24 on page 3048.

$$SADR\_MBHF = (i\gamma 8) + FR\_RFSYMBADR[SMBA]; (0 \le i \le 1023)$$

Equation 24

2. The message buffer header fields for each FIFO have to be a contiguous area.

60.8.4.6 Message Buffer Data Area

The message buffer data area contains all the message buffer data fields of the physical message buffers. Each message buffer data field must start at a 16-bit boundary.

60.8.4.7 Sync Frame Table Area

The sync frame table area is used to provide a copy of the internal sync frame tables for application access. Refer to Sync Frame ID and Sync Frame Deviation Tables for the description of the sync frame table area.

60.8.5 Physical Message Buffer Description

This section provides a detailed description of the usage and the content of the two parts of a physical message buffer, the message buffer header field and the message buffer data field.

60.8.5.1 Message Buffer Protection and Data Consistency

The physical message buffers are located in the FlexRay memory area. The CC provides no means to protect the FlexRay memory area from uncontrolled or illegal host or other client write access. To ensure data consistency of the physical message buffers, the application must follow the write access scheme that is given in the description of each of the physical message buffer fields.

60.8.5.2 Message Buffer Header Field Description

This section provides a detailed description of the usage and content of the message buffer header field. A description of the structure of the message buffer header fields is given in Message Buffer Header Field. Each message buffer header field consists of two sections: the frame header section and the slot status section.

60.8.5.2.1 Frame Header Description

Frame header content, access, and checks are discussed in this section.

60.8.5.2.1.1 Frame Header Content

The semantic and content of the frame header section depends on the message buffer type.

For individual receive message buffers and receive FIFOs, the frame header receives the frame header data of the *first valid frame* received on the assigned channels.

For receive shadow buffers, the frame header receives the frame header data of the current frame received regardless of whether the frame is valid or not.

For transmit message buffers, the application writes the frame header of the frame to be transmitted into this location. The frame header will be read out when the frame is transferred to the FlexRay bus.

The structure of the frame header in the message buffer header field for receive message buffers and the receive FIFO is given in the figure below. A detailed description is given in Table 60-23.

Table 60-19. Frame Header Structure (Receive Message Buffer and Receive FIFO)

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
0x0	R	PPI	NUF	SYF	SUF	FID										
0x2	0	0	CYCCNT						0	PLDLEN						
0x4	0	0	0	0	0	HDCRC										

The structure of the frame header in the message buffer header field for transmit message buffers is given in the following figure. A detailed description is given in Table 60-24. The checks that will be performed are described in Frame Header Checks.

Table 60-20. Frame Header Structure (Transmit Message Buffer)

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
0x0	R	PPI	NUF	SYF	SUF	FID [1]										
0x2			CYCCNT							PLDLEN [2]						
0x4						HDCRC										

= not used

1. checked
2. checked if not static

The structure of the frame header in the message buffer header field for transmit message buffers assigned to key slot is given in the figure below.

Table 60-21. Frame Header Structure (Transmit Message Buffer for Key Slot)

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
0x0	R	PPI	NUF	SYF	SUF	FID										
0x2			CYCCNT							PLDLEN						
0x4						HDCRC										

= not used

60.8.5.2.1.2 Frame Header Access

The frame header is located in the FlexRay memory area. To ensure data consistency, the application must follow the write access scheme described below.

For receive message buffers, receive shadow buffers, and receive FIFOs, the application must not write to the frame header field.

For transmit message buffers, the application must follow the write access restrictions given in the following table. This table shows the condition under which the application can write to the frame header entries without corrupting the FlexRay message transmission.

Table 60-22. Frame Header Write Access Constraints (Transmit Message Buffer)

Field	Static Segment	Dynamic Segment
FID	*POC:config* or MB_DIS	
PPI, PLDLEN, HDCRC	*POC:config* or MB_DIS or	MB_LCK

60.8.5.2.1.3 Frame Header Checks

As shown in Table 60-20 and Table 60-21 not all fields in the message buffer frame header are used for transmission. Some fields in the message buffer frame header are ignored, some are used for transmission, and some of them are checked for correct values. All checks that will be performed are described below.

For message buffers assigned to the key slot, no checks will be performed.

The value of the FID field must be equal to the value of the corresponding Message Buffer Frame ID Registers (FR_MBFIDRn). If the CC detects a mismatch while transmitting the frame header, it will set the frame ID error flag FID_EF in the CHI Error Flag Register (FR_CHIERFR). The value of the FID field will be ignored and replaced by the value provided in the Message Buffer Frame ID Registers (FR_MBFIDRn).

For transmit message buffers assigned to the *static* segment, the PLDLEN value must be equal to the value of the payload_length_static field in the Protocol Configuration Register 19 (FR_PCR19). If this is not fulfilled, the static payload length error flag SPL_EF in the CHI Error Flag Register (FR_CHIERFR) is set when the message buffer is under transmission. A syntactically and semantically correct frame is generated with payload_length_static payload words and the payload length field in the transmitted frame header set to payload_length_static.

For transmit message buffers assigned to the *dynamic* segment, the PLDLEN value must be less than or equal to the value of the max_payload_length_dynamic field in the Protocol Configuration Register 24 (FR_PCR24). If this is not fulfilled, the dynamic payload length error flag DPL_EF in the CHI Error Flag Register (FR_CHIERFR) is set when the message buffer is under transmission. A syntactically and semantically correct dynamic frame is generated with PLDLEN payload words and the payload length field in the frame header set to PLDLEN.

Table 60-23. Frame Header Field Descriptions (Receive Message Buffer and Receive FFO)

Field	Description
R	**Reserved Bit** — This is the value of the *Reserved bit* of the received frame stored in the message buffer
PPI	**Payload Preamble Indicator** — This is the value of the *Payload Preamble Indicator* of the received frame stored in the message buffer.
NUF	**Null Frame Indicator** — This is the value of the *Null Frame Indicator* of the received frame stored in the message buffer.
SYF	**Sync Frame Indicator** — This is the value of the *Sync Frame Indicator* of the received frame stored in the message buffer.
SUF	**Startup Frame Indicator** — This is the value of the *Startup Frame Indicator* of the received frame stored in the message buffer.
FID	**Frame ID** — This is the value of the *Frame ID* field of the received frame stored in the message buffer.
CYCCNT	**Cycle Count** — This is the number of the communication cycle in which the frame stored in the message buffer was received.
PLDLEN	**Payload Length** — This is the value of the *Payload Length* field of the received frame stored in the message buffer.
HDCRC	**Header CRC** — This is the value of the *Header CRC* field of the received frame stored in the message buffer.

Table 60-24. Frame Header Field Descriptions (Transmit Message Buffer)

Field	Description
R	**Reserved Bit** — This bit is not used, the value of the *Reserved bit* is generated internally according to *FlexRay Communications System Protocol Specification, Version*2.1 Rev A.
PPI	**Payload Preamble Indicator** — This bit provides the value of the *Payload Preamble Indicator* for the frame transmitted from the message buffer.
NUF	**Null Frame Indicator** — This bit is not used, the value of the *Null Frame Indicator* is generated internally according to *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*.
SYF	**Sync Frame Indicator** — This bit is not used, the value of the *Sync Frame Indicator* is generated internally according to *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*.
SUF	**Startup Frame Indicator** — This bit is not used, the value of the *Startup Frame Indicator* is generated internally according to *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*.
FID	**Frame ID** — This field is checked as described in Frame Header Checks.
CYCCNT	**Cycle Count** — This field is not used, the value of the transmitted *Cycle Count* field is taken from the internal communication cycle counter.
PLDLEN	**Payload Length** — This field is checked and used as described in Frame Header Checks.

Table continues on the next page...

Table 60-24. Frame Header Field Descriptions (Transmit Message Buffer) (continued)

Field	Description
HDCRC	**Header CRC** — This field provides the value of the *Header CRC* field for the frame transmitted from the message buffer.

60.8.5.2.2 Slot Status Description

The slot status is a read-only structure for the application and a write-only structure for the CC. The meaning and content of the slot status in the message buffer header field depends on the message buffer type.

60.8.5.2.2.1 Receive Message Buffer and Receive FIFO Slot Status Description

This section describes the slot status structure for the individual receive message buffers and receive FIFOs. The content of the slot status structure for receive message buffers depends on the message buffer type and on the channel assignment for individual receive message buffers as given in the next table.

Table 60-25. Receive Message Buffer Slot Status Content

Receive Message Buffer Type	Slot Status Content
Individual Receive Message Buffer assigned to both channels FR_MBCCFRn[CHA]=1 and FR_MBCCFRn[CHB]=1	see Table 60-26
Individual Receive Message Buffer assigned to channel A FR_MBCCFRn[CHA]=1 and FR_MBCCFRn[CHB]=0	see Table 60-27
Individual Receive Message Buffer assigned to channel B FR_MBCCFRn[CHA]=0 and FR_MBCCFRn[CHB]=1	see Table 60-28
Receive FIFO Channel A Message Buffer	see Table 60-27
Receive FIFO Channel B Message Buffer	see Table 60-28

The meaning of the bits in the slot status structure is explained in the Receive Message Buffer Slot Status Field Description table below.

60.8.5.2.2.2 Transmit Message Buffer Slot Status Description

This section describes the slot status structure for transmit message buffers. Only the TCA and TCB status bits are directly related to the transmission process. All other status bits in this structure are related to a receive process that may have occurred. The content of the slot status structure for transmit message buffers depends on the channel assignment as given in the table below.

Table 60-30. Transmit Message Buffer Slot Status Content

Transmit Message Buffer Type	Slot Status Content
Individual Transmit Message Buffer assigned to both channels FR_MBCCFRn[CHA]=1 and FR_MBCCFRn[CHB]=1	see Table 60-31

60.8.5.3 Message Buffer Data Field Description

The message buffer data field is used to store the frame payload data, or a part of it, of the frame to be transmitted to or received from the FlexRay bus. The minimum required length of this field depends on the message buffer type that the physical message buffer is assigned to and is given in the table below. The structure of the message buffer data field is given in the next figure.

Table 60-35. Message Buffer Data Field Minimum Length

physical message buffer assigned to	minimum length defined by
Individual Message Buffer in Segment 1	FR_MBDSR[MBSEG1DS]
Receive Shadow Buffer in Segment 1	FR_MBDSR[MBSEG1DS]
Individual Message Buffer in Segment 2	FR_MBDSR[MBSEG2DS]
Receive Shadow Buffer in Segment 2	FR_MBDSR[MBSEG2DS]
Receive FIFO for channel A	FR_RFDSR[ENTRY_SIZE] (FR_RFWMSR[SEL] = 0)
Receive FIFO for channel B	FR_RFDSR[ENTRY_SIZE] (FR_RFWMSR[SEL] = 1)

Note

The CC will not access any locations outside the message buffer data field boundaries given in the table above.

Table 60-36. Message Buffer Data Field Structure

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
0x0	DATA0 / MID0 / NMV0								DATA1 / MID1 / NMV1							
0x2	DATA2 / NMV2								DATA3 / NMV3							
…	…								…							
0xN-2	DATA N-2								DATA N-1							

The message buffer data field is located in the FlexRay memory area; thus, the CC has no means to control application write access to the field. To ensure data consistency, the application must follow a write and read access scheme.

60.8.5.3.1 Message Buffer Data Field Read Access

For transmit message buffers, the CC will not modify the content of the Message Buffer Data Field. Thus the application can read back the data at any time without any impact on data consistency.

For receive message buffers the application must lock the related receive message buffer and retrieve the message buffer header index from the Message Buffer Index Registers (FR_MBIDXRn). While the message buffer is locked, the CC will not update the Message Buffer Data Field.

For receive FIFOs, the application can read the message buffer indicated by the Receive FIFO A Read Index Register (FR_RFARIR) or the Receive FIFO B Read Index Register (FR_RFBRIR) when the related fill levels in the Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR) indicate an non-empty FIFO.

60.8.5.3.2 Message Buffer Data Field Write Access

For receive message buffers, receive shadow buffers, and receive FIFOs, the application must not write to the message buffer data field.

For transmit message buffers, the application must follow the write access restrictions given in the Frame Data Write Access Constraints table below.

Table 60-37. Frame Data Write Access Constraints

Field	CC/MB State
DATA, MID, NMV	*POC:config* or MB_DIS or MB_LCK

Table 60-38. Frame Data Field Descriptions

Field	Description
DATA 0, DATA 1, … DATA N-1	**Message Data** — Provides the message data received or to be transmitted.For receive message buffer and receive FIFOs, this field provides the message data received for this message buffer. For transmit message buffers, the field provides the message data to be transmitted.
MID 0, MID 1	**Message Identifier** — If the payload preamble bit PPI is set in the message buffer frame header, the MID field holds the message ID of a dynamic frame located in the message buffer. The receive FIFO filter uses the received message ID for message ID filtering.

Table continues on the next page...

Table 60-38. Frame Data Field Descriptions (continued)

Field	Description
NMV 0, NMV 1, … NMV 11	**Network Management Vector** — If the payload preamble bit PPI is set in the message buffer frame header, the network management vector field holds the network management vector of a static frame located in the message buffer. **Note:** The MID and NMV bytes replace the corresponding DATA bytes.

60.8.6 Individual Message Buffer Functional Description

The CC provides these basic types of individual message buffers:

1. Transmit Message Buffers
2. Receive Message Buffers

Before an individual message buffer can be used, it must be configured by the application. After the initial configuration, the message buffer can be reconfigured later. The set of the configuration data for individual message buffers is given in Individual Message Buffer Configuration Data.

60.8.6.1 Individual Message Buffer Configuration

The individual message buffer configuration consists of two steps. The first step is the allocation of the required amount of memory for the FlexRay memory area. The second step is the programming of the message buffer configuration registers, which is described in this section.

60.8.6.1.1 Common Configuration Data

One part of the message buffer configuration data is common to all individual message buffers and the receive shadow buffers. These data can only be set when the protocol is in the *POC:config* state.

The application configures the number of utilized individual message buffers by writing the message buffer number of the last utilized message buffer into the LAST_MB_UTIL field in the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR).

The application configures the size of the two segments of individual message buffers by writing the message buffer number of the last message buffer in the first segment into the LAST_MB_SEG1 field in the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR).

The application configures the length of the message buffer data fields for both of the message buffer segments by writing to the MBSEG2DS and MBSEG1DS fields in the Message Buffer Data Size Register (FR_MBDSR).

Depending on the current receive functionality of the CC, the application must configure the receive shadow buffers. For each segment and for each channel with at least one individual receive message buffer assigned, the application must configure the related receive shadow buffer using the Receive Shadow Buffer Index Register (FR_RSBIR).

60.8.6.1.2 Specific Configuration Data

The second part of the message buffer configuration data is specific for each message buffer.

These data can be changed only when either

- *the protocol is in the POC:config state or*
- *the message buffer is disabled, i.e. FR_MBCCSRn[EDS] = 0*

The individual message buffer type is defined by the MTD and MBT bits in the Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn) as given in the following table.

Table 60-39. Individual Message Buffer Types

FR_MBCCSRn		Individual Message Buffer Description
MTD	MBT	
0	0	Receive Message Buffer
0	1	Reserved
1	0	Transmit Message Buffer
1	1	Reserved

The message buffer specific configuration data are

1. MTD bits in Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn)
2. all fields and bits in Message Buffer Cycle Counter Filter Registers (FR_MBCCFRn)

3. all fields and bits in Message Buffer Frame ID Registers (FR_MBFIDRn)
4. all fields and bits in Message Buffer Index Registers (FR_MBIDXRn)

The meaning of the specific configuration data depends on the message buffer type, as given in the detailed message buffer type descriptions in the Transmit Message Buffers section and Receive Message Buffers section.

60.8.6.2 Transmit Message Buffers

The section provides a detailed description of the functionality of single buffered transmit message buffers.

A transmit message buffer is used by the application to provide message data to the CC that will be transmitted over the FlexRay Bus. The CC uses the transmit message buffers to provide information about the transmission process and status information about the slot in which message was transmitted.

The individual message buffer with message buffer number n is configured to be a transmit message buffer by the following settings:

- FR__ MBCCSRn[MBT] = 0(singlebufferedmessagebuffer)
- FR_ MBCCSRn[MDT] = 1(transmitmessagebuffer)

60.8.6.2.1 Access Regions

To certain message buffer fields, both the application and the CC have access. To ensure data consistency, a message buffer locking scheme is implemented, which is used to control the access to the data, control, and status bits of a message buffer. The access regions for transmit message buffers are depicted in the figure below. A description of the regions is given in Table 60-41. If an region is active as indicated in Table 60-42, the access scheme given for that region applies to the message buffer.

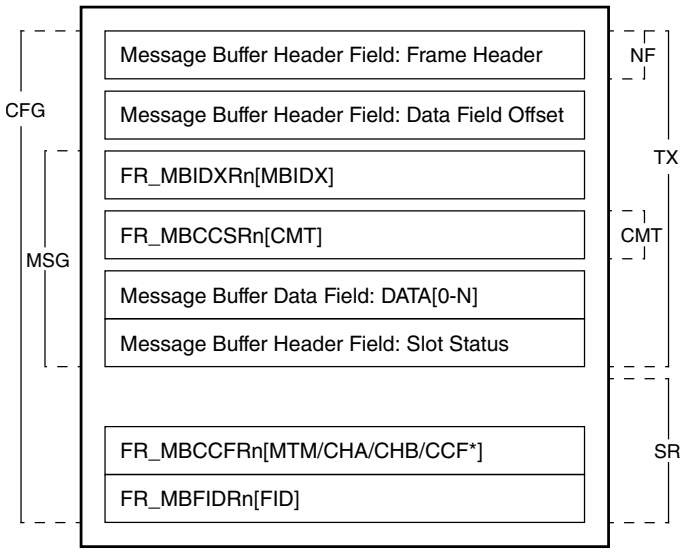

Figure 60-8. Transmit Message Buffer Access Regions

Table 60-40. Transmit Message Buffer Access Regions Description

Region	Access from		Region used for
	Application	Module	
CFG	read/write	-	Message Buffer Configuration
MSG	read/write	-	Message Data and Slot Status Access
NF	-	read-only	Message Header Access for Null Frame Transmission
TX	-	read/write	Message Transmission and Slot Status Update
CM	-	read-only	Message Buffer Validation
SR	-	read-only	Message Buffer Search

The trigger bits FR_MBCCSRn[EDT] and FR_MBCCSRn[LCKT], and the interrupt enable bit FR_MBCCSRn[MBIE] are not under access control and can be accessed from the application at any time. The status bits FR_MBCCSRn[EDS] and FR_MBCCSRn[LCKS] are not under access control and can be accessed from the CC at any time.

The interrupt flag FR_MBCCSRn[MBIF] is not under access control and can be accessed from the application and the CC at any time. CC clear access has higher priority.

The CC restricts its access to the regions depending on the current state of the message buffer. The application must adhere to these restrictions in order to ensure data consistency. The transmit message buffer states are given in the next figure. A description of the states is given in Table 60-41, which also provides the access scheme for the access regions.

The status bits FR_MBCCSRn[EDS] and FR_MBCCSRn[LCKS] provide the application with the required message buffer status information. The internal status information is not visible to the application.

60.8.6.2.2 Message Buffer States

This section describes the transmit message buffer states and provides a state diagram.

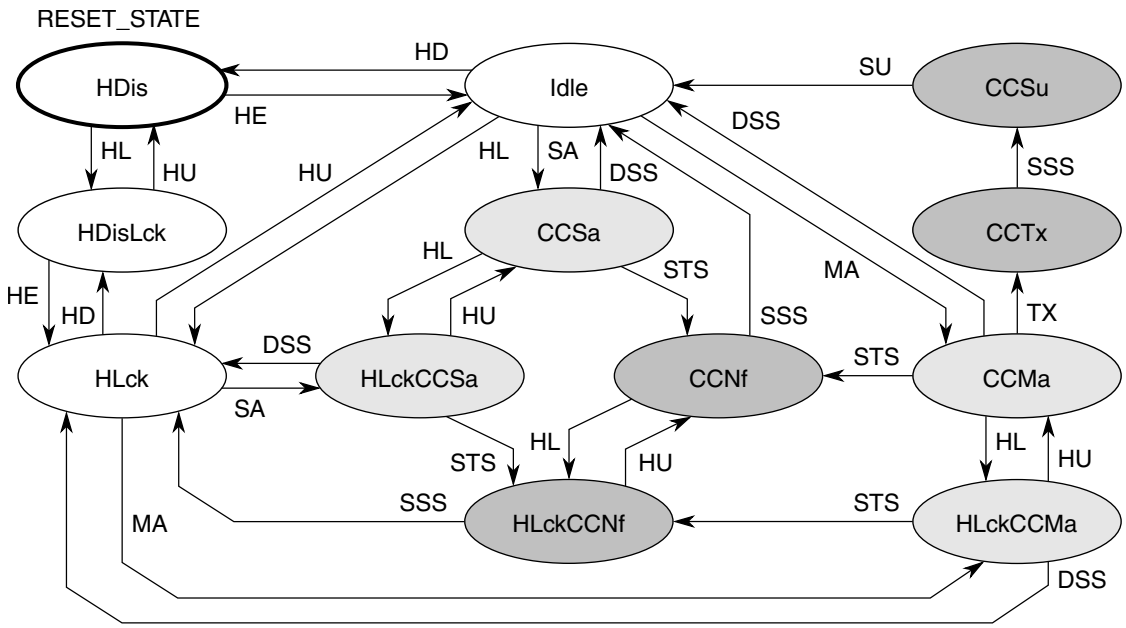

Figure 60-9. Transmit Message Buffer States

Table 60-41. Transmit Message Buffer State Description (Sheet 1 of 2)

State	FR_MBCCSRn		Access Region		Description
	EDS	LCKS	Appl.	Module	
Idle	1	0	–	CM,SR	**Idle** - Message Buffer is idle. Included in message buffer search.
HDis	0	0	CFG	–	**Disabled** - Message Buffer under configuration. Excluded from message buffer search.
HDisLck	0	1	CFG	–	**Disabled and Locked** - Message Buffer under configuration.Excluded from message buffer search.
HLck	1	1	MSG	SR	**Locked** - Applications access to data, control, and status.Included in message buffer search.
CCSa	1	0	–	–	**Slot Assigned** - Message buffer assigned to next static slot.Ready for Null Frame transmission.
HLckCCSa	1	1	MSG	–	**Locked and Slot Assigned** - Applications access to data, control, and status.Message buffer assigned to next static slot
CCNf	1	0	–	NF	**Null Frame Transmission** Header is used for null frame transmission.

Table continues on the next page...

Table 60-41. Transmit Message Buffer State Description (Sheet 1 of 2) (continued)

State	FR_MBCCSRn		Access Region		Description
	EDS	LCKS	Appl.	Module	
HLckCCNf	1	1	MSG	NF	**Locked and Null Frame Transmission** - Applications access to data, control, and status. Header is used for null frame transmission.
CCMa	1	0	–	CM	**Message Available** - Message buffer is assigned to next slot and cycle counter filter matches.
HLckCCMa	1	1	MSG	–	**Locked and Message Available** - Applications access to data, control, and status. Message buffer is assigned to next slot and cycle counter filter matches.
CCTx	1	0	–	TX	**Message Transmission** - Message buffer data transmit. Payload data from buffer transmitted
CCSu	1	0	–	TX	**Status Update** - Message buffer status update. Update of status flags, the slot status field, and the header index.

60.8.6.2.3 Message Buffer Transitions

Application transitions, module transitions, and transition priorities are discussed in this section.

60.8.6.2.3.1 Application Transitions

The application transitions can be triggered by the application using the commands described in the table below. The application issues the commands by writing to the Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn). Only one command can be issued with one write access. Each command is executed immediately. If the command is ignored, it must be issued again.

60.8.6.2.3.1.1 Message Buffer Enable and Disable

The enable and disable commands issued by writing 1 to the trigger bit FR_MBCCSRn[EDT]. The transition that will be triggered by each of these command depends on the current value of the status bit FR_MBCCSRn[EDS]. If the command triggers the disable transition HD and the message buffer is in one of the states CCSa, HLckCCSa, CCMa, HLckCCMa, CCNf, HLckCCNf, or CCTx, the disable transition has no effect (command is ignored) and the message buffer state is not changed. No notification is given to the application.

60.8.6.2.3.1.2 Message Buffer Lock and Unlock

The lock and unlock commands issued by writing 1 to the trigger bit FR_MBCCSRn[LCKT]. The transition that will be triggered by each of these commands depends on the current value of the status bit FR_MBCCSRn[LCKS]. If the command triggers the lock transition HL and the message buffer is in the state CCTx, the lock transition has no effect (command is ignored) and message buffer state is not changed. In this case, the message buffer lock error flag LCK_EF in the CHI Error Flag Register (FR_CHIERFR) is set.

Table 60-42. Transmit Message Buffer Application Transitions

Transition	Command	Condition	Description
HE	FR_MBCCSRn[EDT]:= 1	FR_MBCCSRn[EDS] = 0	Application triggers message buffer enable.
HD		FR_MBCCSRn[EDS] = 1	Application triggers message buffer disable.
HL	FR_MBCCSRn[LCKT]:= 1	FR_MBCCSRn[LCKS] = 0	Application triggers message buffer lock.
HU		FR_MBCCSRn[LCKS] = 1	Application triggers message buffer unlock.

60.8.6.2.3.2 Module Transitions

The module transitions that can be triggered by the CC are described in the following table. Each transition will be triggered for certain message buffers when the related condition is fulfilled.

Table 60-43. Transmit Message Buffer Module Transitions

Transition	Condition	Description
SA	slot match andstatic slot	**Slot Assigned** - Message buffer is assigned to next static slot.
MA	slot match andCycleCounter match	**Message Available** - Message buffer is assigned to next slot and cycle counter filter matches.
TX	slot start and FR_MBCCSRn[CMT] = 1	**Transmission Slot Start** - Slot Start and commit bit CMT is set. In case of a dynamic slot, pLatestTx is not exceeded.
SU	status updated	**Status Updated** - Slot Status field and message buffer status flags updated. Interrupt flag set.
STS	static slot start	**Static Slot Start** - Start of static slot.
DSS	dynamic slot start orsymbol window start orNIT start	**Dynamic Slot or Segment Start.** - Start of dynamic slot or symbol window or NIT.
SSS	slot start orsymbol window start orNIT start	**Slot or Segment Start** - Start of static slot or dynamic slot or symbol window or NIT.

60.8.6.2.3.3 Transition Priorities

The application can trigger only one transition at a time. There is no need to specify priorities among them.

As shown in the first part of the next table, the module transitions have a higher priority than the application transitions. For all states except the CCMa state, both a lock/unlock transition HL/HD and a module transition can be executed at the same time. The result state is reached by first applying the application transition and subsequently the module transition to the intermediately reached state. For example, if the message buffer is in the HLck state and the application unlocks the message buffer by the HU transition and the module triggers the slot assigned transition SA, the intermediate state is Idle and the resulting state is CCSa.

The priorities among the module transitions is given in the second part of the table below.

Table 60-44. Transmit Message Buffer Transition Priorities

State	Priorities	Description
module vs. application		
Idle, HLck	SA > HD	Slot Assigned > Message Buffer Disable
	MA > HD	Message Available > Message Buffer Disable
CCMa	TX > HL	Transmission Start > Message Buffer Lock
module internal		
Idle, HLck	MA > SA	Message Available > Slot Assigned
CCMa	TX > STS	Transmission Slot Start > Static Slot Start
	TX > DSS	Transmission Slot Start > Dynamic Slot Start

60.8.6.2.4 Transmit Message Setup

To transmit a message over the FlexRay bus, the application writes the message data into the message buffer data field and sets the commit bit CMT in the Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn). The physical access to the message buffer data field is described in Individual Message Buffers.

As indicated by Table 60-34, the application shall write to the message buffer data field and change the commit bit CMT only if the transmit message buffer is in one of the states HDis, HDisLck, HLck, HLckCCSa, HLckCCMa, or HLckCCMa. The application can change the state of a message buffer if it issues the appropriate commands shown in Table 60-34. The state change is indicated through the FR_MBCCSRn[EDS] and FR_MBCCSRn[LCKS] status bits.

If the transmit message buffer enters one of the states HDis, HDisLck, HLck, HLckCCSa, HLckCCMa, or HLckCCMa the FR_MBCCSRn[DVAL] flag is negated.

60.8.6.2.5 Message Transmission

As a result of the message buffer search described in Individual Message Buffer Search, the CC triggers the message available transition MA for up to two transmit message buffers. This changes the message buffer state from Idle to CCMa and the message buffers can be used for message transmission in the next slot.

The CC transmits a message from a message buffer if both of the following two conditions are fulfilled at the start of the transmission slot:

1. the message buffer is in the message available state CCMa
2. the message data are still valid, i.e. FR_MBCCSRn[CMT] = 1

In this case, the CC triggers the TX transition and changes the message buffer state to CCTx. A transmit message buffer timing and state change diagram for message transmission is given in the "Message Transmission Timing" figure below. In this example, the message buffer with message buffer number n is Idle at the start of the search slot, matches the slot and cycle number of the next slot, and message buffer data are valid, i.e. FR_MBCCSRn[CMT] = 1.

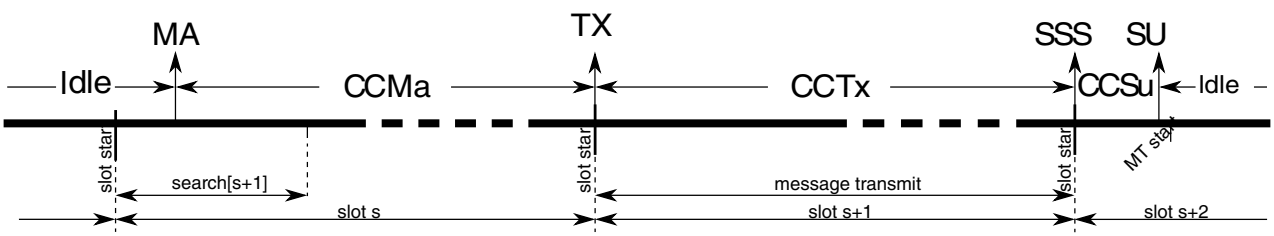

Figure 60-10. Message Transmission Timing

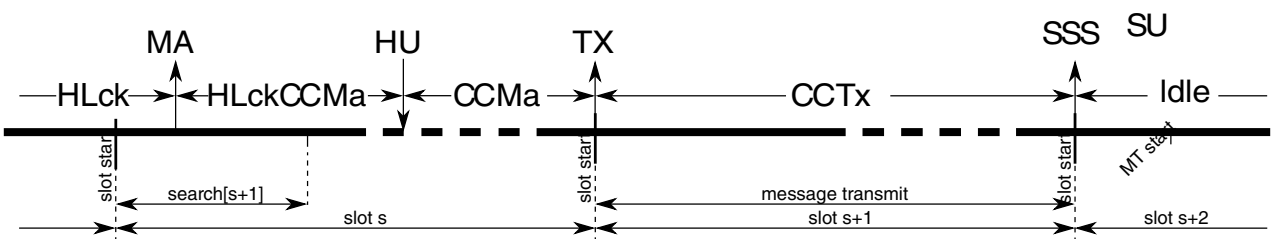

Figure 60-11. Message Transmission from HLck state with unlock

The amount of message data read from the FlexRay memory area and transferred to the FlexRay bus is determined by the following three items

1. the message buffer segment that the message buffer is assigned to, as defined by the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR).
2. the message buffer data field size, as defined by the related field of the Message Buffer Data Size Register (FR_MBDSR)

3. the value of the PLDLEN field in the message buffer header field, as described in Frame Header Description

If a message buffer is assigned to message buffer segment 1, and PLDLEN > MBSEG1DS, then 2 × MBSEG1DS bytes will be read from the message buffer data field and zero padding is used for the remaining bytes for the FlexRay bus transfer. If PLDLEN <= MBSEG1DS, the CC reads and transfers 2 ×PLDLEN bytes. The same holds for segment 2 and MBSEG2DS.

60.8.6.2.6 Null Frame Transmission

A static slot with slot number S is assigned to the CC for channel A, if at least one transmit message buffer is configured with the FR_MBFIDRn[FID] set to S and FR_MBCCFRn[CHA] set to 1. A Null Frame is transmitted in the static slot S on channel A, if this slot is assigned to the CC for channel A, and all transmit message buffers with FR_MBFIDRn[FID] = s and FR_MBCCFRn[CHA] = 1 are either not committed, i.e FR_MBCCSRn[CMT] = 0, or locked by the application, i.e. FR_MBCCSRn[LCKS] = 1, or the cycle counter filter is enabled and does not match.

Additionally, the application can clear the commit bit of a message buffer that is in the CCMa state, which is called *uncommit* or *transmit abort*. This message buffer will be used for null frame transmission.

As a result of the message buffer search described in Individual Message Buffer Search, the CC triggers the slot assigned transition SA for up to two transmit message buffers if at least one of the conditions mentioned above is fulfilled for these message buffers. The transition SA changes the message buffer states from either Idle to CCSa or from HLck to HLckCCSa. In each case, these message buffers will be used for null frame transmission in the next slot. A message buffer timing and state change diagram for null frame transmission from Idle state is given in the figure below.

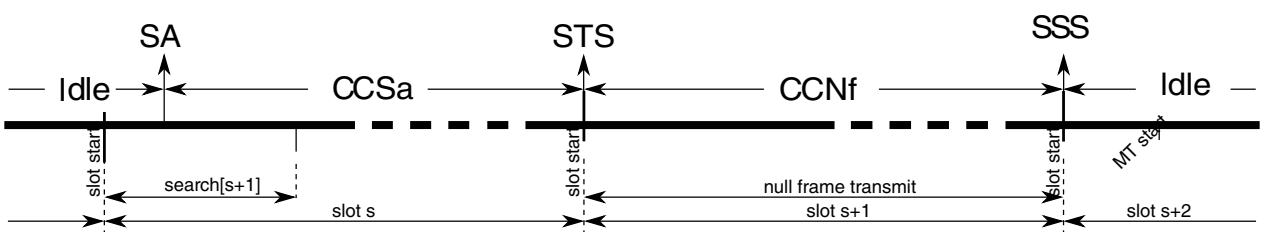

Figure 60-12. Null Frame Transmission from Idle state

A message buffer timing and state change diagram for null frame transmission from HLck state is given in the following figure.

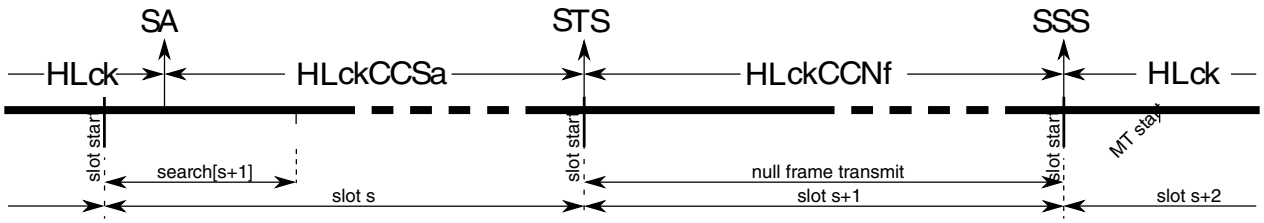

Figure 60-13. Null Frame Transmission from HLck state

If a transmit message buffer is in the CCSa or HLckCCSa state at the start of the transmission slot, a null frame is transmitted in any case, even if the message buffer is unlocked or committed before the transmission slot starts. A transmit message buffer timing and state change diagram for null frame transmission for this case is given in the next figure.

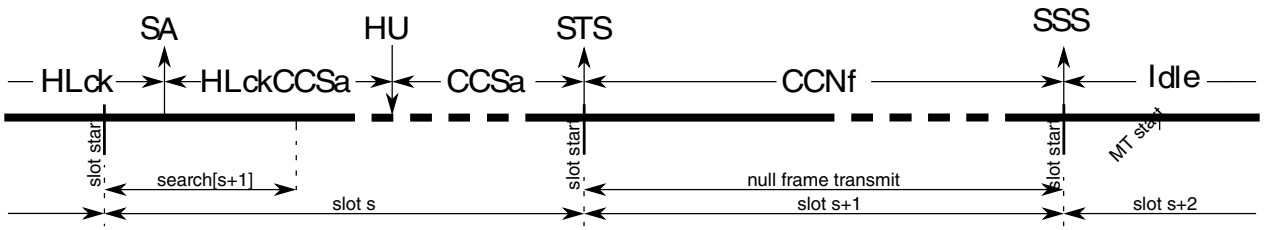

Figure 60-14. Null Frame Transmission from HLck state with unlock

Since the null frame transmission will not use the message buffer data, the application can lock/unlock the message buffer during null frame transmission. A transmit message buffer timing and state change diagram for null frame transmission for this case is given in the figure below.

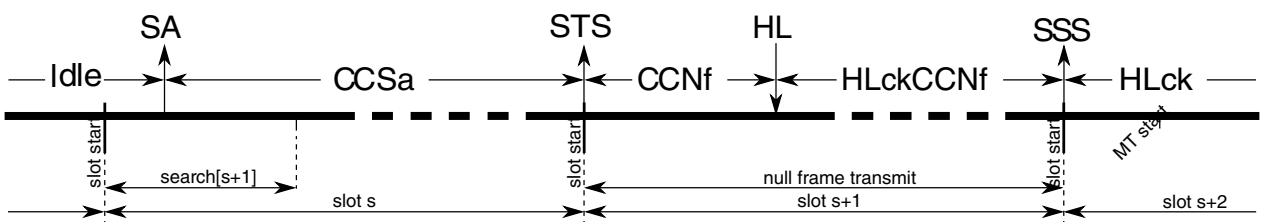

Figure 60-15. Null Frame Transmission from Idle state with locking

60.8.6.2.7 Message Buffer Status Update

After the end of each slot, the PE generates the slot status vector. Depending on the this status, the transmitted frame type, and the amount of transmitted data, the message buffer status is updated.

60.8.6.2.7.1 Message Buffer Status Update after Complete Message Transmission

The term complete message transmission refers to the fact that all payload data stored in the message buffer were send to FlexRay bus. In this case, the CC updates the slot status field of the message buffer and triggers the status updated transition SU. With the SU transition, the CC sets the message buffer interrupt flag FR_MBCCSRn[MBIF] to indicate the successful message transmission.

Depending on the transmission mode flag FR_MBCCFRn[MTM], the CC changes the commit flag FR_MBCCSRn[CMT] and the valid flag FR_MBCCSRn[DVAL]. If the FR_MBCCFRn[MTM] flag is negated, the message buffer is in the *event transmission mode*. In this case, each committed message is transmitted only once. The commit flag FR_MBCCSRn[CMT] is cleared with the SU transition. If the FR_MBCCFRn[MTM] flag is asserted, the message buffer is in the *state transmission mode*. In this case, each committed message is transmitted as long as the application provides new data or locks the message buffers. The CC will not clear the FR_MBCCSRn[CMT] flag at the end of transmission and will set the valid flag FR_MBCCSRn[DVAL] to indicate that the message will be transmitted again.

60.8.6.2.7.2 Message Buffer Status Update after Incomplete Message Transmission

The term incomplete message transmission refers to the fact that not all payload data that should be transmitted were send to FlexRay bus. This may be caused by the following regular conditions in the dynamic segment:

1. The transmission slot starts in a minislot with a minislot number greater than *pLatestTx*.
2. The transmission slot did not exist in the dynamic segment at all.

In any of these two aforementioned conditions occur, the status of the message buffer is not changed at all with the SU transition. The slot status field is not updated, the status and control flags are not changed, and the interrupt flag is not set.

Additionally, an incomplete message transmission can be caused by internal communication errors. If those errors occur, the Protocol Engine Communication Failure Interrupt Flag PECF_IF is set in the Protocol Interrupt Flag Register 1 (FR_PIFR1).

60.8.6.2.7.3 Message Buffer Status Update after Null Frame Transmission

After the transmission of a null frame, the status of the message buffer that was used for the null frame transmission is not changed at all. The slot status field is not updated, the status and control flags are not changed, and the interrupt flag is not set.

60.8.6.3 Receive Message Buffers

The section provides a detailed description of the functionality of the receive message buffers. If receive message buffers are used it is required to configure the related receive shadow buffer as described in Receive Shadow Buffers.

A receive message buffer is used to receive a message from the FlexRay Bus based on individual filter criteria. The CC uses the receive message buffer to provide the following data to the application.

1. message data received
2. information about the reception process
3. status information about the slot in which the message was received

A individual message buffer with message buffer number *n* is configured as a receive message buffer by the following configuration settings

$$FR\_MBCCSRn[MTD] = 0 (receive message buffer)$$

Equation 25

To certain message buffer fields, both the application and the CC have access. To ensure data consistency, a message buffer locking scheme is implemented that is used to control the access to the data, control, and status bits of a message buffer. The access regions for receive message buffers are depicted in the figure below. A description of the regions is given in the following table. If a region is active as indicated in the "Receive Message Buffer States and Access (Sheet 2 of 2)" table below, the access scheme given for that region applies to the message buffer.

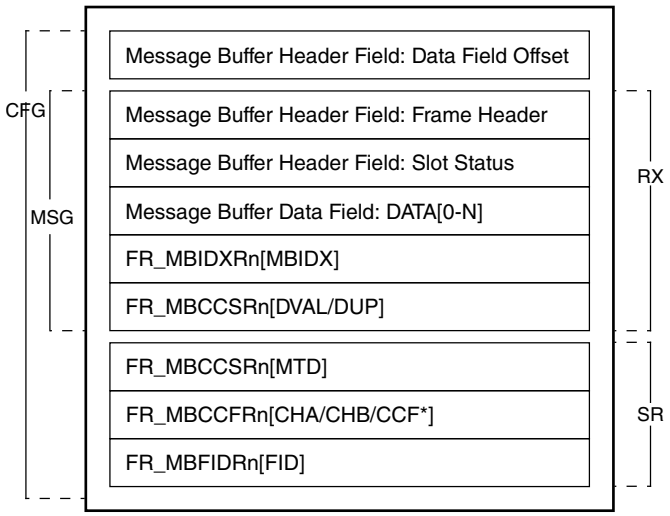

Figure 60-16. Receive Message Buffer Access Regions

Table 60-45. Receive Message Buffer Access Region Description

Region	Access from		Region used for
	Application	Module	
CFG	read/write	-	Message Buffer Configuration, Message Data and Status Access
MSG	read/write	-	Message Data, Header, and Status Access
RX	-	write-only	Message Reception and Status Update
SR	-	read-only	Message Buffer Search Data

The trigger bits FR_MBCCSRn[EDT] and FR_MBCCSRn[LCKT] and the interrupt enable bit FR_MBCCSRn[MBIE] are not under access control and can be accessed from the application at any time. The status bits FR_MBCCSRn[EDS] and FR_MBCCSRn[LCKS] are not under access control and can be accessed from the CC at any time.

The interrupt flag FR_MBCCSRn[MBIF] is not under access control and can be accessed from the application and the CC at any time. CC set access has higher priority.

The CC restricts its access to the regions depending on the current state of the message buffer. The application must adhere to these restrictions in order to ensure data consistency. The receive message buffer states are given in the figure below. A description of the message buffer states is given in Table 60-41, which also provides the access scheme for the access regions.

The status bits FR_MBCCSRn[EDS] and FR_MBCCSRn[LCKS] provide the application with the required status information. The internal status information is not visible to the application.

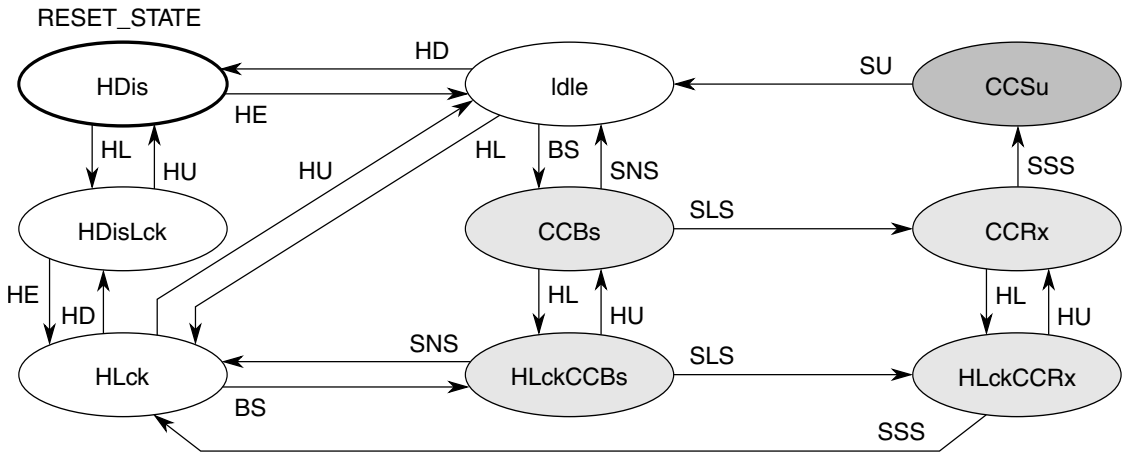

Figure 60-17. Receive Message Buffer States

Table 60-46. Receive Message Buffer States and Access (Sheet 2 of 2)

State	FR_MBCCSRn		Access from		Description
	EDS	LCKS	Appl.	Module	
Idle	1	0	–	SR	**Idle** - Message Buffer is idle. Included in message buffer search.
HDis	0	0	CFG	–	**Disabled** - Message Buffer under configuration. Excluded from message buffer search.
HDisLck	0	1	CFG	–	**Disabled and Locked** - Message Buffer under configuration.Excluded from message buffer search.
HLck	1	1	MSG	–	**Locked** - Applications access to data, control, and status.Included in message buffer search.
CCBs	1	0	–	–	**Buffer Subscribed** - Message buffer subscribed for reception. Filter matches next (slot, cycle, channel) tuple.
HLckCCBs	1	1	MSG	–	**Locked and Buffer Subscribed** - Applications access to data, control, and status. Message buffer subscribed for reception.
CCRx	1	0	–	–	**Message Receive** - Message data received into related shadow buffer.
HLckCCRx	1	1	MSG	–	**Locked and Message Receive** - Applications access to data, control, and status. Message data received into related shadow buffer.
CCSu	1	0	–	RX	**Status Update** - Message buffer status update. Update of status flags, the slot status field, and the header index.

60.8.6.3.1 Message Buffer Transitions

Application transitions, message buffer enable and disable, message buffer lock and unlock, module transitions, and transition priorities are discussed in this section.

60.8.6.3.1.1 Application Transitions

The application transitions that can be triggered by the application using the commands described in Table 60-42. The application issues the commands by writing to the Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn). Only one command can be issued with one write access. Each command is executed immediately. If the command is ignored, it must be issued again.

60.8.6.3.1.2 Message Buffer Enable and Disable

The enable and disable commands issued by writing 1 to the trigger bit FR_MBCCSRn[EDT]. The transition that will be triggered by each of these command depends on the current value of the status bit FR_MBCCSRn[EDS]. If the command triggers the disable transition HD and the message buffer is in one of the states CCBs, HLckCCBs, or CCRx, the disable transition has no effect (command is ignored) and the message buffer state is not changed. No notification is given to the application.

60.8.6.3.1.3 Message Buffer Lock and Unlock

The lock and unlock commands issued by writing 1 to the trigger bit FR_MBCCSRn[LCKT]. The transition that will be triggered by each of these commands depends on the current value of the status bit FR_MBCCSRn[LCKS]. If the command triggers the lock transition HL while the message buffer is in the state CCRx, the lock transition has no effect (command is ignored) and message buffer state is not changed. In this case, the message buffer lock error flag LCK_EF in the CHI Error Flag Register (FR_CHIERFR) is set.

Table 60-47. Receive Message Buffer Application Transitions

Transition	Host Command	Condition	Description
HE	FR_MBCCSRn[EDT]:= 1	FR_MBCCSRn[EDS] = 0	Application triggers message buffer enable.
HD		FR_MBCCSRn[EDS] = 1	Application triggers message buffer disable.
HL	FR_MBCCSRn[LCKT]: = 1	FR_MBCCSRn[LCKS] = 0	Application triggers message buffer lock.
HU		FR_MBCCSRn[LCKS] = 1	Application triggers message buffer unlock.

60.8.6.3.1.4 Module Transitions

The module transitions that can be triggered by the CC are described in the next table. Each transition will be triggered for certain message buffers when the related condition is fulfilled.

Table 60-48. Receive Message Buffer Module Transitions

Transition	Condition	Description
BS	slot match and CycleCounter match	**Buffer Subscribed** - The message buffer filter matches next slot and cycle.
SLS	slot start	**Slot Start** - Start of either Static Slot or Dynamic Slot.
SNS	symbol window start or NIT start	**Symbol Window or NIT Start** - Start of either Symbol Window or NIT.
SSS	slot start or symbol window start or NIT start	**Slot or Segment Start** - Start of either Static Slot, Dynamic Slot, Symbol Window, or NIT.
SU	status updated	**Status Updated** - Slot Status field, message buffer status flags, header index updated. Interrupt flag set.

60.8.6.3.1.5 Transition Priorities

The application can trigger only one transition at a time. There is no need to specify priorities among them.

As shown in the table below, the module transitions have a higher priority than the application transitions. For all states except the CCRx state, a module transition and the application lock/unlock transition HL/HU and can be executed at the same time. The result state is reached by first applying the module transition and subsequently the application transition to the intermediately reached state. For example, if the message buffer is in the buffer subscribed state CCBs and the module triggers the slot start transition SLS at the same time as the application locks the message buffer by the HL transition, the intermediate state is CCRx and the resulting state is locked buffer subscribed state HLckCCRx.

Table 60-49. Receive Message Buffer Transition Priorities

State	Priorities	Description
module vs. application		
Idle	BS > HD	Buffer Subscribed > Message Buffer Disable
HLck	BS > HD	Buffer Subscribed > Message Buffer Disable
CCRx	SSS > HL	Slot or Segment Start > Message Buffer Lock

60.8.6.3.2 Message Reception

As a result of the message buffer search, the CC changes the state of up to two enabled receive message buffers from either idle state Idle or locked state HLck to the either subscribed state CCBs or locked buffer subscribed state HLckCCBs by triggering the buffer subscribed transition BS.

If the receive message buffers for the next slot are assigned to both channels, then at most one receive message buffer is changed to a buffer subscribed state.

If more than one matching message buffers assigned to a certain channel, then only the message buffer with the lowest message buffer number is in one of the states mentioned above.

With the start of the next static or dynamic slot the module trigger the slot start transition SLS. This changes the state of the subscribed receive message buffers from either CCBs to CCRx or from HLckCCBs to HLckCCRx, respectively.

During the reception slot, the received frame data are written into the shadow buffers. For details on receive shadow buffers, see Receive Shadow Buffers Concept. The data and status of the receive message buffers that are the CCRx or HLckCCRx are not modified in the reception slot.

60.8.6.3.3 Message Buffer Update

With the start of the next static or dynamic slot or with the start of the symbol window or NIT, the module triggers the slot or segment start transition SSS. This transition changes the state of the receiving receive message buffers from either CCRx to CCSu or from HLckCCRx to HLck, respectively.

If a message buffer was in the locked state HLckCCRx, no update will be performed. The received data are lost. This is indicated by setting the Frame Lost Channel A/B Error Flag FRLA_EF/FRLB_EF in the CHI Error Flag Register (FR_CHIERFR).

If a message buffer was in the CCRx state it is now in the CCSu state. After the evaluation of the slot status provided by the PE the message buffer is updated. The message buffer update depends on the slot status bits and the segment the message buffer is assigned to. This is described in Table 60-52.

Table 60-50. Receive Message Buffer Update (Continued)

vSS!ValidFrame	*vRF!Header! NFIndicator*	Update description
1	1	**Valid non-null frame received.** - Message Buffer Data Field updated. - Frame Header Field updated. - Slot Status Field updated. - DUP:= 1 - DVAL:= 1 - MBIF:= 1
1	0	**Valid null frame received.**

Table continues on the next page...

Table 60-50. Receive Message Buffer Update (Continued) (continued)

vSS!ValidFrame	*vRF!Header! NFIndicator*	Update description
		- Message Buffer Data Field *not* updated. - Frame Header Field *not* updated. - Slot Status Field updated. - DUP:= 0 - DVAL *not* changed - MBIF:= 1
0	x	**No valid frame received.** - Message Buffer Data Field not updated. - Frame Header Field not updated. - Slot Status Field updated. - DUP:= 0 - DVAL *not* changed. - MBIF:= 1, if the slot was not an empty dynamic slot. **Note:** An empty dynamic slot is indicated by the following frame and slot status bit values: *vSS!ValidFrame* = 0 and *vSS!SyntaxError* = 0 and *vSS! ContentError* = 0 and *vSS!BViolation* = 0.

Note

If the number of the last slot in the current communication cycle on a given channel is n, then all receive message buffers assigned to this channel with FR_MBFIDRn[FID] > *n* will not be updated at all.

When the receive message buffer update has finished the status updated transition SU is triggered, which changes the buffer state from CCSu to Idle. An example receive message buffer timing and state change diagram for a normal frame reception is given in the following figure.

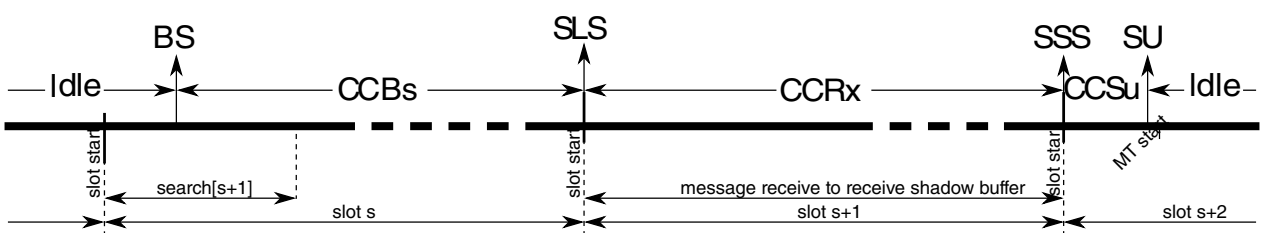

Figure 60-18. Message Reception Timing

The amount of message data written into the message buffer data field of the receive shadow buffer is determined by the following two items:

1. the message buffer segment that the message buffer is assigned to, as defined by the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR).
2. the message buffer data field size, as defined by the related field of the Message Buffer Data Size Register (FR_MBDSR)
3. the number of bytes received over the FlexRay bus

If the message buffer is assigned to the message buffer segment 1, and the number of received bytes is greater than 2 ×FR_MBDSR.MBSEG1DS, the CC writes only 2 × FR_MBDSR.MBSEG1DS bytes into the message buffer data field of the receive shadow buffer. If the number of received bytes is less than 2 × FR_MBDSR.MBSEG1DS, the CC writes only the received number of bytes and will not change the trailing bytes in the message buffer data field of the receive shadow buffer. The same holds for the message buffer segment 2 with FR_MBDSR.MBSEG2DS.

60.8.6.3.4 Received Message Access

To access the message data received over the FlexRay bus, the application reads the message data stored in the message buffer data field of the corresponding receive message buffer. The access to the message buffer data field is described in Individual Message Buffers.

The application can read the message buffer data field if the receive message buffer is one of the states HDis, HDisLck, or HLck. If the message buffer is in one of these states, the CC will not change the content of the message buffer.

60.8.6.3.5 Receive Shadow Buffers Concept

The receive shadow buffer concept applies only to individual receive message buffers. The intention of this concept is to ensure that only syntactically and semantically valid received non-null frames are presented to the application in a receive message buffer. The basic structure of a receive shadow buffer is described in Receive Shadow Buffers.

The receive shadow buffers temporarily store the received frame header and message data. After the slot boundary the slot status information is generated. If the slot status information indicates the reception of the valid non-null frame (see Table 60-50), the CC writes the slot status into the slot status field of the receive shadow buffer and exchanges the content of the Message Buffer Index Registers (FR_MBIDXRn) with the content of the corresponding internal shadow buffer index register. In all other cases, the CC writes the slot status into the identified receive message buffer, depending on the slot status and the FlexRay segment the message buffer is assigned to.

The shadow buffer concept, with its index exchange, results in the fact that the FlexRay memory area located message buffer associated to an individual receive message buffer changes after successful reception of a valid frame. This means that the message buffer area in the FlexRay memory area accessed by the application for reading the received message is different from the initial setting of the message buffer. Therefore, the application must not rely on the index information written initially into the Message Buffer Index Registers (FR_MBIDXRn). Instead, the index of the message buffer header field must be fetched from the Message Buffer Index Registers (FR_MBIDXRn).

60.8.7 Individual Message Buffer Search

This section provides a detailed description of the message buffer search algorithm.

The message buffer search determines for each enabled channel if a slot s in a communication cycle c is assigned for frame or null frame transmission or if it is subscribed for frame reception on that channel.

The message buffer search is a sequential algorithm which is invoked at the following protocol related events:

1. NIT start
2. slot start in the static segment
3. minislot start in the dynamic segment

The message buffer search within the NIT searches for message buffers assigned or subscribed to slot 1. The message buffer search within slot *n* searches for message buffers assigned or subscribed to slot *n+1*.

In general, the message buffer search for the next slot *n* considers only message buffers which are

1. enabled, i.e. FR_MBCCSRn[EDS] = 1, and
2. matches the next slot *n*, i.e. FR_MBFIDRn[FID] = *n*, and

On top of that, for the static segment only those message buffers are considered, that match the condition of at least one row of the "Message Buffer Search Priority (static segment)" table shown below. For the dynamic segment only those message buffers are considered, that match the condition of at least one row of the next "Message Buffer Search Priority (dynamic segment)" table. These message buffers are called *matching* message buffers.

For each enabled channel the message buffer search may identify multiple *matching* message buffers. Among all matching message buffers the message buffers with highest priority according to the "Message Buffer Search Priority (static segment)" table for the static segment and according to the "Message Buffer Search Priority (dynamic segment)" table for the dynamic segment are selected.

Table 60-51. Message Buffer Search Priority (static segment)

Priority	MTD	LCKS	CMT	CCFM[1]	Description	Transition
(highest) 0	1	0	1	1	transmit buffer, matches cycle count, not locked and committed	MA
1	1	-	0	1	transmit buffer, matches cycle count, not committed	SA
	1	1	-	1	transmit buffer, matches cycle count, locked	SA
2	1	-	-	-	transmit buffer	SA
3	0	0	n/a	1	receive buffer, matches cycle count, not locked	SB
(lowest) 4	0	1	n/a	1	receive buffer, matches cycle count, locked	SB

1. Cycle Counter Filter Match, see Message Buffer Cycle Counter Filtering.

Table 60-52. Message Buffer Search Priority (dynamic segment)

Priority	MTD	LCKS	CMT	CCFM[1]	Description	Transition
(highest) 0	1	0	1	1	transmit buffer, matches cycle count, not locked and committed	MA
1	0	0	n/a	1	receive buffer, matches cycle count, not locked	SB
(lowest) 2	0	1	n/a	1	receive buffer, matches cycle count, locked	SB

1. Cycle Counter Filter Match, see Message Buffer Cycle Counter Filtering.

If there are multiple message buffer with highest priority, the message buffer with the lowest message buffer number is selected. All message buffer which have the highest priority must have a consistent channel assignment as specified in Message Buffer Channel Assignment Consistency.

Depending on the message buffer channel assignment the same message buffer can be found for both channel A and channel B. In this case, this message buffer is used as described in Individual Message Buffers.

60.8.7.1 Message Buffer Cycle Counter Filtering

The message buffer cycle counter filter is a value-mask filter defined by the CCFE, CCFMSK, and CCFVAL fields in the Message Buffer Cycle Counter Filter Registers (FR_MBCCFRn). This filter determines a set of communication cycles in which the

message buffer is considered for message reception or message transmission. If the cycle counter filter is disabled, i.e. CCFE = 0, this set of cycles consists of all communication cycles.

If the cycle counter filter of a message buffer does not match a certain communication cycle number, this message buffer is not considered for message transmission or reception in that communication cycle. In case of a transmit message buffer assigned to a slot in the static segment, though, this buffer is added to the matching message buffers to indicate the slot assignment and to trigger the null frame transmission.

The cycle counter filter of a message buffer matches the communication cycle with the number CYCCNT if at least one of the following conditions evaluates to true:

$$MBCCFRn[CCFE] = 0$$

$$CYCCNT \,\&\, MBCCFRn[CCFMSK] = MBCCFRn[CCFVAL] \,\&\, MBCCFRn[CCFMSK]$$

60.8.7.2 Message Buffer Channel Assignment Consistency

The message buffer channel assignment given by the CHA and CHB bits in the Message Buffer Cycle Counter Filter Registers (FR_MBCCFRn) defines the channels on which the message buffer will receive or transmit. The message buffer with number *n* transmits or receives on channel A if FR_MBCCFRn[CHA] = 1 and transmits or receives on channel B if FR_MBCCFRn[CHB] = 1.

To ensure correct message buffer operation, all message buffers assigned to the same slot and with the same priority must have a *consistent* channel assignment. That means they must be either assigned to one channel only, or must be assigned to *both* channels. The behavior of the message buffer search is not defined, if both types of channel assignments occur for one slot and priority. An inconsistent channel assignment for message buffer 0 and message buffer 1 is depicted in the figure below.

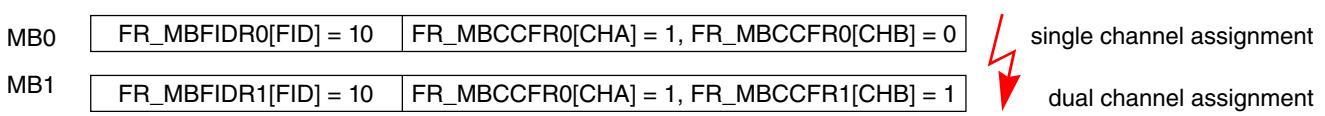

Figure 60-19. Inconsistent Channel Assignment

60.8.7.3 Node Related Slot Multiplexing

The term *Node Related Slot Multiplexing* applies to the dynamic segment only and refers to the functionality if there are transmit as well as receive message buffers are configured for the same slot.

According to Table 60-52 the transmit buffer is only found if the cycle counter filter matches, and the buffer is not locked and committed. In all other cases, the receive buffer will be found. Thus, if the block has no data to transmit in a dynamic slot, it is able to receive frames on that slot.

60.8.7.4 Message Buffer Search Error

There are two kinds of errors which may occur during message buffer search[1].

60.8.7.4.1 Message Buffer Search Start while Running

If the message buffer search is running in slot *n-1* and the next message buffer search start event appears due to the start of slot *n*, the message buffer search engine is stopped and the Message Buffer Search Error Flag MBS_EF is set in the CHI Error Flag Register (FR_CHIERFR). As a result of this stop, no individual message buffer is identified for transmission or reception in slot *n*. Additionally, the search engine will not be started in slot *n*, and consequently no individual message buffer is identified for transmission or reception in slot *n+1*.

A message buffer search error appears only if the CHI frequency is too slow to allow the search through all message buffers to be completed within the NIT or a minislot.

For more details of minimum required CHI frequency see Number of Usable Message Buffers.

60.8.7.4.2 Illegal Message Buffer Index Found

If the message buffer search has finished the message buffer search in slot *n-1*, it retrieves the data offset values for the found message buffers and the receive shadow buffers. If one of these message buffers contains an illegal message buffer index, the Message Buffer Search Error Flag MBS_EF is set in the CHI Error Flag Register (FR_CHIERFR) is set and no individual message buffer is identified for transmission or reception in slot *n*. The legal message buffer index values for the individual and receive shadow buffers are specified in the Receive Shadow Buffer Index Register section (FR_RSBIR) and the Message Buffer Index Registers sections (FR_MBIDXRn).

1. The FIFO reception is not affected by the search errors. Additionally, if no rx buffer has been found due to an search error, the received frame is considered for FIFO reception.

60.8.8 Individual Message Buffer Reconfiguration

The initial configuration of each individual message buffer can be changed even when the protocol is not in the *POC:config* state. This is referred to as individual message buffer *reconfiguration*. The configuration bits and fields that can be changed are given in the section on Specific Configuration Data. The common configuration data given in the section on Specific Configuration Data can not be reconfigured when the protocol is out of the *POC:config* state.

60.8.8.1 Reconfiguration Schemes

Depending on the target and destination basic state of the message buffer that is to be reconfigured, there are three reconfiguration schemes.

60.8.8.1.1 Basic Type Not Changed (RC1)

A reconfiguration will not change the basic type of the individual message buffer, if the message buffer transfer direction bit FR_MBCCSRn[MTD] are not changed. This type of reconfiguration is denoted by RC1 in Figure 60-20. Transmit and receive message buffers can be RC1-reconfigured when in the HDis or HDisLck state.

60.8.8.1.2 Buffer Type Not Changed (RC2)

A reconfiguration will not change the buffer type of the individual message buffer. This type of reconfiguration is denoted by RC2 in the figure below. It applies to transmit and receive message buffers. Transmit and receive message buffers can be RC2-reconfigured when in the HDis or HDisLck state.

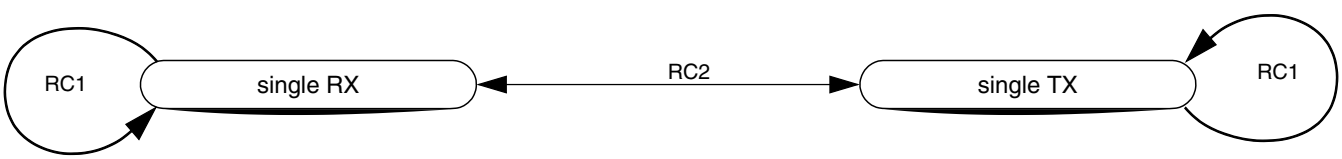

Figure 60-20. Message Buffer Reconfiguration Scheme

60.8.9 Receive FIFOs

This section provides the functional description of the two receive FIFOs.

60.8.9.1 Overview

The two receive FIFOs implement the queued message buffer concept defined by the *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*. One FIFO is assigned to channel A, the other FIFO is assigned to channel B. Both FIFOs work completely independent from each other.

The message buffer structure of each FIFO is described in Receive FIFO. The area in the FlexRay memory area for each of the two FIFOs is characterized by:

- *The FIFO system memory base address*
- *The index of the first FIFO entry given by Receive FIFO Start Index Register (FR_RFSIR)*
- *The data field offset of the data field belonging to the first FIFO entry given by Receive FIFO Start Data Offset Register (FR_RFSDOR)*
- *The number of FIFO entries and the length of each FIFO entry as given by Receive FIFO Depth and Size Register (FR_RFDSR)*

60.8.9.2 FIFO Configuration

The FIFOs can be configured for two different locations of the system memory base address via the FIFO address mode bit FAM in the Module Configuration Register (FR_MCR).

60.8.9.2.1 Single System Memory Base Address Mode

This mode is configured, when the FIFO address mode flag FR_MCR[FAM] is set to 0. In this mode, the location of the system memory base address for the FIFO buffers is System Memory Base Address Register (FR_SYMBADR).

60.8.9.2.2 Dual System Memory Base Address Mode

This mode is configured, when the FIFO address mode flag FR_MCR[FAM] is set to 1. In this mode, the location of the system memory base address for the FIFO buffers is Receive FIFO System Memory Base Address Register (FR_RFSYMBADR).

The FIFO control and configuration data are given in Receive FIFO Control and Configuration Data. The configuration of the FIFOs consists of two steps.

The first step is the allocation of the required amount of FlexRay memory area for the FlexRay window. This includes the allocation of the message buffer header area and the allocation of the message buffer data fields. For more details see FlexRay Memory Area Layout.

The second step is the programming of the configuration data register while the PE is in *POC:config*.

The following steps configure the layout of the FIFO.

- Configure the FIFO update and address modes in Module Configuration Register (FR_MCR)
- Configure the FIFO system memory base address
- Configure the Receive FIFO Start Index Register (FR_RFSIR) with the first message buffer header index that belongs to the FIFO
- Configure the Receive FIFO Start Data Offset Register (FR_RFSDOR) with the data field offset of the data field belonging to the first message buffer that belongs to the FIFO
- Configure the Receive FIFO Depth and Size Register (FR_RFDSR) with FIFO entry size
- Configure the Receive FIFO Depth and Size Register (FR_RFDSR) with FIFO depth
- Configure the FIFO Filters

60.8.9.3 FIFO Periodic Timer

The FIFO periodic timer is used to generate an FIFO almost-full interrupt at certain point in time, if the almost-full watermark is not reached, but the FIFO is not empty. This can be used to prevent frames from get stuck in the FIFO for a long time.

The FIFO periodic timer is configured via the Receive FIFO Periodic Timer Register (FR_RFPTR). If the periodic timer duration FR_RFPTR[PTD] is configured to 0x0000, the periodic timer is continuously expired. If the periodic timer duration FR_RFPTR[PTD] is configured to 0x3FFF, the periodic timer never expires. If the periodic timer is configured to a value *ptd*, greater than 0x0000 and smaller 0x3FFF, the periodic timer expires and is restarted at the start of every communication cycle, and expires and is restarted after *ptd* macroticks have been elapsed.

60.8.9.4 FIFO Reception

The FIFO reception is a CC internal operation.

A message frame reception is directed into the FIFO, if no individual message buffer is assigned for transmission or subscribed for reception for the current slot. In this case the FIFO filter path shown in Figure 60-21 is activated.

If the FIFO filter path indicates that the received frame has to be appended to the FIFO and the FIFO is not full, the CC writes the received frame header into the message buffer header field indicated by the CC internal FIFO write index. The frame payload data are written into the corresponding message buffer data field. If the status of the received frame indicates a valid non-null frame, the slot status information is written into the message buffer header field and the CC internal FIFO write index is updated by 1 and the fifo fill level FLA (FLB) in the Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR) is incremented. If the status of the received frame indicates an invalid or null frame, the frame is not appended to the FIFO.

60.8.9.5 FIFO Almost-Full Interrupt Generation

If the fifo fill level FLA (FLB) is updated after a frame reception and exceeds the FIFO watermark level WM, i.e. FLA>WM_A (FLB>WM_B), then the FIFO almost-full interrupt flag FR_GIFER[FAFAIF] (FR_GIFER[FAFBIF]) is asserted.

If the periodic timer expires, and FIFOA (FIFOB) is not empty, i.e. FLA>0 (FLB>0), then the FIFO almost-full interrupt flag FR_GIFER[FAFAIF] (FR_GIFER[FAFBIF]) is asserted.

60.8.9.6 FIFO Overflow Error Generation

If the FIFOA (FIFOB) is full, i.e. FLA=$FIFO\_DEPTH_A$ (FLB=$FIFO\_DEPTH_B$) and the conditions for a FIFO reception as described in FIFO Reception are fulfilled, then the fifo overflow error flag FR_CHIERFR[FOVA_EF] (FR_CHIERFR[FOVB_EF]) is asserted.

60.8.9.7 FIFO Message Access

The FIFOA (FIFOB) contains valid messages if the FIFO fill level given in the fields FLA (FLB) in the Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR) is greater than 0. The Receive FIFO A Read Index Register (FR_RFARIR) and the

(Receive FIFO B Read Index Register (FR_RFBRIR)) point to a message buffer with valid content and the oldest frames stored in the FIFO.The respective read data field offsets can be calculated according to Equation 1-125.

If the FIFO fill level FLA (FLB) in the Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR) is 0, than the FIFOA (FIFOB) contains no valid messages and the corresponding read index register Receive FIFO A Read Index Register (FR_RFARIR) or (Receive FIFO B Read Index Register (FR_RFBRIR) point to a message buffer with invalid content. In this case the application must not read data from this FIFO.

To access the oldest message in the FIFOA (FIFOB), the application first reads the read index RDIDX out of the Receive FIFO A Read Index Register (FR_RFARIR) (Receive FIFO B Read Index Register (FR_RFBRIR)). This read index points to the message buffer header field of the oldest message buffer that contains valid received message data. The data field offset belonging to this message buffer must be calculated by the application according to Equation 1-125. The application can access the message data as described in Receive FIFO. When the application has read the message buffer data and status information, it can update the FIFO as described in FIFO Update.

60.8.9.8 FIFO Update

The application updates the FIFOA (FIFOB) by writing a pop count value *pc* different from 0 to the PCA (PCB) field in the Receive FIFO Fill Level and POP Count Register (FR_RFFLPCR).

As a result of the this operation, the CC removes the oldest *pc* entries from FIFOA (FIFOB).

If the specified pop count value *pc* is greater than the current fill level *fl* provided in FLA (FAB) field, then only *fl* entries are removed from the FIFOA (FIFOB), the remaining *fl-pc* requested pop operations are discarded without any notification. In this case FIFOA (FIFOB) is empty after the update operation.

The read index in the Receive FIFO A Read Index Register (FR_RFARIR) (Receive FIFO B Read Index Register (FR_RFBRIR)) is incremented by the number of removed items. If the read index reaches the top of the FIFO, it wraps around to the FIFO start index defined in Receive FIFO Start Index Register (FR_RFSIR) automatically.

60.8.9.8.1 FIFO Interrupt Flag Update

The FIFO Interrupt Flag Update mode is configured, when the FIFO update mode flag FR_MCR[FUM] is set to 0. In this mode FIFOA (FIFOB) will be updated by 1 entry, when the interrupt flag FR_GIFER[FAFAIF] (FR_GIFER[FAFBIF]) is written with 1 by the application.

If the FIFO is empty, the update request is ignored without any notification.

The read index in the Receive FIFO A Read Index Register (FR_RFARIR) (Receive FIFO B Read Index Register (FR_RFBRIR)) is incremented by 1, if the FIFO was not empty. If the read index reaches the top of the FIFO, it wraps around to the FIFO start index automatically.

60.8.9.9 FIFO Filtering

The FIFO filtering is activated after all enabled individual receive message buffers have been searched without success for a message buffer to receive the current frame.

The CC provides three sets of FIFO filters. The FIFO filters are applied to valid non-null frames only. The FIFO will not receive invalid or null-frames. For each FIFO filter, the pass criteria is specified in the related section given below. Only frames that have passed all filters will be appended to the FIFO. The FIFO filter path is depicted in the figure below.

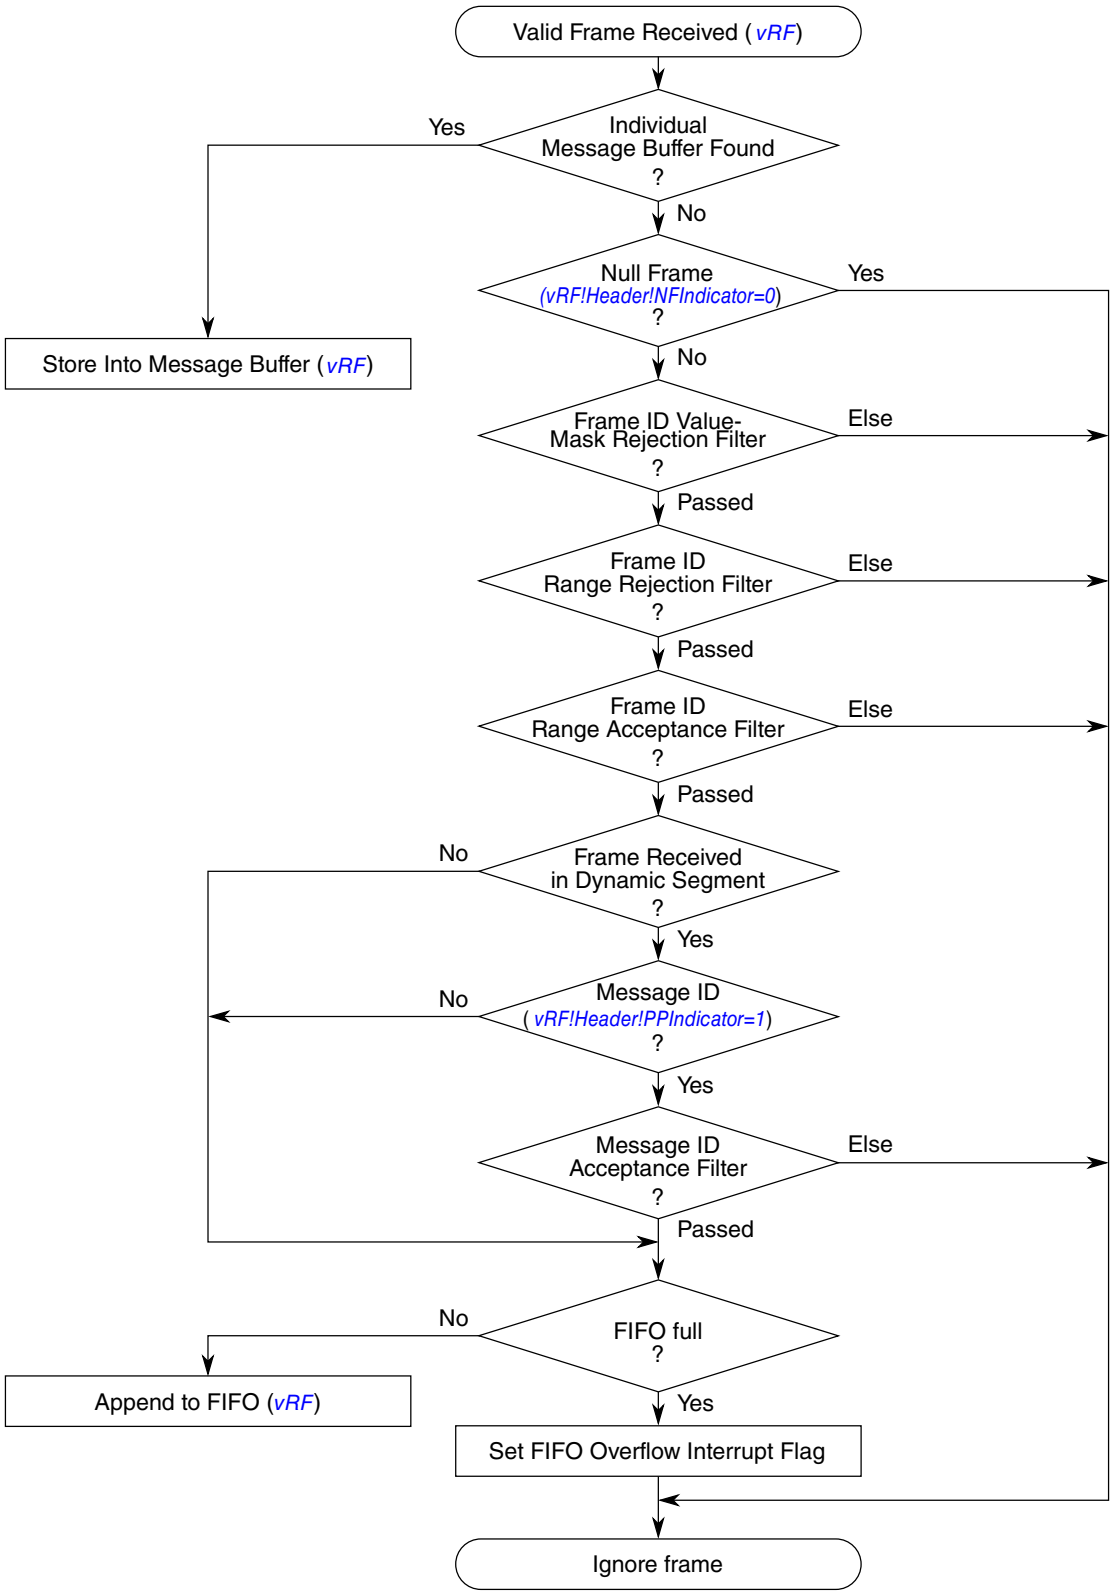

Figure 60-21. Received Frame FIFO Filter Path

A received frame passes the FIFO filtering if it has passed all three type of filter.

60.8.9.9.1 RX FIFO Frame ID Value-Mask Rejection Filter

The frame ID value-mask rejection filter is a value-mask filter and is defined by the fields in the Receive FIFO Frame ID Rejection Filter Value Register (FR_RFFIDRFVR) and the Receive FIFO Frame ID Rejection Filter Mask Register (FR_RFFIDRFMR). Each received frame with a frame ID FID that does not match the value-mask filter value passes the filter, i.e. is not rejected.

Consequently, a received valid frame with the frame ID FID passes the RX FIFO Frame ID Value-Mask Rejection Filter if Equation 26 on page 3091 is fulfilled.

$$FID \,\&\, FR\_RFFIDRFMR[FIDRFMSK] \neq FR\_RFFIDRFVR[FIDRFVAL] \,\&\, FR\_RFFIDRFMR[FIDRFMSK]$$

Equation 26

The RX FIFO Frame ID Value-Mask Rejection Filter can be configured to pass all frames by the following settings.

$$FR\_RFFIDRFVR[FIDRFVAL] = 0x000 \text{ and } FR\_RFFIDRFMR[FIDRFMSK] = 0x7FF$$

Equation 27

Using the settings above, only the frame with frame ID 0 will be rejected, which is an invalid frame. All other frames will pass.

The RX FIFO Frame ID Value-Mask Rejection Filter can be configured to reject all frames by the following settings.

$$FR\_RFFIDRFMR[FIDRFMSK] = 0x000$$

Equation 28

Using these settings, Equation 26 on page 3091 can never be fulfilled (0!= 0) and thus all frames are rejected; no frame will pass. This is the reset value for the RX FIFO.

60.8.9.9.2 RX FIFO Frame ID Range Rejection Filter

Each of the four RX FIFO Frame ID Range filters can be configured as a rejection filter. The filters are configured by the Receive FIFO Range Filter Configuration Register (FR_RFRFCFR) and controlled by the Receive FIFO Range Filter Control Register (FR_RFRFCTR). The RX FIFO Frame ID range filters apply to all received valid frames. A received frame with the frame ID FID passes the RX FIFO Frame ID Range rejection filters if either no rejection filter is enabled, or, for all of the enabled RX FIFO Frame ID Range rejection filters, i.e. FR_RFRFCTR[FiMD] = 1 and FR_RFRFCTR[FiEN] = 1, Equation 29 on page 3092 is fulfilled.

$$FID < FR\_RFRFCFR_{SEL}[SID_{IBD=0}]) or (FR\_RFRFCFR_{SEL}[SID_{IBD=1}] < FID)$$

Equation 29

Consequently, all frames with a frame ID that fulfills Equation 30 on page 3092 for at least one of the enabled rejection filters will be rejected and thus not pass.

$$FR\_RFRFCFR_{SEL}[SID_{IBD=0}] \leq FID \leq FR\_RFRFCFR_{SEL}[SID_{IBD=1}]$$

Equation 30

60.8.9.9.3 RX FIFO Frame ID Range Acceptance filter

Each of the four RX FIFO Frame ID Range filters can be configured as an acceptance filter. The filters are configured by the Receive FIFO Range Filter Configuration Register (FR_RFRFCFR) and controlled by the Receive FIFO Range Filter Control Register (FR_RFRFCTR). The RX FIFO Frame ID range filters apply to all received valid frames. A received frame with the frame ID FID passes the RX FIFO Frame ID Range acceptance filters if either no acceptance filter is enabled, or, for at least one of the enabled RX FIFO Frame ID Range acceptance filters, i.e. FR_RFRFCTR[FiMD] = 0 and FR_RFRFCTR[FiEN] = 1, Equation 31 on page 3092 is fulfilled.

$$FR\_RFRFCFR_{SEL}[SID_{IBD=0}] \leq FID \leq FR\_RFRFCFR_{SEL}[SID_{IBD=1}]$$

Equation 31

60.8.9.9.4 RX FIFO Message ID Acceptance Filter

The RX FIFO Message ID Acceptance Filter is a value-mask filter and is defined by the Receive FIFO Message ID Acceptance Filter Value Register (FR_RFMIDAFVR) and the Receive FIFO Message ID Acceptance Filter Mask Register (FR_RFMIDAFMR). This filter applies only to valid frames received in the dynamic segment with the payload preamble indicator bit PPI set to 1. All other frames will pass this filter.

A received valid frame in the dynamic segment with the payload preamble indicator bit PPI set to 1 and with the message ID MID (the first two bytes of the payload) will pass the RX FIFO Message ID Acceptance Filter if Equation 32 on page 3092 is fulfilled.

$$MID \,\&\, FR\_RFMIDAFMR[MIDAFMSK] = FR\_RFMIDAFMR[MIDAFVAL] \,\&\, FR\_RFMIDAFMR[MIDAFMSK]$$

Equation 32

The RX FIFO Message ID Acceptance Filter can be configured to accept all frames by setting

$$FR\_RFMIDAFMR[MIDAFMSK] := 0x000$$

Equation 33

Using these settings, Equation 32 on page 3092 is always fulfilled and all frames will pass.

60.8.10 Channel Device Modes

This section describes the two FlexRay channel device modes that are supported by the CC.

60.8.10.1 Dual Channel Device Mode

In the dual channel device mode, both FlexRay ports are connected to physical FlexRay bus lines. The FlexRay port consisting of FR_A_RX, FR_A_TX, and $\overline{\text{FR\_A\_TX\_EN}}$ is connected to the physical bus channel A and the FlexRay port consisting of FR_B_RX, FR_B_TX, and $\overline{\text{FR\_B\_TX\_EN}}$ is connected to the physical bus channel B. The dual channel system is shown in the following figure.

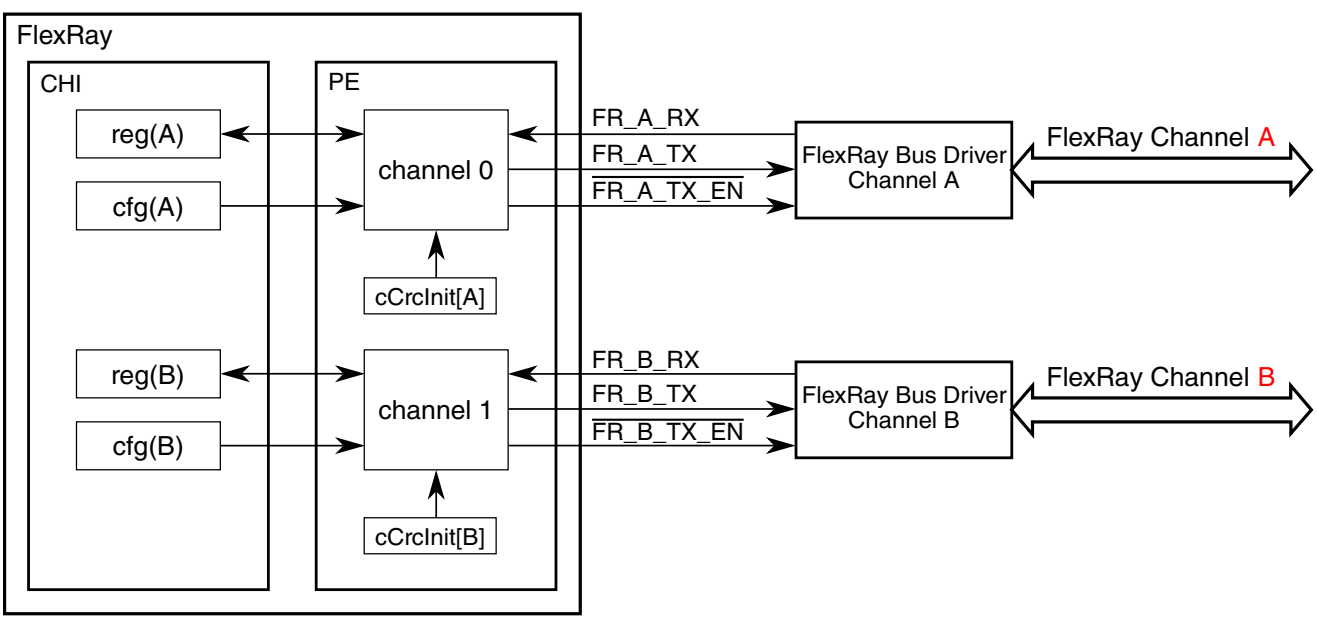

Figure 60-22. Dual Channel Device Mode

60.8.10.2 Single Channel Device Mode

The single channel device mode supports devices that have only one FlexRay port available. This FlexRay port consists of the signals FR_A_RX, FR_A_TX, and $\overline{\text{FR\_A\_TX\_EN}}$ and can be connected to either the physical bus channel A (shown in the "Single Channel Device Mode (Channel A)" figure below) or the physical bus channel B (shown in the "Single Channel Device Mode (Channel B)" figure below).

If the device is configured as a single channel device by setting FR_MCR[SCM] to 1, only the internal channel A and the FlexRay Port A is used. Depending on the setting of FR_MCR[CHA] and FR_MCR[CHB], the internal channel A behaves either as a FlexRay Channel A or FlexRay Channel B. The bit FR_MCR[CHA] must be set, if the FlexRay Port A is connected to a FlexRay Channel A. The bit FR_MCR[CHB] must be set if the FlexRay Port A is connected to a FlexRay Channel B. The two FlexRay channels differ only in the initial value for the frame CRC *cCrcInit*. For a single channel device, the application can access and configure only the registers related to internal channel A.

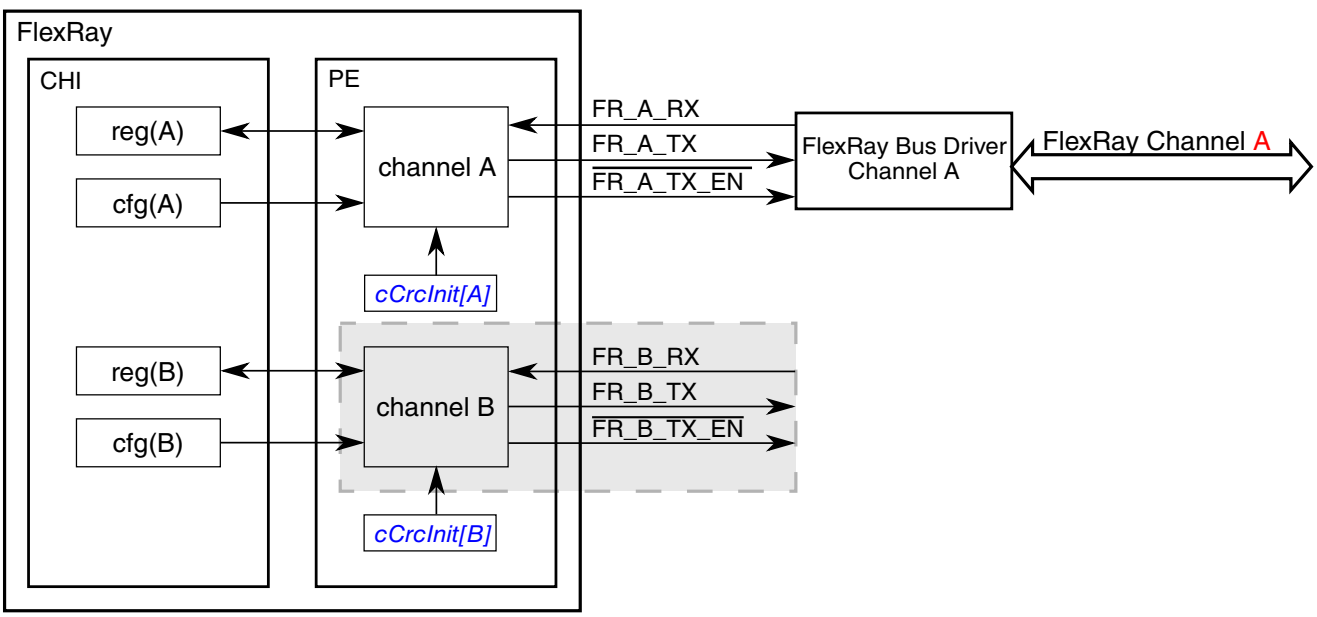

Figure 60-23. Single Channel Device Mode (Channel A)

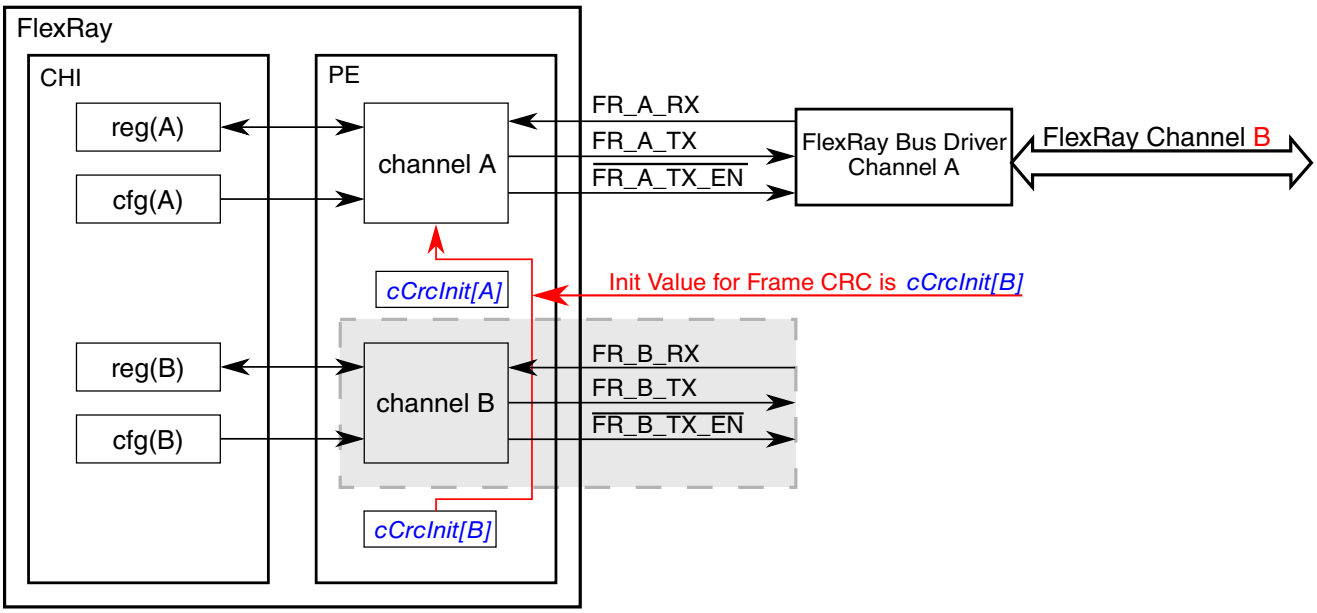

Figure 60-24. Single Channel Device Mode (Channel B)

60.8.11 External Clock Synchronization

The application of the external rate and offset correction is triggered when the application writes to the EOC_AP and ERC_AP fields in the Protocol Operation Control Register (FR_POCR). The PE applies the external correction values in the next even-odd cycle pair as shown in the "External Offset Correction Write and Application Timing" figure and the "External Rate Correction Write and Application Timing" figures below.

Note

The values provided in the EOC_AP and ERC_AP fields are the values that were written from the application most recently. If these value were already applied, they will not be applied in the current cycle pair again.

If the offset correction applied in the NIT of cycle 2n+1 shall be affect by the external offset correction, the EOC_AP field must be written to after the start of cycle 2n and before the end of the static segment of cycle 2n+1. If this field is written to after the end of the static segment of cycle 2n+1, it is not guaranteed that the external correction value is applied in cycle 2n+1. If the value is not applied in cycle 2n+1, then the value will be applied in the cycle 2n+3. Refer to the following for timing details.

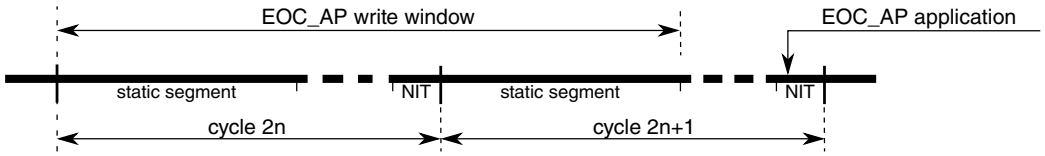

Figure 60-25. External Offset Correction Write and Application Timing

If the rate correction for the cycle pair [2n+2, 2n+3] shall be affect by the external offset correction, the ERC_AP field must be written to after the start of cycle 2n and before the end of the static segment start of cycle 2n+1. If this field is written to after the end of the static segment of cycle 2n+1, it is not guaranteed that the external correction value is applied in cycle pair [2n+2, 2n+3]. If the value is not applied for cycle pair [2n+2, 2n+3], then the value will be applied for cycle pair [2n+4, 2n+5]. Refer to the following for details.

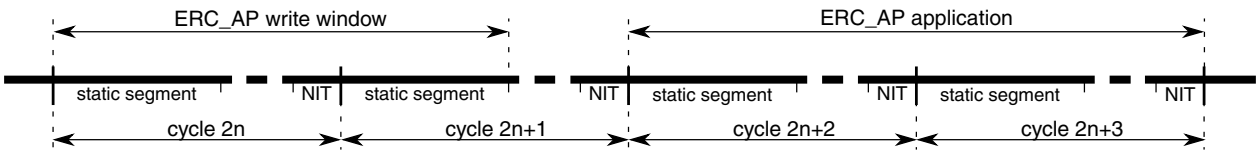

Figure 60-26. External Rate Correction Write and Application Timing

60.8.12 Sync Frame ID and Sync Frame Deviation Tables

The FlexRay protocol requires the provision of a snapshot of the Synchronization Frame ID tables for the even and odd communication cycle for both channels. The CC provides the means to write a copy of these internal tables into the FlexRay memory area and ensures application access to consistent tables by means of table locking. Once the application has locked the table successfully, the CC will not overwrite these tables and the application can read a consistent snapshot.

Note

Only synchronization frames that have passed the synchronization frame filters are considered for clock synchronization and appear in the sync frame tables.

60.8.12.1 Sync Frame ID Table Content

The Sync Frame ID Table is a snapshot of the protocol related variables *vsSyncIdListA* and *vsSyncIdListB* for each even and odd communication cycle. This table provides a list of the frame IDs of the synchronization frames received on the corresponding channel and cycle that are used for the clock synchronization.

60.8.12.2 Sync Frame Deviation Table Content

The Sync Frame Deviation Table is a snapshot of the protocol related variable zsDev(id)(oe)(ch)!Value. Each Sync Frame Deviation Table entry provides the deviation value for the sync frame, with the frame ID presented in the corresponding entry in the Sync Frame ID Table.

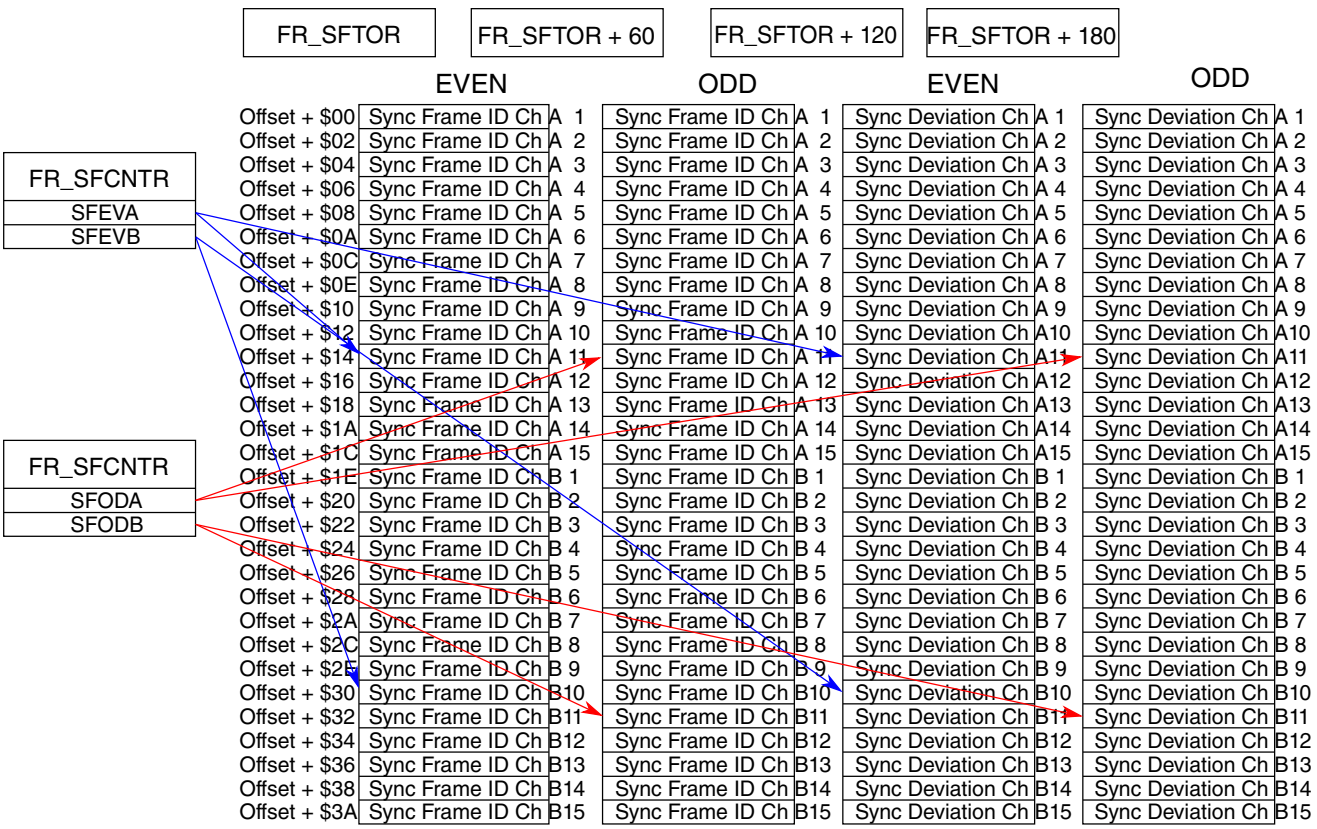

Figure 60-27. Sync Table Memory Layout

60.8.12.3 Sync Frame ID and Sync Frame Deviation Table Setup

The CC writes a copy of the internal synchronization frame ID and deviation tables into the FlexRay memory area if requested by the application. The application must provide the appropriate amount of FlexRay memory area for the tables. The memory layout of the tables is given in Figure 60-27. Each table occupies 120 16-bit entries.

While the protocol is in *POC:config* state, the application must program the offsets for the tables into the Sync Frame Table Offset Register (FR_SFTOR).

60.8.12.4 Sync Frame ID and Sync Frame Deviation Table Generation

The application controls the generation process of the Sync Frame ID and Sync Frame Deviation Tables into the FlexRay memory area using the Sync Frame Table Configuration, Control, Status Register (FR_SFTCCSR). A summary of the copy modes is given in the table below.

Table 60-53. Sync Frame Table Generation Modes

FR_SFTCCSR			Description
OPT	SDVEN	SIDEN	
0	0	0	No Sync Frame Table copy
0	0	1	Sync Frame ID Tables will be copied continuously
0	1	0	Reserved
0	1	1	Sync Frame ID Tables and Sync Frame Deviation Tables will be copied continuously
1	0	0	No Sync Frame Table copy
1	0	1	Sync Frame ID Tables for next even-odd-cycle pair will be copied
1	1	0	Reserved
1	1	1	Sync Frame ID Tables and Sync Frame Deviation Tables for next even-odd-cycle pair will be copied

The Sync Frame Table generation process is described in the following for the even cycle. The same sequence applies to the odd cycle.

If the application has enabled the sync frame table generation by setting FR_SFTCCSR[SIDEN] to 1, the CC starts the update of the even cycle related tables after the start of the NIT of the next even cycle. The CC checks if the application has locked the tables by reading the FR_SFTCCSR[ELKS] lock status bit. If this bit is set, the CC will not update the table in this cycle. If this bit is cleared, the CC locks this table and starts the table update. To indicate that these tables are currently updated and may contain inconsistent data, the CC clears the even table valid status bit FR_SFTCCSR[EVAL]. Once all table entries related to the even cycle have been transferred into the FlexRay memory area, the CC sets the even table valid bit FR_SFTCCSR[EVAL] and the Even Cycle Table Written Interrupt Flag EVT_IF in the Protocol Interrupt Flag Register 1 (FR_PIFR1). If the interrupt enable flag EVT_IE is set, an interrupt request is generated.

To read the generated tables, the application must lock the tables to prevent the CC from updating these tables. The locking is initiated by writing a 1 to the even table lock trigger FR_SFTCCSR[ELKT]. When the even table is not currently updated by the CC, the lock is granted and the even table lock status bit FR_SFTCCSR[ELKS] is set. This indicates that the application has successfully locked the even sync tables and the corresponding

status information fields SFRA, SFRB in the Sync Frame Counter Register (FR_SFCNTR). The value in the FR_SFTCCSR[CYCNUM] field provides the number of the cycle that this table is related to.

The number of available table entries per channel is provided in the FR_SFCNTR[SFEVA] and FR_SFCNTR[SFEVB] fields. The application can now start to read the sync table data from the locations given in Figure 60-27.

After reading all the data from the locked tables, the application must unlock the table by writing to the even table lock trigger FR_SFTCCSR[ELKT] again. The even table lock status bit FR_SFTCCSR[ELKS] is reset immediately.

If the sync frame table generation is disabled, the table valid bits FR_SFTCCSR[EVAL] and FR_SFTCCSR[EVAL] are reset when the counter values in the Sync Frame Counter Register (FR_SFCNTR) are updated. This is done because the tables stored in the FlexRay memory area are no longer related to the values in the Sync Frame Counter Register (FR_SFCNTR).

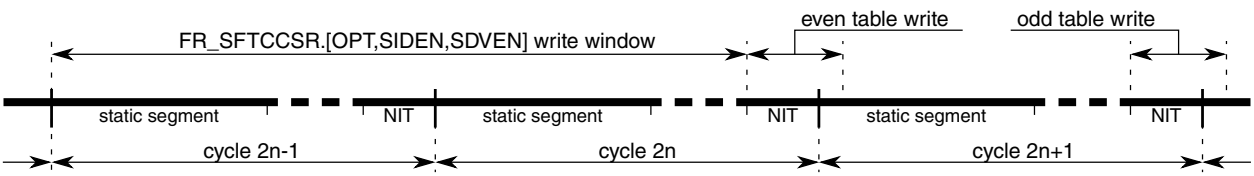

Figure 60-28. Sync Frame Table Trigger and Generation Timing

60.8.12.5 Sync Frame Table Access

The sync frame tables will be transferred into the FlexRay memory area during the table write windows shown in Figure 60-27. During the table write, the application can not lock the table that is currently written. If the application locks the table outside of the table write window, the lock is granted immediately.

60.8.12.5.1 Sync Frame Table Locking and Unlocking

The application locks the even/odd sync frame table by writing 1 to the lock trigger bit ELKT/OLKT in the Sync Frame Table Configuration, Control, Status Register (FR_SFTCCSR). If the affected table is not currently written to the FlexRay memory area, the lock is granted immediately, and the lock status bit ELKS/OLKS is set. If the affected table is currently written to the FlexRay memory area, the lock is not granted. In this case, the application must issue the lock request again until the lock is granted.

The application unlocks the even/odd sync frame table by writing 1 to the lock trigger bit ELKT/OLKT. The lock status bit ELKS/OLKS is cleared immediately.

60.8.13 MTS Generation

The CC provides a flexible means to request the transmission of the Media Access Test Symbol MTS in the symbol window on channel A or channel B.

The application can configure the set of communication cycles in which the MTS will be transmitted over the FlexRay bus by programming the CYCCNTMSK and CYCCNTVAL fields in the MTS A Configuration Register (FR_MTSACFR) and MTS B Configuration Register (FR_MTSBCFR).

The application enables or disables the generation of the MTS on either channel by setting or clearing the MTE control bit in the MTS A Configuration Register (FR_MTSACFR) or MTS B Configuration Register (FR_MTSBCFR). If an MTS is to be transmitted in a certain communication cycle, the application must set the MTE control bit during the static segment of the preceding communication cycle.

The MTS is transmitted over channel A in the communication cycle with number CYCCNT, if the following equations are fulfilled.

$$FR\_PSR0[PROTSTATE] = POC:\ normalactive$$

Equation 34

$$FR\_MTSACRF[MTE] = 1$$

Equation 35

$$CYCCNT \,\&\, FR\_MTSACFR[CYCCNTMSK] = FR\_MTSACFR[CYCCNTVAL] \,\&\, FR\_MTSACFR[CYCCNTMSK]$$

Equation 36

The MTS is transmitted over channel B in the communication cycle with number CYCCNT, if the following equations are fulfilled.

$$FR\_MTSBCRF[MTE] = 1$$

Equation 37

$$CYCCNT \,\&\, FR\_MTSBCFR[CYCCNTMSK] = FR\_MTSBCFR[CYCCNTVAL] \,\&\, FR\_MTSBCFR[CYCCNTMSK]$$

Equation 38

60.8.14 Key Slot Transmission

Key slot assignment, transmission in POC:startup state, and transmission in POC:normal active state are discussed in this section.

60.8.14.1 Key Slot Assignment

A key slot is assigned to the CC if the key_slot_id field in the Protocol Configuration Register 18 (FR_PCR18) is configured with a value greater than 0 and less or equal to number_of_static_slots in Protocol Configuration Register 2 (FR_PCR2), otherwise no key slot is assigned.

60.8.14.2 Key Slot Transmission in POC:startup

If a key slot is assigned and the CC is in the *POC:startup* state, startup null frames will be transmitted as specified by FlexRay Communications System Protocol Specification, Version *2.1 Rev A* .

60.8.14.3 Key Slot Transmission in POC:normal active

If a key slot is assigned and the CC is in *POC:normal active*, a frame of the type as shown in the following table is transmitted. If a transmit message buffer is configured for the key slot and a valid message is available, a message frame is transmitted (see Message Transmission). If no transmit message buffer is configured for the key slot or no valid message is available, a null frame is transmitted (see Null Frame Transmission).

Table 60-54. Key Slot Frame Type

FR_PCR11[key_slot_used_for_sync]	FR_PCR11[key_slot_used_for_startup]	key slot frame type
0	0	normal frame
0	1	normal frame1[1]
1	0	sync frame
1	1	startup frame

1. The frame transmitted has an semantically incorrect header and will be detected as an invalid frame at the receiver.

60.8.15 Sync Frame Filtering

Each received synchronization frame must pass the Sync Frame Acceptance Filter and the Sync Frame Rejection Filter before it is considered for clock synchronization. If the synchronization frame filtering is globally disabled, i.e. the SFFE control bit in the Module Configuration Register (FR_MCR) is cleared, all received synchronization

frames are considered for clock synchronization. If a received synchronization frame did not pass at least one of the two filters, this frame is processed as a normal frame and is not considered for clock synchronization.

60.8.15.1 Sync Frame Acceptance Filtering

The synchronization frame acceptance filter is implemented as a value-mask filter. The value is configured in the Sync Frame ID Acceptance Filter Value Register (FR_SFIDAFVR) and the mask is configured in the Sync Frame ID Acceptance Filter Mask Register (FR_SFIDAFMR). A received synchronization frame with the frame ID FID passes the sync frame acceptance filter, if the following equations evaluates to true.

$$FR\_MCR[SFFE] = 0$$

Equation 39

$$FID \,\&\, FR\_SFIDAFMR[FMSK] = FR\_SFIDAFVR[FVAL] \,\&\, FR\_SFIDAFMR[FMSK]$$

Equation 40

Note

Sync frames are transmitted in the static segment only. Thus FID <= 1023.

60.8.15.2 Sync Frame Rejection Filtering

The synchronization frame rejection filter is a comparator. The compare value is defined by the Sync Frame ID Rejection Filter Register (FR_SFIDRFR). A received synchronization frame with the frame ID FID passes the sync frame rejection filter if the following equations evaluates to true.

$$FR\_MCR[SFFE] = 0$$

Equation 41

$$FID \neq FR\_SFIDRFR[SYNFRID]$$

Equation 42

Note

Sync frames are transmitted in the static segment only. Thus FID <= 1023.

60.8.16 Strobe Signal Support

The CC provides a number of strobe signals for observing internal protocol timing related signals in the protocol engine. The signals are listed and described in the Strobe Signal Mapping table, located in the Register Descriptions section.

60.8.16.1 Strobe Signal Assignment

Each of the strobe signals listed in the Strobe Signal Mapping table, located in the Register Descriptions section, can be assigned to one of the four strobe ports using the Strobe Signal Control Register (FR_STBSCR). To assign multiple strobe signals, the application must write multiple times to the Strobe Signal Control Register (FR_STBSCR) with appropriate settings.

To read out the current settings for a strobe signal with number N, the application must execute the following sequence.

1. Write to FR_STBSCR with WMD = 1 and SEL = N. (updates SEL field only)
2. Read STBCSR.

   The SEL field provides N and the ENB and STBPSEL fields provides the settings for signal N.

60.8.16.2 Strobe Signal Timing

This section provides detailed timing information of the strobe signals with respect to the protocol engine clock.

The strobe signals display internal PE signals. Due to the internal architecture of the PE, some signals are generated several PE clock cycles before the actual action is performed on the FlexRay Bus. These signals are listed in the Strobe Signal Mapping table, located in the Register Descriptions section, with a negative clock offset. An example waveform is given in the following figure.

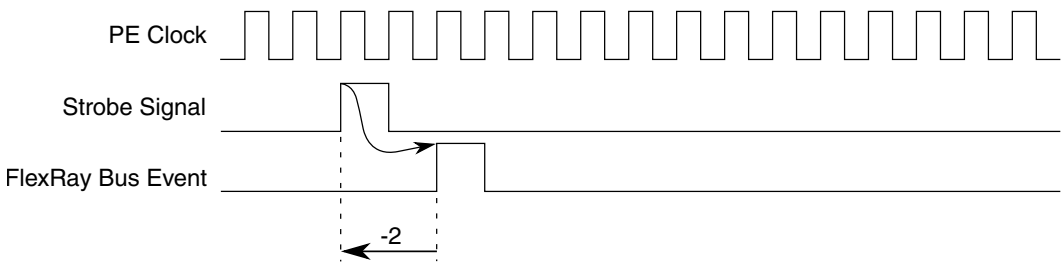

Figure 60-29. Strobe Signal Timing (type = pulse, clk_offset = -2)

Other signals refer to events that occurred on the FlexRay Bus some cycles before the strobe signal is changed. These signals are listed in the Strobe Signal Mapping table, located in the Register Descriptions section, with a positive clock offset. An example waveform is given in the figure below.

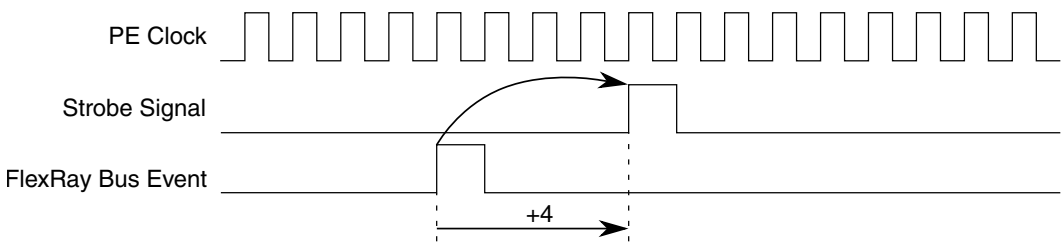

Figure 60-30. Strobe Signal Timing (type = pulse, clk_offset = +4)

60.8.17 Timer Support

The CC provides two timers, which run on the FlexRay time base. Each timer generates a maskable interrupt when it reaches a configured point in time. Timer T1 is an absolute timer. Timer T2 can be configured to be an absolute or a relative timer. Both timers can be configured to be repetitive. In the non-repetitive mode, timer stops if it expires. In repetitive mode, timer is restarted when it expires.

Both timers are active only when the protocol is in *POC:normal active* or *POC:normal passive* state. If the protocol is not in one of these modes, the timers are stopped. The application must restart the timers when the protocol has reached the *POC:normal active* or *POC:normal passive* state.

60.8.17.1 Absolute Timer T1

The absolute timer T1 has the protocol cycle count and the macrotick count as the time base. The timer 1 interrupt flag TI1_IF in the Protocol Interrupt Flag Register 0 (FR_PIFR0) is set at the macrotick start event, if the following equations are fulfilled.

$$CYCTR[CTCCNT] \& FR\_TI1CYSR[T1\_CYC\_MSK] = FR\_TI1CYSR[T1\_CYC\_VAL] \& FR\_TI1CYSR[T1\_CYC\_MSK]$$

Equation 43

$$FR\_MTCTR[MTCT] = FR\_TI1MTOR[T1\_MTOFFSET]$$

Equation 44

If the timer 1 interrupt enable bit TI1_IE in the Protocol Interrupt Enable Register 0 (FR_PIER0) is asserted, an interrupt request is generated.

The status bit T1ST is set when the timer is triggered, and is cleared when the timer expires and is non-repetitive. If the timer expires but is repetitive, the T1ST bit is not cleared and the timer is restarted immediately. The T1ST is cleared when the timer is stopped.

60.8.17.2 Absolute / Relative Timer T2

The timer T2 can be configured to be an absolute or relative timer by setting the T2_CFG control bit in the Timer Configuration and Control Register (FR_TICCR). The status bit T2ST is set when the timer is triggered, and is cleared when the timer expires and is non-repetitive. If the timer expires but is repetitive, the T2ST bit is not cleared and the timer is restarted immediately. The T2ST is cleared when the timer is stopped.

60.8.17.2.1 Absolute Timer T2

If timer T2 is configured as an absolute timer, it has the same functionality timer T1 but the configuration from Timer 2 Configuration Register 0 (FR_TI2CR0) and Timer 2 Configuration Register 1 (FR_TI2CR1) is used. On expiration of timer T2, the interrupt flag TI2_IF in the Protocol Interrupt Flag Register 0 (FR_PIFR0) is set. If the timer 1 interrupt enable bit TI1_IE in the Protocol Interrupt Enable Register 0 (FR_PIER0) is asserted, an interrupt request is generated.

60.8.17.2.2 Relative Timer T2

If the timer T2 is configured as a relative timer, the interrupt flag TI2_IF in the Protocol Interrupt Flag Register 0 (FR_PIFR0) is set, when the programmed amount of macroticks MT[31:0], defined by Timer 2 Configuration Register 0 (FR_TI2CR0) and Timer 2 Configuration Register 1 (FR_TI2CR1), has expired since the trigger or restart of timer 2. The relative timer is implemented as a down counter and expires when it has reached 0. At the macrotick start event, the value of MT[31:0] is checked and then decremented. Thus, if the timer is started with MT[31:0] == 0, it expires at the next macrotick start.

60.8.18 Slot Status Monitoring

The CC provides several means for slot status monitoring. All slot status monitors use the same slot status vector provided by the PE. The PE provides a slot status vector for each static slot, for each dynamic slot, for the symbol window, and for the NIT, on a per channel base. The content of the slot status vector is described in the "Slot Status Content" table below. The PE provides the slot status vector within the first macrotick after the end of the related slot/window/NIT, as shown in the below figure.

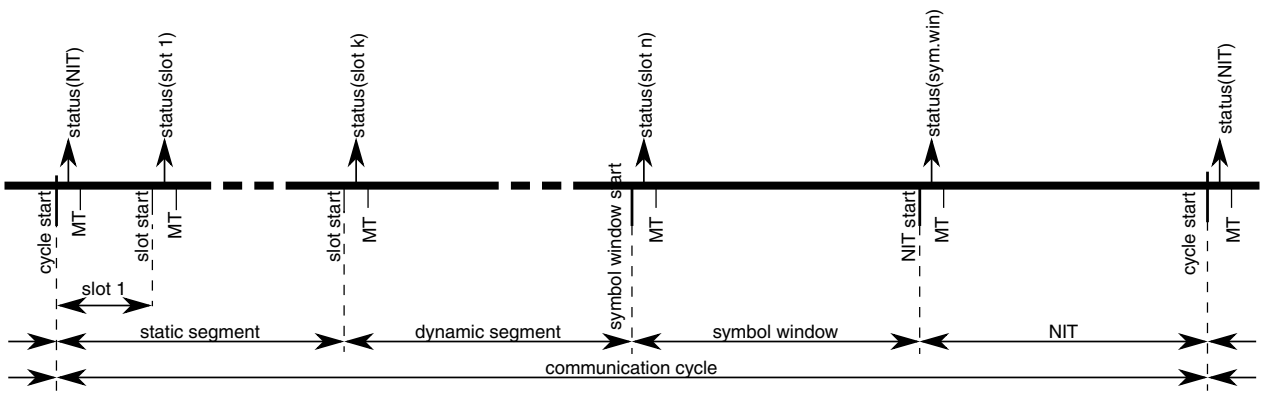

Figure 60-31. Slot Status Vector Update

Note

The slot status for the NIT of cycle n is provided after the start of cycle n+1.

Table 60-55. Slot Status Content

	Status Content
static /dynamic Slot	**slot related status**
	vSS!ValidFrame - valid frame received
	vSS!SyntaxError - syntax error occurred while receiving
	vSS!ContentError - content error occurred while receiving
	vSS!BViolation - boundary violation while receiving
	for slots in which the module transmits:
	vSS!TxConflict - reception ongoing while transmission starts
	for slots in which the module does not transmit:
	vSS!TxConflict - reception ongoing while transmission starts
	first valid - channel that has received the first valid frame
	received frame related status
	extracted from
	a)header of valid frame, if vSS!ValidFrame = 1

Table continues on the next page...

Table 60-55. Slot Status Content (continued)

	Status Content
	b) last received header, if vSS!ValidFrame = 0
	c) set to 0, if nothing was received
	vRF!Header!NFIndicator - Null Frame Indicator (0 for null frame)
	vRF!Header!SuFIndicator - Startup Frame Indicator
	vRF!Header!SyFIndicator - Sync Frame Indicator
Symbol Window	**window related status**
	vSS!ValidFrame - always 0
	vSS!ContentError - content error occurred while receiving
	vSS!SyntaxError - syntax error occurred while receiving
	vSS!BViolation - boundary violation while receiving
	vSS!TxConflict - reception ongoing while transmission starts
	received symbol related status
	vSS!ValidMTS - valid Media Test Access Symbol received
	received frame related status
	see static/dynamic slot
NIT	**NIT related status**
	vSS!ValidFrame - always 0
	vSS!ContentError - content error occurred while receiving
	vSS!SyntaxError - syntax error occurred while receiving
	vSS!BViolation - boundary violation while receiving
	vSS!TxConflict - always 0
	received frame related status
	see static/dynamic slot

60.8.18.1 Channel Status Error Counter Registers

The two channel status error counter registers, Channel A Status Error Counter Register (FR_CASERCR) and Channel B Status Error Counter Register (FR_CBSERCR), incremented by one, if at least one of four slot status error bits, *vSS!SyntaxError, vSS! ContentError, vSS!BViolation*, or *vSS!TxConflict* is set to 1. The status vectors for all slots in the static and dynamic segment, in the symbol window, and in the NIT are taken into account. The counters wrap round after they have reached the maximum value.

60.8.18.2 Protocol Status Registers

The Protocol Status Register 2 (FR_PSR2) provides slot status information about the Network Idle Time NIT and the Symbol Window. The Protocol Status Register 3 (FR_PSR3) provides aggregated slot status information.

60.8.18.3 Slot Status Registers

The eight slot status registers, Slot Status Registers (FR_SSR0–FR_SSR7), can be used to observe the status of static slots, dynamic slots, the symbol window, or the NIT without individual message buffers. These registers provide all slot status related and received frame / symbol related status information, as given in Table 60-55, except of the *first valid* indicator for non-transmission slots.

60.8.18.4 Slot Status Counter Registers

The CC provides four slot status error counter registers, Slot Status Counter Registers (FR_SSCR0–FR_SSCR3). Each of these slot status counter registers is updated with the value of an internal slot status counter at the start of a communication cycle. The internal slot status counter is incremented if its increment condition, defined by the Slot Status Counter Condition Register (FR_SSCCR), matches the status vector provided by the PE. All static slots, the symbol window, and the NIT status are taken into account. *Dynamic* slots are *excluded*. The internal slot status counting and update timing is shown in the figure below.

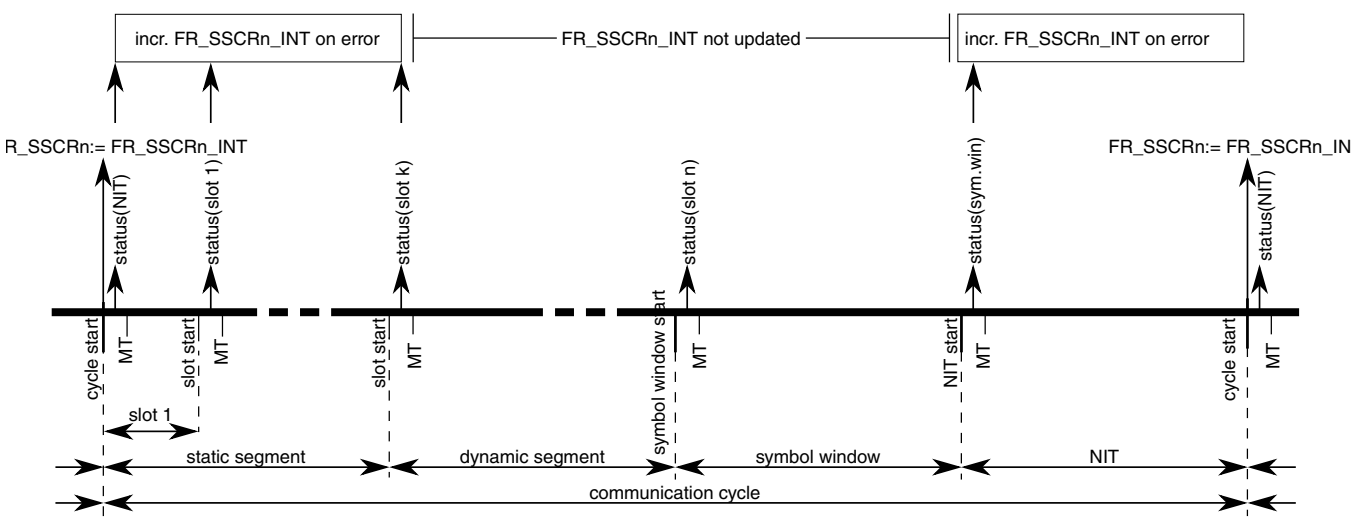

Figure 60-32. Slot Status Counting and FR_SSCRn Update

The PE provides the status of the NIT in the first slot of the next cycle. Due to these facts, the FR_SSCRn register reflects, in cycle n, the status of the NIT of cycle n-2, and the status of all static slots and the symbol window of cycle n-1.

The increment condition for each slot status counter consists of two parts, the frame related condition part and the slot related condition part. The internal slot status counter FR_SSCRn_INT is incremented if at least one of the conditions is fulfilled:

1. frame related condition:

   (FR_SSCCRn[VFR] | FR_SSCCRn[SYF] | FR_SSCCRn[NUF] | FR_SSCCRn[SUF]) // count on frame condition

   = 1;

   and

   ((~FR_SSCCRn[VFR] | vSS!ValidFrame) & // valid frame restriction

   (~FR_SSCCRn[SYF] | vRF!Header!SyFIndicator) & // sync frame indicator restriction

   (~FR_SSCCRn[NUF] | ~vRF!Header!NFIndicator) & // null frame indicator restriction

   (~FR_SSCCRn[SUF] | vRF!Header!SuFIndicator)) // startup frame indicator restriction

   = 1;

   Note

   The indicator bits SYF, NUF, and SUF are valid only when a valid frame was received. Thus it is required to set the VFR always, whenever count on frame condition is used.

   slot related condition:

   ((FR_SSCCRn[STATUSMASK[3]] & vSS!SyntaxError) | // increment on syntax error

   (FR_SSCCRn[STATUSMASK[2]] & vSS!ContentError) | // increment on content error

   (FR_SSCCRn[STATUSMASK[1]] & vSS!BViolation) | // increment on boundary violation

   (FR_SSCCRn[STATUSMASK[0]] & vSS!TxConflict)) // increment on transmission conflict

= 1;

If the slot status counter is in single cycle mode, i.e. FR_SSCCRn[MCY] = 0, the internal slot status counter FR_SSCRn_INT is reset at each cycle start. If the slot status counter is in the multicycle mode, i.e. FR_SSCCRn[MCY] = 1, the counter is not reset and incremented, until the maximum value is reached.

60.8.18.5 Message Buffer Slot Status Field

Each individual message buffer and each FIFO message buffer provides a slot status field, which provides the information shown in Table 60-55 for the static/dynamic slot. The update conditions for the slot status field depend on the message buffer type. Refer to the Message Buffer Update Sections in Individual Message Buffer Configuration Data.

60.8.19 System Bus Access

This section provides a description of the system bus accesses failures and the related CC behavior. System bus access failures may occur when the CC transfers data to or from the FlexRay memory area.

The system bus access failure types are described in System Bus Access Failure Types.

The behavior of the CC after the occurrence of a system bus access failure is described in System Bus Access Failure Response.

60.8.19.1 System Bus Access Failure Types

This section describes the two types of system bus access failures.

60.8.19.1.1 System Bus Illegal Address Access

A system bus illegal address access is detected when the CC has used an illegal or invalid address to access the FlexRay system memory area. There are three conditions which are treated as a system bus illegal address access:

- The system bus subsystem detects an CC access to an illegal system memory address.

- The CC detects the usage of an data field offset with the value of 0.
- The CC detects a memory error while reading a data field offset from the CHI LRAM memory (see CHI LRAM Error Response after CC Read).

If a system bus illegal address access is detected, the CC sets the ILSA_EF flag in the CHI Error Flag Register (FR_CHIERFR).

60.8.19.1.2 System Bus Access Timeout

A system bus access timout is detected if an access to the FlexRay memory area is not finished in time. The timeout value is derived from the SYMATOR[TIMEOUT] setting (see Configure System Memory Access Time-Out Register (FR_SYMATOR)).

If a system bus access timout is detected, the CC sets the SBCF_EF flag in the CHI Error Flag Register (FR_CHIERFR).

60.8.19.2 System Bus Access Failure Response

This section describes the two types of behavior of the CC after the occurrence of a system bus access failure. The actual behavior is defined by the SBFF bit in the Module Configuration Register (FR_MCR).

60.8.19.2.1 Continue after System Bus Access Failure

If the SBFF bit in the Module Configuration Register (FR_MCR) is 0, the CC will continue its operation after the occurrence of the system bus access failure, but will not generate any system bus accesses until the start of the next communication cycle.Since no data are read from or written to the FlexRay memory area, no messages are received or transmitted. Consequently, none of the individual message buffers or receive FIFOs will be updated until the next communication cycle starts.

If a frame is under transmission when the system bus failure occurs, a correct frame is generated with the remaining header and frame data are replaced by all zeros. Depending on the point in time this can affect the PPI bit, the Header CRC, the Payload Length in case of an dynamic slot, and the payload data. Starting from the next slot in the current cycle, no frames will be transmitted and received, except for the key slot, where a sync or startup null-frame is transmitted, if the key slot is assigned.

If a frame is received when the system bus failure occurs, the reception is aborted and the related receive message buffer is not updated.

Normal operation is resumed after the start of next communication cycle.

60.8.19.2.2 Freeze after System Bus Access Failure

If the SBFF bit in the Module Configuration Register (FR_MCR) is set to 1, the CC will go into the freeze mode immediately after the occurrence of one of the system bus access failures.

60.8.20 Interrupt Support

The CC provides 172 individual interrupt sources and five combined interrupt sources.

60.8.20.1 Individual Interrupt Sources

Message buffer interrupts are discussed in this section.

60.8.20.1.1 Message Buffer Interrupts

The CC provides 128 message buffer interrupt sources.

Each individual message buffer provides an interrupt flag FR_MBCCSRn[MBIF] and an interrupt enable bit FR_MBCCSRn[MBIE]. The CC sets the interrupt flag when the slot status of the message buffer was updated. If the interrupt enable bit is asserted, an interrupt request is generated.

60.8.20.1.2 FIFO Interrupts

The CC provides 2 FIFO interrupt sources.

Each of the 2 FIFO provides a Receive FIFO Almost Full Interrupt Flag. The CC sets the Receive FIFO Almost Full Interrupt Flags (FR_GIFER[FAFBIF], FR_GIFER[FAFAIF]) in the Global Interrupt Flag and Enable Register (FR_GIFER) if the corresponding Receive FIFO fill level exceeds the defined watermark.

60.8.20.1.3 Wakeup Interrupt

The CC provides one interrupt source related to the wakeup.

The CC sets the Wakeup Interrupt Flag FR_GIFER[WUPIF] when it has received a wakeup symbol on the FlexRay bus. The CC generates an interrupt request if the interrupt enable bit FR_GIFER[WUPIE] is asserted.

60.8.20.1.4 Protocol Interrupts

The CC provides 25 interrupt sources for protocol related events. For details, see Protocol Interrupt Flag Register 0 (FR_PIFR0) and Protocol Interrupt Flag Register 1 (FR_PIFR1). Each interrupt source has its own interrupt enable bit.

60.8.20.1.5 CHI Interrupts

The CC provides 16 interrupt sources for CHI related error events. For details, see CHI Error Flag Register (FR_CHIERFR). There is one common interrupt enable bit FR_GIFER[CHIE] for all CHI error interrupt sources.

60.8.20.2 Combined Interrupt Sources

Each combined interrupt source generates an interrupt request only when at least one of the interrupt sources that is combined generates an interrupt request.

60.8.20.2.1 Receive Message Buffer Interrupt

The Receive Message Buffer Interrupt request is generated when at least one of the individual receive message buffers generates an interrupt request MBXIRQ[n] and the interrupt enable bit FR_GIFER[RBIE] is set.

60.8.20.2.2 Transmit Message Buffer Interrupt

The Transmit Message Buffer Interrupt request is generated when at least one of the individual transmit message buffers generates an interrupt request MBXIRQ[n] and the interrupt enable bit FR_GIFER[TBIE] is asserted.

60.8.20.2.3 Protocol Interrupt

The Protocol Interrupt request is generated when at least one of the individual protocol interrupt sources generates an interrupt request and the interrupt enable bit FR_GIFER[PRIE] is set..

60.8.20.2.4 CHI Interrupt

The CHI Interrupt request is generated when at least one of the individual chi error interrupt sources generates an interrupt request and the interrupt enable bit FR_GIFER[CHIE] is set.

60.8.20.2.5 Module Interrupt

The Module Interrupt request is generated if at least one of the combined interrupt sources generates an interrupt request and the interrupt enable bit FR_GIFER[MIE] is set.

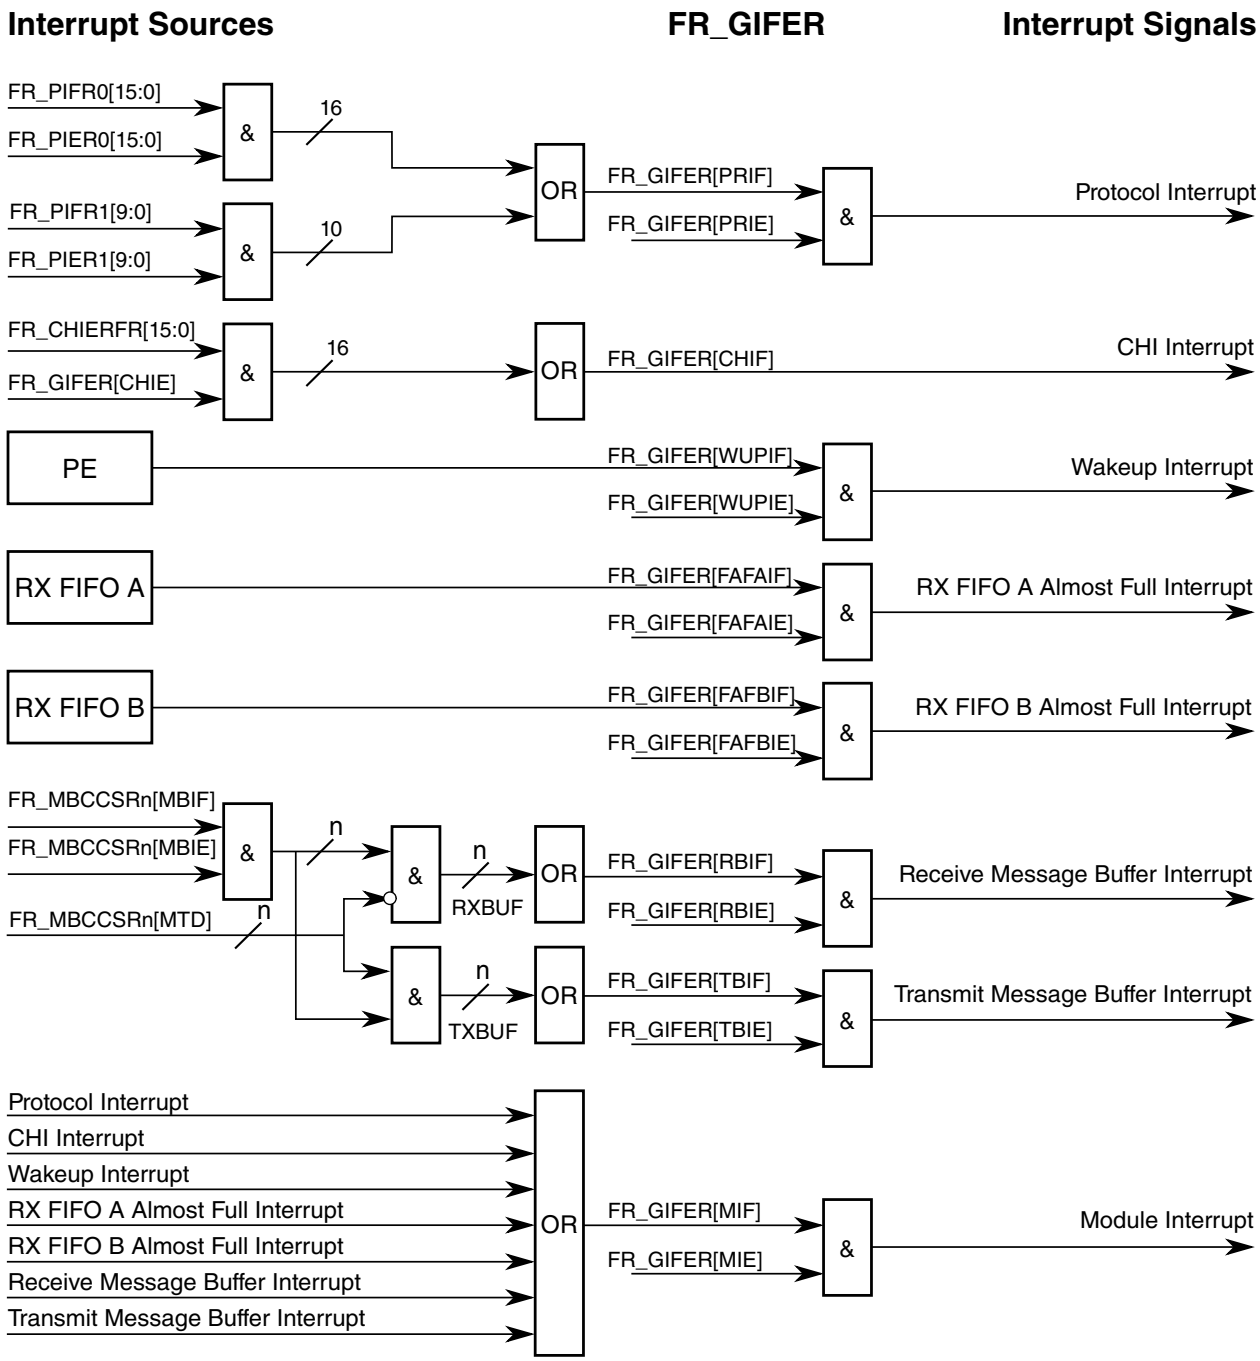

Figure 60-33. Scheme of FR_GIFER interrupt signal generation

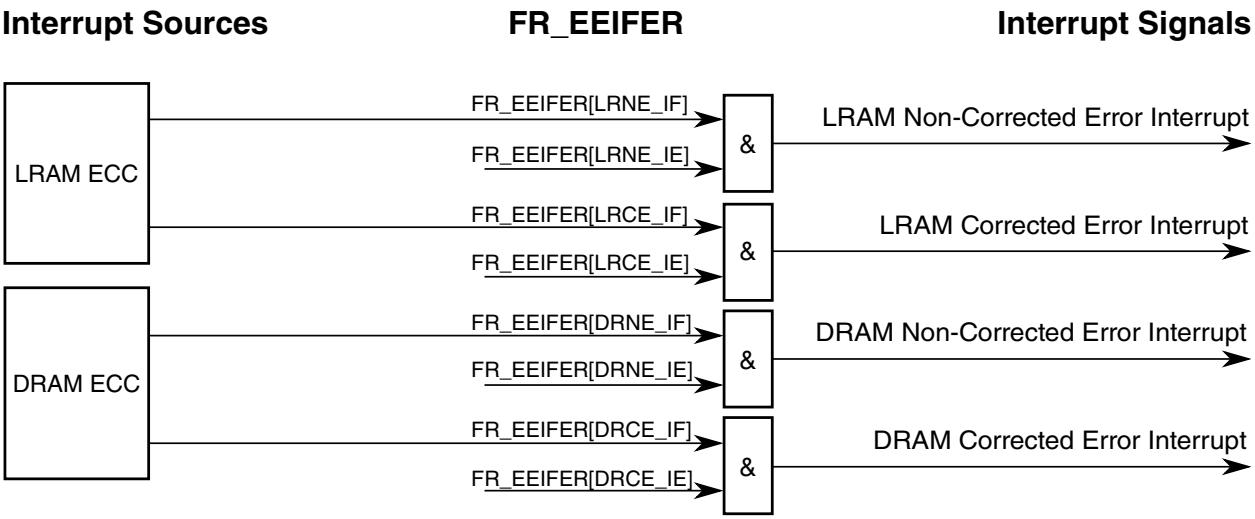

Figure 60-34. Scheme of FR_EEIFER interrupt signal generation

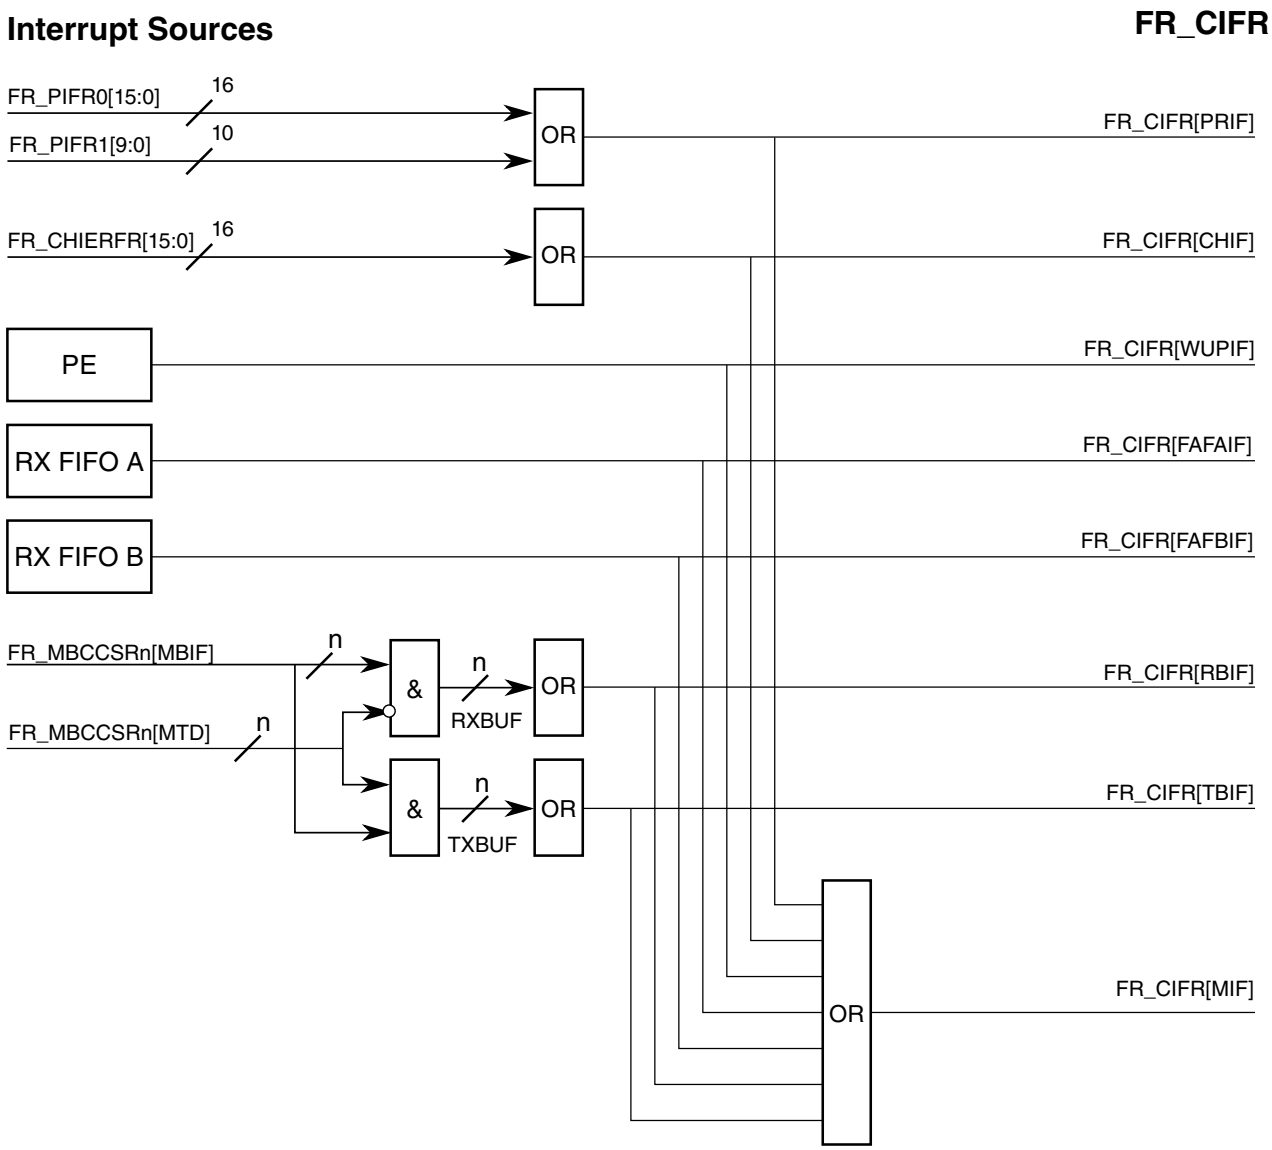

Figure 60-35. Scheme of FR_CIFR flags generation

60.8.21 Lower Bit Rate Support

The CC supports a number of lower bit rates on the FlexRay bus channels. The lower bit rates are implemented by modifying the duration of the microtick *pdMicrotick*, the number of samples per microtick *pSamplesPerMicrotick*, the number of samples per bit *cSamplesPerBit*, and the strobe offset *cStrobeOffset*. The application configures the FlexRay channel bit rate by setting the BITRATE field in the Module Configuration Register (FR_MCR). The protocol values are set internally. The available bit rates, the related BITRATE field configuration settings and related protocol parameter values are shown in the "FlexRay Channel Bit Rate Control" table below.

Table 60-56. FlexRay Channel Bit Rate Control

FlexRay Channel Bit Rate [Mbit/s]	FR_MCR[BITRATE]	*pdMicrotick [ns]*	*gdSampleClockPeriod [ns]*	*pSamplesPerMicrotick*	*cSamplesPerBit*	*cStrobeOffset*
10.0	000	25.0	12.5	2	8	5
8.0	011	25.0	12.5	2	10	6
5.0	001	25.0	25.0	1	8	5
2.5	010	50.0	50.0	1	8	5

Note

The bit rate of 8 Mbit/s is not defined by the *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*.

60.8.22 PE Data Memory (PE DRAM)

The PE Data Memory (PE DRAM) is 128 word, 16-bit wide memory with byte access, which contains the program data of the PE internal CPU. The PE DRAM is divided into two banks, 8-bit each. The memory data [7:0] are assigned to BANK0, the memory data [15:8] are assigned to BANK1.

Table 60-57. PE DRAM Layout

ADDR	BANK1	BANK0
0x00	byte1	byte0
0x01	byte3	byte2
…		
0x7F	byte255	byte254

The FlexRay module provides means to access the PE DRAM from the application. The PE DRAM application access is initiated and controlled via PE DRAM Access Register (FR_PEDRAR) and PE DRAM Access Register (FR_PEDRAR). This functionality is used to check the memory error detection.

60.8.22.1 PE DRAM Read Access

A read access from the PE DRAM can be initiated in any protocol state. The following sequence describes a read access from the PE DRAM address 0x70.

1. FR_PEDRAR:= 0x50E0;

   // INST=0x5; ADDR=070

2. wait until FR_PEDRAR[DAD] == 1;

   // wait for end of PE DRAM access

3. val = FR_PEDRDR[DATA];

   // read PE DRAM data

The read access is handled by the PE internal CPU with the lowest execution priority. This may cause an response delay with a maximum of 1000 PE clock cycle (25us).

60.8.22.2 PE DRAM Write Access

A write access into the PE DRAM can be initiated in any protocol state. The following sequence describes a write access to the PE DRAM address 0x70.

1. FR_PEDRDR:= DATA;

   // write value to be written into data register

2. FR_PEDRAR:= 0x30E0;

   // INST=0x3; ADDR=0x70

3. wait until FR_PEDRAR[DAD] == 1;

   // wait for end of PE DRAM access

4. val = FR_PEDRDR[DATA];

   // read back PE DRAM data

The write access is handled by the PE internal CPU with the lowest execution priority. This may causes an response delay with a maximum of 1000 PE clock cycle (25us).

If the conditions given in PE DRAM Write Access Limitations are fulfilled, the data provided in PE DRAM Access Regsiter (FR_PEDRAR) are written into the PE DRAM, read back in the next clock cycle and stored into the PE DRAM Access Register (FR_PEDRAR). Otherwise, data are not written into the PE DRAM and 0x0000 is stored into the PE DRAM Access Register (FR_PEDRAR).

60.8.22.3 PE DRAM Write Access Limitations

The PE DRAM is used by the protocol engine if the module is not in *POC:default config* state. The only address not used by the protocol engine is 0x70. To prevent the corruption of protocol engine data the following PE DRAM write access limitations apply for application writes.

1. When the module is in *POC:default config* state, all PE DRAM addresses are writable.
2. When the module is not *in POC:default config* state, only PE DRAM address 0x70 is writable.

60.8.23 CHI Lookup-Table Memory (CHI LRAM)

The CHI Lookup-Table Memory (CHI LRAM) is an CHI internal memory which contains the message buffer configuration data and the data field offsets for the physical message buffers. The configuration data for two message buffers or 6 data field offsets are contained in one memory row. The CHI LRAM is divided into 6 memory BANKs.

Table 60-58. CHI LRAM Layout

ADR	BANK5	BANK4	BANK3	BANK2	BANK1	BANK0
0x00	FR_MBIDXR1	FR_MBFIDR1	FR_MBCCFR1	FR_MBIDXR0	FR_MBFIDR0	FR_MBCCFR0
0x01	FR_MBIDXR3	FR_MBFIDR3	FR_MBCCFR3	FR_MBIDXR2	FR_MBFIDR2	FR_MBCCFR2
…						
0x3F	FR_MBIDXR127	FR_MBFIDR127	FR_MBCCFR127	FR_MBIDXR126	FR_MBFIDR126	FR_MBCCFR126
0x40	FR_MBDOR5	FR_MBDOR4	FR_MBDOR3	FR_MBDOR2	FR_MBDOR1	FR_MBDOR0
…						
0x55	FR_MBDOR131	FR_MBDOR130	FR_MBDOR129	FR_MBDOR128	FR_MBDOR127	FR_MBDOR126
0x56	FR_LEETR5	FR_LEETR4	FR_LEETR3	FR_LEETR2	FR_LEETR1	FR_LEETR0

60.8.23.1 CHI LRAM Read and Write Access

The CHI LRAM is accessed by the application via regular register read and write accesses.

60.8.24 Memory Content Fault Detection

The FlexRay module provides integrated memory content error detection for both the CHI LRAM and PE DRAM, and memory content error correction for the PE DRAM. The memory error detection for the CHI LRAM uses an standard Hamming code with a Hamming distance of 3 and detects all single-bit and double-bit errors (SEDDED) . The memory error detection and correction for the PE DRAM uses an enhanced Hamming code with a Hamming distance of 4 and detects and corrects all single-bit errors and detects all double-bit errors (SECDED).

This section describes the reporting of the occurrence of memory content errors, the reaction of the module on the occurrence, and how the application can inject memory errors in order to trigger the report and response behavior.

60.8.24.1 Memory Error Types

A memory error is the distortion of one or more bits read out of the memory. The reading of the values of all zeros and all ones is considered as an special case. The FlexRay module detects and indicates the memory errors as shown in the "Detected Memory Error Types" table below. The entries on the top have higher priority.

Each memory read access reads out *all* banks of the addressed row, and runs error detection on *all* banks, even in the case that the application has triggered a read from only one bank. This may lead to the reporting of an memory error if at least one bank contains a memory error, even if an error free bank has been read.

Table 60-59. Detected Memory Error Types

Memory	Priority	Memory Data	Indication
CHI LRAM	0 (highest)	All Zero's	Non-Corrected Error
PE DRAM			Non-Corrected Error
CHI LRAM		All One's	Non-Corrected Error
PE DRAM			
CHI LRAM	1 (lowest)	One Bit Flipped	Non-Corrected Error
PE DRAM			Corrected Error

Table continues on the next page...

Table 60-59. Detected Memory Error Types (continued)

Memory	Priority	Memory Data	Indication
CHI LRAM		Two Bits Flipped	Non-Corrected Error
PE DRAM			
CHI LRAM		Three or more Bits Flipped	one out of {No error, Non-Corrected Error}, defined by coding given in CHI LRAM Checkbits and CHI LRAM Syndrome
PE DRAM			one out of {No error, Corrected Error, Non-Corrected Error}, defined by coding given in PE DRAM Checkbits and PE DRAM Syndrome

60.8.24.2 Memory Error Reporting

The memory error reporting is enabled only if the ECC functionality enable bit ECCE in the Module Configuration Register (FR_MCR) is set.

For each of the two memories exists two sets of internal registers to store the detection of one corrected and one non-corrected memory error.

If a memory error is detected, the module checks whether the related error interrupt flag in the ECC Error Interrupt Flag and Enable Register (FR_EEIFER) is set.

- *If the error interrupt flag is set, the related internal error reporting register is not updated and the related error overflow flag is set to 1 to indicate a loss of error condition.*
- *If the error interrupt flag is not set, the internal reporting register is updated and the error interrupt flag is set to 1. If two or more memory errors of the same type are detected, the error for the bank with the lower bank number will be reported, and the error overflow flag will be set to 1.*

If a memory error is detected for at least two banks of one memory, the related error overflow flag is set to 1 to indicate a loss of error condition.

In addition to above the Error indications (corrected / non corrected) along with the failing address is sent out from the module for external error logging and corrective actions by the Software.

60.8.24.2.1 PE DRAM Checkbits

The coding of the checkbits reported in ECC Error Report Code Register (FR_EERCR) for PE DRAM memory errors is shown in Table 60-59. This table shows the implemented enhanced Hamming code. If the error injection was applied to distort the checkbits, then the distorted checkbits are reported.

Table 60-60. PE DRAM checkbits coding

CODE	CODE				DATA							
	3	2	1	0	7	6	5	4	3	2	1	0
4[1]	X	X	X	X	X	X	X	X	X	X	X	X
3[2]	-	-	-	-	X	X	X	X	-	-	-	-
2	-	-	-	-	X	-	-	-	X	X	X	-
1	-	-	-	-	-	X	X	-	X	X	-	X
0	-	-	-	-	-	X	-	X	X	-	X	X

1. The checkbit CODE[4] is set to 1 if and only if there is a even number of 1's in columns with X.
2. The checkbits CODE[3]… CODE[0] are set to 1 if and only if there is a odd number of 1's in all columns with X.

This coding of the checkbit ensures that neither 0x000 nor 0xFFF are valid code words and written into the memory.

60.8.24.2.2 PE DRAM Syndrome

The coding of the syndrome reported in ECC Error Report Code Register (FR_EERCR) for PE DRAM memory errors is shown in the following table.

Table 60-61. FR_EERCR[CODE] PE DRAM Syndrome Coding

FR_EERCR[CODE]		Description
[4]	[3:0]	
0x1	0x0	No Error (Never appears in error report registers)
0x0	0x0	If data == 0: Non Corrected Error (Dedicated Handling of All Zero Code Word) If data!= 0: Corrected Error (Parity Bit 4)
0x0	0x1	Corrected Error (Parity Bit 0)
0x0	0x2	Corrected Error (Parity Bit 1)
0x0	0x3	Corrected Error (Data Bit 0)
0x0	0x4	Corrected Error (Parity Bit 2)
0x0	0x5	Corrected Error (Data Bit 1)
0x0	0x6	Corrected Error (Data Bit 2)
0x0	0x7	Corrected Error (Data Bit 3)
0x0	0x8	Corrected Error (Parity Bit 3)
0x0	0x9	Corrected Error (Data Bit 4)

Table continues on the next page...

Table 60-61. FR_EERCR[CODE] PE DRAM Syndrome Coding (continued)

FR_EERCR[CODE]		Description
[4]	[3:0]	
0x0	0xA	Corrected Error (Data Bit 5)
0x0	0xB	Corrected Error (Data Bit 6)
0x0	0xC	Corrected Error (Data Bit 7)
0x0	0xD-0xF	Non-Corrected Error
0x1	0x1-0xF	Non-Corrected Error

60.8.24.2.3 CHI LRAM Checkbits

The coding of the checkbits reported in ECC Error Report Code Register (FR_EERCR) for CHI LRAM memory errors is shown in the table below. This table shows the implemented Hamming code. If the error injection was applied to distort the checkbits, then the distorted checkbits are reported.

Table 60-62. CHI LRAM checkbits coding

CODE[1]	DATA															
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
4	X	X	X	X	X	-	-	-	-	-	-	-	-	-	-	-
3	-	-	-	-	-	X	X	X	X	X	X	X	-	-	-	-
2	X	X	-	-	-	X	X	X	X	-	-	-	X	X	X	-
1	-	-	X	X	-	X	X	-	-	X	X	-	X	X	-	X
0	X	-	X	-	X	X	-	X	-	X	-	X	X	-	X	X

1. The checkbit CODE[n] is set to 1 if and only if there is a odd number of 1's in all columns with X.

60.8.24.2.4 CHI LRAM Syndrome

The coding of the syndrome reported in ECC Error Report Code Register (FR_EERCR) for CHI LRAM memory errors is shown in the next table.

Table 60-63. FR_EERCR[CODE] CHI LRAM Syndrome Coding

FR_EERCR[CODE]	Description
0x00	No Error (Never appears in error report registers)
0x01-0x1F	Non Corrected Error

60.8.24.3 Memory Error Response

The memory error response is enabled only when the ECC functionality enable bit ECCE in the Module Configuration Register (FR_MCR) is set.

In case of the detection of a *corrected* memory error, the FlexRay module continues its normal operation using the corrected data word. This section describes the behavior of the FlexRay module after the detection of a *non-corrected* memory error.

60.8.24.3.1 CHI LRAM Error Response after CC Read

When the CC is out of the *POC:default config* state, it reads the configuration data and the data field offsets of all utilized message buffers in every slot and in the NIT. If a non-corrected memory error is detected during this module read access the error response of the module depends from LRAM location where the error occurred.

- *If the LRAM address belongs to physical message buffer configuration data the FlexRay module will consider the affected message buffer as disabled for the current search and will exclude this buffer from the search. The configuration of the affected message buffer is not changed.*

  If the affected message buffer is a tx message buffer, no frame will be transmitted from this message buffer in the next slot. If the affected message buffer is a rx message buffer, no frame will be received to this message buffer in the next slot.

- *If the LRAM address belongs to the data field offset area and the related physical message buffer is used for Rx or Tx the first access to the system memory caused by payload read or write yields to the assertion of the FR_CHIERFR[ILSA_EF]. No memory access occurs w.r.t. payload access is performed for the complete frame.*

60.8.24.3.2 CHI LRAM Error Response after Application Read

The application can read the content of the CHI LRAM via reading the FR_MBCCFRn, FR_MBFIDRn, FR_MBIDXRn, FR_MBDORn, and FR_LEETRn registers. If a non-corrected memory error is detected during this kind of read access, the module indicates the detected memory error, delivers the non-corrected data read and continues its normal operation.

60.8.24.3.3 PE DRAM Error Response after CC Read

If the CC detects an non-corrected memory error during internal read of program data which is contained in PE DRAM, this is considered as an fatal protocol error and the module enters the protocol freeze state immediately.

60.8.24.3.4 PE DRAM Error Response after Application Read in *POC:default config* state

If the CC detects an non-corrected memory error during an application triggered read from any PE DRAM address and the protocol is in the *POC:default config* state, this is considered as an fatal protocol error and the module enters the protocol freeze state. This behavior allows for checking the freeze functionality in case of the detection of non-corrected errors.

60.8.24.3.5 PE DRAM Error Response after Application Read out of *POC:default config*

If the CC detects an non-corrected memory error during an application triggered read from any PE DRAM address, and the protocol is not in the *POC:default config* state, this error is not considered as an fatal error and the protocol state is not changed. This prevents any interference of the running protocol by PE DRAM error injection reads.

60.8.25 Memory Fault Injection

The error injection functionality is used by the application to inject data errors into the memories to trigger and check the memory error detection functionality.

The error injection is enabled only if the ECC functionality enable bit ECCE in the Module Configuration Register (FR_MCR) and the error injection enable control bit EIE in the ECC Error Report and Injection Control Register (FR_EERICR) are set.

The error injection mode is configured by the EIM configuration bit in the ECC Error Report and Injection Control Register (FR_EERICR).

When the error injection is enabled, each write access to the configured memory location will be distorted.

The injector has the same behavior for FlexRay module memory writes and application memory writes.

60.8.25.1 CHI LRAM Error Injection

The following sequence describes an memory error injection sequence for the CHI LRAM memory. This sequence consists of the setup of the error injector followed by an application triggered write access to provoke an distortion of the memory content. The content of the CHI LRAM is described in Table 60-58.

When the CC is in *POC:default config*, there are no limitations for the error injection and no impacts of error injection to the application. For error injection out of *POC:default config* see Memory Fault Injection out of POC:default config.

Injector Setup:

1. FR_MCR[ECCE]:= 1;

   // enable ECC functionality

2. FR_EERICR[EIE]:=I_MODE;

   // configure error injection mode

3. FR_EEIAR[MID]:= 1;

   // select CHI LRAM for error injection

4. FR_EEIAR[BANK]:= I_BANK;

   // select bank for error injection; I_BANK = {0,1,2,3,4,5}

5. FR_EEIAR[ADDR]:= I_ADDR;

   // select address for error injection; I_ADDR <= 0x 56

6. FR_EEIDR[DATA]:= D_DIST;

   // define data distortion pattern

7. FR_EEICR[CODE]:= C_DIST;

   // define checkbit distortion pattern

8. FR_EERICR[EIE]:=1;

   // enable error injection

Application Write Access:

If (I_BANK==0) -> FR_MBCCFR(2n) / FR_MBDOR(6k) / FR_LEETR0 := DATA;

If (I_BANK==1) -> FR_MBFIDR(2n) / FR_MBDOR(6k+1) / FR_LEETR1 := DATA;

If (I_BANK==2) -> FR_MBIDXR(2n) / FR_MBDOR(6k+2) / FR_LEETR2 := DATA;

If (I_BANK==3) -> FR_MBCCFR(2n+1) / FR_MBDOR(6k+3) / FR_LEETR3 := DATA;

If (I_BANK==4) -> FR_MBFIDR(2n+1) / FR_MBDOR(6k+4) / FR_LEETR4 := DATA;

If (I_BANK==5) -> FR_MBIDXR(2n+1) / FR_MBDOR(6k+5) / FR_LEETR5 := DATA;

// write DATA to the defined injection bank and injection address (see Table 60-58).

60.8.25.2 PE DRAM Error Injection

The following sequence describes an memory error injection sequence for the PE DRAM memory. This sequence consists of the setup of the error injector followed by an application triggered write access to provoke an distortion of the memory content.

When the FlexRay module is in *POC:default config*, there are no limitations for the error injection and no impacts of error injection to the application. For error injection out of *POC:default config* see PE DRAM Error Injection out of POC:default config.

Injector Setup:

1. FR_MCR[ECCE]:= 1;

   // enable ECC functionality

2. FR_EERICR[EIE]:=I_MODE;

   // configure error injection mode

3. FR_EEIAR[MID]:= 0;

   // select PE DRAM for error injection

4. FR_EEIAR[BANK]:= I_BANK;

   // define bank for error injection; I_BANK = {0,1}

5. FR_EEIAR[ADDR]:= I_ADDR;

   // define address for error injection; I_ADDR <= 0x7F

6. FR_EEIDR[DATA]:= D_DIST;

   // define data distortion pattern

7. FR_EEICR[CODE]:= C_DIST;

   // define checkbit distortion pattern

8. FR_EERICR[EIE]:=1;

   // enable error injection

Application Write Access (e.g. I_ADDR=0x70):

1. FR_PEDRAR:= 0x30E0;

   // INST=0x3; ADDR=0x70

2. wait until FR_PEDRAR[DAD] == 1;

   // wait for end of PE DRAM access

3. val = FR_PEDRDR[DATA]; |

   // get read back PE DRAM data

Note

The write access to the PE DRAM triggers an subsequent read access from PE DRAM in the next cycle, which triggers the detection of the distorted data.

60.9 Application Information

Module operation is discussed in this section.

60.9.1 Module Configuration

This section describes essential parts of the module configuration.

60.9.1.1 Configure System Memory Access Time-Out Register (FR_SYMATOR)

To ensure reliable operation of the CC, the application must ensure that the TIMEOUT value in System Memory Access Time-Out Register (FR_SYMATOR) and the CHI clock frequency f_{CHI} in MHz fulfill this equation[1] :

$$0 \le \mathrm{SYMATOR}[\mathrm{TIMEOUT}] \le \lfloor 0.45 \cdot f_{\mathrm{CHI}} - 8 \rfloor$$

Equation 45

1. See Controller Host Interface Clocking for all constraints of minimum CHI clock frequency.

For a given SYMATOR[TIMEOUT] value, f_{CHI} can be increased without causing unreliable operation of the CC. The same holds for reducing the SYMATOR[TIMEOUT] value for a given f_{CHI}.

Some examples for maximum values of the SYMATOR[TIMEOUT] for a minimum CHI frequency are given in the table below.

Table 60-64. Maximum SYMATOR[TIMEOUT] examples

f_{CHI}	SYMATOR[TIMEOUT]	f_{CHI}	SYMATOR[TIMEOUT]
>= 18 MHz	0	>= 100 MHz	<= 37
>= 23 MHz	<= 2	>= 120 MHz	<= 46
>= 27 MHz	<= 4	>= 140 MHz	<= 55
>= 32 MHz	<= 6	>= 160 MHz	<= 64
>= 60 MHz	<= 19	>= 180 MHz	<= 73
>= 80 MHz	<= 28	>= 200 MHz	<= 82

60.9.1.1.1 System Bus Wait State Constraints

The SYMATOR[TIMEOUT] value corresponds directly to a certain acceptable number of wait states on the system bus.

For single channel configurations and if the sync frame table generation functionality is *not* used (FR_SFTCCSR[SDVEN,SIDEN] = 0) no timeout will be detected if less than 2 × SYMATOR[TIMEOUT]+1 wait states will be seen on the system bus for each system bus access.

For dual channel configurations, or if the sync frame table generation functionality is used, no timeout will be detected if less than SYMATOR[TIMEOUT]-1 wait states will be seen on the system bus for each system bus access.

60.9.1.2 Configure Data Field Offsets

The data field offsets are located in the Message Buffer Data Field Offset Registers (FR_MBDORn) and Receive FIFO Start Data Offset Register (FR_RFSDOR). The application has to configure the data field offset values for all message buffers which are used.

When the module is enabled, the initilization value of the FR_MBDORn[MBDO] and FR_RFSDOR[SDO] is 0. This value is considered to be illegal (see System Bus Illegal Address Access).

60.9.2 Initialization Sequence

This section describes the required steps to initialize the CC. The first subsection describes the steps required after a module reset, the second section describes the steps required after preceding shutdown of the CC.

60.9.2.1 Module Initialization

This section describes the module related initialization steps after a system reset.

1. Configure CC.
    a. configure the control bits in the Module Configuration Register (FR_MCR)
    b. configure the system memory base address in System Memory Base Address Register (FR_SYMBADR)
2. Enable the CC.
    a. write 1 to the module enable bit MEN in the Module Configuration Register (FR_MCR)

The CC now enters the Normal Mode. The application can commence with the protocol initialization described in Protocol Initialization.

60.9.2.2 Protocol Initialization

This section describes the protocol related initialization steps.

1. Configure the Protocol Engine.
    a. issue CONFIG command via Protocol Operation Control Register (FR_POCR)
    b. wait for *POC:config* in Protocol Status Register 0 (FR_PSR0)
    c. configure the FR_PCR0,…, FR_PCR30 registers to set all protocol parameters
2. Configure the Message Buffers and FIFOs.
    a. set the number of message buffers used and the message buffer segmentation in the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR)

b. define the message buffer data size in the Message Buffer Data Size Register (FR_MBDSR)

c. configure each message buffer by setting the configuration values in the Message Buffer Configuration, Control, Status Registers (FR_MBCCSRn), Message Buffer Cycle Counter Filter Registers (FR_MBCCFRn), Message Buffer Frame ID Registers (FR_MBFIDRn), Message Buffer Index Registers (FR_MBIDXRn)

d. configure the FIFOs

e. issue CONFIG_COMPLETE command via Protocol Operation Control Register (FR_POCR)

f. wait for *POC:ready* in Protocol Status Register 0 (FR_PSR0)

After this sequence, the CC is configured as a FlexRay node and is ready to integrate into the FlexRay cluster.

60.9.2.3 CHI LRAM Initialization

The initialization of the CHI LRAM is performed by the CC when it leaves the Disabled Mode. The unitization runs for 87 CHI clock cycles. All fields in the FR_MBCCSRn, FR_MBCCFRn, FR_MBFIDRn, FR_MBDORn, and LEETRn registers are initialized to 0. All application read or write accesses to these registers are delayed until the initialization is finished.

60.9.2.4 PE DRAM Initialization

The PE DRAM initialization is performed by the CC in the *POC:default config* state. This initialization runs for 4.8 µs, and will delay the state transition from *POC:default config* into *POC:config*.

60.9.3 Memory Fault Injection out of POC:default config

This section provides information for application driven memory fault injection out if *POC:default config*. The CC provides means to inject memory faults from the application without any impacts to the internal protocol operation of the CC.

60.9.3.1 CHI LRAM Error Injection out of POC:default config

The CC will never perform any internal read access from the LRAM ECC Error Test Registers (FR_LEETRn). Any memory errors injected into these CHI LRAM locations will never be detected by internal access, independent from the protocol state.

The application should use these registers and related CHI LRAM location to inject memory errors into the CHI LRAM. The injection sequence is described in CHI LRAM Error Injection.

60.9.3.2 PE DRAM Error Injection out of POC:default config

The CC will never perform any internal read access from the PE DRAM address 0x70. This is the only one PE DRAM address writable by the application out of the *POC:default config* state.

The application should use these PE DRAM location to inject memory errors into the PE DRAM. The injection sequence is described in PE DRAM Error Injection.

60.9.4 Shut Down Sequence

This section describes a secure shut down sequence to stop the CC gracefully. The main targets of this sequence are

- *finish all ongoing reception and transmission*
- *do not corrupt FlexRay bus and do not disturb ongoing FlexRay bus communication*

For a graceful shutdown the application shall perform the following tasks:

1. Disable all enabled message buffers.
   a. repeatedly write 1 to FR_MBCCSRn[EDT] until FR_MBCCSRn[EDS] == 0.
2. Stop Protocol Engine.
   a. issue HALT command via Protocol Operation Control Register (FR_POCR)
   b. wait for *POC:halt* in Protocol Status Register 0 (FR_PSR0)

60.9.5 Number of Usable Message Buffers

This section describes the required minimum CHI clock frequency for a specified number of utilized message buffers configured in the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR), a configured mini-slot length *gdMinislot*, and a configured nominal macrotick length *gdMacrotick*[1].

Additional constraints for the minimum CHI clock frequency are given in Controller Host Interface Clocking.

The CC uses a sequential search algorithm to determine the individual message buffer assigned or subscribed to the next slot. This search is started at the start of slot and must be finished before the start of the next slot.

The shortest FlexRay slot is a corrected empty dynamic slot. An corrected empty dynamic slot is a mini-slot and consists of gdMinislot corrected macroticks with a duration of *gdMacrotick*. The minimum duration of an corrected macrotick is $gdMacrotick_{min}$ = 39 µT. This results in a minimum length of an correct slot

$$\Delta_{slotmin} = 39 \bullet pdMicrotick \bullet gdMinislot$$

Equation 46

The message buffer search engine runs on the CHI clock and evaluates one individual message buffer per CHI clock cycle. For internal status update operations and to account for clock domain crossing jitter, an additional amount of 27 CHI clock cycles is required to ensure correct search engine operation.

For a given number of utilized message buffers FR_MBSSUTR[LAST_MB_UTIL] + 1 and for a given CHI clock frequency f_{chi}, this results in a search duration of

$$\Delta_{search} = \frac{1}{f_{chi}} \bullet (FR\_MBSSUTR[LAST\_MB\_UTIL] + 27)$$

Equation 47

The message buffer search must be finished within one slot which requires fulfillment of this equation::

$$\Delta_{search} \leq \Delta_{slotmin}$$

Equation 48

This results in the formula given below which determines the required minimum CHI frequency for a given number of message buffers that are utilized.

1. See Controller Host Interface Clocking for all constraints of minimum CHI clock frequency.

$$f_{chi} \geq \frac{(FR\_MBSSUTR[LAST\_MB\_UTIL]+27)}{39 \cdot pdMicrotick \cdot gdMinislot}$$

Equation 49

The required minimum CHI Clock frequency for a selected set of relevant protocol parameters and for the LAST_MB_UTIL field in the Message Buffer Segment Size and Utilization Register (FR_MBSSUTR) set to 127 is given in the following table.

Table 60-65. Minimum fchi [MHz] examples (128 message buffers used)

pdMicrotick [ns]	*gdMinislot*					
	2	**3**	**4**	**5**	**6**	**7**
25.0	79.5	53	39.8	31.8	26.5	22.8
50.0	39.8	26.5	19.9	15.9	13.3	11.4

Note

If the minimum CHI frequency is not met the CHIERFR[MBS_EF] flag is set. Refer to the CHI Error Flag Register (FR_CHIERFR) for details.

60.9.6 Protocol Control Command Execution

This section considers the issues of the protocol control command execution.

The application issues any of the protocol control commands listed in the POCCMD field of the FR_POCR Field Descriptions table, located in the Register Descriptions section, by writing the command to the POCCMD field of the Protocol Operation Control Register (FR_POCR). As a result the CC sets the BSY bit while the command is transferred to the PE. When the PE has accepted the command, the BSY flag is cleared. All commands are accepted by the PE.

The PE maintains a protocol command vector. For each command that was accepted by the PE, the PE sets the corresponding command bit in the protocol command vector. If a command is issued while the corresponding command bit is set, the command is not queued and is lost.

If the command execution block of the PE is idle, it selects the next accepted protocol command with the highest priority from the current protocol command vector according to the protocol control command priorities given in the next table. If the current protocol state does not allow the execution of this protocol command (see POC state changes in *FlexRay Communications System Protocol Specification, Version 2.1 Rev A*) the CC asserts the illegal protocol command interrupt flag IPC_IF in the Protocol Interrupt Flag Register 1 (FR_PIFR1). The protocol command is not executed in this case.

Some protocol commands may be interrupted by other commands or the detection of a fatal protocol error as indicated by the table below. If the application issues the FREEZE or READY command, or if the PE detects a fatal protocol error, some commands already stored in the command vector will be removed from this vector.

Table 60-66. Protocol Control Command Priorities

Protocol Command	Priority	Interrupted By	Cleared and Terminated By
FREEZE	(highest) 1	none	
READY	2		
CONFIG_COMPLETE	3		
ALL_SLOTS	4	FREEZE, READY, CONFIG_COMPLET, fatal protocol error	FREEZE, READY, CONFIG_COMPLETE,fatal protocol error
ALLOW_COLDSTART	5		
RUN	6		FREEZE, fatal protocol error
WAKEUP	7		FREEZE, fatal protocol error
DEFAULT_CONFIG	8		FREEZE, fatal protocol error
CONFIG	9		
HALT	(lowest) 10		FREEZE, READY, CONFIG_COMPLETE,fatal protocol error

60.9.7 Message Buffer Search On Simple Message Buffer Configuration

This sections describes the message buffer search behavior for a simplified message buffer configuration. The FIFO behavior is not considered in this section.

60.9.7.1 Simple Message Buffer Configuration

A simple message buffer configuration is a configuration that has at most one transmit message buffer and at most one receive message buffer assigned to a slot *S*. The simple configuration used in this section utilizes two message buffers, one single buffered transmit message buffer and one receive message buffer.

The transmit message buffer has the message buffer number *t* and has following configuration

Table 60-67. Transmit Buffer Configuration

Register	Field	Value	Description
FR_MBCCSR*t*	MTD	1	transmit buffer

Table continues on the next page...

Table 60-67. Transmit Buffer Configuration (continued)

Register	Field	Value	Description
FR_MBCCFR*t*	MTM	0	event transition mode
	CHA	1	assigned to channel A
	CHB	0	not assigned to channel B
	CCFE	1	cycle counter filter enabled
	CCFMSK	000011	cycle set = {4n} = {0,4,8,12,…}
	CCFVAL	000000	
FR_MBFIDR*t*	FID	*S*	assigned to slot S

The availability of data in the transmit buffer is indicated by the commit bit FR_MBCCSRt[CMT] and the lock bit FR_MBCCSRt[LCKS].

The receive message buffer has the message buffer number r and has following configuration

Table 60-68. Receive Buffer Configuration

Register	Field	Value	Description
FR_MBCCSR*r*	MTD	0	receive buffer
FR_MBCCFR*r*	MTM	-	n/a
	CHA	1	assigned to channel A
	CHB	0	not assigned to channel B
	CCFE	1	cycle counter filter enabled
	CCFMSK	000001	cycle set = {2n} = {0,2,4,6,…}
	CCFVAL	000000	
FR_MBFIDR*r*	FID	*S*	subscribed slot

Furthermore the assumption is that both message buffers are enabled (FR_MBCCSRt[EDS] = 1 and FR_MBCCSRr[EDS] = 1)

Note

The cycle set {4n+2} = {2,6,10,…} is assigned to the receive buffer only.

The cycle set {4n} = {0,4,8,12,…} is assigned to both buffers.

60.9.7.2 Behavior in static segment

In this case, both message buffers are assigned to a slot *S* in the *static* segment.

The configuration of a transmit buffer for a static slot *S* assigns this slot to the node as a transmit slot. The FlexRay protocol requires:

- When a slot occurs, if the slot is assigned to a node on a channel that node must transmit either a normal frame or a null frame on that channel. Specifically, a null frame will be sent if there is no data ready, or if there is no match on a transmit filter (cycle counter filtering, for example).

Regardless of the availability of data and the cycle counter filter, the node will transmit a frame in the static slot *S*. In any case, the result of the message buffer search will be the transmit message buffer *t*. The receive message buffer *r* will not be found, no reception is possible.

60.9.7.3 Behavior in dynamic segment

In this case, both message buffers are assigned to a slot *S* in the *dynamic* segment. The FlexRay protocol requires:

- When a slot occurs, if a slot is assigned to a node on a channel that node only transmits a frame on that channel if there is data ready and there is a match on relevant transmit filters (no null frames are sent).

The transmission of a frame in the dynamic segment is determined by the availability of data and the match of the cycle counter filter of the transmit message buffer.

60.9.7.3.1 Transmit Data Not Available

If transmit data are *not available*, i.e. the transmit buffer is not committed FR_MBCCSR*t*[CMT]=0 and/or locked FR_MBCCSR*t*[LCKS]=1,

1. for the cycles in the set {4n}, which is assigned to both buffers, the receive buffer will be found and the node can receive data, and
2. for the cycles in the set {4n+2}, which is assigned to the receive buffer only, the receive buffer will be found and the node can receive data.

The receive cycles are shown in the following figure.

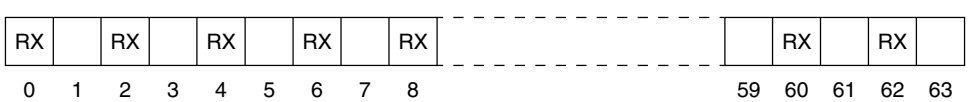

Figure 60-36. Transmit Data Not Available

60.9.7.3.2 Transmit Data Available

If transmit data are *available*, i.e. the transmit buffer is committed FR_MBCCSR*t*[CMT]=1 and not locked FR_MBCCSR*t*[LCKS]=0,

1. for the cycles in the set {4n}, which is assigned to both buffers, the transmit buffer will be found and the node transmits data.
2. for the cycles in the set {4n+2}, which is assigned to the receive buffer only, the receive buffer will be found and the node can receive data.

The receive and transmit cycles are shown in the following figure.

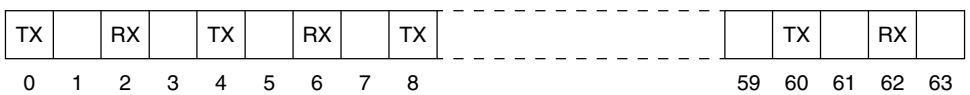

Figure 60-37. Transmit Data Available

Chapter 61
Ethernet MAC (ENET)

61.1 Chip-specific ENET information

61.1.1 ENET Register accesses

Always configure ENET registers before configuring RGMII pads. The ENET registers cannot be accessed in user mode until at least one supervisor-mode access is made to the ENET module and then the register protection user access allowed bit (REG_PROT_GCR[UAA]) is programmed. See the Register Protection chapter for more details on user access enabling of protected registers.

61.1.2 IEEE1588 (Ethernet PTP) to eTimer synchronization

The following tables lists IEEE1588 Ethernet timer input events and output events.

NOTE

For details on the PADS listed in the following tables, refer the device I/O Signal Description and Input Multiplexing Tables (Excel file) attached to this document.

Table 61-1. IEEE 1588 Ethernet timer input connectivity

Input module	Input signal	Driving module	Driver signal
ENET	TIMER0	eTIMER1	TIMER7
ENET	TIMER1	From PAD	-
ENET	TIMER2	CTE	RCS
ENET	TIMER3	CTE	RFS

Table 61-2. IEEE 1588 Ethernet timer output connectivity

Output module	Output signal	Target module	Target signal
ENET	TIMER0	To PAD	-
ENET	TIMER1	To PAD	-
ENET	TIMER2	To PAD	-
ENET	TIMER3	eTIMER1, eTIMER2	AUX_TMR6

61.1.3 ENET Interrupt mapping

Table 61-3. ENET Interrupt mapping

Interrupt name	Description	Interrupt slot

61.1.4 Overview

This chapter will be made available in the next release of this reference manual.

61.2 Introduction

The MAC-NET core, in conjunction with a 10/100/1000[1]-Mbit/s MAC, implements layer 3 network acceleration functions. These functions are designed to accelerate the processing of various common networking protocols, such as IP, TCP, UDP, and ICMP, providing wire speed services to client applications.

61.3 Overview

The core implements a triple-speed 10/100/1000[1]-Mbit/s Ethernet MAC compliant with the IEEE802.3-2002 standard. The MAC layer provides compatibility with half- or full-duplex 10/100-Mbit/s and full-duplex gigabit[1] Ethernet LANs.

The MAC operation is fully programmable and can be used in Network Interface Card (NIC), bridging, or switching applications. The core implements the remote network monitoring (RMON) counters according to IETF RFC 2819.

The core also implements a hardware acceleration block to optimize the performance of network controllers providing TCP/IP, UDP, and ICMP protocol services. The acceleration block performs critical functions in hardware, which are typically implemented with large software overhead.

The core implements programmable embedded FIFOs that can provide buffering on the receive path for lossless flow control.

Advanced power management features are available with magic packet detection and programmable power-down modes.

A unified DMA (uDMA), internal to the ENET module, optimizes data transfer between the ENET core and the SoC, and supports an enhanced buffer descriptor programming model to support IEEE 1588 functionality.

The programmable Ethernet MAC with IEEE 1588 integrates a standard IEEE 802.3 Ethernet MAC with a time-stamping module. The IEEE 1588 standard provides accurate clock synchronization for distributed control nodes for industrial automation applications.

1. Actual throughput is greater than 100 Mbit/s but significantly less than 1000 Mbit/s.

61.3.1 Features

61.3.1.1 Ethernet MAC features

- Implements the full 802.3 specification with preamble/SFD generation, frame padding generation, CRC generation and checking
- Supports zero-length preamble
- Dynamically configurable to support 10/100-Mbit/s and gigabit[2] operation
- Supports 10/100 Mbit/s full-duplex and configurable half-duplex operation
- Supports gigabit[2] full-duplex operation
- Compliant with the AMD magic packet detection with interrupt for node remote power management
- Seamless interface to commercial ethernet PHY devices via one of the following:
  - a 4-bit Media Independent Interface (MII) operating at 2.5/25 MHz.
  - a 4-bit non-standard MII-Lite (MII without the CRS and COL signals) operating at 2.5/25 MHz.
  - a 2-bit Reduced MII (RMII) operating at 50 MHz.
- Simple 64-Bit FIFO user-application interface
- CRC-32 checking at full speed with optional forwarding of the frame check sequence (FCS) field to the client
- CRC-32 generation and append on transmit or forwarding of user application provided FCS selectable on a per-frame basis
- In full-duplex mode:
  - Implements automated pause frame (802.3 x31A) generation and termination, providing flow control without user application intervention
  - Pause quanta used to form pause frames — dynamically programmable
  - Pause frame generation additionally controllable by user application offering flexible traffic flow control
  - Optional forwarding of received pause frames to the user application
  - Implements standard flow-control mechanism
- In half-duplex mode: provides full collision support, including jamming, backoff, and automatic retransmission
- Supports VLAN-tagged frames according to IEEE 802.1Q
- Programmable MAC address: Insertion on transmit; discards frames with mismatching destination address on receive (except broadcast and pause frames)
- Programmable promiscuous mode support to omit MAC destination address checking on receive

2. Actual throughput is greater than 100 Mbit/s but significantly less than 1000 Mbit/s.

- Multicast and unicast address filtering on receive based on 64-entry hash table, reducing higher layer processing load
- Programmable frame maximum length providing support for any standard or proprietary frame length
- Statistics indicators for frame traffic and errors (alignment, CRC, length) and pause frames providing for IEEE 802.3 basic and mandatory management information database (MIB) package and remote network monitoring (RFC 2819)
- Simple handshake user application FIFO interface with fully programmable depth and threshold levels
- Provides separate status word for each received frame on the user interface providing information such as frame length, frame type, VLAN tag, and error information
- Multiple internal loopback options
- MDIO master interface for PHY device configuration and management supports two programmable MDIO base addresses, and standard (IEEE 802.3 Clause 22) and extended (Clause 45) MDIO frame formats
- Supports legacy FEC buffer descriptors
- Interrupt coalescing reduces the number of interrupts generated by the MAC, reducing CPU loading

61.3.1.2 IP protocol performance optimization features

- Operates on TCP/IP and UDP/IP and ICMP/IP protocol data or IP header only
- Enables wire-speed processing
- Supports IPv4 and IPv6
- Transparent passing of frames of other types and protocols
- Supports VLAN tagged frames according to IEEE 802.1q with transparent forwarding of VLAN tag and control field
- Automatic IP-header and payload (protocol specific) checksum calculation and verification on receive
- Automatic IP-header and payload (protocol specific) checksum generation and automatic insertion on transmit configurable on a per-frame basis
- Supports IP and TCP, UDP, ICMP data for checksum generation and checking
- Supports full header options for IPv4 and TCP protocol headers
- Provides IPv6 support to datagrams with base header only — datagrams with extension headers are passed transparently unmodifed/unchecked

- Provides statistics information for received IP and protocol errors
- Configurable automatic discard of erroneous frames
- Configurable automatic host-to-network (RX) and network-to-host (TX) byte order conversion for IP and TCP/UDP/ICMP headers within the frame
- Configurable padding remove for short IP datagrams on receive
- Configurable Ethernet payload alignment to allow for 32-bit word-aligned header and payload processing
- Programmable store-and-forward operation with clock and rate decoupling FIFOs

61.3.1.3 IEEE 1588 features

- Supports all IEEE 1588 frames.
- Allows reference clock to be chosen independently of network speed.
- Software-programmable precise time-stamping of ingress and egress frames
- Timer monitoring capabilities for system calibration and timing accuracy management
- Precise time-stamping of external events with programmable interrupt generation
- Programmable event and interrupt generation for external system control
- Supports hardware- and software-controllable timer synchronization.
- Provides a 4-channel IEEE 1588 timer. Each channel supports input capture and output compare using the 1588 counter.

61.3.2 Block diagram

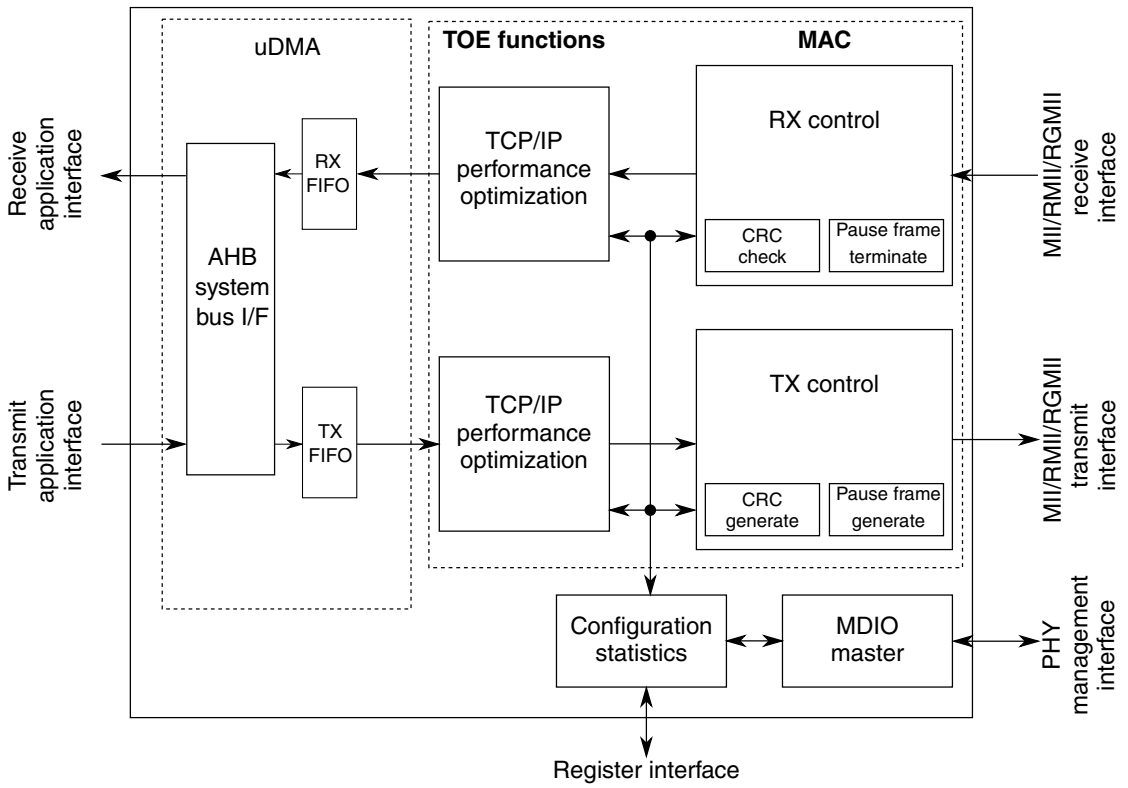

Figure 61-1. Ethernet MAC-NET core block diagram

61.4 External signal description

NOTE

The MII column pertains only to devices that support MII.

MII	RMII	RGMII	Description	I/O
MII_COL	—	—	Asserted upon detection of a collision and remains asserted while the collision persists. This signal is not defined for full-duplex mode.	I
MII_CRS	—	—	Carrier sense. When asserted, indicates transmit or receive medium is not idle. In RMII mode, this signal is present on the RMII_CRS_DV pin.	I

Table continues on the next page...

MII	RMII	RGMII	Description	I/O
MII_MDC	RMII_MDC	RGMII_MDC	Output clock provides a timing reference to the PHY for data transfers on the MDIO signal.	O
MII_MDIO	RMII_MDIO	RGMII_MDIO	Transfers control information between the external PHY and the media-access controller. Data is synchronous to MDC. This signal is an input after reset.	I/O
MII_RXCLK	—	RGMII_RXC	In MII mode, provides a timing reference for RXDV, RXD[3:0], and RXER. In RGMII mode, provides a timing reference for RGMII_RXD[3:0] and RGMII_RX_CTL.	I
MII_RXDV	RMII_CRS_DV	RGMII_RX_CTL	Asserting this input indicates the PHY has valid nibbles present on the MII. RXDV must remain asserted from the first recovered nibble of the frame through to the last nibble. Asserting RXDV must start no later than the SFD and exclude any EOF. In RMII mode, this pin also generates the CRS signal. In RGMII mode, contains RXDV on the rising edge of RGMII_RXC, and a logical derivative of RXDV and RXERR (RXDV XOR RXERR) on the falling edge of RGMII_RXC.	I
MII_RXD[3:0]	RMII_RXD[1:0]	RGMII_RXD[3:0]	Contains the Ethernet input data transferred from the PHY to the media-access controller when RXDV is asserted.	I

Table continues on the next page...

MII	RMII	RGMII	Description	I/O
MII_RXER	RMII_RXER	—	When asserted with RXDV, indicates the PHY detects an error in the current frame.	I
MII_TXCLK	—	—	Input clock, which provides a timing reference for TXEN, TXD[3:0], and TXER.	I
—	—	RGMII_TXC	Provides a timing reference for RGMII_TXD[3:0] and RGMII_TX_CTL. **NOTE:** This is an output signal.	O
MII_TXD[3:0]	RMII_TXD[1:0]	RGMII_TXD[3:0]	Serial output Ethernet data. Only valid during TXEN assertion.	O
MII_TXEN	RMII_TXEN	RGMII_TX_CTL	Indicates when valid nibbles are present on the MII. This signal is asserted with the first nibble of a preamble and is deasserted before the first TXCLK following the final nibble of the frame. In RGMII mode, contains TXEN on the rising edge of RGMII_TXC, and a logical derivative of TXEN and TXERR (TXEN XOR TXERR) on the falling edge of RGMII_TXC.	O
MII_TXER	—	—	When asserted for one or more clock cycles while TXEN is also asserted, PHY sends one or more illegal symbols.	O
—	RMII_REF_CLK	—	In RMII mode, this signal is the reference clock for receive, transmit, and the control interface.	I
—	—	RGMII_REF_CLK	In RGMII mode, this signal provide 125Mhz external reference clock input.	I
1588_TMR*n*	1588_TMR*n*	1588_TMR*n*	Capture/Compare block input/output event bus.	I/O

Table continues on the next page...

MII	RMII	RGMII	Description	I/O
			When configured for capture and a rising edge is detected, the current timer value is latched and transferred into the corresponding ENET_TCCR*n* register for inspection by software. When configured for compare, the corresponding signal 1588_TMR*n* is asserted for 1 to 32 cycles when the timer reaches the compare value programmed in ENET_TCCR*n*. An interrupt can be triggered if ENET_TCSR*n*[TIE] is set. A DMA request can be triggered if ENET_TCSR*n*[TDRE] is set.	
ENET_1588_CLKIN	ENET_1588_CLKIN	—	Alternate IEEE 1588 Ethernet clock input; Clock period should be an integer number of nanoseconds	I

61.5 Memory map/register definition

ENET registers must be read or written with 32-bit accesses. Non-32 bit accesses will terminate with an error.

Reserved bits should be written with 0 and ignored on read. Unused registers read zero and a write has no effect.

This table shows Ethernet registers organization.

Table 61-4. Register map summary

Offset Address	Section	Description
0x0000 – 0x01FF	Configuration	Core control and status registers
0x0200 – 0x03FF	Statistics counters	MIB and Remote Network Monitoring (RFC 2819) registers
0x0400 – 0x0430	1588 control	1588 adjustable timer (TSM) and 1588 frame control
0x0600 – 0x07FC	Capture/Compare block	Registers for the Capture/Compare block

ENET memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4	Interrupt Event Register (ENET_EIR)	32	w1c	0000_0000h	61.5.1/3153
8	Interrupt Mask Register (ENET_EIMR)	32	R/W	0000_0000h	61.5.2/3156
10	Receive Descriptor Active Register (ENET_RDAR)	32	R/W	0000_0000h	61.5.3/3159
14	Transmit Descriptor Active Register (ENET_TDAR)	32	R/W	0000_0000h	61.5.4/3159

61.5.1 Interrupt Event Register (ENET_EIR)

When an event occurs that sets a bit in EIR, an interrupt occurs if the corresponding bit in the interrupt mask register (EIMR) is also set. Writing a 1 to an EIR bit clears it; writing 0 has no effect. This register is cleared upon hardware reset.

NOTE

TxBD[INT] and RxBD[INT] must be set to 1 to allow setting the corresponding EIR register flags in enhanced mode, ENET_ECR[EN1588] = 1. Legacy mode does not require these flags to be enabled.

Address: 0h base + 4h offset = 4h

ENET_EIR field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 BABR	Babbling Receive Error Indicates a frame was received with length in excess of RCR[MAX_FL] bytes.
2 BABT	Babbling Transmit Error Indicates the transmitted frame length exceeds RCR[MAX_FL] bytes. Usually this condition is caused when a frame that is too long is placed into the transmit data buffer(s). Truncation does not occur.
3 GRA	Graceful Stop Complete This interrupt is asserted after the transmitter is put into a pause state after completion of the frame currently being transmitted. See Graceful Transmit Stop (GTS) for conditions that lead to graceful stop. **NOTE:** The GRA interrupt is asserted only when the TX transitions into the stopped state. If this bit is cleared by writing 1 and the TX is still stopped, the bit is not set again.
4 TXF	Transmit Frame Interrupt Indicates a frame has been transmitted and the last corresponding buffer descriptor has been updated.
5 TXB	Transmit Buffer Interrupt Indicates a transmit buffer descriptor has been updated.
6 RXF	Receive Frame Interrupt Indicates a frame has been received and the last corresponding buffer descriptor has been updated.

Table continues on the next page...

ENET_EIR field descriptions (continued)

Field	Description
7 RXB	Receive Buffer Interrupt Indicates a receive buffer descriptor is not the last in the frame has been updated.
8 MII	MII Interrupt. Indicates that the MII has completed the data transfer requested.
9 EBERR	Ethernet Bus Error Indicates a system bus error occurred when a uDMA transaction is underway. When this bit is set, ECR[ETHEREN] is cleared, halting frame processing by the MAC. When this occurs, software must ensure proper actions, possibly resetting the system, to resume normal operation.
10 LC	Late Collision Indicates a collision occurred beyond the collision window (slot time) in half-duplex mode. The frame truncates with a bad CRC and the remainder of the frame is discarded.
11 RL	Collision Retry Limit Indicates a collision occurred on each of 16 successive attempts to transmit the frame. The frame is discarded without being transmitted and transmission of the next frame commences. This error can only occur in half-duplex mode.
12 UN	Transmit FIFO Underrun Indicates the transmit FIFO became empty before the complete frame was transmitted. A bad CRC is appended to the frame fragment and the remainder of the frame is discarded.
13 PLR	Payload Receive Error Indicates a frame was received with a payload length error. See Frame Length/Type Verification: Payload Length Check for more information.
14 WAKEUP	Node Wakeup Request Indication Read-only status bit to indicate that a magic packet has been detected. Will act only if ECR[MAGICEN] is set.
15 TS_AVAIL	Transmit Timestamp Available Indicates that the timestamp of the last transmitted timing frame is available in the ATSTMP register.
16 TS_TIMER	Timestamp Timer The adjustable timer reached the period event. A period event interrupt can be generated if ATCR[PEREN] is set and the timer wraps according to the periodic setting in the ATPER register. Set the timer period value before setting ATCR[PEREN].
17–18 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
19 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
20–22 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
23 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
24–31 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.

61.5.2 Interrupt Mask Register (ENET_EIMR)

EIMR controls which interrupt events are allowed to generate actual interrupts. A hardware reset clears this register. If the corresponding bits in the EIR and EIMR registers are set, an interrupt is generated. The interrupt signal remains asserted until a 1 is written to the EIR field (write 1 to clear) or a 0 is written to the EIMR field.

Address: 0h base + 8h offset = 8h

ENET_EIMR field descriptions

Field	Description
0 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
1 BABR	BABR Interrupt Mask Corresponds to interrupt source EIR[BABR] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR BABR field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
2 BABT	BABT Interrupt Mask Corresponds to interrupt source EIR[BABT] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR BABT field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
3 GRA	GRA Interrupt Mask Corresponds to interrupt source EIR[GRA] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The

Table continues on the next page...

ENET_EIMR field descriptions (continued)

Field	Description
	corresponding EIR GRA field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
4 TXF	TXF Interrupt Mask Corresponds to interrupt source EIR[TXF] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TXF field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
5 TXB	TXB Interrupt Mask Corresponds to interrupt source EIR[TXB] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TXF field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
6 RXF	RXF Interrupt Mask Corresponds to interrupt source EIR[RXF] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR RXF field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
7 RXB	RXB Interrupt Mask Corresponds to interrupt source EIR[RXB] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR RXB field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
8 MII	MII Interrupt Mask Corresponds to interrupt source EIR[MII] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR MII field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
9 EBERR	EBERR Interrupt Mask Corresponds to interrupt source EIR[EBERR] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR EBERR field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
10 LC	LC Interrupt Mask Corresponds to interrupt source EIR[LC] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR LC field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.

Table continues on the next page...

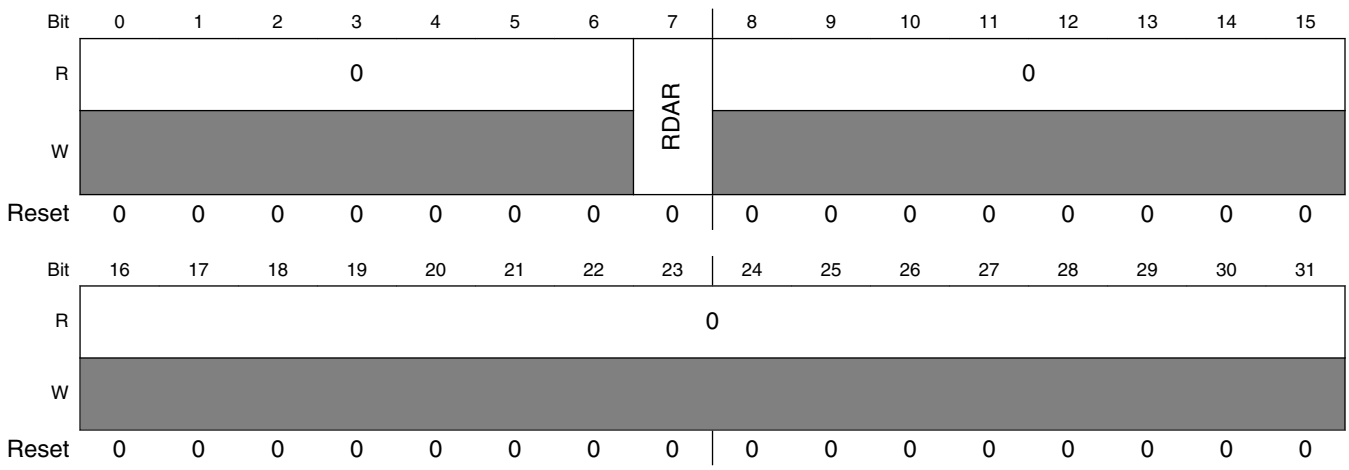
ENET_EIMR field descriptions (continued)

Field	Description
11 RL	RL Interrupt Mask Corresponds to interrupt source EIR[RL] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR RL field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
12 UN	UN Interrupt Mask Corresponds to interrupt source EIR[UN] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR UN field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
13 PLR	PLR Interrupt Mask Corresponds to interrupt source EIR[PLR] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR PLR field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
14 WAKEUP	WAKEUP Interrupt Mask Corresponds to interrupt source EIR[WAKEUP] register and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR WAKEUP field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
15 TS_AVAIL	TS_AVAIL Interrupt Mask Corresponds to interrupt source EIR[TS_AVAIL] register and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TS_AVAIL field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
16 TS_TIMER	TS_TIMER Interrupt Mask Corresponds to interrupt source EIR[TS_TIMER] register and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TS_TIMER field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.
17–18 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
19 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
20–22 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
23 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
24–31 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.

61.5.3 Receive Descriptor Active Register (ENET_RDAR)

RDAR is a command register, written by the user, to indicate that the receive descriptor ring has been updated, that is, that the driver produced empty receive buffers with the empty bit set.

Address: 0h base + 10h offset = 10h



ENET_RDAR field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 RDAR	Receive Descriptor Active Always set to 1 when this register is written, regardless of the value written. This field is cleared by the MAC device when no additional empty descriptors remain in the receive ring. It is also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

61.5.4 Transmit Descriptor Active Register (ENET_TDAR)

The TDAR is a command register that the user writes to indicate that the transmit descriptor ring has been updated, that is, that transmit buffers have been produced by the driver with the ready bit set in the buffer descriptor.

The TDAR register is cleared at reset, when ECR[ETHEREN] transitions from set to cleared, or when ECR[RESET] is set.

Address: 0h base + 14h offset = 14h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0							TDAR	0							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ENET_TDAR field descriptions

Field	Description
0–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 TDAR	Transmit Descriptor Active Always set to 1 when this register is written, regardless of the value written. This bit is cleared by the MAC device when no additional ready descriptors remain in the transmit ring. Also cleared when ECR[ETHEREN] transitions from set to cleared or when ECR[RESET] is set.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

61.5.5 Ethernet Control Register (ENET_ECR)

ECR is a read/write user register, though hardware may also alter fields in this register. It controls many of the high level features of the Ethernet MAC, including legacy FEC support through the EN1588 field.

Address: 0h base + 24h offset = 24h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	Reserved														Reserved	
W																
Reset	1	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	Reserved				Reserved	Reserved	Reserved	DBSWP	STOPEN	DBGEN	SPEED	EN1588	SLEEP	MAGICEN	ETHEREN	RESET
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ENET_ECR field descriptions

Field	Description
0–13 Reserved	This field is reserved. Always write 11110000000000b to this field.
14–19 Reserved	This field is reserved. Always write 0 to this field.
20 Reserved	This field is reserved. Always write 0 to this field.
21 Reserved	This field is reserved. Always write 0 to this field.
22 Reserved	This field is reserved. Always write 0 to this field.
23 DBSWP	Descriptor Byte Swapping Enable Swaps the byte locations of the buffer descriptors. **NOTE:** This field resets to 0 and must not be changed. 0 The buffer descriptor bytes are not swapped to support big-endian devices. 1 The buffer descriptor bytes are swapped to support little-endian devices.
24 STOPEN	STOPEN Signal Control Controls device behavior in doze mode. In doze mode, if this field is set then all the clocks of the ENET assembly are disabled, except the RMII /MII clock. Doze mode is similar to a conditional stop mode entry for the ENET assembly depending on ECR[STOPEN]. **NOTE:** If module clocks are gated in this mode, the module can still wake the system after receiving a magic packet in stop mode. MAGICEN must be set prior to entering sleep/stop mode.
25 DBGEN	Debug Enable Enables the MAC to enter hardware freeze mode when the device enters debug mode. 0 MAC continues operation in debug mode. 1 MAC enters hardware freeze mode when the processor is in debug mode.
26 SPEED	Selects between 10/100-Mbit/s and 1000-Mbit/s modes of operation. 0 10/100-Mbit/s mode 1 1000-Mbit/s mode (Actual throughput is greater than 100 Mbit/s but significantly less than 1000 Mbit/s.)
27 EN1588	EN1588 Enable Enables enhanced functionality of the MAC. 0 Legacy FEC buffer descriptors and functions enabled. 1 Enhanced frame time-stamping functions enabled.
28 SLEEP	Sleep Mode Enable 0 Normal operating mode. 1 Sleep mode.
29 MAGICEN	Magic Packet Detection Enable Enables/disables magic packet detection.

Table continues on the next page...

ENET_ECR field descriptions (continued)

Field	Description
	NOTE: MAGICEN is relevant only if the SLEEP field is set. If MAGICEN is set, changing the SLEEP field enables/disables sleep mode and magic packet detection. 0 Magic detection logic disabled. 1 The MAC core detects magic packets and asserts EIR[WAKEUP] when a frame is detected.
30 ETHEREN	Ethernet Enable Enables/disables the Ethernet MAC. When the MAC is disabled, the buffer descriptors for an aborted transmit frame are not updated. The uDMA, buffer descriptor, and FIFO control logic are reset, including the buffer descriptor and FIFO pointers. Hardware clears this field under the following conditions: • RESET is set by software • An error condition causes the EBERR field to set. **NOTE:** • ETHEREN must be set at the very last step during ENET configuration/setup/initialization, only *after* all other ENET-related registers have been configured. • If ETHEREN is cleared to 0 by software then next time ETHEREN is set, the EIR interrupts must cleared to 0 due to previous pending interrupts. 0 Reception immediately stops and transmission stops after a bad CRC is appended to any currently transmitted frame. 1 MAC is enabled, and reception and transmission are possible.
31 RESET	Ethernet MAC Reset When this field is set, it clears the ETHEREN field.

61.5.6 MII Management Frame Register (ENET_MMFR)

Writing to MMFR triggers a management frame transaction to the PHY device unless MSCR is programmed to zero.

If MSCR is changed from zero to non-zero during a write to MMFR, an MII frame is generated with the data previously written to the MMFR. This allows MMFR and MSCR to be programmed in either order if MSCR is currently zero.

If the MMFR register is written while frame generation is in progress, the frame contents are altered. Software must use the EIR[MII] interrupt indication to avoid writing to the MMFR register while frame generation is in progress.

Address: 0h base + 40h offset = 40h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	ST		OP		PA					RA					TA		DATA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ENET_MMFR field descriptions

Field	Description
0–1 ST	Start Of Frame Delimiter See Table 61-42 (Clause 22) or Table 61-44 (Clause 45) for correct value.
2–3 OP	Operation Code See Table 61-42 (Clause 22) or Table 61-44 (Clause 45) for correct value.
4–8 PA	PHY Address See Table 61-42 (Clause 22) or Table 61-44 (Clause 45) for correct value.
9–13 RA	Register Address See Table 61-42 (Clause 22) or Table 61-44 (Clause 45) for correct value.
14–15 TA	Turn Around This field must be programmed to 10 to generate a valid MII management frame.
16–31 DATA	Management Frame Data This is the field for data to be written to or read from the PHY register.

61.5.7 MII Speed Control Register (ENET_MSCR)

MSCR provides control of the MII clock (MDC pin) frequency and allows a preamble drop on the MII management frame.

The MII_SPEED field must be programmed with a value to provide an MDC frequency of less than or equal to 2.5 MHz to be compliant with the IEEE 802.3 MII specification. The MII_SPEED must be set to a non-zero value to source a read or write management frame. After the management frame is complete, the MSCR register may optionally be cleared to turn off MDC. The MDC signal generated has a 50% duty cycle except when MII_SPEED changes during operation. This change takes effect following a rising or falling edge of MDC.

For example, if the internal module clock (i.e., IPS bus clock) is 25 MHz, programming MII_SPEED to 0x4 results in an MDC as given in the following equation:

MII clock frequency = 25 MHz / ((4 + 1) x 2) = 2.5 MHz

The following table shows the optimum values for MII_SPEED as a function of IPS bus clock frequency.

Table 61-5. Programming Examples for MSCR

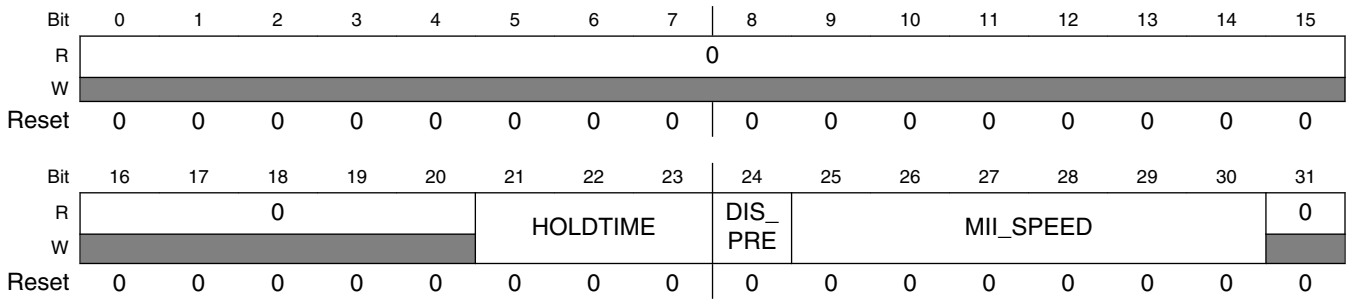
Internal module clock frequency	MSCR [MII_SPEED]	MDC frequency
25 MHz	0x4	2.50 MHz

Table continues on the next page...

Table 61-5. Programming Examples for MSCR (continued)

Internal module clock frequency	MSCR [MII_SPEED]	MDC frequency
33 MHz	0x6	2.36 MHz
40 MHz	0x7	2.50 MHz
50 MHz	0x9	2.50 MHz
66 MHz	0xD	2.36 MHz

Address: 0h base + 44h offset = 44h



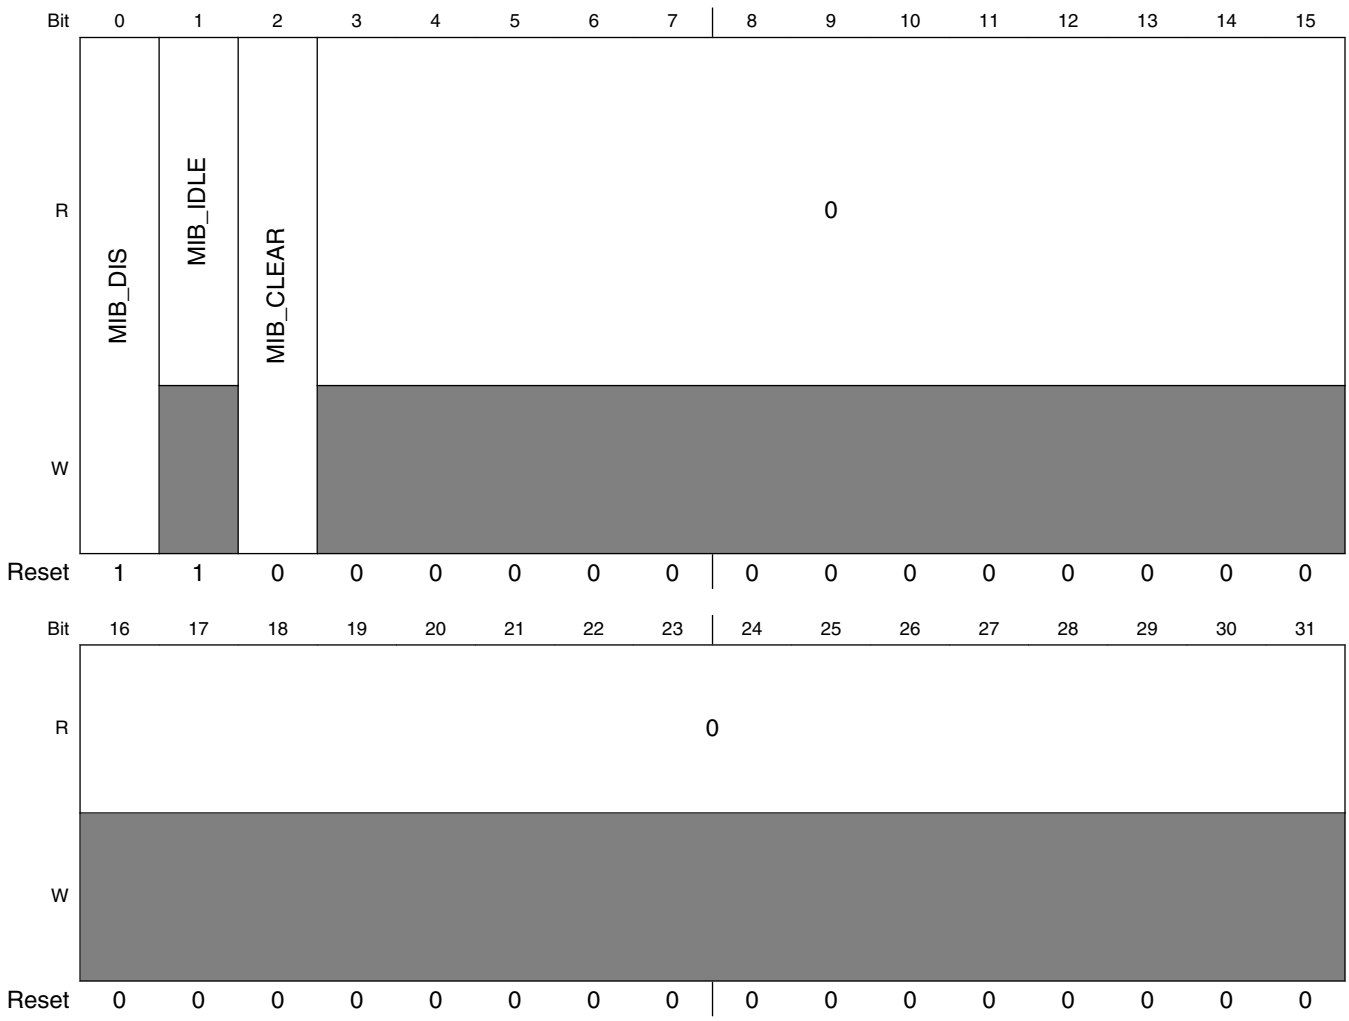
ENET_MSCR field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–23 HOLDTIME	Hold time On MDIO Output IEEE802.3 clause 22 defines a minimum of 10 ns for the hold time on the MDIO output. Depending on the host bus frequency, the setting may need to be increased. 000 1 internal module clock cycle 001 2 internal module clock cycles 010 3 internal module clock cycles 111 8 internal module clock cycles
24 DIS_PRE	Disable Preamble Enables/disables prepending a preamble to the MII management frame. The MII standard allows the preamble to be dropped if the attached PHY devices do not require it. 0 Preamble enabled. 1 Preamble (32 ones) is not prepended to the MII management frame.
25–30 MII_SPEED	MII Speed Controls the frequency of the MII management interface clock (MDC) relative to the internal module clock. A value of 0 in this field turns off MDC and leaves it in low voltage state. Any non-zero value results in the MDC frequency of: 1/((MII_SPEED + 1) x 2) of the internal module clock frequency
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

61.5.8 MIB Control Register (ENET_MIBC)

MIBC is a read/write register controlling and observing the state of the MIB block. Access this register to disable the MIB block operation or clear the MIB counters. The MIB_DIS field resets to 1.

Address: 0h base + 64h offset = 64h



ENET_MIBC field descriptions

Field	Description
0 MIB_DIS	Disable MIB Logic If this control field is set, 0 MIB logic is enabled. 1 MIB logic is disabled. The MIB logic halts and does not update any MIB counters.

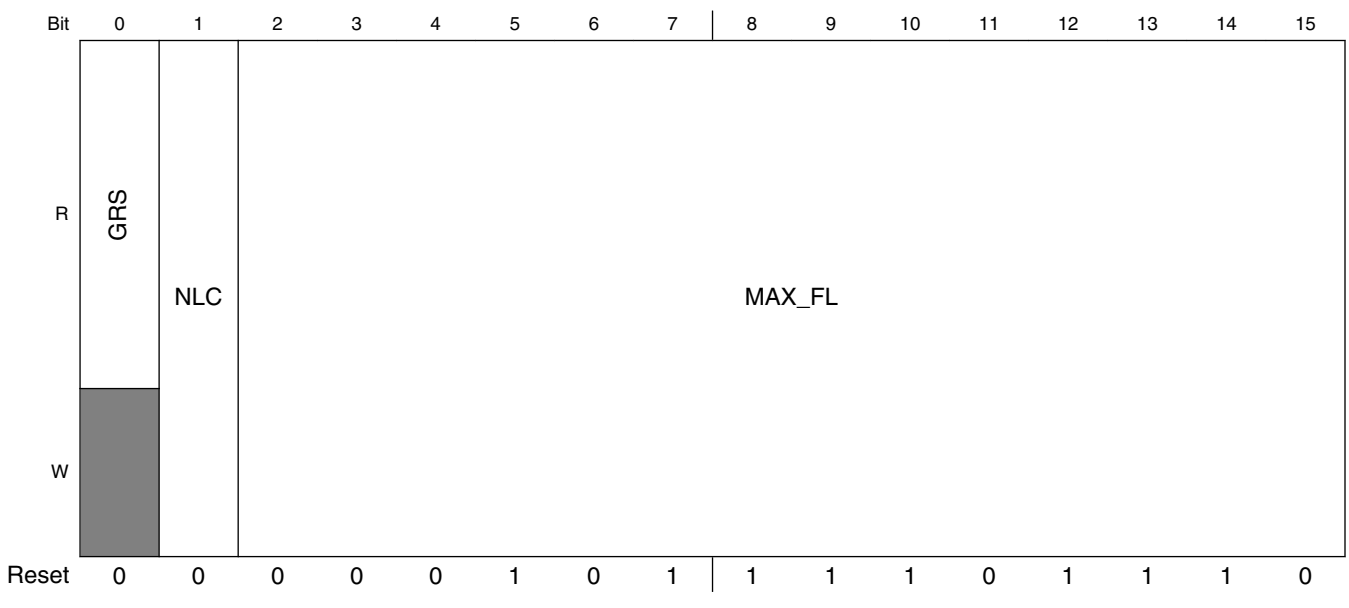
Table continues on the next page...

ENET_MIBC field descriptions (continued)

Field	Description
1 MIB_IDLE	MIB Idle 0 The MIB block is updating MIB counters. 1 The MIB block is not currently updating any MIB counters.
2 MIB_CLEAR	MIB Clear **NOTE:** This field is not self-clearing. To clear the MIB counters set and then clear this field. 0 See note above. 1 All statistics counters are reset to 0.
3–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

61.5.9 Receive Control Register (ENET_RCR)

Address: 0h base + 84h offset = 84h



ENET_RCR field descriptions

Field	Description
0 GRS	Graceful Receive Stopped Read-only status indicating that the MAC receive datapath is stopped.
1 NLC	Payload Length Check Disable Enables/disables a payload length check. 0 The payload length check is disabled. 1 The core checks the frame's payload length with the frame length/type field. Errors are indicated in the EIR[PLC] field.
2–15 MAX_FL	Maximum Frame Length Resets to decimal 1518. Length is measured starting at DA and includes the CRC at the end of the frame. Transmit frames longer than MAX_FL cause the BABT interrupt to occur. Receive frames longer than MAX_FL cause the BABR interrupt to occur and set the LG field in the end of frame receive buffer descriptor. The recommended default value to be programmed is 1518 or 1522 if VLAN tags are supported.
16 CFEN	MAC Control Frame Enable Enables/disables the MAC control frame. 0 MAC control frames with any opcode other than 0x0001 (pause frame) are accepted and forwarded to the client interface. 1 MAC control frames with any opcode other than 0x0001 (pause frame) are silently discarded.
17 CRCFWD	Terminate/Forward Received CRC Specifies whether the CRC field of received frames is transmitted or stripped. **NOTE:** If padding function is enabled (PADEN = 1), CRCFWD is ignored and the CRC field is checked and always terminated and removed. 0 The CRC field of received frames is transmitted to the user application. 1 The CRC field is stripped from the frame.
18 PAUFWD	Terminate/Forward Pause Frames Specifies whether pause frames are terminated or forwarded. 0 Pause frames are terminated and discarded in the MAC. 1 Pause frames are forwarded to the user application.
19 PADEN	Enable Frame Padding Remove On Receive Specifies whether the MAC removes padding from received frames. 0 No padding is removed on receive by the MAC. 1 Padding is removed from received frames.
20–21 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
22 RMII_10T	Enables 10-Mbit/s mode of the RMII or RGMII . 0 100-Mbit/s operation. 1 10-Mbit/s operation.

Table continues on the next page...

ENET_RCR field descriptions (continued)

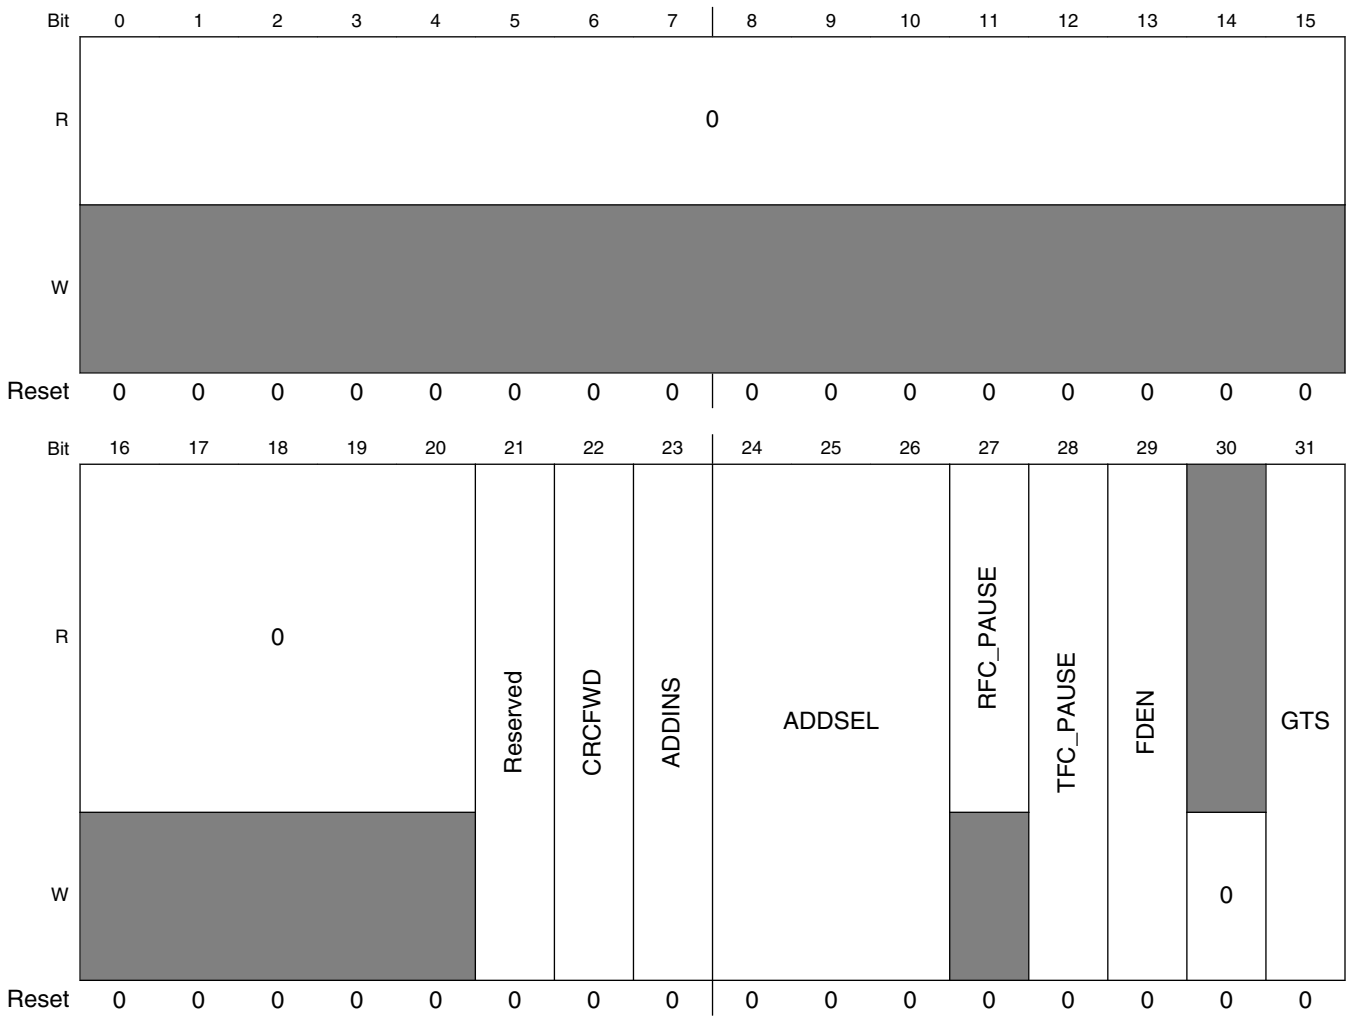
Field	Description
23 RMII_MODE	RMII Mode Enable Specifies whether the MAC is configured for MII mode or RMII operation , when ECR[SPEED] is cleared . **NOTE:** Do not set both RCR[RGMII_EN] and RCR[RMII_MODE]. 0 MAC configured for MII mode. 1 MAC configured for RMII operation.
24 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
25 RGMII_EN	RGMII Mode Enable **NOTE:** Do not set both RCR[RGMII_EN] and RCR[RMII_MODE]. 0 MAC configured for non-RGMII operation 1 MAC configured for RGMII operation. If ECR[SPEED] is set, the MAC is in RGMII 1000-Mbit/s[1] mode. If ECR[SPEED] is cleared, the MAC is in RGMII 10/100-Mbit/s mode.
26 FCE	Flow Control Enable If set, the receiver detects PAUSE frames. Upon PAUSE frame detection, the transmitter stops transmitting data frames for a given duration.
27 BC_REJ	Broadcast Frame Reject If set, frames with destination address (DA) equal to 0xFFFF_FFFF_FFFF are rejected unless the PROM field is set. If BC_REJ and PROM are set, frames with broadcast DA are accepted and the MISS (M) is set in the receive buffer descriptor.
28 PROM	Promiscuous Mode All frames are accepted regardless of address matching. 0 Disabled. 1 Enabled.
29 MII_MODE	Media Independent Interface Mode This field must always be set. 0 Reserved. 1 MII or RMII mode, as indicated by the RMII_MODE field.
30 DRT	Disable Receive On Transmit 0 Receive path operates independently of transmit (i.e., full-duplex mode). Can also be used to monitor transmit activity in half-duplex mode. 1 Disable reception of frames while transmitting. (Normally used for half-duplex mode.)
31 LOOP	Internal Loopback This is an MII internal loopback, therefore MII_MODE must be written to 1 and RMII_MODE must be written to 0. 0 Loopback disabled. 1 Transmitted frames are looped back internal to the device and transmit MII output signals are not asserted. DRT must be cleared.

1. Actual throughput is greater than 100 Mbit/s but significantly less than 1000 Mbit/s.

61.5.10 Transmit Control Register (ENET_TCR)

TCR is read/write and configures the transmit block. This register is cleared at system reset. FDEN can only be modified when ECR[ETHEREN] is cleared.

Address: 0h base + C4h offset = C4h



ENET_TCR field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 Reserved	This field is reserved. This field is read/write and must be set to 0.
22 CRCFWD	Forward Frame From Application With CRC

Table continues on the next page...

ENET_TCR field descriptions (continued)

Field	Description
	0 TxBD[TC] controls whether the frame has a CRC from the application. 1 The transmitter does not append any CRC to transmitted frames, as it is expecting a frame with CRC from the application.
23 ADDINS	Set MAC Address On Transmit 0 The source MAC address is not modified by the MAC. 1 The MAC overwrites the source MAC address with the programmed MAC address according to ADDSEL.
24–26 ADDSEL	Source MAC Address Select On Transmit If ADDINS is set, indicates the MAC address that overwrites the source MAC address. 000 Node MAC address programmed on PADDR1/2 registers. 100 Reserved. 101 Reserved. 110 Reserved.
27 RFC_PAUSE	Receive Frame Control Pause This status field is set when a full-duplex flow control pause frame is received and the transmitter pauses for the duration defined in this pause frame. This field automatically clears when the pause duration is complete.
28 TFC_PAUSE	Transmit Frame Control Pause Pauses frame transmission. When this field is set, EIR[GRA] is set. With transmission of data frames stopped, the MAC transmits a MAC control PAUSE frame. Next, the MAC clears TFC_PAUSE and resumes transmitting data frames. If the transmitter pauses due to user assertion of GTS or reception of a PAUSE frame, the MAC may continue transmitting a MAC control PAUSE frame. 0 No PAUSE frame transmitted. 1 The MAC stops transmission of data frames after the current transmission is complete.
29 FDEN	Full-Duplex Enable If this field is set, frames transmit independent of carrier sense and collision inputs. Only modify this bit when ECR[ETHEREN] is cleared.
30 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
31 GTS	Graceful Transmit Stop When this field is set, MAC stops transmission after any frame currently transmitted is complete and EIR[GRA] is set. If frame transmission is not currently underway, the GRA interrupt is asserted immediately. After transmission finishes, clear GTS to restart. The next frame in the transmit FIFO is then transmitted. If an early collision occurs during transmission when GTS is set, transmission stops after the collision. The frame is transmitted again after GTS is cleared. There may be old frames in the transmit FIFO that transmit when GTS is reasserted. To avoid this, clear ECR[ETHEREN] following the GRA interrupt.

61.5.11 Physical Address Lower Register (ENET_PALR)

PALR contains the lower 32 bits (bytes 0, 1, 2, 3) of the 48-bit address used in the address recognition process to compare with the destination address (DA) field of receive frames with an individual DA. In addition, this register is used in bytes 0 through 3 of the six-byte source address field when transmitting PAUSE frames.

Address: 0h base + E4h offset = E4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	PADDR1																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ENET_PALR field descriptions

Field	Description
0–31 PADDR1	Pause Address Bytes 0 (bits 31:24), 1 (bits 23:16), 2 (bits 15:8), and 3 (bits 7:0) of the 6-byte individual address are used for exact match and the source address field in PAUSE frames.

61.5.12 Physical Address Upper Register (ENET_PAUR)

PAUR contains the upper 16 bits (bytes 4 and 5) of the 48-bit address used in the address recognition process to compare with the destination address (DA) field of receive frames with an individual DA. In addition, this register is used in bytes 4 and 5 of the six-byte source address field when transmitting PAUSE frames. Bits 15:0 of PAUR contain a constant type field (0x8808) for transmission of PAUSE frames.

Address: 0h base + E8h offset = E8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

ENET_PAUR field descriptions

Field	Description
0–15 PADDR2	Bytes 4 (bits 31:24) and 5 (bits 23:16) of the 6-byte individual address used for exact match, and the source address field in PAUSE frames.
16–31 TYPE	Type Field In PAUSE Frames These fields have a constant value of 0x8808.

61.5.13 Opcode/Pause Duration Register (ENET_OPD)

OPD is read/write accessible. This register contains the 16-bit opcode and 16-bit pause duration fields used in transmission of a PAUSE frame. The opcode field is a constant value, 0x0001. When another node detects a PAUSE frame, that node pauses transmission for the duration specified in the pause duration field. The lower 16 bits of this register are not reset and you must initialize it.

Address: 0h base + ECh offset = ECh

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Field	Description
0 ICEN	Interrupt Coalescing Enable

Table continues on the next page...

ENET_TXIC field descriptions (continued)

Field	Description
	0 Disable Interrupt coalescing. 1 Enable Interrupt coalescing.
1 ICCS	Interrupt Coalescing Timer Clock Source Select 0 Use MII/GMII TX clocks. 1 Use ENET system clock.
2–3 Reserved	This field must be set to 0. This field is reserved.
4–11 ICFT	Interrupt coalescing frame count threshold This value determines the number of frames needed to be transmitted for raising an interrupt. Frame counter restarts after reaching this threshold value or after the expiring of the coalescing timer. Must be greater than zero to avoid unpredictable behavior.
12–15 Reserved	This field must be set to 0. This field is reserved.
16–31 ICTT	Interrupt coalescing timer threshold Interrupt coalescing timer threshold in units of 64 clock periods. This value determines the maximum amount of time after transmitting a frame before raising an interrupt. The threshold timer is disabled after expiring or number of frame transmission defined by ICFT and starts again upon transmission of the next first frame. Must be greater than zero to avoid unpredictable behavior.

61.5.15 Receive Interrupt Coalescing Register (ENET_RXIC)

See Interrupt coalescence for more information.

Address: 0h base + 100h offset = 100h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Field	Description
1 ICCS	Interrupt Coalescing Timer Clock Source Select 0 Use MII/GMII TX clocks. 1 Use ENET system clock.
2–3 Reserved	This field must be set to 0. This field is reserved.
4–11 ICFT	Interrupt coalescing frame count threshold This value determines the number of frames needed to be received for raising an interrupt. Frame counter restarts after reaching this threshold value or after the expiring of the coalescing timer. Must be greater than zero to avoid unpredictable behavior.
12–15 Reserved	This field must be set to 0. This field is reserved.
16–31 ICTT	Interrupt coalescing timer threshold Interrupt coalescing timer threshold in units of 64 clock periods. This value determines the maximum amount of time after receiving a frame before raising an interrupt. The threshold timer is disabled after expiring or number of frame reception defined by ICFT and starts again upon reception of the next first frame. Must be greater than zero to avoid unpredictable behavior.

61.5.16 Descriptor Individual Upper Address Register (ENET_IAUR)

IAUR contains the upper 32 bits of the 64-bit individual address hash table. The address recognition process uses this table to check for a possible match with the destination address (DA) field of receive frames with an individual DA. This register is not reset and you must initialize it.

Address: 0h base + 118h offset = 118h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

ENET_GALR field descriptions

Field	Description
0–31 GADDR2	Contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. Bit 31 of GADDR2 contains hash index bit 31. Bit 0 of GADDR2 contains hash index bit 0.

61.5.20 Transmit FIFO Watermark Register (ENET_TFWR)

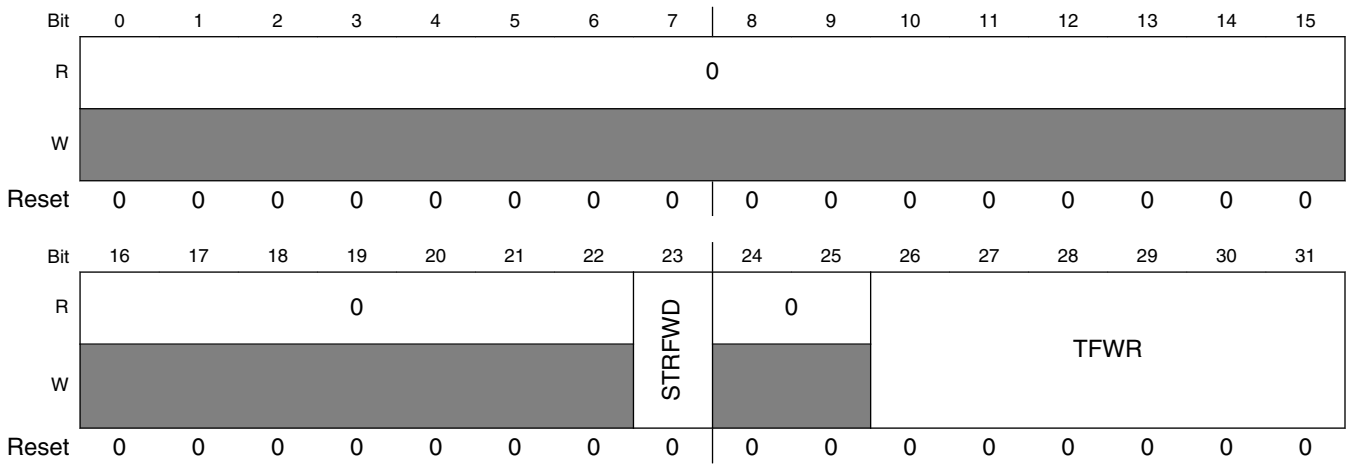
If TFWR[STRFWD] is cleared, TFWR[TFWR] controls the amount of data required in the transmit FIFO before transmission of a frame can begin. This allows you to minimize transmit latency (TFWR = 00 or 01) or allow for larger bus access latency (TFWR = 11) due to contention for the system bus. Setting the watermark to a high value minimizes the risk of transmit FIFO underrun due to contention for the system bus. The byte counts associated with the TFWR field may need to be modified to match a given system requirement, for example, worst-case bus access latency by the transmit data uDMA channel.

When the FIFO level reaches the value the TFWR field and when the STR_FWD is set to ‘0’, the MAC transmit control logic starts frame transmission even before the end-of-frame is available in the FIFO (cut-through operation).

If a complete frame has a size smaller than the threshold programmed with TFWR, the MAC also transmits the Frame to the line.

To enable store and forward on the Transmit path, set STR_FWD to ‘1’. In this case, the MAC starts to transmit data only when a complete frame is stored in the Transmit FIFO.

Address: 0h base + 144h offset = 144h



ENET_TFWR field descriptions

Field	Description
0–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 STRFWD	Store And Forward Enable 0 Reset. The transmission start threshold is programmed in TFWR[TFWR]. 1 Enabled.
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–31 TFWR	Transmit FIFO Write If TFWR[STRFWD] is cleared, this field indicates the number of bytes, in steps of 64 bytes, written to the transmit FIFO before transmission of a frame begins. **NOTE:** If a frame with less than the threshold is written, it is still sent independently of this threshold setting. The threshold is relevant only if the frame is larger than the threshold given. 000000 64 bytes written. 000001 64 bytes written. 000010 128 bytes written. 000011 192 bytes written. ... ... 111111 4032 bytes written.

61.5.21 Receive Descriptor Ring Start Register (ENET_RDSR)

RDSR points to the beginning of the circular receive buffer descriptor queue in external memory. This pointer must be 64-bit aligned (bits 29–31 must be zero); however, for optimal performance the pointer should be 512-bit aligned, that is, evenly divisible by 64.

NOTE

This register must be initialized prior to operation

Address: 0h base + 180h offset = 180h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	R_DES_START															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

W														0		
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ENET_RDSR field descriptions

Field	Description
0–28 R_DES_START	Pointer to the beginning of the receive buffer descriptor queue.
29 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

61.5.22 Transmit Buffer Descriptor Ring Start Register (ENET_TDSR)

TDSR provides a pointer to the beginning of the circular transmit buffer descriptor queue in external memory. This pointer must be 64-bit aligned (bits 29–31 must be zero); however, for optimal performance the pointer should be 512-bit aligned, that is, evenly divisible by 64.

NOTE

This register must be initialized prior to operation.

Address: 0h base + 184h offset = 184h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R W	X_DES_START															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	X_DES_START														0	
W														0		
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ENET_TDSR field descriptions

Field	Description
0–28 X_DES_START	Pointer to the beginning of the transmit buffer descriptor queue.

Table continues on the next page...

ENET_TDSR field descriptions (continued)

Field	Description
29 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

61.5.23 Maximum Receive Buffer Size Register (ENET_MRBR)

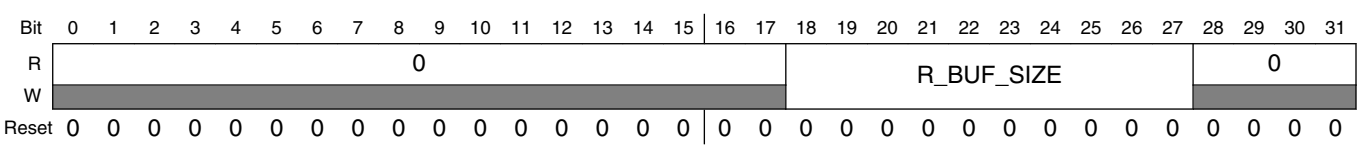
The MRBR is a user-programmable register that dictates the maximum size of all receive buffers. This value should take into consideration that the receive CRC is always written into the last receive buffer.

- R_BUF_SIZE is concatentated with the four least-significant bits of this register and are used as the maximum receive buffer size.
- To allow one maximum size frame per buffer, MRBR must be set to RCR[MAX_FL] or larger.
- To properly align the buffer, MRBR must be evenly divisible by 64. To ensure this, set the lower two bits of R_BUF_SIZE to zero. The lower four bits of this register are already set to zero by the device.
- To minimize bus usage (descriptor fetches), set MRBR greater than or equal to 256 bytes.

NOTE

This register must be initialized before operation.

Address: 0h base + 188h offset = 188h

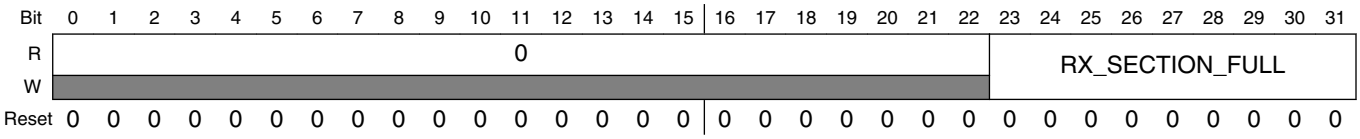


ENET_MRBR field descriptions

Field	Description
0–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–27 R_BUF_SIZE	Receive buffer size in bytes. This value, concatenated with the four least-significant bits of this register (which are always zero), is the effective maximum receive buffer size.
28–31 Reserved	This field, which is always zero, is the four least-significant bits of the maximum receive buffer size. This field is reserved. This read-only field is reserved and always has the value 0.

61.5.24 Receive FIFO Section Full Threshold (ENET_RSFL)

Address: 0h base + 190h offset = 190h

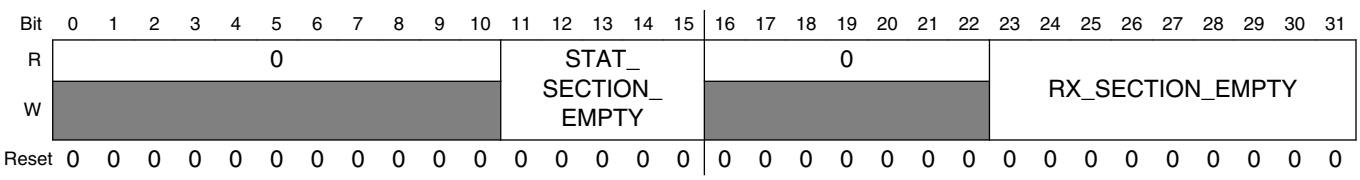


ENET_RSFL field descriptions

Field	Description
0–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–31 RX_SECTION_FULL	Value Of Receive FIFO Section Full Threshold Value, in 64-bit words, of the receive FIFO section full threshold. Clear this field to enable store and forward on the RX FIFO. When programming a value greater than 0 (cut-through operation), it must be greater than RAEM[RX_ALMOST_EMPTY]. When the FIFO level reaches the value in this field, data is available in the Receive FIFO (cut-through operation).

61.5.25 Receive FIFO Section Empty Threshold (ENET_RSEM)

Address: 0h base + 194h offset = 194h



ENET_RSEM field descriptions

Field	Description
0–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–15 STAT_ SECTION_ EMPTY	RX Status FIFO Section Empty Threshold Defines number of frames in the receive FIFO, independent of its size, that can be accepted. If the limit is reached, reception will continue normally, however a pause frame will be triggered to indicate a possible congestion to the remote device to avoid FIFO overflow. A value of 0 disables automatic pause frame generation
16–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–31 RX_SECTION_ EMPTY	Value Of The Receive FIFO Section Empty Threshold Value, in 64-bit words, of the receive FIFO section empty threshold. When the FIFO has reached this level, a pause frame will be issued.

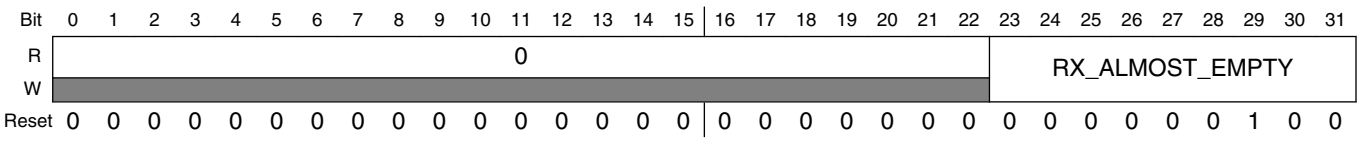
Table continues on the next page...

ENET_RSEM field descriptions (continued)

Field	Description
	A value of 0 disables automatic pause frame generation. When the FIFO level goes below the value programmed in this field, an XON pause frame is issued to indicate the FIFO congestion is cleared to the remote Ethernet client. **NOTE:** The section-empty threshold indications from both FIFOs are OR'ed to cause XOFF pause frame generation.

61.5.26 Receive FIFO Almost Empty Threshold (ENET_RAEM)

Address: 0h base + 198h offset = 198h

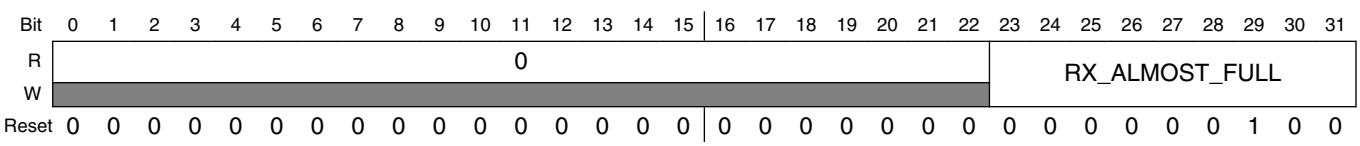


ENET_RAEM field descriptions

Field	Description
0–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–31 RX_ALMOST_EMPTY	Value Of The Receive FIFO Almost Empty Threshold Value, in 64-bit words, of the receive FIFO almost empty threshold. When the FIFO level reaches the value programmed in this field and the end-of-frame has not been received for the frame yet, the core receive read control stops FIFO read (and subsequently stops transferring data to the MAC client application). It continues to deliver the frame, if again more data than the threshold or the end-of-frame is available in the FIFO. A minimum value of 4 should be set.

61.5.27 Receive FIFO Almost Full Threshold (ENET_RAFL)

Address: 0h base + 19Ch offset = 19Ch



ENET_RAFL field descriptions

Field	Description
0–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

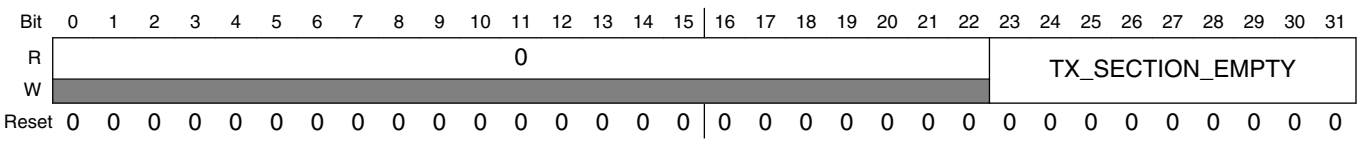
Table continues on the next page...

ENET_RAFL field descriptions (continued)

Field	Description
23–31 RX_ALMOST_FULL	Value Of The Receive FIFO Almost Full Threshold Value, in 64-bit words, of the receive FIFO almost full threshold. When the FIFO level comes close to the maximum, so that there is no more space for at least RX_ALMOST_FULL number of words, the MAC stops writing data in the FIFO and truncates the received frame to avoid FIFO overflow. The corresponding error status will be set when the frame is delivered to the application. A minimum value of 4 should be set.

61.5.28 Transmit FIFO Section Empty Threshold (ENET_TSEM)

Address: 0h base + 1A0h offset = 1A0h

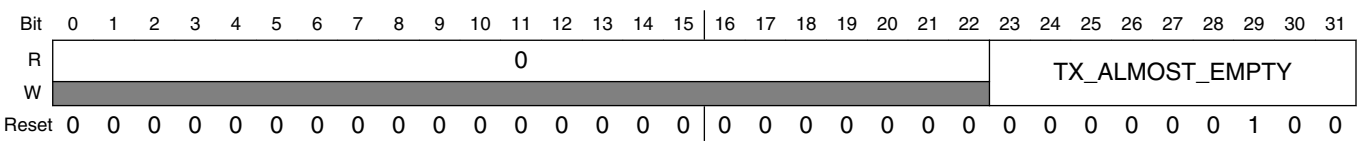


ENET_TSEM field descriptions

Field	Description
0–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–31 TX_SECTION_EMPTY	Value Of The Transmit FIFO Section Empty Threshold Value, in 64-bit words, of the transmit FIFO section empty threshold. See Transmit FIFO for more information.

61.5.29 Transmit FIFO Almost Empty Threshold (ENET_TAEM)

Address: 0h base + 1A4h offset = 1A4h



ENET_TAEM field descriptions

Field	Description
0–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–31 TX_ALMOST_EMPTY	Value of Transmit FIFO Almost Empty Threshold Value, in 64-bit words, of the transmit FIFO almost empty threshold.

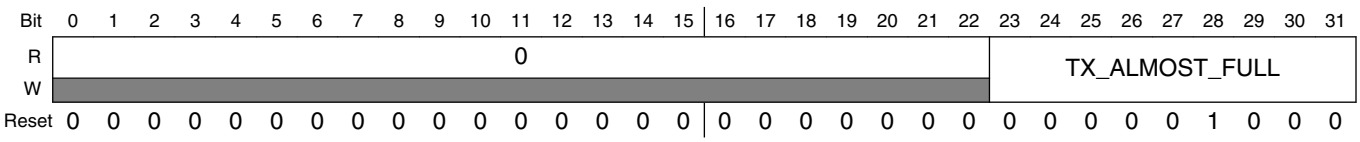
Table continues on the next page...

ENET_TAEM field descriptions (continued)

Field	Description
	When the FIFO level reaches the value programmed in this field, and no end-of-frame is available for the frame, the MAC transmit logic, to avoid FIFO underflow, stops reading the FIFO and transmits a frame with an MII error indication. See Transmit FIFO for more information. A minimum value of 4 should be set.

61.5.30 Transmit FIFO Almost Full Threshold (ENET_TAFL)

Address: 0h base + 1A8h offset = 1A8h

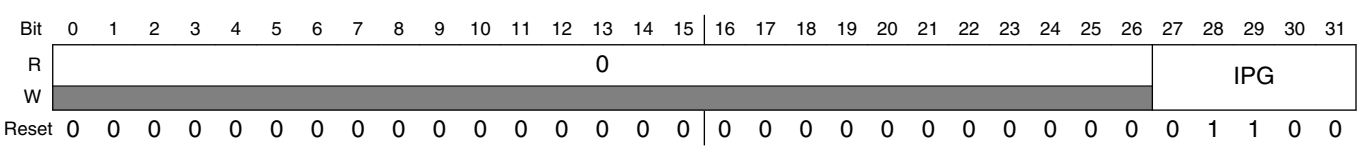


ENET_TAFL field descriptions

Field	Description
0–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–31 TX_ALMOST_FULL	Value Of The Transmit FIFO Almost Full Threshold Value, in 64-bit words, of the transmit FIFO almost full threshold. A minimum value of six is required . A recommended value of at least 8 should be set allowing a latency of two clock cycles to the application. If more latency is required the value can be increased as necessary (latency = TAFL - 5). When the FIFO level comes close to the maximum, so that there is no more space for at least TX_ALMOST_FULL number of words, the pin ff_tx_rdy is deasserted. If the application does not react on this signal, the FIFO write control logic, to avoid FIFO overflow, truncates the current frame and sets the error status. As a result, the frame will be transmitted with an GMII/MII error indication. See Transmit FIFO for more information. **NOTE:** A FIFO overflow is a fatal error and requires a global reset on the transmit datapath or at least deassertion of ETHEREN.

61.5.31 Transmit Inter-Packet Gap (ENET_TIPG)

Address: 0h base + 1ACh offset = 1ACh

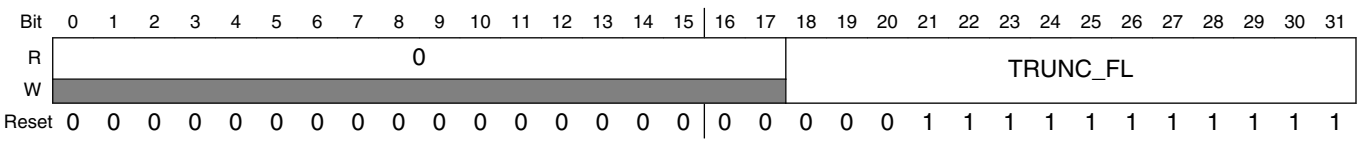


ENET_TIPG field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 IPG	Transmit Inter-Packet Gap Indicates the IPG, in bytes, between transmitted frames. Valid values range from 8 to 26. If the written value is less than 8 or greater than 26, the internal (effective) IPG is 12. **NOTE:** The IPG value read will be the value that was written, even if it is out of range.

61.5.32 Frame Truncation Length (ENET_FTRL)

Address: 0h base + 1B0h offset = 1B0h



ENET_FTRL field descriptions

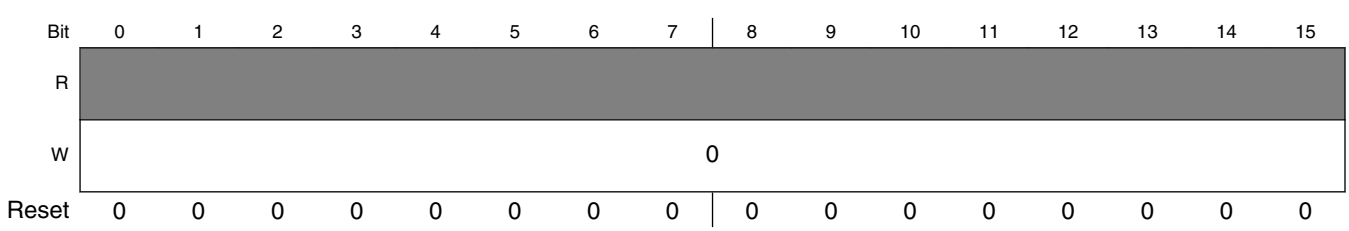
Field	Description
0–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–31 TRUNC_FL	Frame Truncation Length Indicates the value a receive frame is truncated, if it is greater than this value. Must be greater than or equal to RCR[MAX_FL]. **NOTE:** Truncation happens at TRUNC_FL. However, when truncation occurs, the application (FIFO) may receive less data, guaranteeing that it never receives more than the set limit.

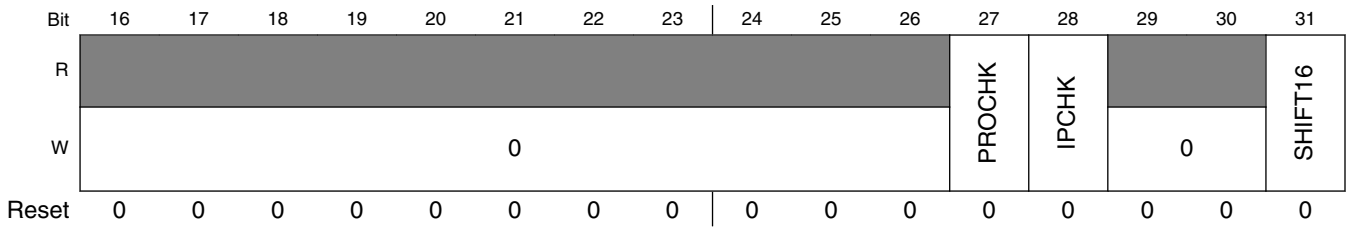
61.5.33 Transmit Accelerator Function Configuration (ENET_TACC)

TACC controls accelerator actions when sending frames. The register can be changed before or after each frame, but it must remain unmodified during frame writes into the transmit FIFO.

The TFWR[STRFWD] field must be set to use the checksum feature.

Address: 0h base + 1C0h offset = 1C0h



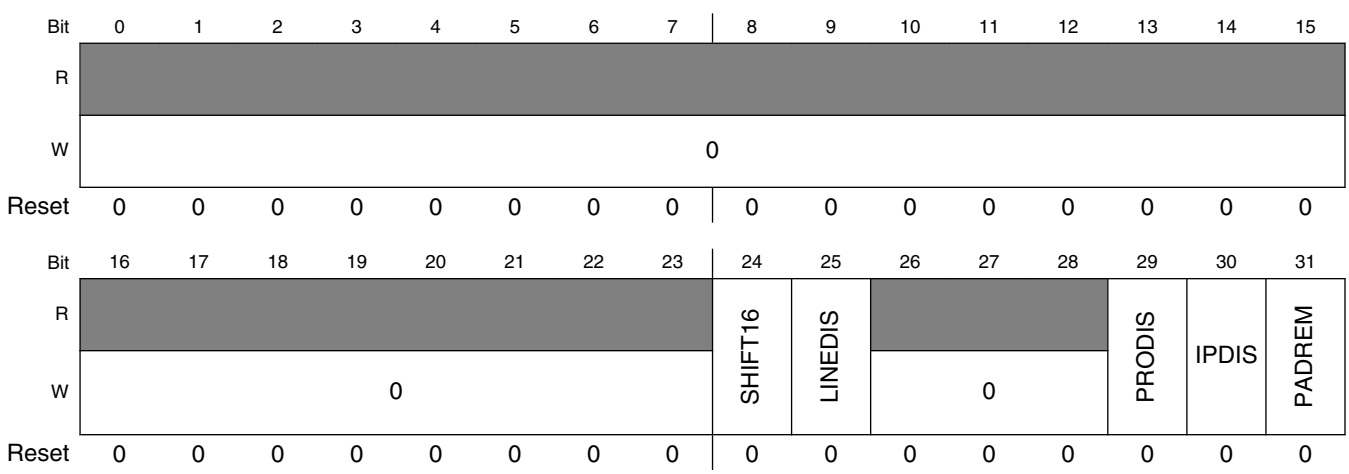


ENET_TACC field descriptions

Field	Description
0–26 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
27 PROCHK	Enables insertion of protocol checksum. 0 Checksum not inserted. 1 If an IP frame with a known protocol is transmitted, the checksum is inserted automatically into the frame. The checksum field must be cleared. The other frames are not modified.
28 IPCHK	Enables insertion of IP header checksum. 0 Checksum is not inserted. 1 If an IP frame is transmitted, the checksum is inserted automatically. The IP header checksum field must be cleared. If a non-IP frame is transmitted the frame is not modified.
29–30 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
31 SHIFT16	TX FIFO Shift-16 0 Disabled. 1 Indicates to the transmit data FIFO that the written frames contain two additional octets before the frame data. This means the actual frame begins at bit 16 of the first word written into the FIFO. This function allows putting the frame payload on a 32-bit boundary in memory, as the 14-byte Ethernet header is extended to a 16-byte header.

61.5.34 Receive Accelerator Function Configuration (ENET_RACC)

Address: 0h base + 1C4h offset = 1C4h

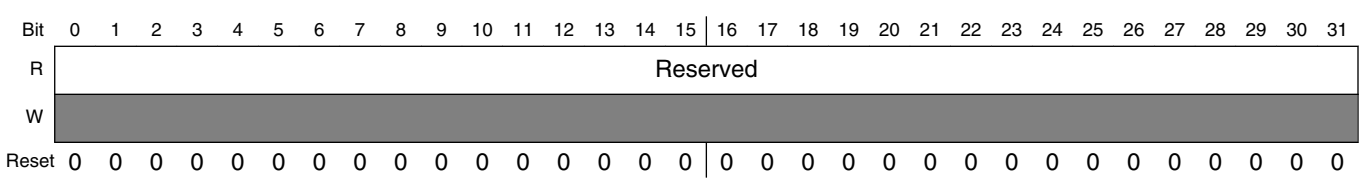


ENET_RACC field descriptions

Field	Description
0–23 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
24 SHIFT16	RX FIFO Shift-16 When this field is set, the actual frame data starts at bit 16 of the first word read from the RX FIFO aligning the Ethernet payload on a 32-bit boundary. **NOTE:** This function only affects the FIFO storage and has no influence on the statistics, which use the actual length of the frame received. 0 Disabled. 1 Instructs the MAC to write two additional bytes in front of each frame received into the RX FIFO.
25 LINEDIS	Enable Discard Of Frames With MAC Layer Errors 0 Frames with errors are not discarded. 1 Any frame received with a CRC, length, or PHY error is automatically discarded and not forwarded to the user application interface.
26–28 Reserved	This field is reserved. This write-only field is reserved. It must always be written with the value 0.
29 PRODIS	Enable Discard Of Frames With Wrong Protocol Checksum 0 Frames with wrong checksum are not discarded. 1 If a TCP/IP, UDP/IP, or ICMP/IP frame is received that has a wrong TCP, UDP, or ICMP checksum, the frame is discarded. Discarding is only available when the RX FIFO operates in store and forward mode (RSFL cleared).
30 IPDIS	Enable Discard Of Frames With Wrong IPv4 Header Checksum 0 Frames with wrong IPv4 header checksum are not discarded. 1 If an IPv4 frame is received with a mismatching header checksum, the frame is discarded. IPv6 has no header checksum and is not affected by this setting. Discarding is only available when the RX FIFO operates in store and forward mode (RSFL cleared).
31 PADREM	Enable Padding Removal For Short IP Frames 0 Padding not removed. 1 Any bytes following the IP payload section of the frame are removed from the frame.

61.5.35 Reserved Statistic Register (ENET_RMON_T_DROP)

Address: 0h base + 200h offset = 200h

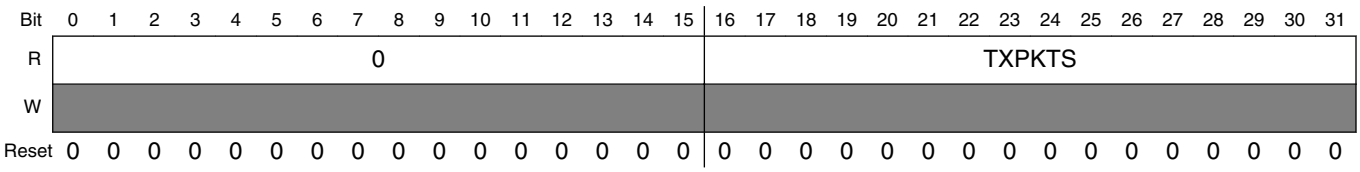


ENET_RMON_T_DROP field descriptions

Field	Description
0–31 Reserved	This read-only field always has the value 0. This field is reserved.

61.5.36 Tx Packet Count Statistic Register (ENET_RMON_T_PACKETS)

Address: 0h base + 204h offset = 204h



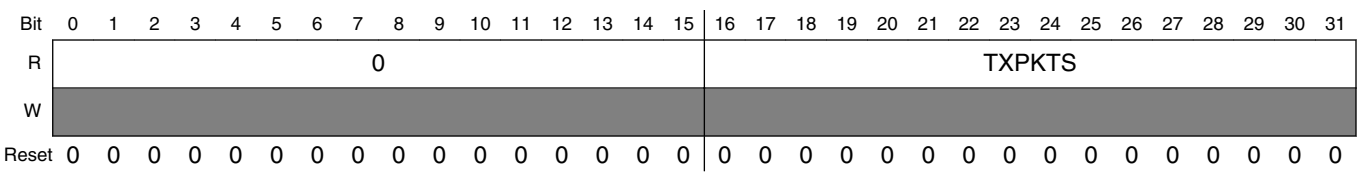
ENET_RMON_T_PACKETS field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 TXPKTS	Packet count Transmit packet count

61.5.37 Tx Broadcast Packets Statistic Register (ENET_RMON_T_BC_PKT)

RMON Tx Broadcast Packets

Address: 0h base + 208h offset = 208h

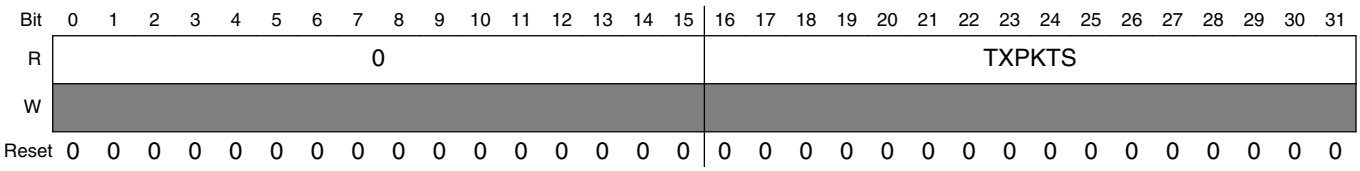


ENET_RMON_T_BC_PKT field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 TXPKTS	Broadcast packets

61.5.38 Tx Multicast Packets Statistic Register (ENET_RMON_T_MC_PKT)

Address: 0h base + 20Ch offset = 20Ch

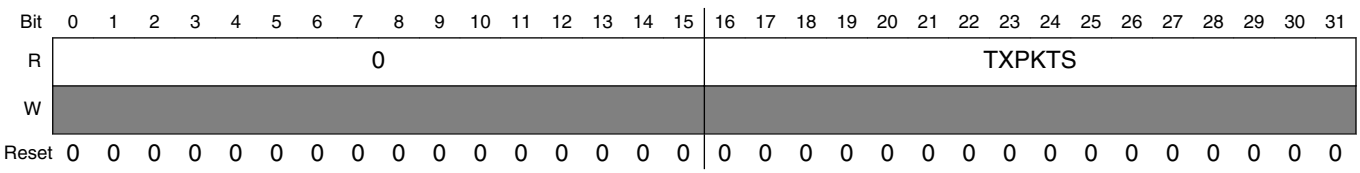


ENET_RMON_T_MC_PKT field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 TXPKTS	Multicast packets

61.5.39 Tx Packets with CRC/Align Error Statistic Register (ENET_RMON_T_CRC_ALIGN)

Address: 0h base + 210h offset = 210h



ENET_RMON_T_CRC_ALIGN field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 TXPKTS	Packets with CRC/align error

61.5.40 Tx Packets Less Than Bytes and Good CRC Statistic Register (ENET_RMON_T_UNDERSIZE)

Address: 0h base + 214h offset = 214h

Bit	0–15	16–31
R	0	TXPKTS
W		
Reset	0	0

ENET_RMON_T_UNDERSIZE field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 TXPKTS	Number of transmit packets less than 64 bytes with good CRC

61.5.41 Tx Packets GT MAX_FL bytes and Good CRC Statistic Register (ENET_RMON_T_OVERSIZE)

Address: 0h base + 218h offset = 218h

Bit	0–15	16–31
R	0	TXPKTS
W		
Reset	0	0

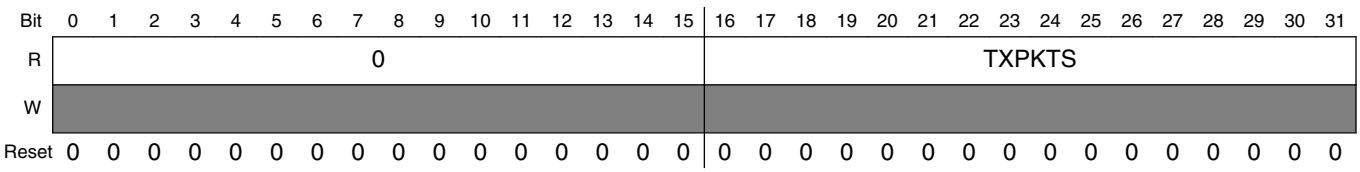
ENET_RMON_T_OVERSIZE field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 TXPKTS	Number of transmit packets greater than MAX_FL bytes with good CRC

61.5.42 Tx Packets Less Than 64 Bytes and Bad CRC Statistic Register (ENET_RMON_T_FRAG)

.

Address: 0h base + 21Ch offset = 21Ch

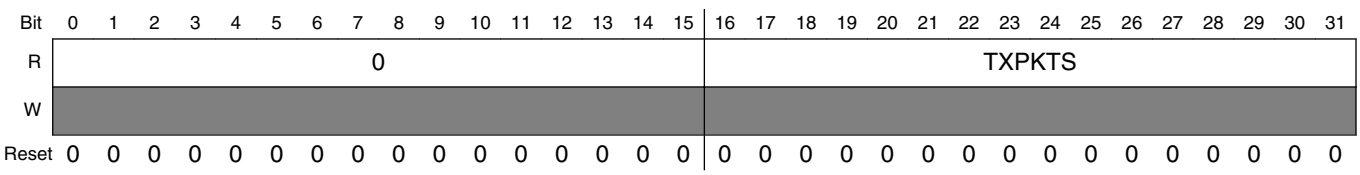


ENET_RMON_T_FRAG field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 TXPKTS	Number of packets less than 64 bytes with bad CRC

61.5.43 Tx Packets Greater Than MAX_FL bytes and Bad CRC Statistic Register (ENET_RMON_T_JAB)

Address: 0h base + 220h offset = 220h



ENET_RMON_T_JAB field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 TXPKTS	Number of transmit packets greater than MAX_FL bytes and bad CRC

61.5.44 Tx Collision Count Statistic Register (ENET_RMON_T_COL)

Address: 0h base + 224h offset = 224h

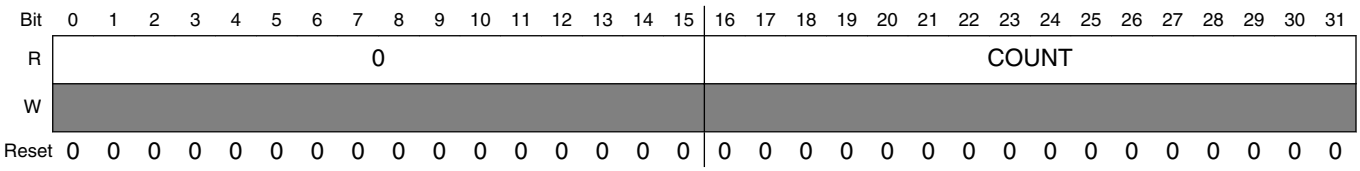
ENET_IEEE_T_MCOL field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of frames transmitted with multiple collisions

61.5.57 Frames Transmitted after Deferral Delay Statistic Register (ENET_IEEE_T_DEF)

Address: 0h base + 258h offset = 258h

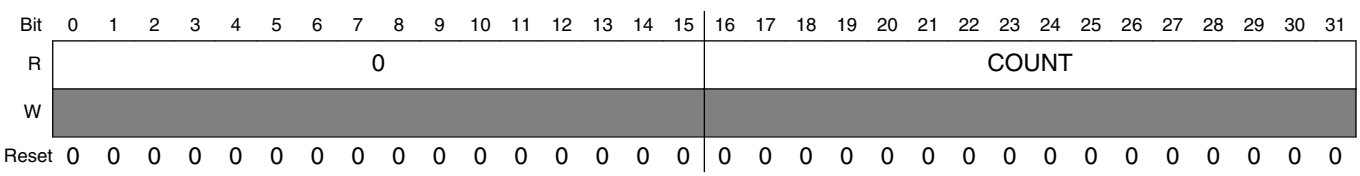


ENET_IEEE_T_DEF field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of frames transmitted with deferral delay

61.5.58 Frames Transmitted with Late Collision Statistic Register (ENET_IEEE_T_LCOL)

Address: 0h base + 25Ch offset = 25Ch

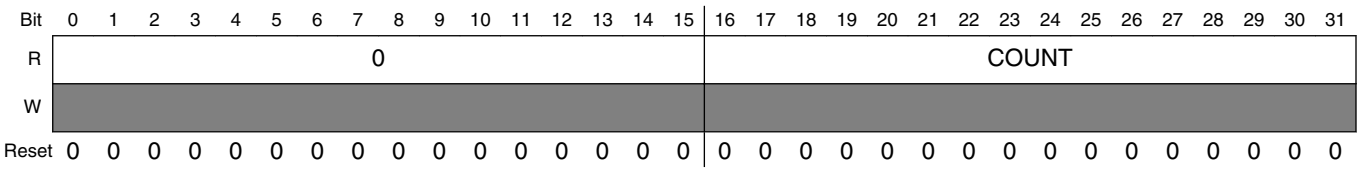


ENET_IEEE_T_LCOL field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of frames transmitted with late collision

61.5.59 Frames Transmitted with Excessive Collisions Statistic Register (ENET_IEEE_T_EXCOL)

Address: 0h base + 260h offset = 260h

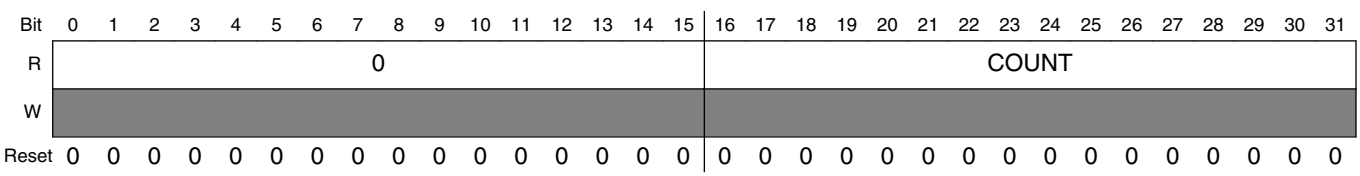


ENET_IEEE_T_EXCOL field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of frames transmitted with excessive collisions

61.5.60 Frames Transmitted with Tx FIFO Underrun Statistic Register (ENET_IEEE_T_MACERR)

Address: 0h base + 264h offset = 264h

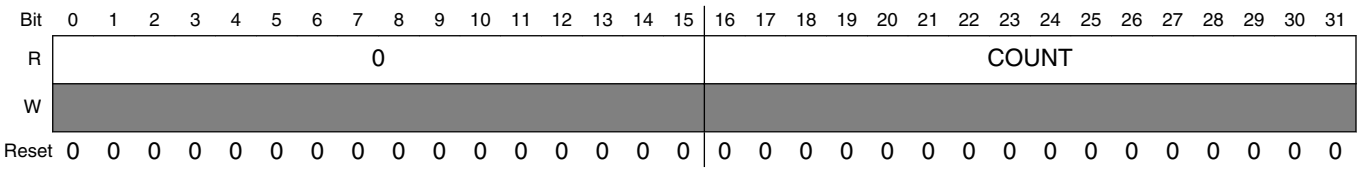


ENET_IEEE_T_MACERR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of frames transmitted with transmit FIFO underrun

61.5.61 Frames Transmitted with Carrier Sense Error Statistic Register (ENET_IEEE_T_CSERR)

Address: 0h base + 268h offset = 268h

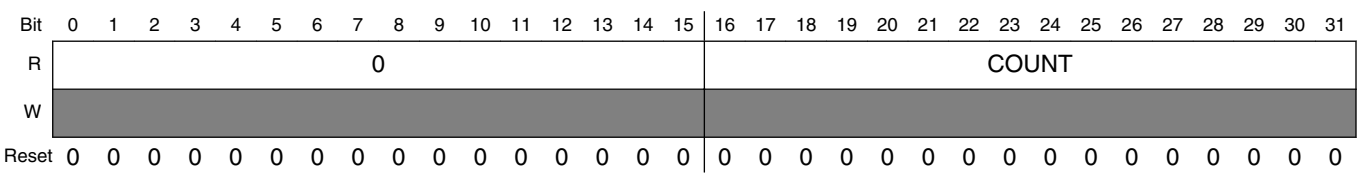


ENET_IEEE_T_CSERR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of frames transmitted with carrier sense error

61.5.62 Reserved Statistic Register (ENET_IEEE_T_SQE)

Address: 0h base + 26Ch offset = 26Ch

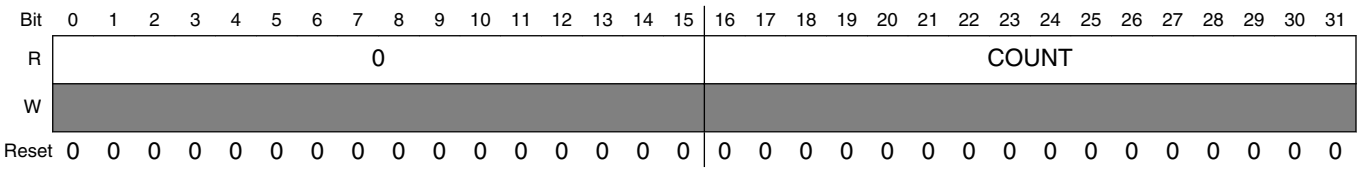


ENET_IEEE_T_SQE field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	This read-only field is reserved and always has the value 0. **NOTE:** Counter not implemented as no SQE information is available.

61.5.63 Flow Control Pause Frames Transmitted Statistic Register (ENET_IEEE_T_FDXFC)

Address: 0h base + 270h offset = 270h

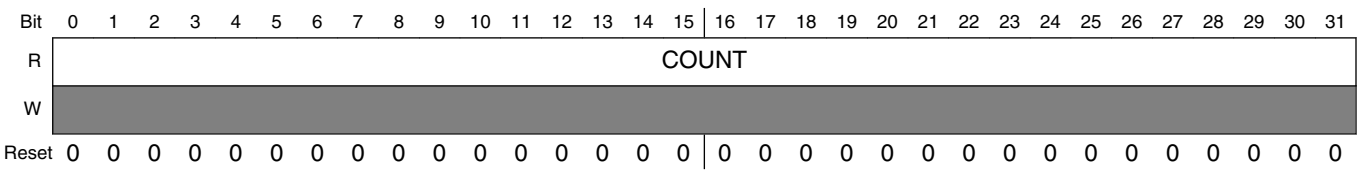


ENET_IEEE_T_FDXFC field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of flow-control pause frames transmitted

61.5.64 Octet Count for Frames Transmitted w/o Error Statistic Register (ENET_IEEE_T_OCTETS_OK)

Address: 0h base + 274h offset = 274h

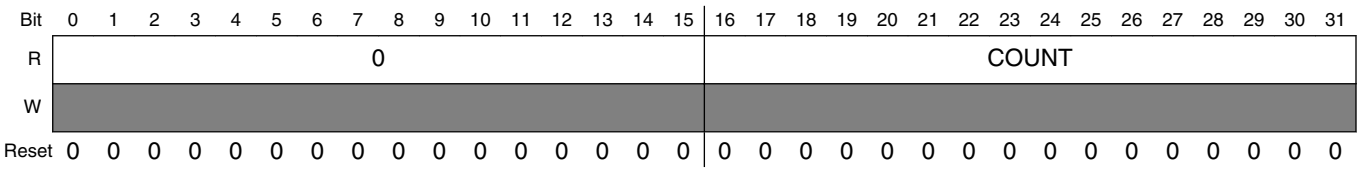


ENET_IEEE_T_OCTETS_OK field descriptions

Field	Description
0–31 COUNT	Octet count for frames transmitted without error **NOTE** Counts total octets (includes header and FCS fields).

61.5.65 Rx Packet Count Statistic Register (ENET_RMON_R_PACKETS)

Address: 0h base + 284h offset = 284h

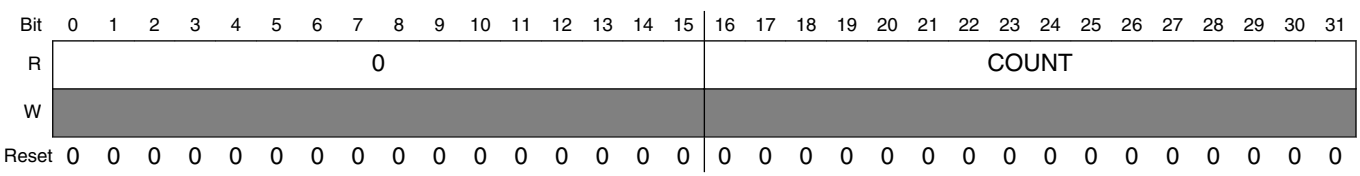


ENET_RMON_R_PACKETS field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of packets received

61.5.66 Rx Broadcast Packets Statistic Register (ENET_RMON_R_BC_PKT)

Address: 0h base + 288h offset = 288h

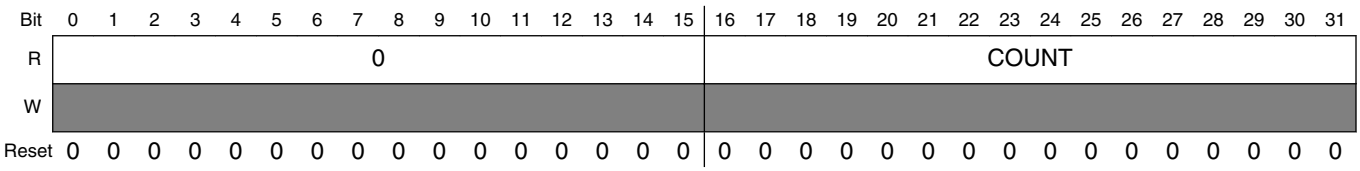


ENET_RMON_R_BC_PKT field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of receive broadcast packets

61.5.67 Rx Multicast Packets Statistic Register (ENET_RMON_R_MC_PKT)

Address: 0h base + 28Ch offset = 28Ch

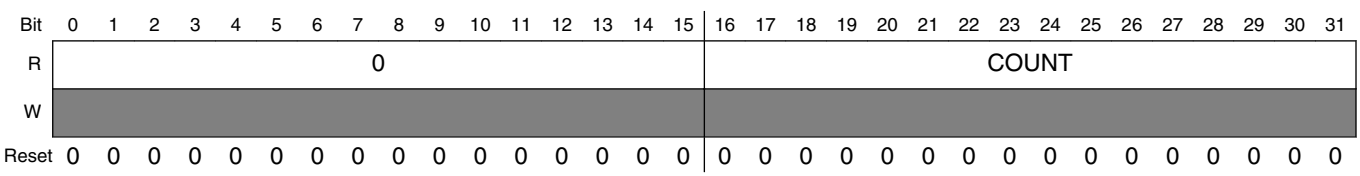


ENET_RMON_R_MC_PKT field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of receive multicast packets

61.5.68 Rx Packets with CRC/Align Error Statistic Register (ENET_RMON_R_CRC_ALIGN)

Address: 0h base + 290h offset = 290h

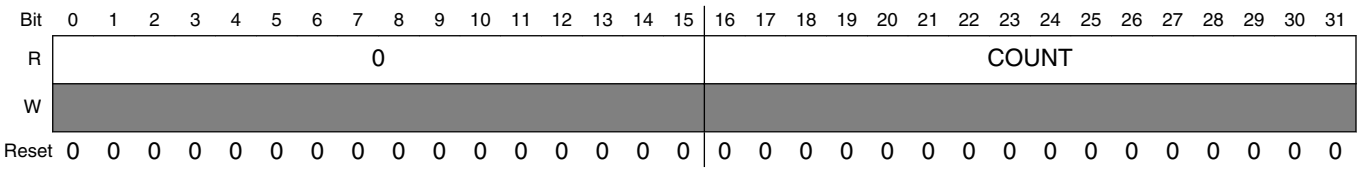


ENET_RMON_R_CRC_ALIGN field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of receive packets with CRC or align error

61.5.69 Rx Packets with Less Than 64 Bytes and Good CRC Statistic Register (ENET_RMON_R_UNDERSIZE)

Address: 0h base + 294h offset = 294h

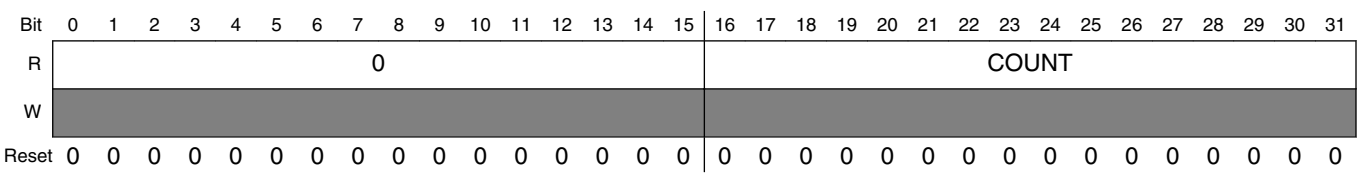


ENET_RMON_R_UNDERSIZE field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of receive packets with less than 64 bytes and good CRC

61.5.70 Rx Packets Greater Than MAX_FL and Good CRC Statistic Register (ENET_RMON_R_OVERSIZE)

Address: 0h base + 298h offset = 298h



ENET_RMON_R_OVERSIZE field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of receive packets greater than MAX_FL and good CRC

61.5.71 Rx Packets Less Than 64 Bytes and Bad CRC Statistic Register (ENET_RMON_R_FRAG)

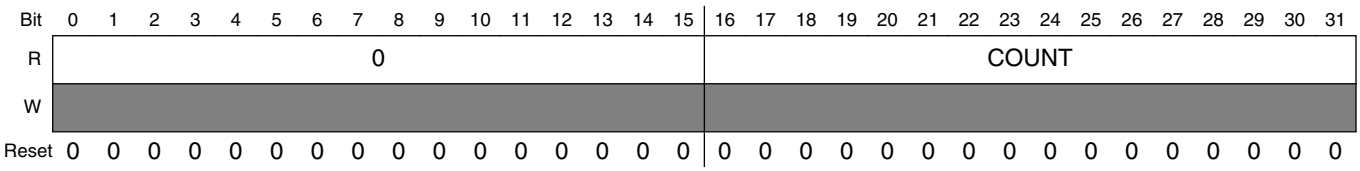
ENET_RMON_R_P1024TO2047 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of 1024- to 2047-byte recieve packets

61.5.80 Rx Packets Greater than 2048 Bytes Statistic Register (ENET_RMON_R_P_GTE2048)

Address: 0h base + 2C0h offset = 2C0h

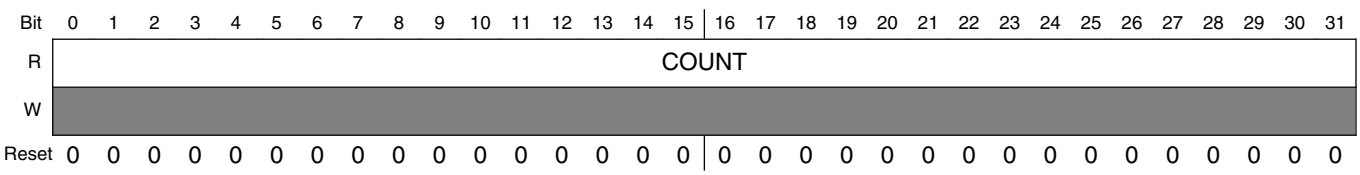


ENET_RMON_R_P_GTE2048 field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of greater-than-2048-byte recieve packets

61.5.81 Rx Octets Statistic Register (ENET_RMON_R_OCTETS)

Address: 0h base + 2C4h offset = 2C4h



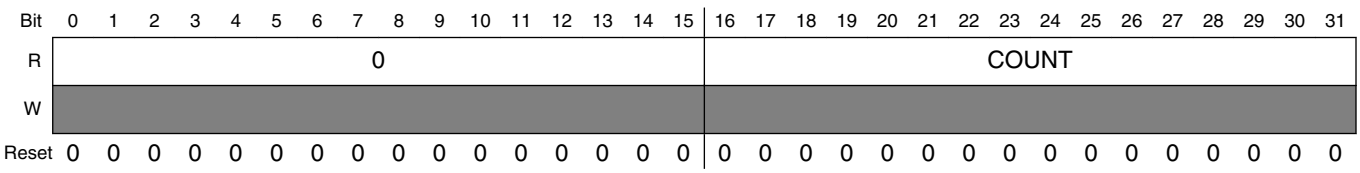
ENET_RMON_R_OCTETS field descriptions

Field	Description
0–31 COUNT	Number of receive octets

61.5.82 Frames not Counted Correctly Statistic Register (ENET_IEEE_R_DROP)

Counter increments if a frame with invalid or missing SFD character is detected and has been dropped. None of the other counters increments if this counter increments.

Address: 0h base + 2C8h offset = 2C8h

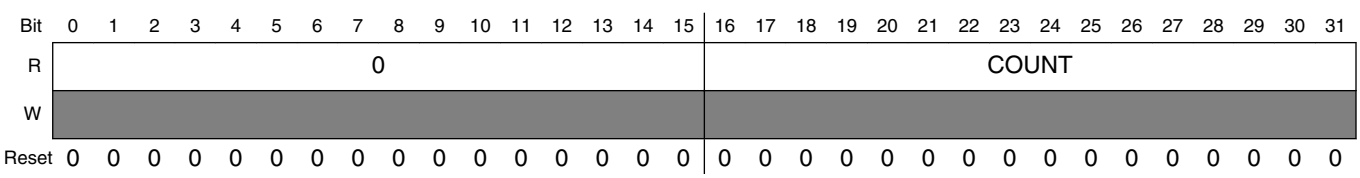


ENET_IEEE_R_DROP field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Frame count

61.5.83 Frames Received OK Statistic Register (ENET_IEEE_R_FRAME_OK)

Address: 0h base + 2CCh offset = 2CCh

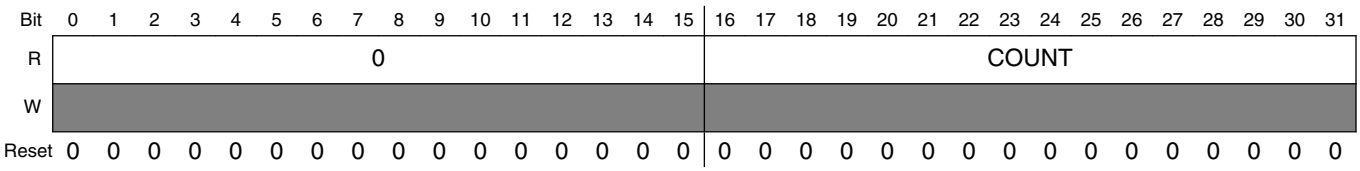


ENET_IEEE_R_FRAME_OK field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of frames received OK

61.5.84 Frames Received with CRC Error Statistic Register (ENET_IEEE_R_CRC)

Address: 0h base + 2D0h offset = 2D0h

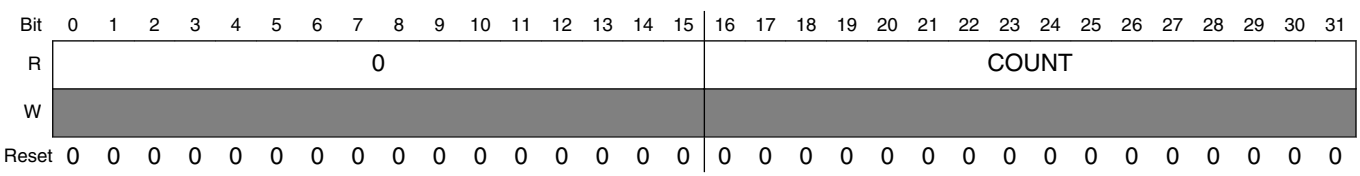


ENET_IEEE_R_CRC field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of frames received with CRC error

61.5.85 Frames Received with Alignment Error Statistic Register (ENET_IEEE_R_ALIGN)

Address: 0h base + 2D4h offset = 2D4h

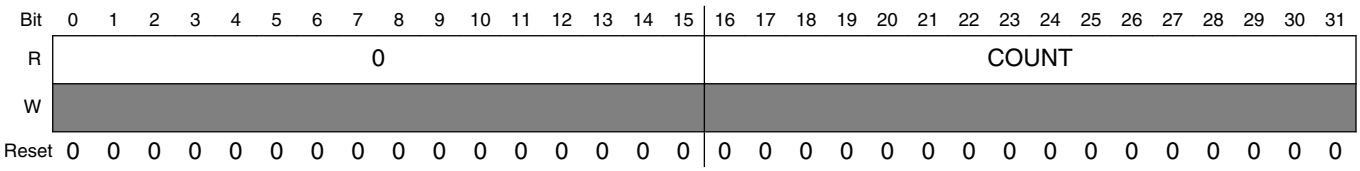


ENET_IEEE_R_ALIGN field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of frames received with alignment error

61.5.86 Receive FIFO Overflow Count Statistic Register (ENET_IEEE_R_MACERR)

Address: 0h base + 2D8h offset = 2D8h

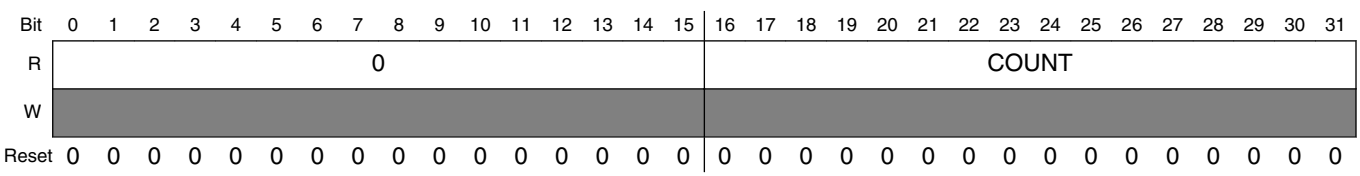


ENET_IEEE_R_MACERR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Receive FIFO overflow count

61.5.87 Flow Control Pause Frames Received Statistic Register (ENET_IEEE_R_FDXFC)

Address: 0h base + 2DCh offset = 2DCh



ENET_IEEE_R_FDXFC field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 COUNT	Number of flow-control pause frames received

61.5.88 Octet Count for Frames Received without Error Statistic Register (ENET_IEEE_R_OCTETS_OK)

Address: 0h base + 2E0h offset = 2E0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

ENET_IEEE_R_OCTETS_OK field descriptions

Field	Description
0–31 COUNT	Number of octets for frames received without error **NOTE:** Counts total octets (includes header and FCS fields). Does not increment for the broadcast frames when broadcast reject is enabled and promiscuous mode is disabled within the receive control register (RCR).

61.5.89 Adjustable Timer Control Register (ENET_ATCR)

ATCR command fields can trigger the corresponding events directly. It is not necessary to preserve any of the configuration fields when a command field is set in the register, that is, no read-modify-write is required.

NOTE

The CAPTURE and RESTART fields and bits 19 and 21 must be 0 in order to write to the other fields in this register.

Address: 0h base + 400h offset = 400h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	0		SLAVE	Reserved	CAPTURE	Reserved	RESTART		PINPER			PEREN	OFFRST	OFFEN		EN
W								0		0	1				0	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ENET_ATCR field descriptions

Field	Description
0–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 SLAVE	Enable Timer Slave Mode 0 The timer is active and all configuration fields in this register are relevant. 1 The internal timer is disabled and the externally provided timer value is used. All other fields, except CAPTURE, in this register have no effect. CAPTURE can still be used to capture the current timer value.
19 Reserved	This field is reserved. Always write 0 to this field.
20 CAPTURE	Capture Timer Value When this field is set, all other fields are ignored during a write. This field automatically clears to 0 after the command completes. 0 No effect. 1 The current time is captured and can be read from the ATVR register.
21 Reserved	This field is reserved. Always write 0 to this field.
22 RESTART	Reset Timer Resets the timer to zero. This has no effect on the counter enable. If the counter is enabled when this field is set, the timer is reset to zero and starts counting from there. When set, all other fields are ignored during a write. This field automatically clears to 0 after the command completes.
23 Reserved	This field is reserved.
24 PINPER	Enables event signal output assertion on period event. **NOTE:** Not all devices contain the event signal output. See the chip configuration details. 0 Disable. 1 Enable.
25 Reserved	This field is reserved.
26 Reserved	This field is reserved. **NOTE:** This field must be written always with one.
27 PEREN	Enable Periodical Event 0 Disable. 1 A period event interrupt can be generated (EIR[TS_TIMER]) and the event signal output is asserted when the timer wraps around according to the periodic setting ATPER. The timer period value must be set before setting this bit. **NOTE:** Not all devices contain the event signal output. See the chip configuration details.
28 OFFRST	Reset Timer On Offset Event 0 The timer is not affected and no action occurs, besides clearing OFFEN, when the offset is reached. 1 If OFFEN is set, the timer resets to zero when the offset setting is reached. The offset event does not cause a timer interrupt.

Table continues on the next page...

ENET_ATCR field descriptions (continued)

Field	Description
29 OFFEN	Enable One-Shot Offset Event 0 Disable. 1 The timer can be reset to zero when the given offset time is reached (offset event). The field is cleared when the offset event is reached, so no further event occurs until the field is set again. The timer offset value must be set before setting this field.
30 Reserved	This field is reserved.
31 EN	Enable Timer 0 The timer stops at the current value. 1 The timer starts incrementing.

61.5.90 Timer Value Register (ENET_ATVR)

Address: 0h base + 404h offset = 404h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

ENET_ATPER field descriptions

Field	Description
0–31 PERIOD	Value for generating periodic events. Each instance the timer reaches this value, the period event occurs and the timer restarts. If the increment value in ATINC is given in true nanoseconds, this value is also given in true nanoseconds. The value should be initialized to 1,000,000,000 (1×10^9) to represent a timer wrap around of one second. The increment value set in ATINC should be set to the true nanoseconds of the period of clock ts_clk, hence implementing a true 1 second counter. **NOTE:** The value of PERIOD has the following constraint: 2^{32} – ENET_ATINC[INC_COR] – 3×ENET_ATINC[INC] ≥ PERIOD > 0.

61.5.93 Timer Correction Register (ENET_ATCOR)

Address: 0h base + 410h offset = 410h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

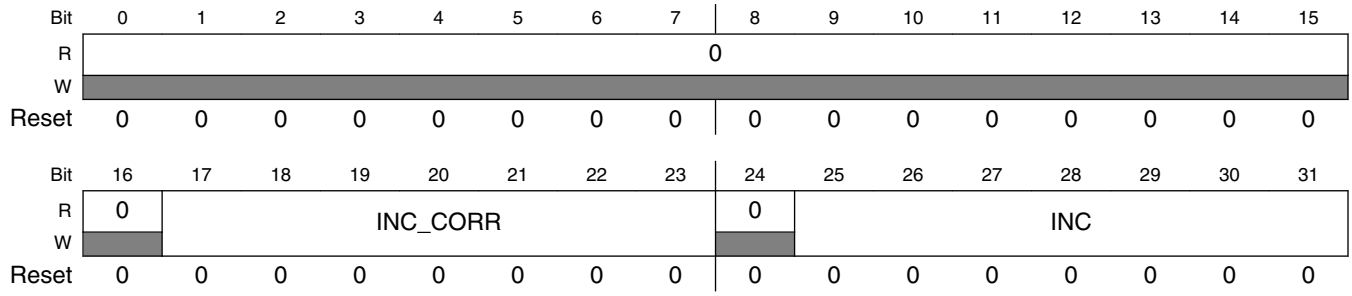
ENET_ATCOR field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–31 COR	Correction Counter Wrap-Around Value Defines after how many timer clock cycles (ts_clk) the correction counter should be reset and trigger a correction increment on the timer. The amount of correction is defined in ATINC[INC_CORR]. A value of 0 disables the correction counter and no corrections occur. **NOTE:** This value is given in clock cycles, not in nanoseconds as all other values.

61.5.94 Time-Stamping Clock Period Register (ENET_ATINC)

Address: 0h base + 414h offset = 414h

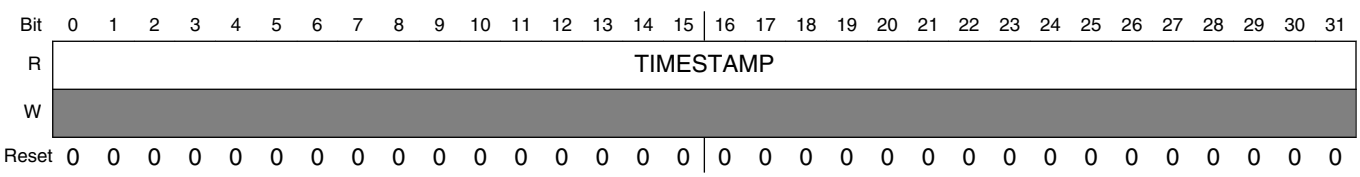


ENET_ATINC field descriptions

Field	Description
0–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–23 INC_CORR	Correction Increment Value This value is added every time the correction timer expires (every clock cycle given in ATCOR). A value less than INC slows down the timer. A value greater than INC speeds up the timer.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–31 INC	Clock Period Of The Timestamping Clock (ts_clk) In Nanoseconds The timer increments by this amount each clock cycle. For example, set to 10 for 100 MHz, 8 for 125 MHz, 5 for 200 MHz. **NOTE:** For highest precision, use a value that is an integer fraction of the period set in ATPER.

61.5.95 Timestamp of Last Transmitted Frame (ENET_ATSTMP)

Address: 0h base + 418h offset = 418h



ENET_ATSTMP field descriptions

Field	Description
0–31 TIMESTAMP	Timestamp of the last frame transmitted by the core that had TxBD[TS] set . This register is only valid when EIR[TS_AVAIL] is set.

61.5.96 Timer Global Status Register (ENET_TGSR)

Address: 0h base + 604h offset = 604h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

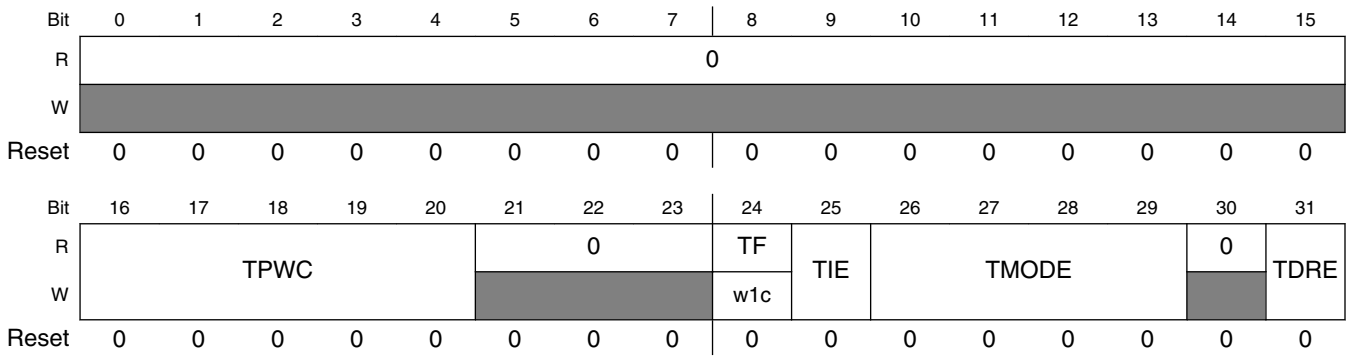
31 TF0	Copy Of Timer Flag For Channel 0 0 Timer Flag for Channel 0 is clear 1 Timer Flag for Channel 0 is set

61.5.97 Timer Control Status Register (ENET_TCSR*n*)

Address: 0h base + 608h offset + (8d × i), where i=0d to 3d



ENET_TCSR*n* field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–20 TPWC	Timer PulseWidth Control Specifies the pulse width associated with TMODE values of 1110 or 11X1. Updating this field takes a few cycles to register because it is synchronized to the 1588 clock. When changing this field: 1. Always disable the channel and read the TMODE field to verify that the channel is disabled. 2. Set TPWC to the desired value. 3. Reenable the channel. 00000 Pulse width is one 1588-clock cycle. 00001 Pulse width is two 1588-clock cycles. 00010 Pulse width is three 1588-clock cycles. 00011 Pulse width is four 1588-clock cycles. ... ... 11111 Pulse width is 32 1588-clock cycles.
21–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 TF	Timer Flag Sets when input capture or output compare occurs. This flag is double buffered between the module clock and 1588 clock domains. When this field is 1, it can be cleared to 0 by writing 1 to it. 0 Input Capture or Output Compare has not occurred. 1 Input Capture or Output Compare has occurred.
25 TIE	Timer Interrupt Enable 0 Interrupt is disabled 1 Interrupt is enabled
26–29 TMODE	Timer Mode

Table continues on the next page...

ENET_TCSR*n* field descriptions (continued)

Field	Description
	Updating the Timer Mode field takes a few cycles to register because it is synchronized to the 1588 clock. The version of Timer Mode returned on a read is from the 1588 clock domain. When changing Timer Mode, always disable the channel and read this register to verify the channel is disabled first. 0000 Timer Channel is disabled. 0001 Timer Channel is configured for Input Capture on rising edge. 0010 Timer Channel is configured for Input Capture on falling edge. 0011 Timer Channel is configured for Input Capture on both edges. 0100 Timer Channel is configured for Output Compare - software only. 0101 Timer Channel is configured for Output Compare - toggle output on compare. 0110 Timer Channel is configured for Output Compare - clear output on compare. 0111 Timer Channel is configured for Output Compare - set output on compare. 1000 Reserved 1010 Timer Channel is configured for Output Compare - clear output on compare, set output on overflow. 10X1 Timer Channel is configured for Output Compare - set output on compare, clear output on overflow. 110X Reserved 1110 Timer Channel is configured for Output Compare - pulse output low on compare for 1 to 32 1588-clock cycles as specified by TPWC. 1111 Timer Channel is configured for Output Compare - pulse output high on compare for 1 to 32 1588-clock cycles as specified by TPWC.
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 TDRE	Timer DMA Request Enable 0 DMA request is disabled 1 DMA request is enabled

61.5.98 Timer Compare Capture Register (ENET_TCCR*n*)

Address: 0h base + 60Ch offset + (8d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	TCC																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ENET_TCCR*n* field descriptions

Field	Description
0–31 TCC	Timer Capture Compare This register is double buffered between the module clock and 1588 clock domains. When configured for compare, the 1588 clock domain updates with the value in the module clock domain whenever the Timer Channel is first enabled and on each subsequent compare. Write to this register with the first compare value before enabling the Timer Channel. When the Timer Channel is enabled, write the second compare value either immediately, or at least before the first compare occurs. After each compare, write the next compare value before the previous compare occurs and before clearing the Timer Flag.

ENET_TCCR*n* field descriptions (continued)

Field	Description
	The compare occurs one 1588 clock cycle after the IEEE 1588 Counter increments past the compare value in the 1588 clock domain. If the compare value is less than the value of the 1588 Counter when the Timer Channel is first enabled, then the compare does not occur until following the next overflow of the 1588 Counter. If the compare value is greater than the IEEE 1588 Counter when the 1588 Counter overflows, or the compare value is less than the value of the IEEE 1588 Counter after the overflow, then the compare occurs one 1588 clock cycle following the overflow. When configured for capture, the value of the IEEE 1588 Counter is captured into the 1588 clock domain and then updated into the module clock domain, provided the Timer Flag is clear. Always read the capture value before clearing the Timer Flag.

61.6 Functional description

This section provides a complete functional description of the MAC-NET core.

61.6.1 Ethernet MAC frame formats

- Minimum length of 64 bytes
- Maximum length of 1518 bytes excluding the preamble and the start frame delimiter (SFD) bytes

An Ethernet frame consists of the following fields:

- Seven bytes preamble
- Start frame delimiter (SFD)
- Two address fields
- Length or type field
- Data field
- Frame check sequence (CRC value)
- Extension field is defined only for Gigabit Ethernet half-duplex implementations and is not supported by the MAC core

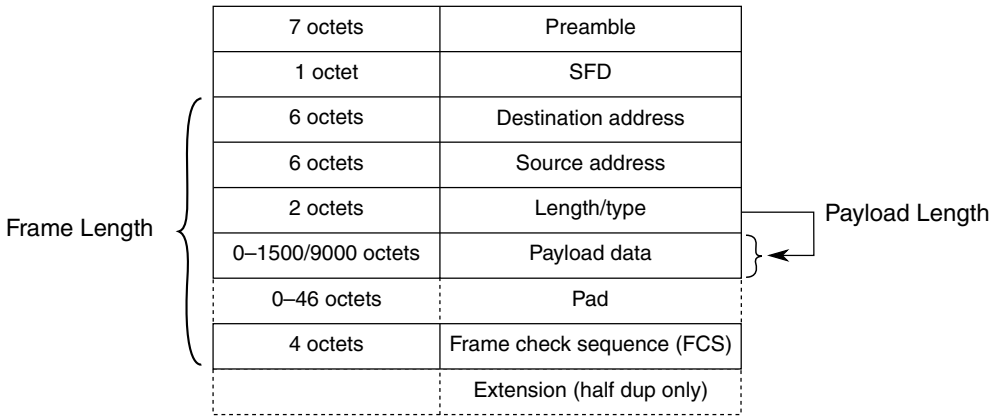


Figure 61-2. MAC frame format overview

Optionally, MAC frames can be VLAN-tagged with an additional four-byte field inserted between the MAC source address and the type/length field. VLAN tagging is defined by the IEEE P802.1q specification. VLAN-tagged frames have a maximum length of 1522 bytes, excluding the preamble and the SFD bytes.

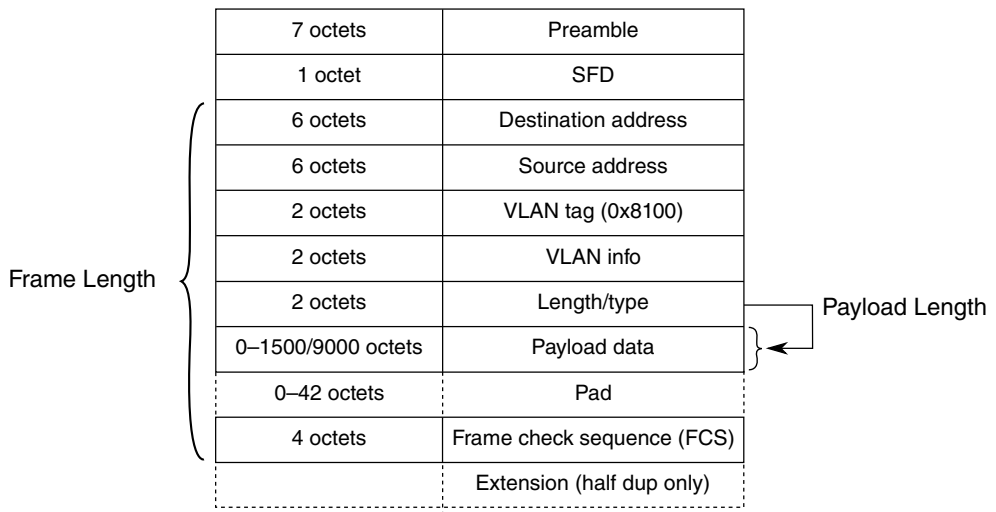

Figure 61-3. VLAN-tagged MAC frame format overview

Table 61-6. MAC frame definition

Term	Description
Frame length	Defines the length, in octets, of the complete frame without preamble and SFD. A frame has a valid length if it contains at least 64 octets and does not exceed the programmed maximum length.
Payload length	The length/type field indicates the length of the frame's payload section. The most significant byte is sent/received first. • If the length/type field is set to a value less than 46, the payload is padded so that the minimum frame length requirement (64 bytes) is met. For VLAN-tagged frames, a value less than 42 indicates a padded frame. • If the length/type field is set to a value larger than the programmed frame maximum length (e.g. 1518) it is interpreted as a type field.

Table continues on the next page...

Table 61-6. MAC frame definition (continued)

Term	Description
Destination and source address	48-bit MAC addresses. The least significant byte is sent/received first and the first two least significant bits of the MAC address distinguish MAC frames, as detailed in MAC address check.

Note

Although the IEEE specification defines a maximum frame length, the MAC core provides the flexibility to program any value for the frame maximum length.

61.6.1.1 Pause Frames

The receiving device generates a pause frame to indicate a congestion to the emitting device, which should stop sending data.

Pause frames are indicated by the length/type set to 0x8808. The two first bytes of a pause frame following the type, defines a 16-bit opcode field set to 0x0001 always. A 16-bit pause quanta is defined in the frame payload bytes 2 (P1) and 3 (P2) as defined in the following table. The P1 pause quanta byte is the most significant.

Table 61-7. Pause Frame Format (Values in Hex)

1	2	3	4	5	6	7	8	9	10	11	12	13	14
55	55	55	55	55	55	55	D5	01	80	C2	00	00	01
Preamble							SFD	Multicast Destination Address					
15	16	17	18	19	20	21	22	23	24	25	26	27 –68	
00	00	00	00	00	00	88	08	00	01	hi	lo	00	
Source Address						Type		Opcode		P1	P2	pad (42)	
69	70	71	72										
26	6B	AE	0A										
CRC-32													

There is no payload length field found within a pause frame and a pause frame is always padded with 42 bytes (0x00).

If a pause frame with a pause value greater than zero (XOFF condition) is received, the MAC stops transmitting data as soon the current frame transfer is completed. The MAC stops transmitting data for the value defined in pause quanta. One pause quanta fraction refers to 512 bit times.

If a pause frame with a pause value of zero (XON condition) is received, the transmitter is allowed to send data immediately (see Full-duplex flow control operation for details).

61.6.1.2 Magic packets

A magic packet is a unicast, multicast, or broadcast packet, which carries a defined sequence in the payload section.

Magic packets are received and inspected only under specific conditions.

The defined sequence to decode a magic packet is formed with a synchronization stream which consists of six consecutive 0xFF bytes, and is followed by sequence of sixteen consecutive unicast MAC addresses of the node to be awakened.

This sequence can be located anywhere in the magic packet payload. The magic packet is formed with a standard Ethernet header, optional padding, and CRC.

61.6.2 IP and higher layers frame format

For example, an IP datagram specifies the payload section of an Ethernet frame. A TCP datagram specifies the payload section within an IP datagram.

61.6.2.1 Ethernet types

IP datagrams are carried in the payload section of an Ethernet frame. The Ethernet frame type/length field discriminates several datagram types.

The following table lists the types of interest:

Table 61-8. Ethernet type value examples

Type	Description
0x8100	VLAN-tagged frame. The actual type is found 4 octets later in the frame.
0x0800	IPv4
0x0806	ARP
0x86DD	IPv6

61.6.2.2 IPv4 datagram format

The following figure shows the IP Version 4 (IPv4) header, which is located at the beginning of an IP datagram. It is organized in 32-bit words. The first byte sent/received is the leftmost byte of the first word (in other words, version/IHL field).

The IP header can contain further options, which are always padded if necessary to guarantee the payload following the header is aligned to a 32-bit boundary.

The IP header is immediately followed by the payload, which can contain further protocol headers (for example, TCP or UDP, as indicated by the protocol field value). The complete IP datagram is transported in the payload section of an Ethernet frame.

Table 61-9. IPv4 header format

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0

Field name	Description
Version	4-bit IP version information. 0x4 for IPv4 frames.
IHL	4-bit Internet header length information. Determines number of 32-bit words found within the IP header. If no options are present, the default value is 0x5.
TOS	Type of service/DiffServ field.
Length	Total length of the datagram in bytes, including all octets of header and payload.
Fragment ID, flags, fragment offset	Fields used for IP fragmentation.
TTL	Time-to-live. In effect, is decremented at each router arrival. If zero, datagram must be discarded.
Protocol	Identifier of protocol that follows in the datagram.
Header checksum	Checksum of IP header. For computational purposes, this field's value is zero.
Source address	Source IP address.
Destination address	Destination IP address.

61.6.2.3 IPv6 datagram format

The following figure shows the IP version 6 (IPv6) header, which is located at the beginning of an IP datagram. It is organized in 32-bit words and has a fixed length of ten words (40 bytes). The next header field identifies the type of the header that follows the IPv6 header. It is defined similar to the protocol identifier within IPv4, with new definitions for identifying extension headers. These headers can be inserted between the

IPv6 header and the protocol header, which will shift the protocol header accordingly.The accelerator currently only supports IPv6 without extension headers (in other words, the next header specifies TCP, UDP, or IMCP).

The first byte sent/received is the leftmost byte of the first word (in other words, version/ traffic class fields).

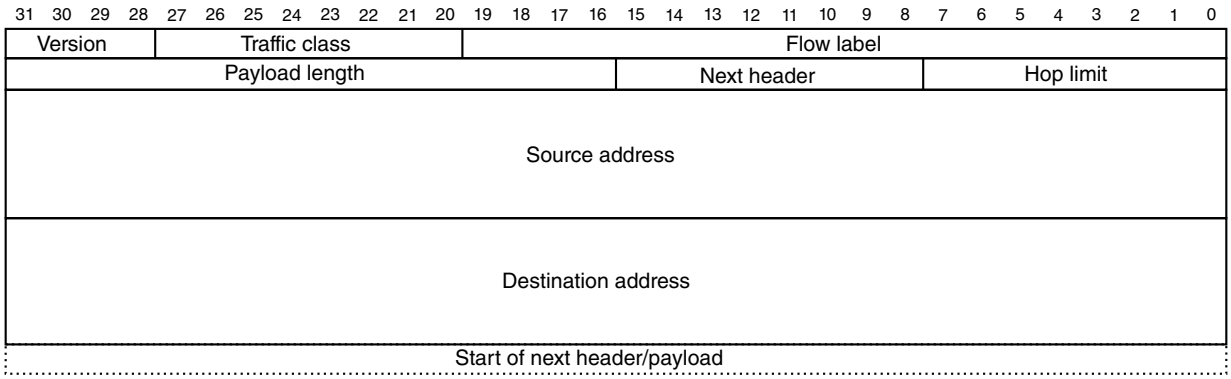

Figure 61-4. IPv6 header format

Table 61-11. IPv6 header fields

Field name	Description
Version	4-bit IP version information. 0x6 for all IPv6 frames.
Traffic class	8-bit field defining the traffic class.
Flow label	20-bit flow label identifying frames of the same flow.
Payload length	16-bit length of the datagram payload in bytes. It includes all octets following the IPv6 header.
Next header	Identifies the header that follows the IPv6 header. This can be the protocol header or any IPv6 defined extension header.
Hop limit	Hop counter, decremented by one by each station that forwards the frame. If hop limit is 0 the frame must be discarded.
Source address	128-bit IPv6 source address.
Destination address	128-bit IPv6 destination address.

61.6.2.4 Internet Control Message Protocol (ICMP) datagram format

An internet control message protocol (ICMP) is found following the IP header, if the protocol identifier is 1. The ICMP datagram has a four-octet header followed by additional message data.

Table 61-12. ICMP header format

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
Type		Code		Checksum			
ICMP message data							

Table 61-13. IP header fields

Field name	Description
Type	8-bit type information
Code	8-bit code that is related to the message type
Checksum	16-bit one's complement checksum over the complete ICMP datagram

61.6.2.5 User Datagram Protocol (UDP) datagram format

A user datagram protocol header is found after the IP header, when the protocol identifier is 17.

The payload of the datagram is after the UDP header. The header byte order follows the conventions given for the IP header above.

Table 61-14. UDP header format

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
Source port				Destination port			
Length				Checksum			

Table 61-15. UDP header fields

Field name	Description
Source port	Source application port
Destination port	Destination application port
Length	Length of user data which immediately follows the header, including the UDP header (that is, minimum value is 8)
Checksum	Checksum over the complete datagram and some IP header information

61.6.2.6 TCP datagram format

A TCP header is found following the IP header, when the protocol identifier has a value of 6.

The TCP payload immediately follows the TCP header.

Table 61-16. TCP header format

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
Source port				Destination port			

Table continues on the next page...

Table 61-16. TCP header format (continued)

Sequence number			
Acknowledgement number			
Offset	Reserved	Flags	Window
Checksum			Urgent pointer
Options			

Table 61-17. TCP header fields

Field name	Description
Source port	Source application port
Destination port	Destination application port
Sequence number	Transmit sequence number
Ack. number	Receive sequence number
Offset	Data offset, which is number of 32-bit words within TCP header — if no options selected, defaults to value of 5
Flags	URG, ACK, PSH, RST, SYN, FIN flags
Window	TCP receive window size information
Checksum	Checksum over the complete datagram (TCP header and data) and IP header information
Options	Additional 32-bit words for protocol options

61.6.3 IEEE 1588 message formats

The following sections describe the IEEE 1588 message formats.

61.6.3.1 Transport encapsulation

The precision time protocol (PTP) datagrams are encapsulated in Ethernet frames using the UDP/IP transport mechanism, or optionally, with the newer 1588v2 directly in Ethernet frames (layer 2).

Typically, multicast addresses are used to allow efficient distribution of the synchronization messages.

61.6.3.1.1 UDP/IP

The 1588 messages (v1 and v2) can be transported using UDP/IP multicast messages.

Table 61-18 shows IP multicast groups defined for PTP. The table also shows their respective MAC layer multicast address mapping according to RFC 1112 (last three octets of IP follow the fixed value of 01-00-5E).

Table 61-18. UDP/IP multicast domains

Name	IP Address	MAC Address mapping
DefaultPTPdomain	224.0.1.129	01-00-5E-00-01-81
AlternatePTPdomain1	224.0.1.130	01-00-5E-00-01-82
AlternatePTPdomain2	224.0.1.131	01-00-5E-00-01-83
AlternatePTPdomain3	224.0.1.132	01-00-5E-00-01-84

Table 61-19. UDP port numbers

Message type	UDP port	Note
Event	319	Used for SYNC and DELAY_REQUEST messages
General	320	All other messages (for example, follow-up, delay-response)

61.6.3.1.2 Native Ethernet (PTPv2)

In addition to using UDP/IP frames, IEEE 1588v2 defines a native Ethernet frame format that uses ethertype = 0x88F7. The payload of the Ethernet frame immediately contains the PTP datagram, starting with the PTPv2 header.

Besides others, version 2 adds a peer delay mechanism to allow delay measurements between individual point-to-point links along a path over multiple nodes. The following multicast domains are also defined in PTPv2.

Table 61-20. PTPv2 multicast domains

Name	MAC address
Normal messages	01-1B-19-00-00-00
Peer delay messages	01-80-C2-00-00-0E

61.6.3.2 PTP header

All PTP frames contain a common header that determines the protocol version and the type of message, which defines the remaining content of the message.

All multi-octet fields are transmitted in big-endian order (the most significant byte is transmitted/received first).

The last four bits of versionPTP are at the same position (second byte) for PTPv1 and PTPv2 headers. This allows accurate identification by inspecting the first two bytes of the message.

61.6.3.2.1 PTPv1 header

Table 61-21. Common PTPv1 message header

Offset	Octets	Bits							
		7	6	5	4	3	2	1	0
0	2	versionPTP = 0x0001							
2	2	versionNetwork							
4	16	subdomain							
20	1	messageType							
21	1	sourceCommunicationTechnology							
22	6	sourceUuid							
28	2	sourcePortId							
30	2	sequenceId							
32	1	control							
33	1	0x00							
34	2	flags							
36	4	reserved							

The type of message is encoded in the messageType and control fields as shown in Table 61-22 :

Table 61-22. PTPv1 message type identification

messageType	control	Message Name	Message
0x01	0x0	SYNC	Event message
0x01	0x1	DELAY_REQ	Event message
0x02	0x2	FOLLOW_UP	General message
0x02	0x3	DELAY_RESP	General message
0x02	0x4	MANAGEMENT	General message
other	other	—	Reserved

The field sequenceId is used to non-ambiguously identify a message.

61.6.3.2.2 PTPv2 header

Table 61-23. Common PTPv2 message header

Offset	Octets	Bits							
		7	6	5	4	3	2	1	0
0	1	transportSpecific				messageId			
1	1	reserved				versionPTP = 0x2			
2	2	messageLength							
4	1	domainNumber							
5	1	reserved							
6	2	flags							
8	8	correctionField							
16	4	reserved							
20	10	sourcePortIdentity							
30	2	sequenceId							
32	1	control							
33	1	logMeanMessageInterval							

The type of message is encoded in the field messageId as follows:

Table 61-24. PTPv2 message type identification

messageId	Message name	Message
0x0	SYNC	Event message
0x1	DELAY_REQ	Event message
0x2	PATH_DELAY_REQ	Event message
0x3	PATH_DELAY_RESP	Event message
0x4–0x7	—	Reserved
0x8	FOLLOW_UP	General message
0x9	DELAY_RESP	General message
0xa	PATH_DELAY_FOLLOW_UP	General message
0xb	ANNOUNCE	General message
0xc	SIGNALING	General message
0xd	MANAGEMENT	General message

The PTPv2 flags field contains further details on the type of message, especially if one-step or two-step implementations are used. The one- or two-step implementation is controlled by the TWO_STEP bit in the first octet of the flags field as shown below. Reserved bits are cleared.

Table 61-25. PTPv2 message flags field definitions

Bit	Name	Description
0	ALTERNATE_MASTER	See IEEE 1588 Clause 17.4
1	TWO_STEP	1 Two-step clock 0 One-step clock
2	UNICAST	1 Transport layer address uses a unicast destination address 0 Multicast is used
3	—	Reserved
4	—	Reserved
5	Profile specific	
6	Profile specific	
7	—	Reserved

61.6.4 MAC receive

- Check frame framing
- Remove frame preamble and frame SFD field
- Discard frame based on frame destination address field
- Terminate pause frames
- Check frame length
- Remove payload padding if it exists
- Calculate and verify CRC-32
- Write received frames in the core receive FIFO

If the MAC is programmed to operate in half-duplex mode, it will also check if the frame is received with a collision.

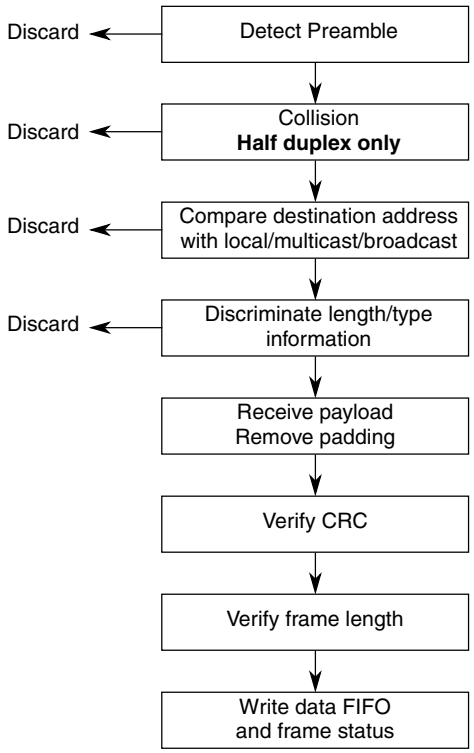

Figure 61-5. MAC receive flow

61.6.4.1 Collision detection in half-duplex mode

If the packet is received with a collision detected during reception of the first 64 bytes, the packet is discarded (if frame size was less than ~14 octets) or transmitted to the user application with an error and RxBD[CE] set.

61.6.4.2 Preamble processing

The IEEE 802.3 standard allows a maximum size of 56 bits (seven bytes) for the preamble, while the MAC core allows any preamble length, including zero length preamble.

The MAC core checks for the start frame delimiter (SFD) byte. If the next byte of the preamble, which is different from 0x55, is not 0xD5, the frame is discarded.

Although the IEEE specification dictates that the inner-packet gap should be at least 96 bits, the MAC core is designed to accept frames separated by only 64 10/100-Mbit/s operation (MII) bits.

The MAC core removes the preamble and SFD bytes.

61.6.4.3 MAC address check

The destination address bit 0 differentiates between multicast and unicast addresses.

- If bit 0 is 0, the MAC address is an individual (unicast) address.
- If bit 0 is 1, the MAC address defines a group (multicast) address.
- If all 48 bits of the MAC address are set, it indicates a broadcast address.

61.6.4.3.1 Unicast address check

If a unicast address is received, the destination MAC address is compared to the node MAC address programmed by the host in the PADDR1/2 registers.

If the destination address matches any of the programmed MAC addresses, the frame is accepted.

If Promiscuous mode is enabled (RCR[PROM] = 1) no address checking is performed and all unicast frames are accepted.

61.6.4.3.2 Multicast and unicast address resolution

The hash table algorithm used in the group and individual hash filtering operates as follows.

- The 48-bit destination address is mapped into one of 64 bits, represented by 64 bits in ENET*n*_GAUR/GALR (group address hash match) or ENET*n*_IAUR/IALR (individual address hash match).
- This mapping is performed by passing the 48-bit address through the on-chip 32-bit CRC generator and selecting the six most significant bits of the CRC-encoded result to generate a number between 0 and 63.
- The msb of the CRC result selects ENET*n*_GAUR (msb = 1) or ENET*n*_GALR (msb = 0).
- The five lsbs of the hash result select the bit within the selected register.
- If the CRC generator selects a bit set in the hash table, the frame is accepted; else, it is rejected.

For example, if eight group addresses are stored in the hash table and random group addresses are received, the hash table prevents roughly 56/64 (or 87.5%) of the group address frames from reaching memory. Those that do reach memory must be further filtered by the processor to determine if they truly contain one of the eight desired addresses.

The effectiveness of the hash table declines as the number of addresses increases.

The user must initialize the hash table registers. Use this CRC32 polynomial to compute the hash:

- $FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^{8} + x^{7} + x^{5} + x^{4} + x^{2} + x^{1} + 1$

If Promiscuous mode is enabled (ENET*n*_RCR[PROM] = 1) all unicast and multicast frames are accepted regardless of ENET*n*_GAUR/GALR and ENET*n*_IAUR/IALR settings.

61.6.4.3.3 Broadcast address reject

All broadcast frames are accepted if BC_REJ is cleared or ENET*n*_RCR[PROM] is set. If PROM is cleared when ENET*n*_RCR[BC_REJ] is set, all broadcast frames are rejected.

Table 61-26. Broadcast address reject programming

PROM	BC_REJ	Broadcast frames
0	0	Accepted
0	1	Rejected
1	0	Accepted
1	1	Accepted

61.6.4.3.4 Miss-bit implementation

For higher layer filtering purposes, RxBD[M] indicates an address miss when the MAC operates in promiscuous mode and accepts a frame that would otherwise be rejected.

If a group/individual hash or exact match does not occur and Promiscuous mode is enabled (RCR[PROM] = 1), the frame is accepted and the M bit is set in the buffer descriptor; otherwise, the frame is rejected.

This means the status bit is set in any of the following conditions during Promiscuous mode:

- A broadcast frame is received when BC_REJ is set
- A unicast is received that does not match either:

- Node address (PALR[PADDR1] and PAUR[PADDR2])
- Hash table for unicast (IAUR[IADDR1] and IALR[IADDR2])

- A multicast is received that does not match the GAUR[GADDR1] and GALR[GADDR2] hash table entries

61.6.4.4 Frame length/type verification: payload length check

If the length/type is less than 0x600 and NLC is set, the MAC checks the payload length and reports any error in the frame status word and interrupt bit PLR.

If the length/type is greater than or equal to 0x600, the MAC interprets the field as a type and no payload length check is performed.

The length check is performed on VLAN and stacked VLAN frames. If a padded frame is received, no length check can be performed due to the extended frame payload because padded frames can never have a payload length error.

61.6.4.5 Frame length/type verification: frame length check

When the receive frame length exceeds MAX_FL bytes, the BABR interrupt is generated and the RxBD[LG] bit is set.

The frame is not truncated unless the frame length exceeds the value programmed in ENET*n*_FTRL[TRUNC_FL]. If the frame is truncated, RxBD[TR] is set. In addition, a truncated frame always has the CRC error indication set (RxBD[CR]).

61.6.4.6 VLAN frames processing

VLAN frames have a length/type field set to 0x8100 immediately followed by a 16-Bit VLAN control information field.

VLAN-tagged frames are received as normal frames because the VLAN tag is not interpreted by the MAC function, and are pushed complete with the VLAN tag to the user application. If the length/type field of the VLAN-tagged frame, which is found four octets later in the frame, is less than 42, the padding is removed. In addition, the frame status word (RxBD[NO]) indicates that the current frame is VLAN tagged.

61.6.4.7 Pause frame termination

The receive engine terminates pause frames and does not transfer them to the receive FIFO. The quanta is extracted and sent to the MAC transmit path via a small internal clock rate decoupling asynchronous FIFO.

The quanta is written only if a correct CRC and frame length are detected by the control state machine. If not, the quanta is discarded and the MAC transmit path is not paused.

Good pause frames are ignored if ENET*n*_RCR[FCE] is cleared and are forwarded to the client interface when ENET*n*_RCR[PAUFWD] is set.

61.6.4.8 CRC check

The CRC-32 field is checked and forwarded to the core FIFO interface if ENET*n*_RCR[CRCFWD] is cleared and ENET*n*_RCR[PADEN] is set.

When CRCFWD is set (regardless of PADEN), the CRC-32 field is checked and terminated (not transmitted to the FIFO).

The CRC polynomial, as specified in the 802.3 standard, is:

- $FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^{8} + x^{7} + x^{5} + x^{4} + x^{2} + x^{1} + 1$

The 32 bits of the CRC value are placed in the frame check sequence (FCS) field with the x^{31} term as right-most bit of the first octet. The CRC bits are thus received in the following order: x^{31}, x^{30},..., x^{1}, x^{0}.

If a CRC error is detected, the frame is marked invalid and RxBD[CR] is set.

61.6.4.9 Frame padding removal

When a frame is received with a payload length field set to less than 46 (42 for VLAN-tagged frames and 38 for frames with stacked VLANs), the zero padding can be removed before the frame is written into the data FIFO depending on the setting of ENET*n*_RCR[PADEN].

Note

If a frame is received with excess padding (in other words, the length field is set as mentioned above, but the frame has more than 64 octets) and padding removal is enabled, then the

padding is removed as normal and no error is reported if the frame is otherwise correct (for example: good CRC, less than maximum length, and no other error).

61.6.5 MAC transmit

Frame transmission starts when the transmit FIFO holds enough data.

After a transfer starts, the MAC transmit function performs the following tasks:

- Generates preamble and SFD field before frame transmission
- Generates XOFF pause frames if the receive FIFO reports a congestion or if ENET*n*_TCR[TFC_PAUSE] is set with ENET*n*_OPD[PAUSE_DUR] set to a non-zero value
- Generates XON pause frames if the receive FIFO congestion condition is cleared or if TFC_PAUSE is set with PAUSE_DUR cleared
- Suspends Ethernet frame transfer (XOFF) if a non-zero pause quanta is received from the MAC receive path
- Adds padding to the frame if required
- Calculates and appends CRC-32 to the transmitted frame
- Sends the frame with correct inter-packet gap (IPG) (deferring)

When the MAC is configured to operate in half-duplex mode, the following additional tasks are performed:

- Collision detection
- Frame retransmit after back-off timer expires

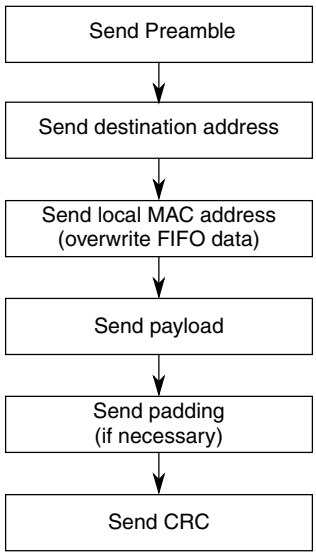

Figure 61-6. Frame transmit overview

61.6.5.1 Frame payload padding

The IEEE specification defines a minimum frame length of 64 bytes.

If the frame sent to the MAC from the user application has a size smaller than 60 bytes, the MAC automatically adds padding bytes (0x00) to comply with the Ethernet minimum frame length specification. Transmit padding is always performed and cannot be disabled.

If the MAC is not allowed to append a CRC (TxBD[TC] = 1), the user application is responsible for providing frames with a minimum length of 64 octets.

61.6.5.2 MAC address insertion

On each frame received from the core transmit FIFO interface, the source MAC address is either:

- Replaced by the address programmed in the PADDR1/2 fields (ENET*n*_TCR[ADDINS] = 1)
- Transparently forwarded to the Ethernet line (ENET*n*_TCR[ADDINS] = 0)

61.6.5.3 CRC-32 generation

The CRC-32 field is optionally generated and appended at the end of a frame.

The CRC polynomial, as specified in the 802.3 standard, is:

- $FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^{8} + x^{7} + x^{5} + x^{4} + x^{2} + x^{1} + 1$

The 32 bits of the CRC value are placed in the FCS field so that the x^{31} term is the right-most bit of the first octet. The CRC bits are thus transmitted in the following order: x^{31}, x^{30},..., x^{1}, x^{0}.

61.6.5.4 Inter-packet gap (IPG)

In full-duplex mode, after frame transmission and before transmission of a new frame, an IPG (programmed in ENET*n*_TIPG) is maintained. The minimum IPG can be programmed between 8 and 26 byte-times (64 and 208 bit-times).

In half-duplex mode, the core constantly monitors the line. Actual transmission of the data onto the network occurs only if it has been idle for a 96-bit time period, and any back-off time requirements have been satisfied. In accordance with the standard, the core begins to measure the IPG from CRS/GMII_CRS de-assertion.

61.6.5.5 Collision detection and handling — half-duplex operation only

A collision occurs on a half-duplex network when concurrent transmissions from two or more nodes take place. During transmission, the core monitors the line condition and detects a collision when the PHY device asserts COL.

When the core detects a collision while transmitting, it stops transmission of the data and transmits a 32-bit jam pattern. If the collision is detected during the preamble or the SFD transmission, the jam pattern is transmitted after completing the SFD, which results in a minimum 96-bit fragment. The jam pattern is a fixed pattern that is not compared to the actual frame CRC, and has a very low probability (0.532) of having a jam pattern identical to the CRC.

If a collision occurs before transmission of 64 bytes (including preamble and SFD), the MAC core waits for the backoff period and retransmits the packet data (stored in a 64-byte re-transmit buffer) that has already been sent on the line. The backoff period is generated from a pseudo-random process (truncated binary exponential backoff).

If a collision occurs after transmission of 64 bytes (including preamble and SFD), the MAC discards the remainder of the frame, optionally sets the LC interrupt bit, and sets TxBD[LCE].

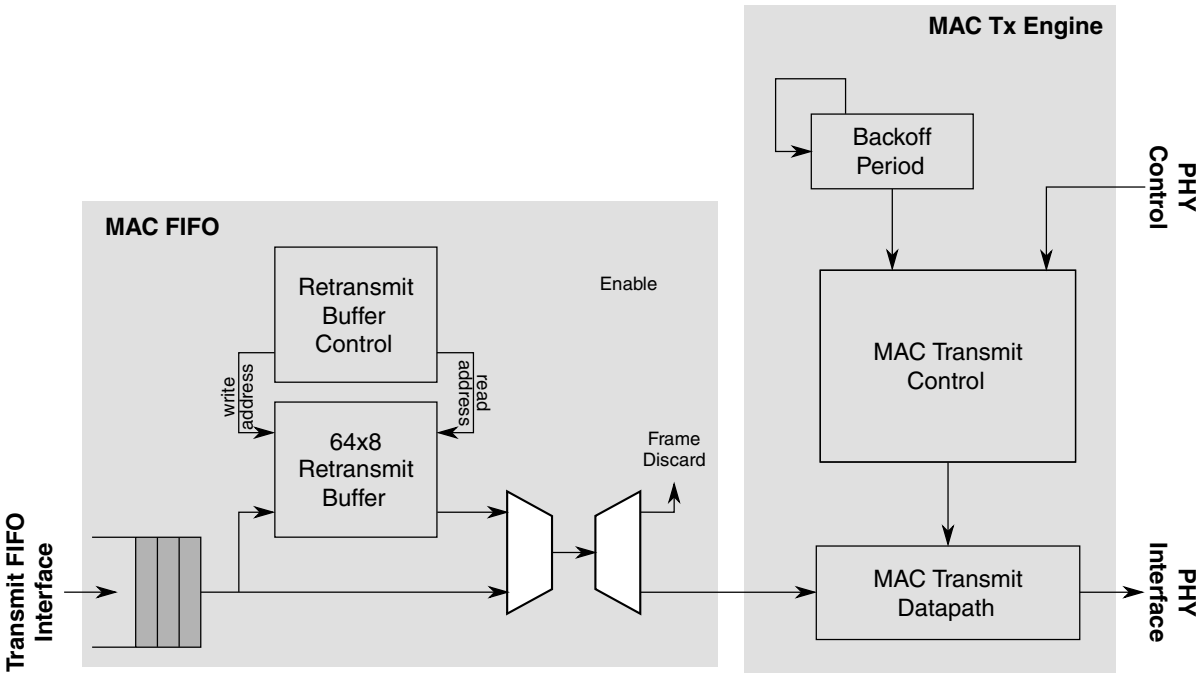

Figure 61-7. Packet re-transmit overview

The backoff time is represented by an integer multiple of slot times. One slot is equal to a 512-bit time period. The number of the delay slot times, before the n^{th} re-transmission attempt, is chosen as a uniformly-distributed random integer in the range:

- $0 < r < 2^k$
- $k = \min(n, N)$; where n is the number of retransmissions and $N = 10$

For example, after the first collision, the backoff period is 0 or 1 slot time. If a collision occurs on the first retransmission, the backoff period is 0, 1, 2, or 3, and so on.

The maximum backoff time (in 512-bit time slots) is limited by N = 10 as specified in the IEEE 802.3 standard.

If a collision occurs after 16 consecutive retransmissions, the core reports an excessive collision condition (ENET*n*_EIR[RL] interrupt field and TxBD[EE]) and discards the current packet from the FIFO.

In networks violating the standard requirements, a collision may occur after transmission of the first 64 bytes. In this case, the core stops the current packet transmission and discards the rest of the packet from the transmit FIFO. The core resumes transmission with the next packet available in the core transmit FIFO.

warning

Ethernet PHYs that support the SQE Test, or "heartbeat,"
feature must disable this feature. When this feature is enabled,

the PHY asserts the collision signal after a frame is transmitted to indicate to the ENET that the PHY's collision logic is working. This may cause data corruption in the next frame from the ENET. This corrupted frame contains up to 21 zero bytes which start somewhere within the MAC destination address field. The ENET, however, will still generate a good FCS (CRC-32) but with corrupted data.

61.6.6 Full-duplex flow control operation

Three conditions are handled by the core's flow control engine:

- Remote device congestion — The remote device connected to the same Ethernet segment as the core reports congestion and requests that the core stop sending data.
- Core FIFO congestion — When the core's receive FIFO reaches a user-programmable threshold (RX section empty), the core sends a pause frame back to the remote device requesting the data transfer to stop.
- Local device congestion — Any device connected to the core can request (typically, via the host processor) the remote device to stop transmitting data.

61.6.6.1 Remote device congestion

When the MAC transmit control gets a valid pause quanta from the receive path and if ENET*n*_RCR[FCE] is set, the MAC transmit logic:

- Completes the transfer of the current frame.
- Stops sending data for the amount of time specified by the pause quanta in 512 bit time increments.
- Sets ENET*n*_TCR[RFC_PAUSE].

Frame transfer resumes when the time specified by the quanta expires and if no new quanta value is received, or if a new pause frame with a quanta value set to 0x0000 is received. The MAC also resets RFC_PAUSE to zero.

If ENET*n*_RCR[FCE] cleared, the MAC ignores received pause frames.

Optionally and independent of ENET*n*_RCR[FCE], pause frames are forwarded to the client interface if PAUFWD is set.

61.6.6.2 Local device/FIFO congestion

The MAC transmit engine generates pause frames when the local receive FIFO is not able to receive more than a pre-defined number of words (FIFO programmable threshold) or when pause frame generation is requested by the local host processor.

- To generate a pause frame, the host processor sets ENET*n*_TCR[TFC_PAUSE]. A single pause frame is generated when the current frame transfer is completed and TFC_PAUSE is automatically cleared. Optionally, an interrupt is generated.
- An XOFF pause frame is generated when the receive FIFO asserts its section empty flag (internal). An XOFF pause frame is generated automatically, when the current frame transfer completes.
- An XON pause frame is generated when the receive FIFO deasserts its section empty flag (internal). An XON pause frame is generated automatically, when the current frame transfer completes.

When an XOFF pause frame is generated, the pause quanta (payload byte P1 and P2) is filled with the value programmed in ENET*n*_OPD[PAUSE_DUR].

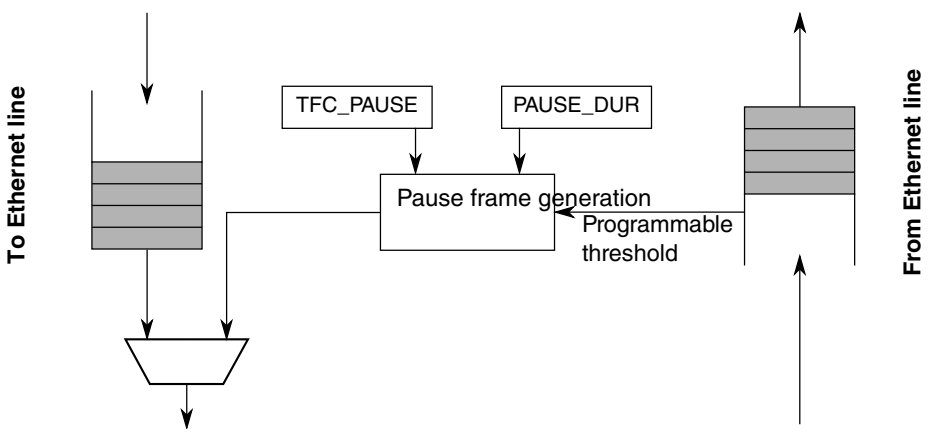

Figure 61-8. Pause frame generation overview

Note

Although the flow control mechanism should prevent any FIFO overflow on the MAC core receive path, the core receive FIFO is protected. When an overflow is detected on the receive FIFO, the current frame is truncated with an error indication set in the frame status word. The frame should subsequently be discarded by the user application.

61.6.7 Magic packet detection

Magic packet detection wakes a node that is put in power-down mode by the node management agent. Magic packet detection is supported only if the MAC is configured in sleep mode.

61.6.7.1 Sleep mode

To put the MAC in Sleep mode, set ENET*n*_ECR[SLEEP]. At the same time ENET*n*_ECR[MAGICEN] should also be set to enable magic packet detection.

In addition, when the processor is in Stop mode, Sleep mode is entered, without affecting the ENET*n*_ECR register bits.

When the MAC is in Sleep mode:

- The transmit logic is disabled.
- The FIFO receive/transmit functions are disabled.
- The receive logic is kept in Normal mode, but it ignores all traffic from the line except magic packets. They are detected so that a remote agent can wake the node.

61.6.7.2 Magic packet detection

The core is designed to detect magic packets with the destination address set to:

- Any multicast address
- The broadcast address
- The unicast address programmed in PADDR1/2

When a magic packet is detected, EIR[WAKEUP] is set and none of the statistic registers are incremented.

61.6.7.3 Wakeup

When a magic packet is detected, indicated by ENET*n*_EIR[WAKEUP], ENET*n*_ECR[SLEEP] should be cleared to resume normal operation of the MAC. Clearing the SLEEP bit automatically masks ENET*n*_ECR[MAGICEN], disabling magic packet detection.

61.6.8 IP accelerator functions

61.6.8.1 Checksum calculation

The IP and ICMP, TCP, UDP checksums are calculated with one's complement arithmetic summing up 16-bit values.

- For ICMP, the checksum is calculated over the complete ICMP datagram, in other words without IP header.
- For TCP and UDP, the checksums contain the header and data sections and values from the IP header, which can be seen as a pseudo-header that is not actually present in the data stream.

Table 61-27. IPv4 pseudo-header for checksum calculation

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
Source address							
Destination address							
Zero			Protocol		TCP/UDP length		

Table 61-28. IPv6 pseudo-header for checksum calculation

31 30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
Source address							
Destination address							
TCP/UDP length							
Zero						Next header	

The TCP/UDP length value is the length of the TCP or UDP datagram, which is equal to the payload of an IP datagram. It is derived by subtracting the IP header length from the complete IP datagram length that is given in the IP header (IPv4), or directly taken from the IP header (IPv6). The protocol field is the corresponding value from the IP header. The Zero fields are all zeroes.

For IPv6, the complete 128-bit addresses are considered. The next header value identifies the upper layer protocol as either TCP or UDP. It may differ from the next header value of the IPv6 header if extension headers are inserted before the protocol header.

The checksum calculation uses 16-bit words in network byte order: The first byte sent/received is the MSB, and the second byte sent/received is the LSB of the 16-bit value to add to the checksum. If the frame ends on an odd number of bytes, a zero byte is appended for checksum calculation only, and is not actually transmitted.

61.6.8.2 Additional padding processing

According to IEEE 802.3, any Ethernet frame must have a minimum length of 64 octets.

The MAC usually removes padding on receive when a frame with length information is received. Because IP frames have a type value instead of length, the MAC does not remove padding for short IP frames, as it is not aware of the frame contents.

The IP accelerator function can be configured to remove the Ethernet padding bytes that might follow the IP datagram.

On transmit, the MAC automatically adds padding as necessary to fill any frame to a 64-byte length.

61.6.8.3 32-bit Ethernet payload alignment

The data FIFOs allow inserting two additional arbitrary bytes in front of a frame. This extends the 14-byte Ethernet header to a 16-byte header, which leads to alignment of the Ethernet payload, following the Ethernet header, on a 32-bit boundary.

This function can be enabled for transmit and receive independently with the corresponding SHIFT16 bits in the ENET*n*_TACC and ENET*n*_RACC registers.

When enabled, the valid frame data is arranged as shown in Table 61-29.

Table 61-29. 64-bit interface data structure with SHIFT16 enabled

63 56	55 48	47 40	39 32	31 24	23 16	15 8	7 0
Byte 5	Byte 4	Byte 3	Byte 2	Byte 1	Byte 0	Any value	Any value
Byte 13	Byte 12	Byte 11	Byte 10	Byte 9	Byte 8	Byte 7	Byte 6
...							

61.6.8.3.1 Receive processing

When ENET*n*_RACC[SHIFT16] is set, each frame is received with two additional bytes in front of the frame.

The user application must ignore these first two bytes and find the first byte of the frame in bits 23–16 of the first word from the RX FIFO.

Note

SHIFT16 must be set during initialization and kept set during the complete operation, because it influences the FIFO write behavior.

61.6.8.3.2 Transmit processing

When ENET*n*_TACC[SHIFT16] is set, the first two bytes of the first word written (bits 15–0) are discarded immediately by the FIFO write logic.

The SHIFT16 bit can be enabled/disabled for each frame individually if required, but can be changed only between frames.

61.6.8.4 Received frame discard

Because the receive FIFO must be operated in store and forward mode (ENET*n*_RSFL cleared), received frames can be discarded based on the following errors:

- The MAC function receives the frame with an error:
  - The frame has an invalid payload length
  - Frame length is greater than MAX_FL
  - Frame received with a CRC-32 error
  - Frame truncated due to receive FIFO overflow
  - Frame is corrupted as PHY signaled an error (RX_ERR asserted during reception)
- An IP frame is detected and the IP header checksum is wrong
- An IP frame with a valid IP header and a valid IP header checksum is detected, the protocol is known but the protocol-specific checksum is wrong

If one of the errors occurs and the IP accelerator function is configured to discard frames (ENET*n*_RACC), the frame is automatically discarded. Statistics are maintained normally and are not affected by this discard function.

61.6.8.5 IPv4 fragments

When an IPv4 IP fragment frame is received, only the IP header is inspected and its checksum verified. 32-bit alignment operates the same way on fragments as it does on normal IP frames.

The IP fragment frame payload is not inspected for any protocol headers. As such, a protocol header would only exist in the very first fragment. To assist in protocol-specific checksum verification, the one's-complement sum is calculated on the IP payload (all bytes following the IP header) and provided with the frame status word.

The frame fragment status field (RxBD[FRAG]) is set to indicate a fragment reception, and the one's-complement sum of the IP payload is available in RxBD[Payload checksum].

Note

After all fragments have been received and reassembled, the application software can take advantage of the payload checksum delivered with the frame's status word to calculate the protocol-specific checksum of the datagram.

For example, if a TCP payload is delivered by multiple IP fragments, the application software can calculate the pseudo-header checksum value from the first fragment, and add the payload checksums delivered with the status for all fragments to verify the TCP datagram checksum.

61.6.8.6 IPv6 support

The following sections describe the IPv6 support.

61.6.8.6.1 Receive processing

An Ethernet frame of type 0x86DD identifies an IP Version 6 frame (IPv6) frame. If an IPv6 frame is received, the first IP header is inspected (first ten words), which is available in every IPv6 frame.

If the receive SHIFT16 function is enabled, the IP header is aligned on a 32-bit boundary allowing more efficient processing.

For TCP and UDP datagrams, the pseudo-header checksum calculation is performed and verified.

To assist in protocol-specific checksum verification, the one's-complement sum is always calculated on the IP payload (all bytes following the IP header) and provided with the frame status word. For example, if extension headers were present, their sums can be subtracted in software from the checksum to isolate the TCP/UDP datagram checksum, if required.

61.6.8.6.2 Transmit processing

For IPv6 transmission, the SHIFT16 function is supported to process 32-bit aligned datagrams.

IPv6 has no IP header checksum; therefore, the IP checksum insertion configuration is ignored.

The protocol checksum is inserted only if the next header of the IP header is a known protocol (TCP, UDP, or ICMP). If a known protocol is detected, the checksum over all bytes following the IP header is calculated and inserted in the correct position.

The pseudo-header checksum calculation is performed for TCP and UDP datagrams accordingly.

61.6.9 Resets and stop controls

61.6.9.1 Hardware reset

To reset the Ethernet module, set ENET*n*_ECR[RESET].

61.6.9.2 Soft reset

When ENET*n*_ECR[ETHER_EN] is cleared during operation, the following occurs:

- uDMA, buffer descriptor, and FIFO control logic are reset, including the buffer descriptor and FIFO pointers.
- A currently ongoing transmit is terminated by asserting GMII/TXER to the PHY.

- A currently ongoing transmit FIFO write from the application is terminated by stopping the write to the FIFO, and all further data from the application is ignored. All subsequent writes are ignored until re-enabled.
- A currently ongoing receive FIFO read is terminated. The RxBD has arbitrary values in this case.

61.6.9.3 Hardware freeze

When the processor enters debug mode and ECR[DBGEN] is set, the MAC enters a freeze state where it stops all transmit and receive activities gracefully.

The following happens when the MAC enters hardware freeze:

- A currently ongoing receive transaction on the receive application interface is completed as normal. No further frames are read from the FIFO.
- A currently ongoing transmit transaction on the transmit application interface is completed as normal (in other words, until writing end-of-packet (EOP)).
- A currently ongoing frame receive is completed normally, after which no further frames are accepted from the MII/GMII.
- A currently ongoing frame transmit is completed normally, after which no further frames are transmitted.

61.6.9.4 Graceful stop

During a graceful stop, any currently ongoing transactions are completed normally and no further frames are accepted. The MAC can resume from a graceful stop without the need for a reset (for example, clearing ETHER_EN is not required).

The following conditions lead to a graceful stop of the MAC transmit or receive datapaths.

61.6.9.4.1 Graceful transmit stop (GTS)

When gracefully stopped, the MAC is no longer reading frame data from the transmit FIFO and has completed any ongoing transmission.

In any of the following conditions, the transmit datapath stops after an ongoing frame transmission has been completed normally.

- ENET*n*_TCR[GTS] is set by software.
- ENET*n*_TCR[TFC_PAUSE] is set by software requesting a pause frame transmission. The status (and register bit) is cleared after the pause frame has been sent.
- A pause frame was received stopping the transmitter. The stopped situation is terminated when the pause timer expires or a pause frame with zero quanta is received.
- MAC is placed in Sleep mode by software or the processor entering Stop mode (see Sleep mode).
- The MAC is in Hardware Freeze mode.

When the transmitter has reached its stopped state, the following events occur:

- The GRA interrupt is asserted, when transitioned into stopped.
- In Hardware Freeze mode, the GRA interrupt does not wait for the application write completion and asserts when the transmit state machine (in other words, line side of TX FIFO) reaches its stopped state.

61.6.9.4.2 Graceful receive stop (GRS)

When gracefully stopped, the MAC is no longer writing frames into the receive FIFO.

The receive datapath stops after any ongoing frame reception has been completed normally, if any of the following conditions occur:

- MAC is placed in Sleep mode either by the software or the processor is in Stop mode). The MAC continues to receive frames and search for magic packets if enabled (see Magic packet detection). However, no frames are written into the receive FIFO, and therefore are not forwarded to the application.
- The MAC is in Hardware Freeze mode. The MAC does not accept any frames from the MII/GMII.

When the receive datapath is stopped, the following events occur:

- If the RX is in the stopped state, RCR[GRS] is set

- The GRA interrupt is asserted when the transmitter and receiver are stopped
- Any ongoing receive transaction to the application (RX FIFO read) continues normally until the frame end of package (EOP) is reached. After this, the following occurs:
  - When Sleep mode is active, all further frames are discarded, flushing the RX FIFO
  - In Hardware Freeze mode, no further frames are delivered to the application and they stay in the receive FIFO.

Note

The assertion of GRS does not wait for an ongoing FIFO read transaction on the application side of the FIFO (FIFO read).

61.6.9.4.3 Graceful stop interrupt (GRA)

The graceful stopped interrupt (GRA) is asserted for the following conditions:

- In Sleep mode, the interrupt asserts only after both TX and RX datapaths are stopped.
- In Hardware Freeze mode, the interrupt asserts only after both TX and RX datapaths are stopped.
- The MAC transmit datapath is stopped for any other condition (GTS, TFC_PAUSE, pause received).

The GRA interrupt is triggered only once when the stopped state is entered. If the interrupt is cleared while the stop condition persists, no further interrupt is triggered.

61.6.10 IEEE 1588 functions

To allow for IEEE 1588 or similar time synchronization protocol implementations, the MAC is combined with a time-stamping module to support precise time-stamping of incoming and outgoing frames. Set ENET*n*_ECR[EN1588] to enable 1588 support.

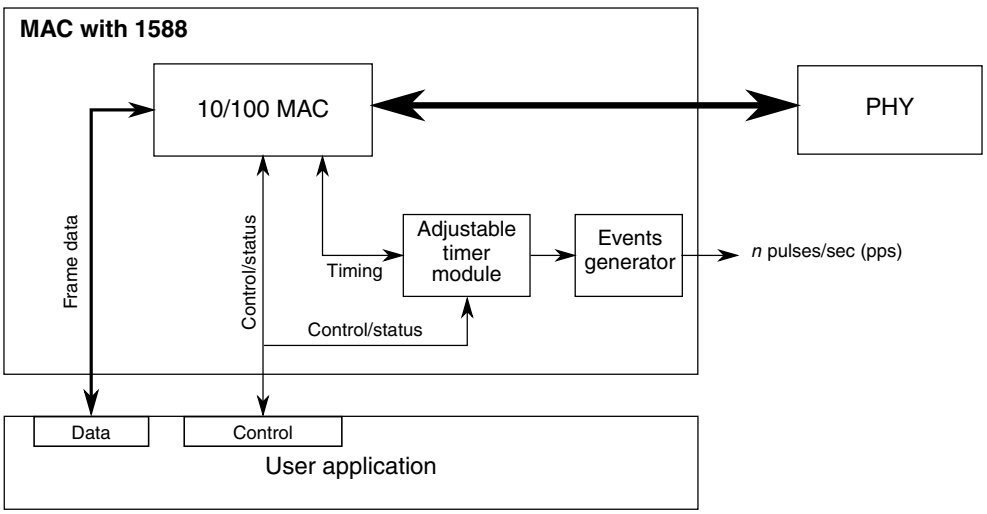

Figure 61-9. IEEE 1588 functions overview

61.6.10.1 Adjustable timer module

The adjustable timer module (TSM) implements the free-running counter (FRC), which generates the timestamps. The FRC operates with the time-stamping clock, which can be set to any value depending on your system requirements.

Through dedicated correction logic, the timer can be adjusted to allow synchronization to a remote master and provide a synchronized timing reference to the local system. The timer can be configured to cause an interrupt after a fixed time period, to allow synchronization of software timers or perform other synchronized system functions.

The timer is typically used to implement a period of one second; hence, its value ranges from 0 to (1×10^9)-1. The period event can trigger an interrupt, and software can maintain the seconds and hours time values as necessary.

61.6.10.1.1 Adjustable timer implementation

The adjustable timer consists of a programmable counter/accumulator and a correction counter. The periods of both counters and their increment rates are freely configurable, allowing very fine tuning of the timer.

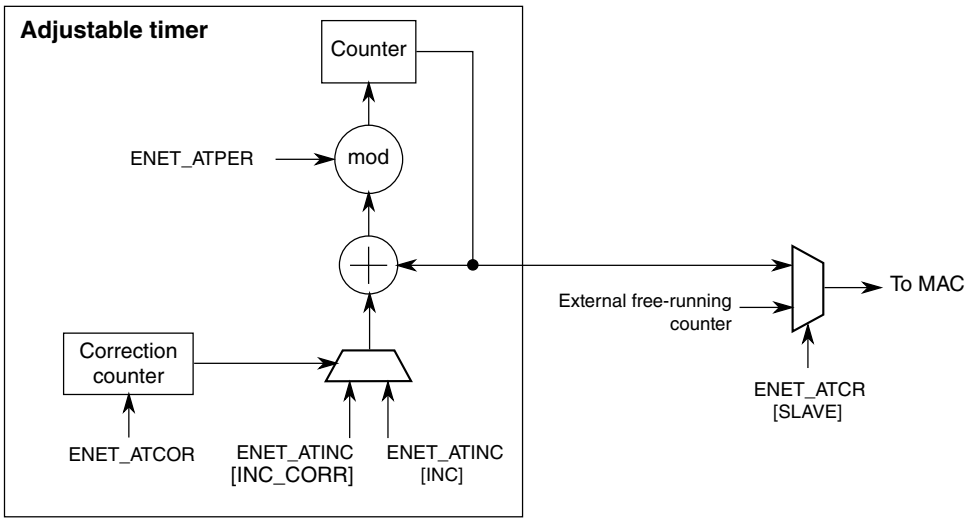

Figure 61-10. Adjustable timer implementation detail

The counter produces the current time. During each time-stamping clock cycle, a constant value is added to the current time as programmed in ENET*n*_ATINC. The value depends on the chosen time-stamping clock frequency. For example, if it operates at 125 MHz, setting the increment to eight represents 8 ns.

The period, configured in ENET*n*_ATPER, defines the modulo when the counter wraps. In a typical implementation, the period is set to 1×10^9 so that the counter wraps every second, and hence all timestamps represent the absolute nanoseconds within the one second period. When the period is reached, the counter wraps to start again respecting the period modulo. This means it does not necessarily start from zero, but instead the counter is loaded with the value (Current + Inc $-(1 \times 10^9)$), assuming the period is set to 1×10^9.

The correction counter operates fully independently, and increments by one with each time-stamping clock cycle. When it reaches the value configured in ENET*n*_ATCOR, it restarts and instructs the timer once to increment by the correction value, instead of the normal value.

The normal and correction increments are configured in ENET*n*_ATINC. To speed up the timer, set the correction increment more than the normal increment value. To slow down the timer, set the correction increment less than the normal increment value.

The correction counter only defines the distance of the corrective actions, not the amount. This allows very fine corrections and low jitter (in the range of 1 ns) independent of the chosen clock frequency.

By enabling slave mode (ENET*n*_ATCR[SLAVE] = 1), the timer is ignored and the current time is externally provided from one of the external modules. See the Chip Configuration details for which clock source is used. This is useful if multiple modules

within the system must operate from a single timer. When slave mode is enabled, you still must set ENET*n*_ATINC[INC] to the value of the master, since it is used for internal comparisons.

61.6.10.2 Transmit timestamping

Only 1588 event frames need to be time-stamped on transmit. The client application (for example, the MAC driver) should detect 1588 event frames and set TxBD[TS] together with the frame.

If TxBD[TS] is set, the MAC records the timestamp for the frame in ENET*n*_ATSTMP. ENET*n*_EIR[TS_AVAIL] is set to indicate that a new timestamp is available.

Software implements a handshaking procedure by setting TxBD[TS] when it transmits the frame for which a timestamp is needed, and then waits for ENET*n*_EIR[TS_AVAIL] to determine when the timestamp is available. The timestamp is then read from ENET*n*_ATSTMP. This is done for all event frames. Other frames do not use TxBD[TS] and, therefore, do not interfere with the timestamp capture.

61.6.10.3 Receive timestamping

When a frame is received, the MAC latches the value of the timer when the frame's start of frame delimiter (SFD) field is detected, and provides the captured timestamp on RxBD[1588 timestamp]. This is done for all received frames.

61.6.10.4 Time synchronization

The adjustable timer module is available to synchronize the local clock of a node to a remote master. It implements a free running 32-bit counter, and also contains an additional correction counter.

The correction counter increases or decreases the rate of the free running counter, enabling very fine granular changes of the timer for synchronization, yet adding only very low jitter when performing corrections.

The application software implements, in a slave scenario, the required control algorithm, setting the correction to compensate for local oscillator drifts and locking the timer to the remote master clock on the network.

The timer and all timestamp-related information should be configured to show the true nanoseconds value of a second (in other words, the timer is configured to have a period of one second). Hence, the values range from 0 to (1×10^9)–1. In this application, the seconds counter is implemented in software using an interrupt function that is executed when the nanoseconds counter wraps at 1×10^9.

61.6.10.5 Input Capture and Output Compare

The Input Capture Output Compare block can be used to provide precise hardware timing for input and output events.

61.6.10.5.1 Input capture

The TCCR*n* capture registers latch the time value when the corresponding external event occurs. An event can be a rising-, falling-, or either-edge of one of the 1588_TMR*n* signals. An event will cause the corresponding TCSR*n*[TF] timer flag to be set, indicating that an input capture has occurred. If the corresponding interrupt is enabled with the TCSR*n*[TIE] field, an interrupt can be generated.

61.6.10.5.2 Output compare

The TCCR*n* compare registers are loaded with the time at which the corresponding event should occur. When the ENET free-running counter value matches the output compare reference value in the TCCR*n* register, the corresponding flag, TCSR*n*[TF], is set, indicating that an output compare has occurred. The corresponding interrupt, if enabled by TCSR*n*[TIE], will be generated.The corresponding 1588_TMR*n* output signal will be asserted according to TCSR*n*[TMODE].

61.6.10.5.3 DMA requests

A DMA request can be enabled by setting TCSR*n*[TDRE]. The corresponding DMA request is generated when the TCSR*n*[TF] timer flag is set. When the DMA has completed, the corresponding TCSRn[TF] flag is cleared.

61.6.11 FIFO thresholds

The core FIFO thresholds are fully programmable to dynamically change the FIFO operation.

For example, store and forward transfer can be enabled by a simple change in the FIFO threshold registers.

The thresholds are defined in 64-bit words.

The receive and transmit FIFOs both have a depth of 512 words.

61.6.11.1 Receive FIFO

Four programmable thresholds are available, which can be set to any value to control the core operation.

Table 61-30. Receive FIFO thresholds definition

Register	Description
ENET*n*_RSFL [RX_SECTION_FULL]	When the FIFO level reaches the ENET*n*_RSFL value, the MAC status signal is asserted to indicate that data is available in the receive FIFO (cut-through operation). Once asserted, if the FIFO empties below the threshold set with ENET*n*_RAEM and if the end-of-frame is not yet stored in the FIFO, the status signal is deasserted again. If a frame has a size smaller than the threshold (in other words, an end-of-frame is available for the frame), the status is also asserted. To enable store and forward on the receive path, clear ENET*n*_RSFL. The MAC status signal is asserted only when a complete frame is stored in the receive FIFO. When programming a non-zero value to ENET*n*_RSFL (cut-through operation) it should be greater than ENET*n*_RAEM.
ENET*n*_RAEM [RX_ALMOST_EMPTY]	When the FIFO level reaches the ENET*n*_RAEM value, and the end-of-frame has not been received, the core receive read control stops the FIFO read (and subsequently stops transferring data to the MAC client application). It continues to deliver the frame, if again more data than the threshold or the end-of-frame is available in the FIFO. Set ENET*n*_RAEM to a minimum of six.
ENET*n*_RAFL [RX_ALMOST_FULL]	When the FIFO level approaches the maximum and there is no more space remaining for at least ENETn_RAFL number of words, the MAC control logic stops writing data in the FIFO and truncates the receive frame to avoid FIFO overflow. The corresponding error status is set when the frame is delivered to the application. Set ENET*n*_RAFL to a minimum of 4.
ENET*n*_RSEM [RX_SECTION_EMPTY]	When the FIFO level reaches the ENET*n*_RSEM value, an indication is sent to the MAC transmit logic, which generates an XOFF pause frame. This indicates FIFO congestion to the remote Ethernet client. When the FIFO level goes below the value programmed in ENET*n*_RSEM, an indication is sent to the MAC transmit logic, which generates an XON pause frame. This indicates the FIFO congestion is cleared to the remote Ethernet client. Clearing ENET*n*_RSEM disables any pause frame generation.

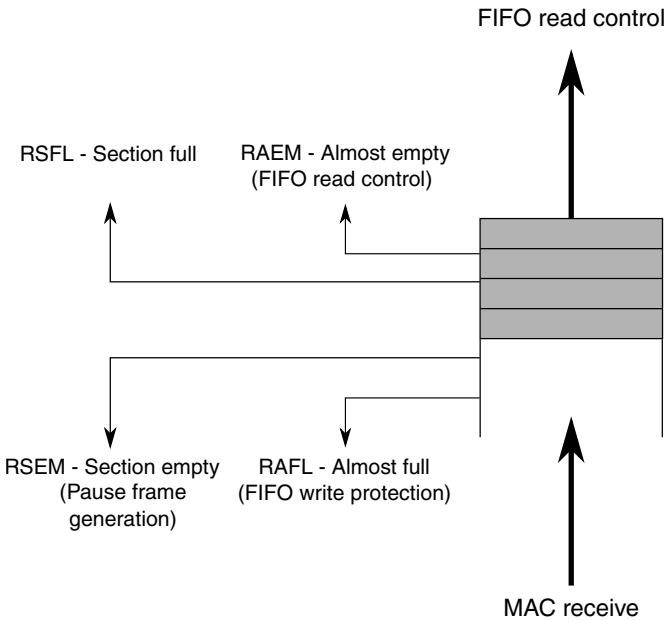

Figure 61-11. Receive FIFO overview

61.6.11.2 Transmit FIFO

Four programmable thresholds are available which control the core operation.

Table 61-31. Transmit FIFO thresholds definition

Register	Description
ENET*n*_TAEM [TX_ALMOST _EMPTY]	When the FIFO level reaches the ENET*n*_TAEM value and no end-of-frame is available for the frame, the MAC transmit logic avoids a FIFO underflow by stopping FIFO reads and transmitting the Ethernet frame with an MII error indication. Set ENET*n*_TAEM to a minimum of 4.
ENET*n*_TAFL [TX_ALMOST _FULL]	When the FIFO level approaches the maximum, so that there is no more space for at least ENET*n*_TAFL number of words, the MAC deasserts its control signal to the application. If the application does not react on this signal, the FIFO write control logic avoids FIFO overflow by truncating the current frame and setting the error status. As a result, the frame is transmitted with an GMII/MII error indication. Set ENET*n*_TAFL to a minimum of 4. Larger values allow more latency for the application to react on the MAC control signal deassertion, before the frame is truncated. A typical setting is 8, which offers 3–4 clock cycles of latency to the application to react on the MAC control signal deassertion.
ENET*n*_TSEM [TX_SECTION _EMPTY]	When the FIFO level reaches the ENET*n*_TSEM value, a MAC status signal is deasserted to indicate that the transmit FIFO is getting full. This gives the ENET module an indication to slow or stop its write transaction to avoid a buffer overflow. This is a pure indication function to the application. It has no effect within the MAC. When ENET*n*_TSEM is 0, the signal is never deasserted.
ENET*n*_TFWR	When the FIFO level reaches the ENET*n*_TFWR value and when STRFWD is cleared, the MAC transmit control logic starts frame transmission before the end-of-frame is available in the FIFO (cut-through operation).

Table 61-31. Transmit FIFO thresholds definition

Register	Description
	If a complete frame has a size smaller than the ENET*n*_TFWR threshold, the MAC also transmits the frame to the line. To enable store and forward on the transmit path, set STRFWD. In this case, the MAC starts to transmit data only when a complete frame is stored in the transmit FIFO.

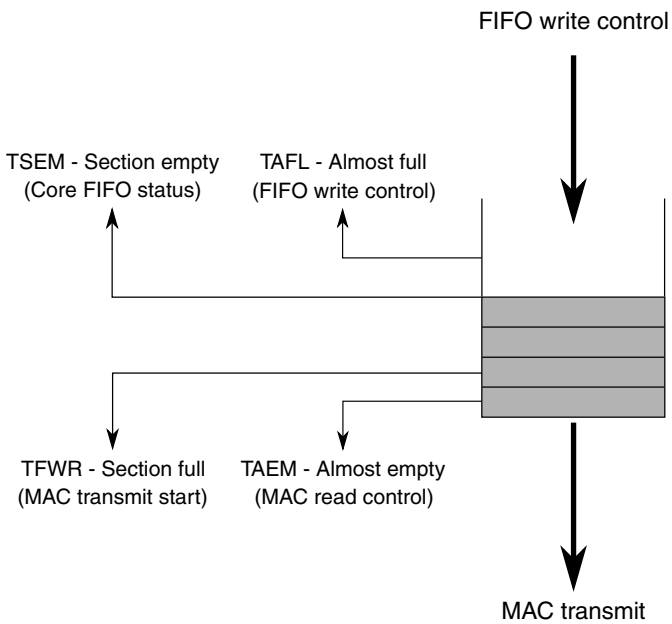

Figure 61-12. Transmit FIFO overview

61.6.12 Loopback options

The core implements external and internal loopback options, which are controlled by the ENET*n*_RCR register fields found here.

Table 61-32. Loopback options

Register field	Description
LOOP	Internal MII loopback. The MAC transmit is returned to the MAC receive. No data is transmitted to the external interfaces. In MII internal loopback, MII_TXCLK and MII_RXCLK must be provided with a clock signal (2.5 MHz for 10 Mbit/s, and 25 MHz for 100 Mbit/s))

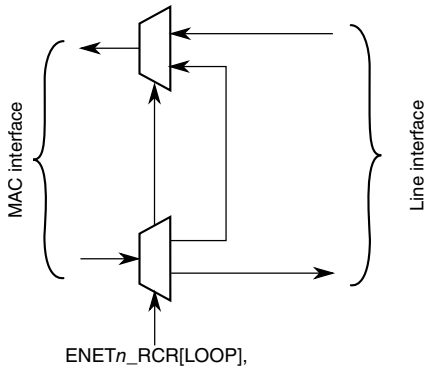

Figure 61-13. Loopback options

61.6.13 Legacy buffer descriptors

To support the Ethernet controller on previous chips, legacy FEC buffer descriptors are available. To enable legacy support, write 0 to ENET*n*_ECR[1588EN].

NOTE

- The legacy buffer descriptor tables show the byte order for big-endian chips. DBSWP must be set to 0 after reset to enable big-endian mode.

61.6.13.1 Legacy receive buffer descriptor

The following table shows the legacy FEC receive buffer descriptor. Table 61-36 contains the descriptions for each field.

Table 61-33. Legacy FEC receive buffer descriptor (RxBD)

	Byte 0								Byte 1							
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Offset + 6	Tx Data Buffer Pointer — low halfword															

1. This field is not supported by the uDMA.

61.6.14 Enhanced buffer descriptors

This section provides a description of the enhanced operation of the driver/uDMA via the buffer descriptors.

It is followed by a detailed description of the receive and transmit descriptor fields. To enable the enhanced features, set ENET*n*_ECR[1588EN].

NOTE

The enhanced buffer descriptor tables show the byte order for big-endian chips. DBSWP must be set to 0 after reset to enable big-endian mode.

61.6.14.1 Enhanced receive buffer descriptor

The following table shows the enhanced uDMA receive buffer descriptor. Table 61-36 contains the descriptions for each field.

Table 61-35. Enhanced uDMA receive buffer descriptor (RxBD)

	Byte 0								Byte 1							
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Table 61-36. Receive buffer descriptor field definitions

Word	Field	Description
Offset + 0	0 E	Empty. Written by the MAC (= 0) and user (= 1). 0 The data buffer associated with this BD is filled with received data, or data reception has aborted due to an error condition. The status and length fields have been updated as required. 1 The data buffer associated with this BD is empty, or reception is currently in progress.
Offset + 0	1 RO1	Receive software ownership. This field is reserved for use by software. This read/write field is not modified by hardware, nor does its value affect hardware.
Offset + 0	2 W	Wrap. Written by user. 0 The next buffer descriptor is found in the consecutive location. 1 The next buffer descriptor is found at the location defined in ENET*n*_RDSR.
Offset + 0	3 RO2	Receive software ownership. This field is reserved for use by software. This read/write field is not modified by hardware, nor does its value affect hardware.
Offset + 0	4 L	Last in frame. Written by the uDMA. 0 The buffer is not the last in a frame. 1 The buffer is the last in a frame.
Offset + 0	5–6	Reserved, must be cleared.
Offset + 0	7 M	Miss. Written by the MAC. This field is set by the MAC for frames accepted in promiscuous mode, but flagged as a miss by the internal address recognition. Therefore, while in promiscuous mode, you can use this field to quickly determine whether the frame was destined to this station. This field is valid only if the L and PROM fields are set to 1. 0 The frame was received because of an address recognition hit. 1 The frame was received because of promiscuous mode. The information needed for this field comes from the promiscuous_miss(ff_rx_err_stat[26]) sideband signal.
Offset + 0	8 BC	Set if the DA is broadcast (FFFF_FFFF_FFFF).

Table continues on the next page...

Table 61-36. Receive buffer descriptor field definitions (continued)

Word	Field	Description
Offset + 0	9 MC	Set if the DA is multicast and not BC.
Offset + 0	10 LG	Receive frame length violation. Written by the MAC. A frame length greater than RCR[MAX_FL] was recognized. This field is valid only if the L field is set. The receive data is not altered in any way unless the length exceeds TRUNC_FL bytes.
Offset + 0	11 NO	Receive non-octet aligned frame. Written by the MAC. A frame that contained a number of bits not divisible by 8 was received, and the CRC check that occurred at the preceding byte boundary generated an error or a PHY error occurred. This field is valid only if the L field is set. If this field is set, the CR field is not set.
Offset + 0	12	Reserved, must be cleared.
Offset + 0	13 CR	Receive CRC or frame error. Written by the MAC. This frame contains a PHY or CRC error and is an integral number of octets in length. This field is valid only if the L field is set.
Offset + 0	14 OV	Overrun. Written by the MAC. A receive FIFO overrun occurred during frame reception. If this field is set, the other status fields, M, LG, NO, and CR, lose their normal meaning and are zero. This field is valid only if the L field is set.
Offset + 0	15 TR	Set if the receive frame is truncated (frame length >TRUNC_FL). If the TR field is set, the frame must be discarded and the other error fields must be ignored because they may be incorrect.
Offset + 2	0–15 Data Length	Data length. Written by the MAC. Data length is the number of octets written by the MAC into this BD's data buffer if L is cleared (the value is equal to EMRBR), or the length of the frame including CRC if L is set. It is written by the MAC once as the BD is closed.
0ffset + 4	0–15 Data buffer pointer high	Receive data buffer pointer, high halfword[1]
Offset + 6	0–15 Data buffer pointer low	Receive data buffer pointer, low halfword
Offset + 8	0 ME	MAC error. This field is written by the uDMA. This field means that the frame stored in the system memory was received with an error (typically, a receive FIFO overflow). This field is only valid when the L field is set.
Offset + 8	1–4	Reserved, must be cleared.
Offset + 8	5 PE	PHY Error. This field is written by the uDMA. Set to "1"when the frame was received with an Error character on the PHY interface. The frame is invalid. This field is valid only when the L field is set.
Offset + 8	6 CE	Collision. This field is written by the uDMA. Set when the frame was received with a collision detected during reception. The frame is invalid and sent to the user application. This field is valid only when the L field is set.
Offset + 8	7 UC	Unicast. This field is written by the uDMA, and means that the frame is unicast. This field is valid regardless of whether the L field is set.
Offset + 8	8 INT	Generate RXB/RXF interrupt. This field is set by the user to indicate that the uDMA is to generate an interrupt on the *dma_int_rxb* / *dma_int_rxfevent*.
Offset + 8	9–15	Reserved, must be cleared.

Table continues on the next page...

Table 61-36. Receive buffer descriptor field definitions (continued)

Word	Field	Description
Offset + A	0–2 VPCP	VLAN priority code point. This field is written by the uDMA to indicate the frame priority level. Valid values are from 0 (best effort) to 7 (highest). This value can be used to prioritize different classes of traffic (e.g., voice, video, data). This field is only valid if the L field is set.
Offset + A	3–9	Reserved, must be cleared.
Offset + A	10 ICE	IP header checksum error. This is an accelerator option. This field is written by the uDMA. Set when either a non-IP frame is received or the IP header checksum was invalid. An IP frame with less than 3 bytes of payload is considered to be an invalid IP frame. This field is only valid if the L field is set.
Offset + A	11 PCR	Protocol checksum error. This is an accelerator option. This field is written by the uDMA. Set when the checksum of the protocol is invalid or an unknown protocol is found and checksumming could not be performed. This field is only valid if the L field is set.
Offset + A	12	Reserved, must be cleared.
Offset + A	13 VLAN	VLAN. This is an accelerator option. This field is written by the uDMA. It means that the frame has a VLAN tag. This field is valid only if the L field is set.
Offset + A	14 IPV6	IPV6 Frame. This field is written by the uDMA. This field indicates that the frame has an IPv6 frame type. If this field is not set it means that an IPv4 or other protocol frame was received. This field is valid only if the L field is set.
Offset + A	15 FRAG	IPv4 Fragment.This is an accelerator option.This field is written by the uDMA. It indicates that the frame is an IPv4 fragment frame. This field is only valid when the L field is set.
Offset + C	0–4 Header length	Header length. This is an accelerator option. This field is written by the uDMA. This field is the sum of 32-bit words found within the IP and its following protocol headers. If an IP datagram with an unknown protocol is found, then the value is the length of the IP header. If no IP frame or an erroneous IP header is found, the value is 0. The following values are minimum values if no header options exist in the respective headers: • ICMP/IP: 6 (5 IP header, 1 ICMP header) • UDP/IP: 7 (5 IP header, 2 UDP header) • TCP/IP: 10 (5 IP header, 5 TCP header) This field is only valid if the L field is set.
Offset + C	5–7	Reserved, must be cleared.
Offset + C	8–15 Protocol type	Protocol type. This is an accelerator option. The 8-bit protocol field found within the IP header of the frame. It is valid only when ICE is cleared. This field is valid only when the L field is set.
Offset + E	0–15 Payload checksum	Internet payload checksum. This is an accelerator option. It is the one's complement sum of the payload section of the IP frame. The sum is calculated over all data following the IP header until the end of the IP payload. This field is valid only when the L field is set.
Offset + 10	0 BDU	Last buffer descriptor update done. Indicates that the last BD data has been updated by uDMA. This field is written by the user (=0) and uDMA (=1).
Offset + 10	1–15	Reserved, must be cleared.
Offset + 12	0–15	Reserved, must be cleared.
Offset + 14	0–15 1588 timestamp	This value is written by the uDMA. It is only valid if the L field is set.
Offset + 16		
Offset + 18	0–15	Reserved, must be cleared.

Table 61-36. Receive buffer descriptor field definitions

Word	Field	Description
– Offset + 1E		

1. The receive buffer pointer, containing the address of the associated data buffer, must always be evenly divisible by 64. The buffer must reside in memory external to the MAC. The Ethernet controller never modifies this value.

61.6.14.2 Enhanced transmit buffer descriptor

Table 61-37. Enhanced transmit buffer descriptor (TxBD)

	Byte 0								Byte 1

Table 61-38. Enhanced transmit buffer descriptor field definitions

Word	Field	Description
Offset + 0	0 R	Ready. Written by the MAC and user. 0 The data buffer associated with this BD is not ready for transmission. You are free to manipulate this BD or its associated data buffer. The MAC clears this field after the buffer has been transmitted or after an error condition is encountered. 1 The data buffer, prepared for transmission by you, has not been transmitted or currently transmits. You may write no fields of this BD after this field is set.
Offset + 0	1	Transmit software ownership. This field is reserved for software use. This read/write field is not modified by hardware and its value does not affect hardware.

Table continues on the next page...

Table 61-38. Enhanced transmit buffer descriptor field definitions (continued)

Word	Field	Description
	TO1	
Offset + 0	2 W	Wrap. Written by user. 0 The next buffer descriptor is found in the consecutive location 1 The next buffer descriptor is found at the location defined in ETDSR.
Offset + 0	3 TO2	Transmit software ownership. This field is reserved for use by software. This read/write field is not modified by hardware and its value does not affect hardware.
Offset + 0	4 L	Last in frame. Written by user. 0 The buffer is not the last in the transmit frame 1 The buffer is the last in the transmit frame
Offset + 0	5 TC	Transmit CRC. Written by user, and valid only when L is set. 0 End transmission immediately after the last data byte 1 Transmit the CRC sequence after the last data byte This field is valid only when the L field is set.
Offset + 0	6 ABC	Append bad CRC. **Note:** This field is not supported by the uDMA and is ignored.
Offset + 0	7–15	Reserved, must be cleared.
Offset + 2	0–15 Data Length	Data length, written by user. Data length is the number of octets the MAC should transmit from this BD's data buffer. It is never modified by the MAC.
Offset + 4	0–15 Data buffer pointer high	Tx data buffer pointer, high halfword. The buffer must reside in memory external to the MAC. This value is never modified by the Ethernet controller. **NOTE:** For optimal performance, make the transmit buffer pointer evenly divisible by 64.
Offset + 6	0–15 Data buffer pointer low	Tx data buffer pointer, low halfword
Offset + 8	0	Reserved, must be cleared.
Offset + 8	1 INT	Generate interrupt flags. This field is written by the user. This field is valid regardless of the L field and must be the same for all EBD for a given frame. The uDMA does not update this value.
Offset + 8	2 TS	Timestamp. This field is written by the user. This indicates that the uDMA is to generate a timestamp frame to the MAC. This field is valid regardless of the L field and must be the same for all EBD for the given frame. The uDMA does not update this value.
Offset + 8	3 PINS	Insert protocol specific checksum. This field is written by the user. If set, the MAC's IP accelerator calculates the protocol checksum and overwrites the corresponding checksum field with the calculated value. The checksum field must be cleared by the application generating the frame. The uDMA does not update this value. This field is valid regardless of the L field and must be the same for all EBD for a given frame.
Offset + 8	4 IINS	Insert IP header checksum. This field is written by the user. If set, the MAC's IP accelerator calculates the IP header checksum and overwrites the corresponding header field with the calculated value. The checksum field must be cleared by

Table continues on the next page...

Table 61-38. Enhanced transmit buffer descriptor field definitions (continued)

Word	Field	Description
		the application generating the frame. The uDMA does not update this value. This field is valid regardless of the L field and must be the same for all EBD for a given frame.
Offset + 8	5–15	Reserved, must be cleared.
Offset + A	0 TXE	Transmit error occurred. This field is written by the uDMA. This field indicates that there was a transmit error of some sort reported with the frame. Effectively this field is an OR of the other error fields including UE, EE, FE, LCE, OE, and TSE. This field is valid only when the L field is set.
Offset + A	1	Reserved, must be cleared.
Offset + A	2 UE	Underflow error. This field is written by the uDMA. This field indicates that the MAC reported an underflow error on transmit. This field is valid only when the L field is set.
Offset + A	3 EE	Excess Collision error. This field is written by the uDMA. This field indicates that the MAC reported an excess collision error on transmit. This field is valid only when the L field is set.
Offset + A	4 FE	Frame with error. This field is written by the uDMA. This field indicates that the MAC reported that the uDMA reported an error when providing the packet. This field is valid only when the L field is set.
Offset + A	5 LCE	Late collision error. This field is written by the uDMA. This field indicates that the MAC reported that there was a Late Collision on transmit. This field is valid only when the L field is set.
Offset + A	6 OE	Overflow error. This field is written by the uDMA. This field indicates that the MAC reported that there was a FIFO overflow condition on transmit. This field is only valid when the L field is set.
Offset + A	7 TSE	Timestamp error. This field is written by the uDMA. This field indicates that the MAC reported a different frame type then a timestamp frame. This field is valid only when the L field is set.
Offset + A	8–15	Reserved, must be cleared.
Offset + C	0–15	Reserved, must be cleared.
Offset + E	0–15	Reserved, must be cleared.
Offset + 10	0 BDU	Last buffer descriptor update done. Indicates that the last BD data has been updated by uDMA. This field is written by the user (=0) and uDMA (=1).
Offset + 10	1–15	Reserved, must be cleared.
Offset + 12	0–15	Reserved, must be cleared.
Offset + 14	0–15	This value is written by the uDMA . It is valid only when the L field is set.
Offset + 16	1588 timestamp	
Offset + 18–Offset + 1E	0–15	Reserved, must be cleared.

61.6.15 Client FIFO application interface

The FIFO interface is completely asynchronous from the Ethernet line, and the transmit and receive interface can operate at a different clock rate.

All transfers to/from the user application are handled independently of the core operation, and the core provides a simple interface to user applications based on a two-signal handshake.

61.6.15.1 Data structure description

The data structure defined in the following tables for the FIFO interface must be respected to ensure proper data transmission on the Ethernet line. Byte 0 is sent to and received from the line first.

Table 61-39. FIFO interface data structure

	63 56	55 48	47 40	39 32	31 24	23 16	15 8	7 0
Word 0	Byte 7	Byte 6	Byte 5	Byte 4	Byte 3	Byte 2	Byte 1	Byte 0
Word 1	Byte 15	Byte 14	Byte 13	Byte 12	Byte 11	Byte 10	Byte 9	Byte 8
...	...							

The size of a frame on the FIFO interface may not be a modulo of 64-bit.

The user application may not care about the Ethernet frame formats in full detail. It needs to provide and receive an Ethernet frame with the following structure:

- Ethernet MAC destination address
- Ethernet MAC source address
- Optional 802.1q VLAN tag (VLAN type and info field)
- Ethernet length/type field
- Payload

Frames on the FIFO interface do not contain preamble and SFD fields, which are inserted and discarded by the MAC on transmit and receive, respectively.

- On receive, CRC and frame padding can be stripped or passed through transparently.
- On transmit, padding and CRC can be provided by the user application, or appended automatically by the MAC independently for each frame. No size restrictions apply.

Note

On transmit, if ENET*n*_TCR[ADDINS] is set, bytes 6–11 of each frame can be set to any value, since the MAC overwrites the bytes with the MAC address programmed in the ENET*n*_PAUR and ENET*n*_PALR registers.

Table 61-40. FIFO interface frame format

Byte number	Field
0–5	Destination MAC address
6–11	Source MAC address
12–13	Length/type field
14–N	Payload data

VLAN-tagged frames are supported on both transmit and receive, and implement additional information (VLAN type and info).

Table 61-41. FIFO interface VLAN frame format

Byte number	Field
0–5	Destination MAC address
6–11	Source MAC address
12–15	VLAN tag and info
16–17	Length/type field
18–N	Payload data

Note

The standard defines that the LSB of the MAC address is sent/received first, while for all the other header fields — in other words, length/type, VLAN tag, VLAN info, and pause quanta — the MSB is sent/received first.

61.6.15.2 Data structure examples

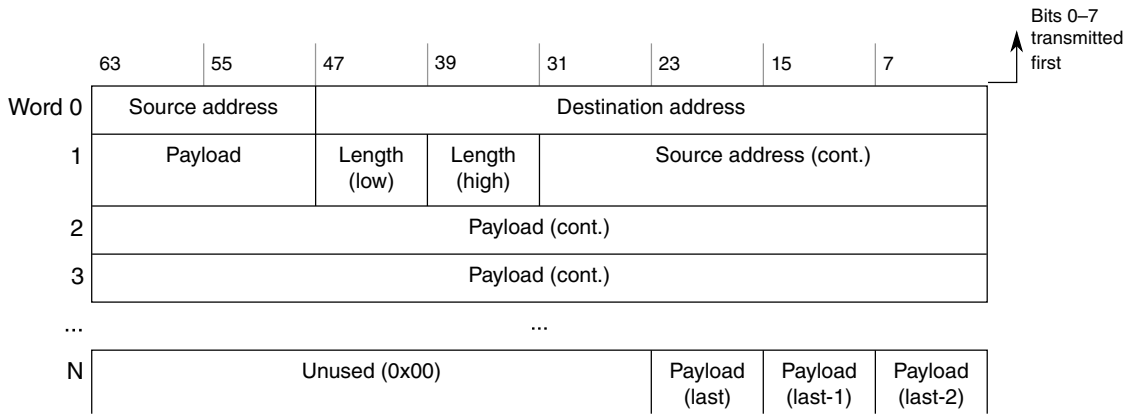

Figure 61-14. Normal Ethernet frame 64-bit mapping example

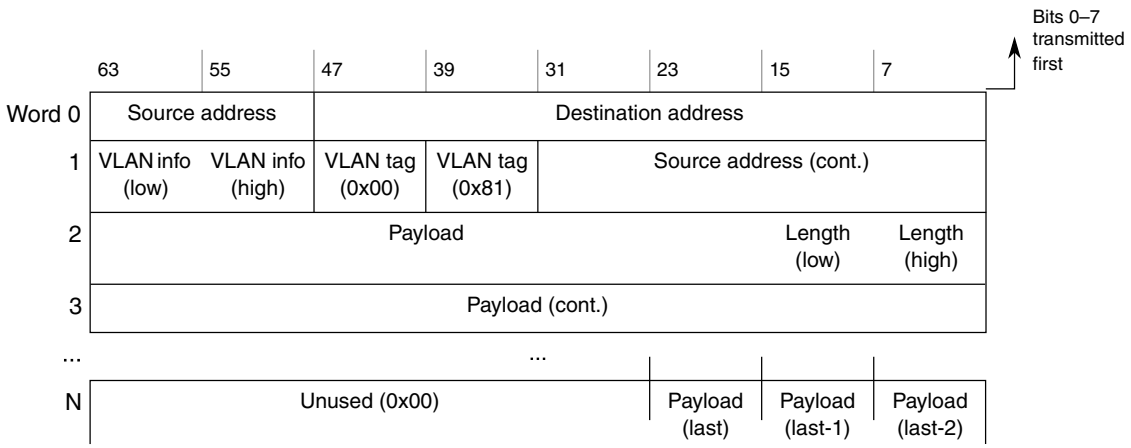

Figure 61-15. VLAN-tagged frame 64-bit mapping example

If CRC forwarding is enabled (CRCFWD = 0), the last four valid octets of the frame contain the FCS field. The non-significant bytes of the last word can have any value.

61.6.15.3 Frame status

A MAC layer status word and an accelerator status word is available in the receive buffer descriptor.

The status is available with each frame with the last data of the frame.

If the frame status contains a MAC layer error (for example, CRC or length error), RxBD[ME] is also set with the last data of the frame.

61.6.16 FIFO protection

61.6.16.1 Transmit FIFO underflow

During a frame transfer, when the transmit FIFO reaches the almost empty threshold with no end-of-frame indication stored in the FIFO, the MAC logic:

- Stops reading data from the FIFO
- Asserts the MII error signal (MII_TXER) (1 in Figure 61-16) to indicate that the fragment already transferred is not valid
- Deasserts the MII transmit enable signal (MII_TXEN) to terminate the frame transfer (2)

After an underflow, when the application completes the frame transfer (3), the MAC transmit logic discards any new data available in the FIFO until the end of packet is reached (4) and sets the enhanced TxBD[UE] field.

The MAC starts to transfer data on the MII interface when the application sends a new frame with a start of frame indication (5).

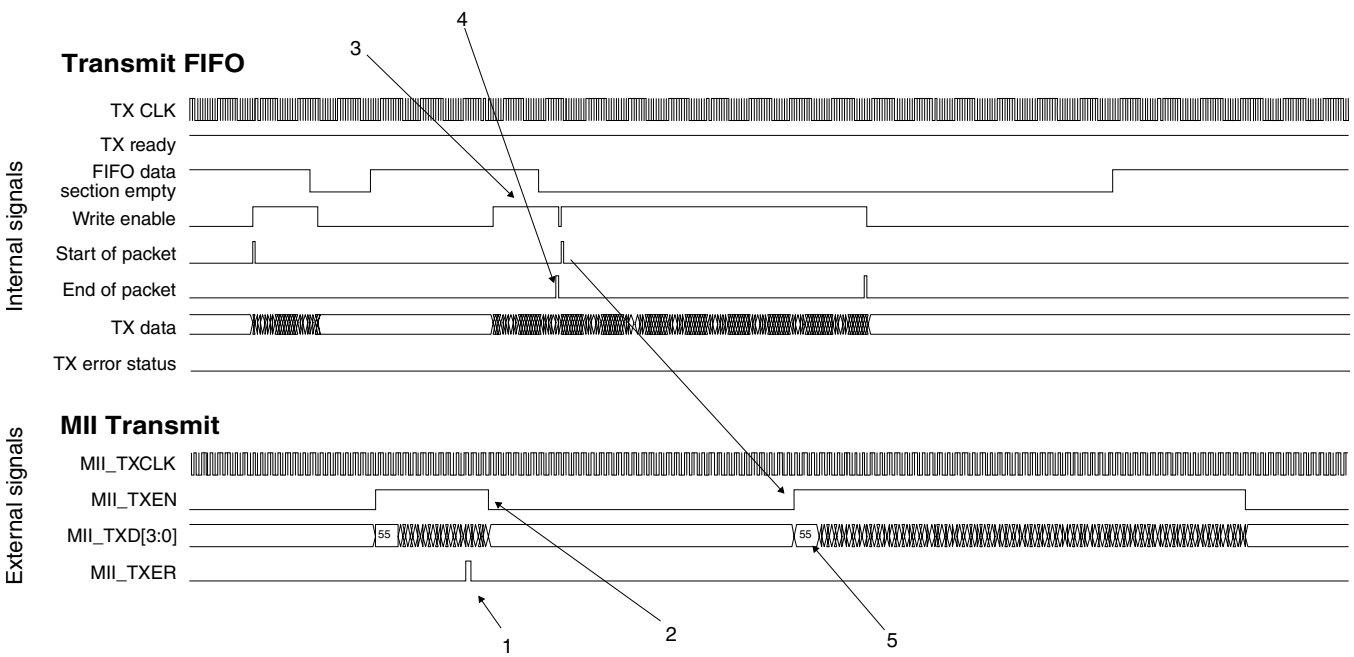

Figure 61-16. Transmit FIFO underflow protection

61.6.16.2 Transmit FIFO overflow

On the transmit path, when the FIFO reaches the programmable almost full threshold, the internal MAC ready signal is deasserted. The application should stop sending new data.

However, if the application keeps sending data, the transmit FIFO overflows, corrupting contents that were previously stored. The core logic sets the enhanced TxBD[OE] field for the next frame transmitted to indicate this overflow occurence.

Note

Overflow is a fatal error and must be addressed by resetting the core or clearing ENET*n*_ECR[ETHER_EN], to clear the FIFOs and prepare for normal operation again.

61.6.16.3 Receive FIFO overflow

During a frame reception, if the client application is not able to receive data (1), the MAC receive control truncates the incoming frame when the FIFO reaches the programmable almost-full threshold to avoid an overflow.

The frame is subsequently received on the FIFO interface with an error indication (enhanced RxBD[ME] field set together with receive end-of-packet) (2) with the truncation error status field set (3).

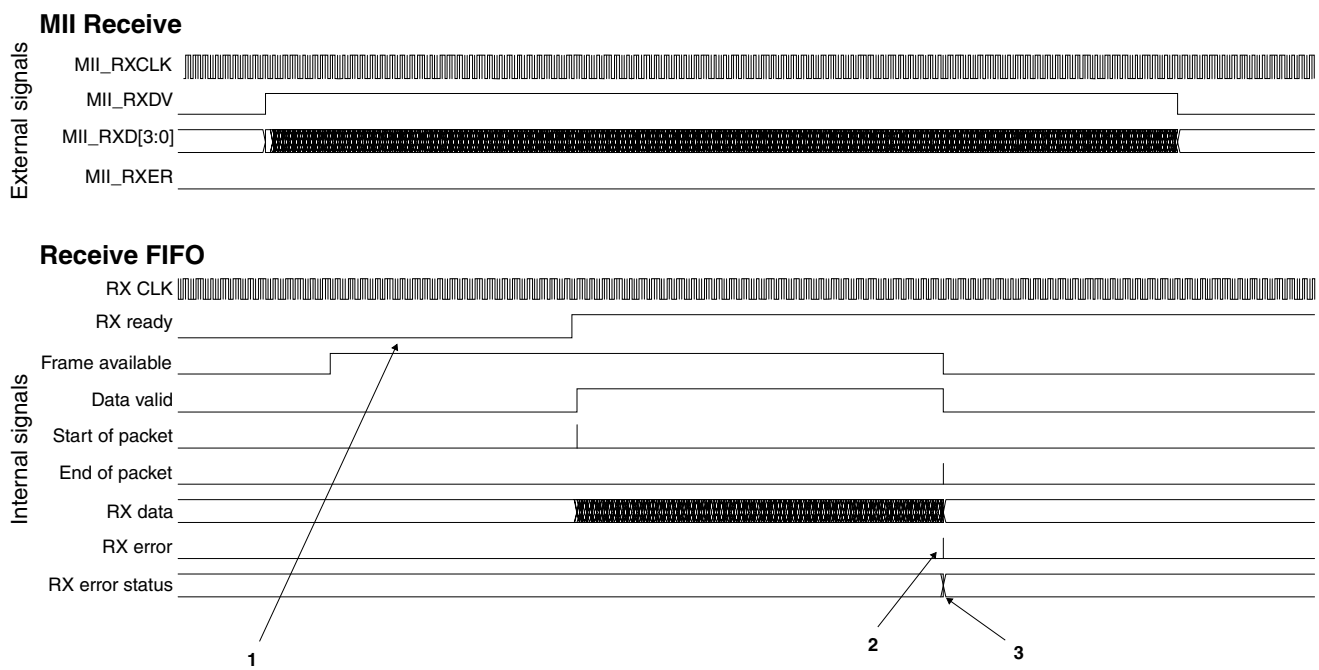

Figure 61-17. Receive FIFO overflow protection

61.6.17 Reference clock

The input clocks to the ENET module must meet the specifications in the following table.

Ethernet speed mode	Ethernet bus clock	Minimum ENET system clock
10 Mbit/s	2.5 MHz	5 MHz
100 Mbit/s	25.0 MHz	50 MHz
1000 Mbit/s[1]	125.0 MHz	133 MHz

1. Actual throughput is greater than 100 Mbit/s but significantly less than 1000 Mbit/s.

61.6.18 PHY management interface

The MDIO interface is a two-wire management interface. The MDIO management interface implements a standardized method to access the PHY device management registers.

The core implements a master MDIO interface, which can be connected to up to 32 PHY devices.

61.6.18.1 MDIO clause 22 frame format

The core MDIO master controller communicates with the slave (PHY device) using frames that are defined in the following table.

A complete frame has a length of 64 bits made up of an optional 32-bit preamble, 14-bit command, 2-bit bus direction change, and 16-bit data. Each bit is transferred on the rising edge of the MDIO clock (MDC signal). The MDIO data signal is tri-stated between frames.

The core PHY management interface supports the standard MDIO specification (IEEE 802.3 Clause 22).

Table 61-42. MDIO clause 22 frame structure

ST	OP	PHYADR	REGADR	TA	DATA

Table 61-43. MDIO frame field descriptions

Field	Description
ST (2 bits)	Start indication field, programmed with ENET*n*_MMFR[ST] and equal to 01 for Standard MDIO (Clause 22).
OP (2 bits)	Opcode defines type of operation. Programmed with ENET*n*_MMFR[OP]. 01 Write operation 10 Read operation
PHYADR	Five-bit PHY device address, programmed with ENET*n*_MMFR[PA]. Up to 32 devices can be addressed.

Table continues on the next page...

Table 61-43. MDIO frame field descriptions (continued)

Field	Description
(5 bits)	
REGADR (5 bits)	Five-bit register address, programmed with ENET*n*_MMFR[RA]. Each PHY can implement up to 32 registers.
TA (2 bits)	Turnaround time, programmed with ENET*n*_MMFR[TA]. Two bit-times are reserved for read operations to switch the data bus from write to read. The PHY device presents its register contents in the data phase and drives the bus from the second bit of the turnaround phase.
Data (16 bits)	Data, set by ENET*n*_MMFR[DATA]. Written to or read from the PHY

61.6.18.2 MDIO clause 45 frame format

The extended MDIO frame structure defined in IEEE 802.3 Clause 45 introduces indirect addressing. First, a write transaction to an address register is done, followed by a write or read transaction which will put the 16-bit data in the register or retrieve the register contents respectively. A preamble of 32 bits of logical ones is sent prior to every transaction. The MDIO data signal is tri-stated between frames.

The extended MDIO defines four transactions, which are determined by the two-bit opcode field.

Table 61-44. MDIO clause 45 frame structure

ST	OP	PRTAD	DEVAD	TA	ADDR/DATA

All bits are transmitted from left to right (Preamble bits first) and all fields have their Most-Significant bit sent first (leftmost in above table). The complete frame has a length of 64 bits (32-bit preamble, 14-bit command, 2-bit bus direction change, 16-bit data). Each bit is transferred with the rising edge of the MDIO clock (MDC).

The fields and transactions are summarized in the following tables.

Table 61-45. MDIO clause 45 frame field descriptions

Field	Description
ST	Start indication. Indicates the end of the preamble and start of the frame. This value is 00 for extended MDIO (Clause 45) frames.
OP	Opcode defines if a read or write operation is performed and is programmed with ENET*n*_MMFR[OP]. See Table 61-46 for more information. 00 Address write 01 Write operation

Table continues on the next page...

Table 61-45. MDIO clause 45 frame field descriptions (continued)

Field	Description
	10 Read inc. operation 11 Read operation
PRTAD	The port address specifies a MDIO port. Each Port can have up to 32 devices which each can have a separate set of registers.
DEVAD	Device address. Up to 32 devices can be addressed (within a port).
TA	Turnaround time, programmed with ENET*n*_MMFR[TA]. Two bit-times are reserved for read operations to switch the data bus from write to read. The PHY device presents its register contents in the data phase and drives the bus from the second bit of the turnaround phase.
ADDR/DATA	16-bit address (for address write) or data, set by ENET*n*_MMFR[DATA], written to or read from the PHY.

Table 61-46. MDIO Clause 45 Transactions

Transaction Type	Description
Address	A write transaction to the internal address register of the device/port. The data section of the frame contains the value to be stored in the device's internal address "pointer" register for further transactions.
Write	Data write to a register. The 16 bit data will be written to the register identified by the device-internal address.
Read	Data is read from the register identified by the device-internal address.
Read inc.	Read with address postincrement. The register identified by the device-internal address is read. After this, the device-internal address is incremented. If the address register is all '1' (0xFFFF) no increment is done (i.e. increment does not wrap around).

61.6.18.3 MDIO clock generation

The MDC clock is generated from the internal bus clock (i.e., IPS bus clock) divided by the value programmed in ENET*n*_MSCR[MII_SPEED].

61.6.18.4 MDIO operation

To perform an MDIO access, set the MDIO command register (ENET*n*_MMFR) according to the description provided in MII Management Frame Register (ENETn_MMFR).

To check when the programmed access completes, read the ENET*n*_EIR[MII] field.

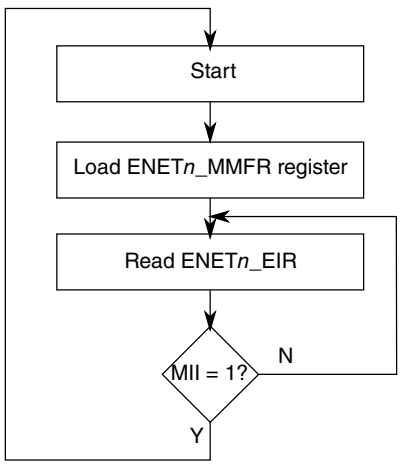

Figure 61-18. MDIO access overview

61.6.19 Ethernet interfaces

The following Ethernet interfaces are implemented:

- Fast Ethernet MII (Media Independent Interface)
- RMII 10/100 using interface converters/gaskets
- RGMII 10/100/1000 by way of interface converters/gaskets

The following table shows how to configure ENET registers to select each interface.

Mode	ECR[SPEED]	RCR[RMII_10T]	RCR[RMII_MODE]	RCR[RGMII_EN]
MII - 10 Mbit/s	0	—	0	0
MII - 100 Mbit/s	0	—	0	0
RMII - 10 Mbit/s	0	1	1	0
RMII - 100 Mbit/s	0	0	1	0
RGMII - 10 Mbit/s	0	1	0	1
RGMII - 100 Mbit/s	0	0	0	1
RGMII - 1000 Mbit/s[1]	1	—	0	1

1. Actual throughput is greater than 100 Mbit/s but significantly less than 1000 Mbit/s.

61.6.19.1 RMII interface

In RMII receive mode, for normal reception following assertion of CRS_DV, RXD[1:0] is 00 until the receiver determines that the receive event has a proper start-of-stream delimiter (SSD).

The preamble appears (RXD[1:0]=01) and the MACs begin capturing data following detection of SFD.

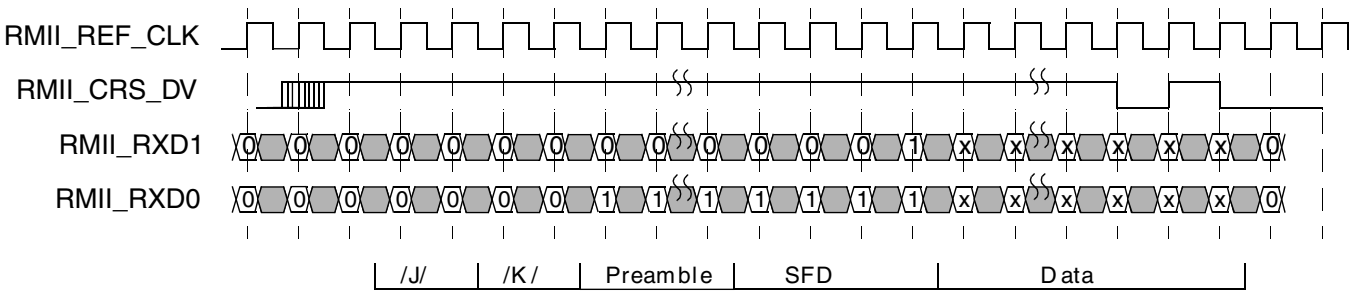

Figure 61-19. RMII receive operation

If a false carrier is detected (bad SSD), then RXD[1:0] is 10 until the end of the receive event. This is a unique pattern since a false carrier can only occur at the beginning of a packet where the preamble is decoded (RXD[1:0] = 01).

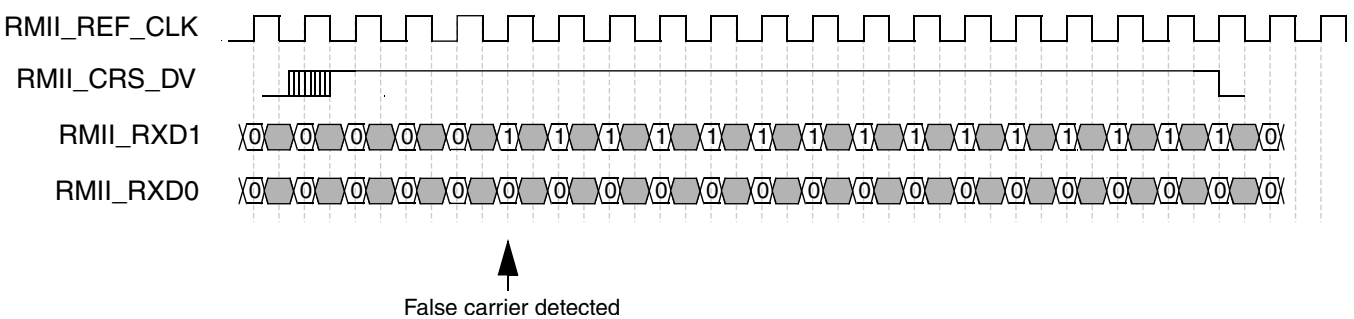

Figure 61-20. RMII receive operation with false carrier

In RMII transmit mode, TXD[1:0] provides valid data for each REF_CLK period while TXEN is asserted.

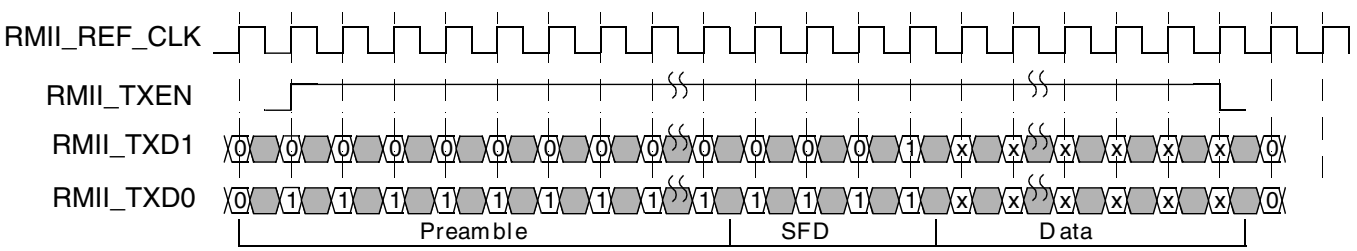

Figure 61-21. RMII transmit operation

61.6.19.2 RGMII interface

In RGMII modes, the data and control information is multiplexed by taking advantage of both edges of the reference clocks.

The data signals contain the lower four data bits on the rising edge and the upper four bits on the falling edge. The control signals are multiplexed into a single clock cycle using the same technique.

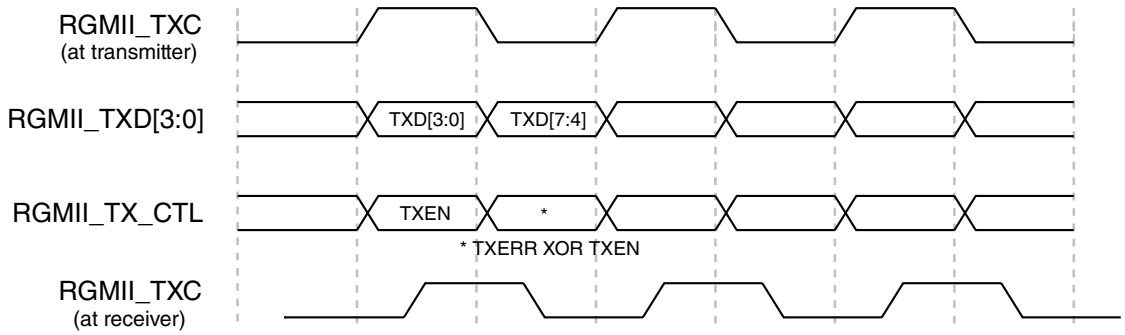

Figure 61-22. RGMII transmit operation

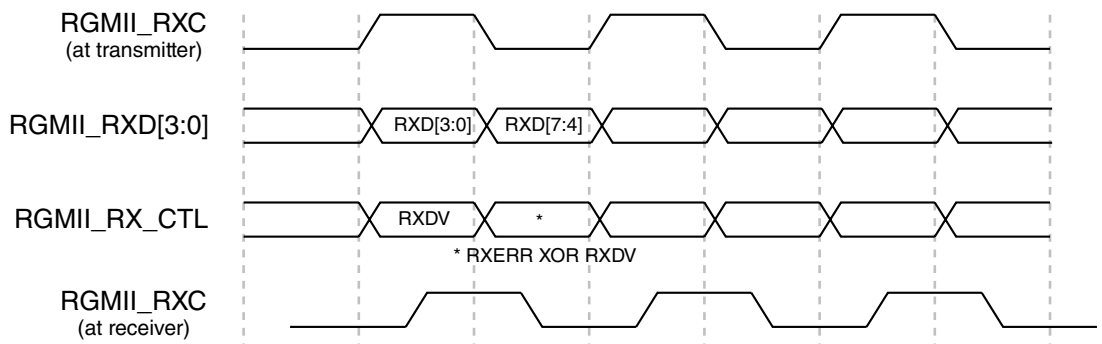

Figure 61-23. RGMII receive operation

61.6.19.3 MII Interface — transmit

On transmit, all data transfers are synchronous to MII_TXCLK rising edge. The MII data enable signal MII_TXEN is asserted to indicate the start of a new frame, and remains asserted until the last byte of the frame is present on the MII_TXD[3:0] bus.

Between frames, MII_TXEN remains deasserted.

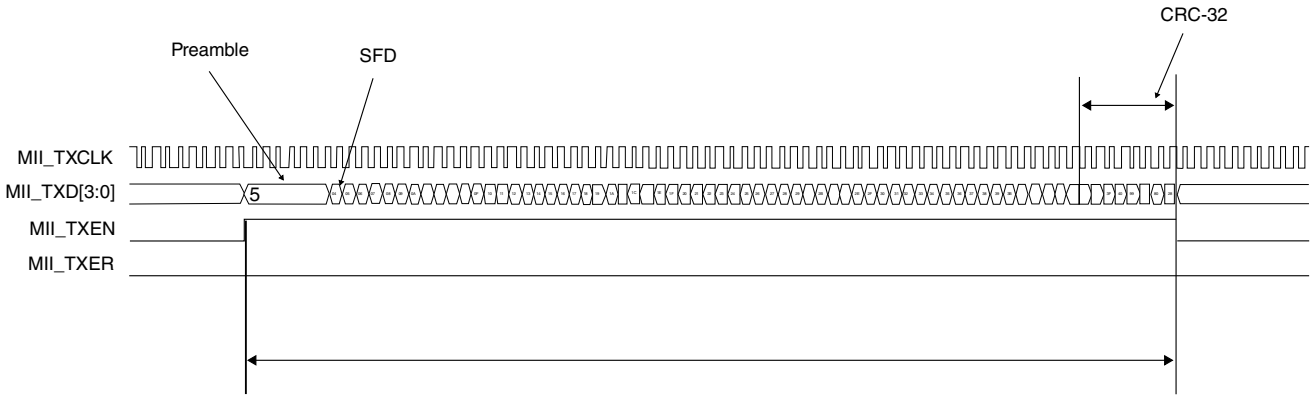

Figure 61-24. MII transmit operation

If a frame is received on the FIFO interface with an error (for example, RxBD[ME] set) the frame is subsequently transmitted with the MII_TXER error signal for one clock cycle at any time during the packet transfer.

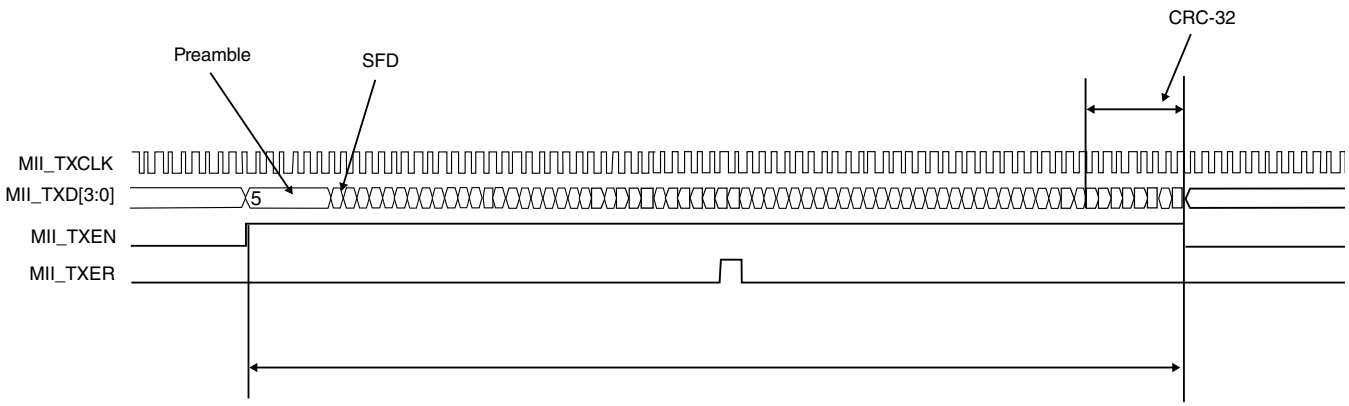

Figure 61-25. MII transmit operation — errored frame

61.6.19.3.1 Transmit with collision — half-duplex

When a collision is detected during a frame transmission (MII_COL asserted), the MAC stops the current transmission, sends a 32-bit jam pattern, and re-transmits the current frame.

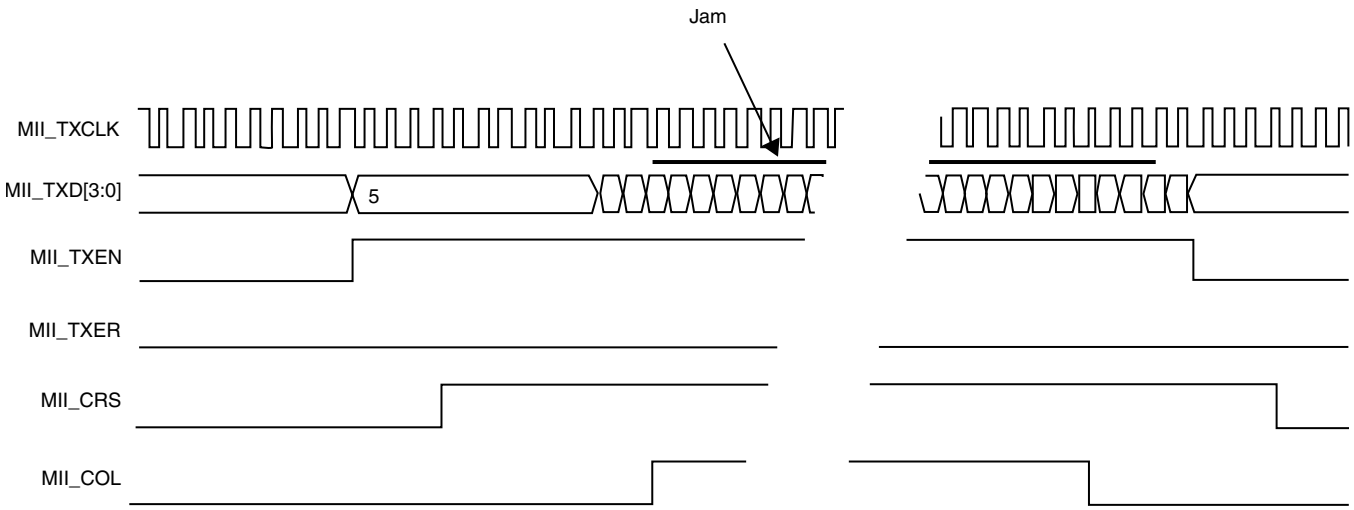

Figure 61-26. MII transmit operation — transmission with collision

61.6.19.4 MII interface — receive

On receive, all signals are sampled on the MII_RXCLK rising edge. The MII data enable signal, MII_RXDV, is asserted by the PHY to indicate the start of a new frame and remains asserted until the last byte of the frame is present on MII_RXD[3:0] bus.

Between frames, MII_RXDV remains deasserted.

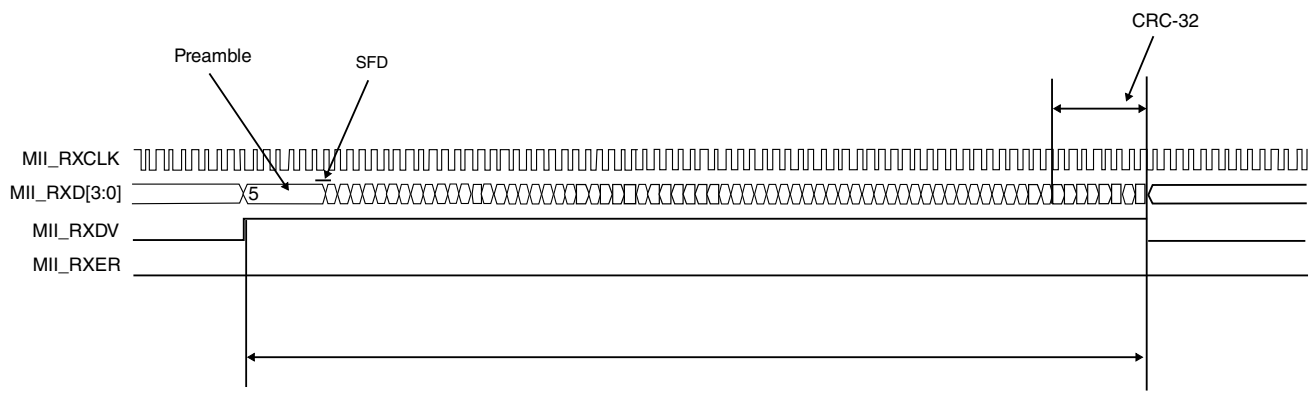

Figure 61-27. MII receive operation

If the PHY detects an error on the frame received from the line, the PHY asserts the MII error signal, MII_RXER, for at least one clock cycle at any time during the packet transfer.

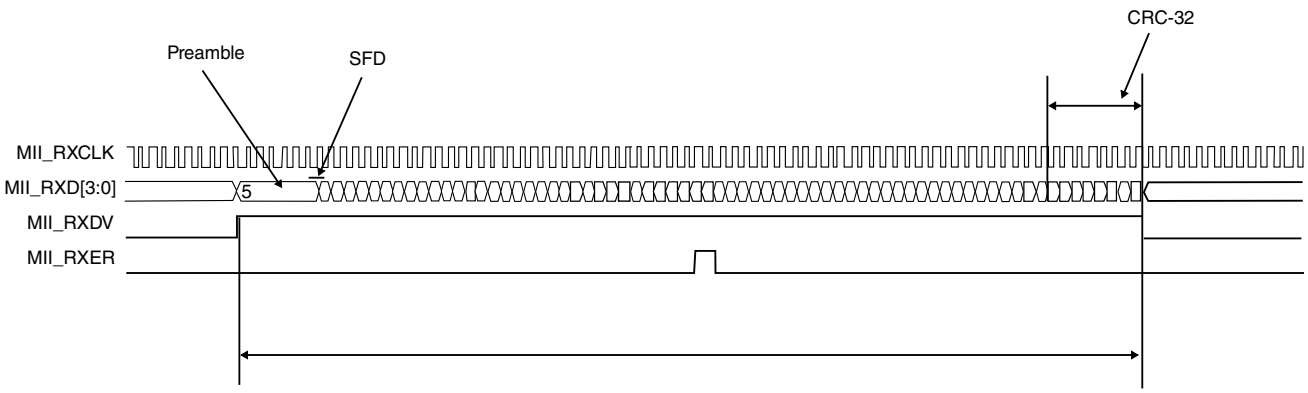

Figure 61-28. MII receive operation — errored frame

A frame received on the MII interface with a PHY error indication is subsequently transferred on the FIFO interface with RxBD[ME] set.

61.6.20 Interrupt coalescence

The purpose of the interrupt coalescing is to reduce the number of interrupts generated by the MAC so as to reduce the CPU loading.

To facilitate this interrupt coalescing, these registers are available with the same control and configuration fields.

- Transmit Interrupt Coalescing Register (ENET_TXIC)
- Receive Interrupt Coalescing Register (ENET_RXIC)

When coalescing is enabled by asserting the corresponding ICEN field and such interrupt is also enabled by the corresponding interrupt mask of the EIMR register, the MAC generates an interrupt when the threshold number of frames is reached (defined by ICFT) or when the threshold timer expires (defined by ICTT).

When coalescing is disabled by de-asserting ICEN, but interrupt is enabled by the corresponding interrupt mask of the EIMR register, the MAC generates an interrupt as they are received without using coalescing. Interrupt coalescing is done for each transmit and receive queue/class independently.

61.6.20.1 Interrupt coalescence setup

Interrupt coalescence supports both legacy and enhanced BDs. The following guidelines are recommended when setting up interrupt coalescence.

- When the MAC is configured for enhanced (IEEE 1588) mode, that is, enhanced BDs:
  - Set the INT bit in the enhanced received buffer descriptor to one.
  - Set the INT bit in the enhanced transmit buffer descriptor(s) to one.
- Clear the TXB and RXB fields in the EIMR register.

61.6.20.2 Updating the frame count threshold on-the-fly

To update the ICFT field in the RXIC and TXIC registers:

1. Disable interrupt coalescence by clearing the appropriate ICEN field. This will allow the internal interrupt coalescence counter to reset to zero.

NOTE

When disabling interrupt coalescence, if an interrupt event is pending, that is, the interrupt counter is not zero, then an interrupt will occur.

2. Write the new threshold value to the ICFT field.
3. Set ICEN to one.

NOTE

The ICFT field can be updated on-the-fly without disabling the ICEN field. The hardware interrupt will continue and there is a possibility that an interrupt will occur depending on the state of the hardware counter and the previous ICFT value.

61.6.20.3 Updating the timer threshold on-the-fly

To update the ICTT field in the RXIC and TXIC registers:

1. Disable interrupt coalescence by clearing the appropriate ICEN field. This will allow the internal interrupt coalescence counter to reset to zero.

NOTE

When disabling interrupt coalescence, if an interrupt event is pending, that is, the interrupt counter is not zero, then an interrupt will occur.

2. Write the new timer value to the ICTT field.
3. Set ICEN to one.

Chapter 62
Reset Generation Module (MC_RGM)

62.1 Introduction

62.1.1 Overview

The reset generation module (MC_RGM) centralizes the different reset sources and manages the reset sequence of the chip. It provides a register interface and the reset sequencer. Various registers are available to monitor and control the chip reset sequence. The reset sequencer is a state machine which controls the different phases (***PHASE0***, ***PHASE1***, ***PHASE2***, ***PHASE3***, and ***IDLE***) of the reset sequence and controls the reset signals generated in the system.

The following figure shows the MC_RGM block diagram.

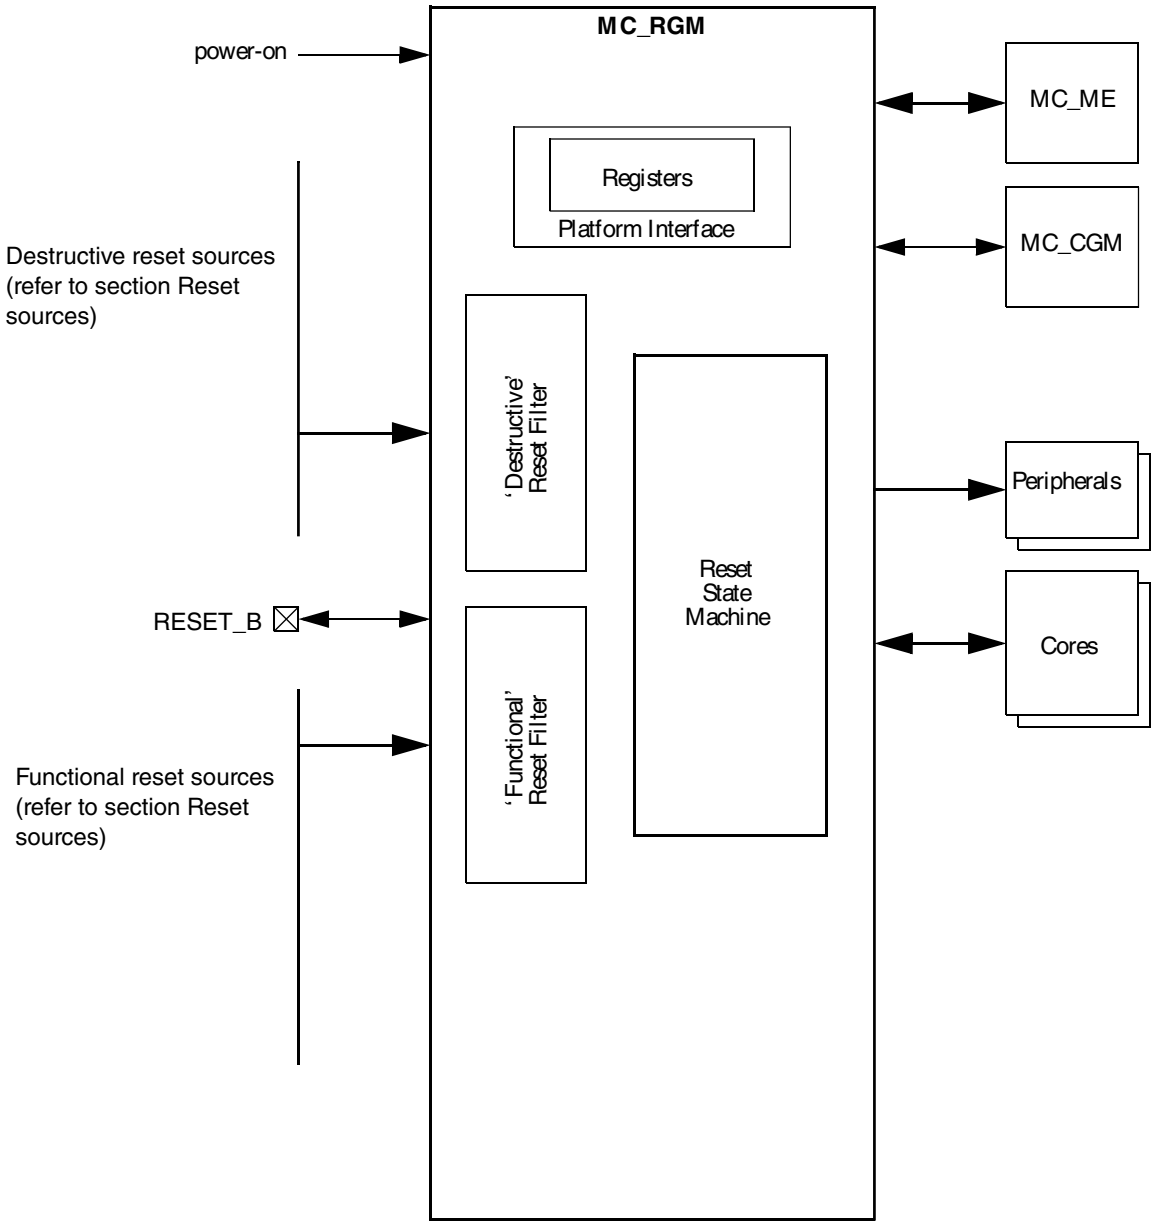

Figure 62-1. MC_RGM block diagram

62.1.2 Features

The MC_RGM contains the functionality for the following features:

- 'destructive' resets management
- 'functional' resets management
- signalling of reset events after each reset sequence (reset status flags)
- conversion of reset events to ***SAFE mode*** or interrupt request events
- short reset sequence configuration
- bidirectional reset behavior configuration

- configurable escalation of recurring 'functional' resets to 'destructive' reset
- configurable escalation of recurring ‘destructive’ resets to keep chip in reset state until next power-on reset

62.2 External signal description

The MC_RGM interfaces to the reset pin RESET_B.

62.3 Reset sources

The different reset sources are organized into two families: ‘destructive’ and ‘functional’.

A ‘destructive’ reset source is associated with an event related to a critical—usually hardware—error or dysfunction. When a ‘destructive’ reset event occurs, the full reset sequence is applied to the chip starting from ***PHASE0***. This resets the full chip ensuring a safe start-up state for both digital and analog modules, and the memory content must be considered to be unknown except in the software ‘destructive’ reset case, which does preserve the system memory content if the chip is not configured to execute a self-test on power-on, ‘destructive’, and external resets. ‘Destructive’ resets are:

- power-on reset
- software ‘destructive’ reset
- FCCU failure to react reset
- ‘functional’ reset escalation
- temperature sensor 'destructive' reset
- voltage out of range ‘destructive’ resets
- STCU critical fault reset
- AFE LVDs
- MIPICSI2 LVDs
- SSCM secure reset request

NOTE

Each destructive reset also asserts external reset pin.

A ‘functional’ reset source is associated with an event related to a less critical—usually non-hardware—error or dysfunction. When a ‘functional’ reset event occurs, a partial reset sequence is applied to the chip starting from ***PHASE1***. In this case, most digital modules are reset normally, and the memory content must be considered to be unknown, while the state of analog modules or specific digital modules (e.g., debug modules, flash

modules) content is preserved, except on an external reset in the case where the chip is configured to execute a self-test on power-on, ‘destructive’, and external resets.
‘Functional’ resets are

- External reset
- STCU self test completed
- Software ‘functional’ reset
- FCCU hard reaction
- FCCU soft reaction
- JTAG ‘functional’ reset
- Temperature sensor 'functional' reset

When a reset is triggered, the MC_RGM state machine is activated and proceeds through the different phases (i.e., ***PHASEn*** states). Each phase is associated with a particular chip reset being provided to the system. A phase is completed when all corresponding phase completion gates from either the system or internal to the MC_RGM are acknowledged. The chip reset associated with the phase is then released, and the state machine proceeds to the next phase up to entering the ***IDLE*** phase. During this entire process, the MC_ME state machine is held in ***RESET*** mode. Only at the end of the reset sequence, when the ***IDLE*** phase is reached, does the MC_ME enter the ***DRUN*** mode.

Alternatively, it is possible for software to configure some reset source events to be converted from a reset to either a ***SAFE*** mode request issued to the MC_ME or to an interrupt issued to the core (see ‘Destructive’ Event Reset Disable Register (RGM_DERD) and ‘Destructive’ Event Alternate Request Register (RGM_DEAR) for ‘destructive’ resets and ‘Functional’ Event Reset Disable Register (RGM_FERD) and ‘Functional’ Event Alternate Request Register (RGM_FEAR) for ‘functional’ resets).

62.4 Memory map and register definition

NOTE

Any access to unused registers as well as write accesses to read-only registers will:

- not change register content
- cause a transfer error

NOTE

Reserved fields should always be written with their reset values only.

The bytes are ordered according to big endian. For example, the **RGM_DES[7:0]** register bits may be accessed as a word at address offset 0x000, as a half-word at address offset offset 0x002, or as a byte at address offset 0x003. Some fields may be read-only, and their reset value of '1' or '0' and the corresponding behaviour cannot be changed.

NOTE

The following registers are reset to their default values during a POR event only:

- RGM_DES
- RGM_DERD
- RGM_DEAR
- RGM_FES
- RGM_DRET

RGM memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	'Destructive' Event Status Register (RGM_DES)	32	R/W	0000_0001h	62.4.1/3287

340	'Functional' Event Short Sequence Register (RGM_FESS)	32	R/W	0000_0040h	62.4.8/3303
604	'Functional' Event Short Sequence Register (RGM_FRET)	8	R/W	0Fh	62.4.9/3305
608	Destructive Reset Escalation Threshold Register (RGM_DRET)	8	R/W	00h	62.4.10/ 3306

62.4.1 'Destructive' Event Status Register (RGM_DES)

This register can be accessed as read/write in either supervisor mode or test mode and accessed as read only in user mode. Register bits are cleared on write '1'. This register is reset only on power-on.

NOTE

If LVD/HVD event is disabled and RGM is configured to issue an interrupt instead of reset, operation below LVD or above HVD levels is not guaranteed. User should guarantee that if LVD/HVD is disabled, then the voltage input is always in range.

NOTE

When RGM_DES[F_POR] is set the user needs to ignore all other bits in this register.

31 F_POR	**Flag for Power-on reset** 0 No power-on event has occurred since the last clear 1 A power-on event has occurred

62.4.2 'Destructive' Event Reset Disable Register (RGM_DERD)

When a 'destructive' reset source is disabled, the associated 'destructive' event will trigger either a SAFE mode request or an interrupt request (see 'Destructive' Event Alternate Request Register (RGM_DEAR)). This register can be accessed as read/write-only in either supervisor mode or test mode. This register can be accessed as read only in user mode. Each byte can be written only once after a 'destructive' or power-on reset.

This register is reset only on power-on.

NOTE

If LVD/HVD event is disabled and RGM is configured to issue an interrupt instead of reset, operation below LVD or above HVD levels is not guaranteed. User should guarantee that if LVD/HVD is disabled, then the voltage input is always in range.

CAUTION

It is important to clear the **RGM_DES** register before setting any of the bits in the **RGM_DERD** register to '1'. Otherwise, a redundant ***SAFE*** mode request or interrupt request may occur.

28 D_SOFT_DEST	**Disable software ‘destructive’ reset** 0 A software ‘destructive’ reset triggers a reset sequence
29–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 D_POR	**Disable Power-on reset** 0 A power-on event triggers a reset sequence

62.4.3 ‘Destructive’ Event Alternate Request Register (RGM_DEAR)

This register defines an alternate request to be generated when a reset on a ‘destructive’ event has been disabled. The alternate request can be either a SAFE mode request to MC_ME or an interrupt request to the system. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode.

This register is reset only on power-on.

NOTE

If LVD/HVD event is disabled and RGM is configured to issue an interrupt instead of reset, operation below LVD or above HVD levels is not guaranteed. User should guarantee that if LVD/HVD is disabled, then the voltage input is always in range.

Address: 0h base + 20h offset = 20h

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 AR_TSR_DEST	**Alternate Request for temperature sensor 'destructive' reset** 0 Generate a ***SAFE*** mode request on a temperature sensor 'destructive' reset event if the reset is disabled 1 Generate an interrupt request on a temperature sensor 'destructive' reset event if the reset is disabled
9–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

62.4.4 'Functional' Event Status Register (RGM_FES)

It can be accessed in read/write on either supervisor mode or test mode. It can be accessed in read only in user mode. Register bits are cleared on write '1' if the triggering event has already been cleared at the source. This register is reset only on power-on.

If functional reset occurs and bidi reset is enabled via RGM_FBRE register with FERD[0] bit set, FES[0] may also get set indicating that external reset event has occurred.

NOTE

If a 'functional' reset source is configured to generate a ***SAFE*** mode request or an interrupt request, software needs to clear the event in the source module at least three system clock cycles

before it clears the associated **RGM_FES** status bit in order to avoid multiple ***SAFE mode*** requests or interrupts for the same event. In order to avoid having to count cycles, it is good practice for software to check whether the **RGM_FES** has been properly cleared, and if not, clear it again

NOTE

Reset value depends on the source of reset.

Address: 0h base + 300h offset = 300h

28 F_SOFT_FUNC	**Flag for software 'functional' reset** 0 No software 'functional' reset event has occurred since either the last clear or the last power-on reset assertion. 1 A software 'functional' reset event has occurred.
29 F_ST_DONE	**Flag for self test completed** 0 No self test completed event has occurred since either the last clear or the last power-on reset assertion. 1 A self test completed event has occurred.
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 F_EXR	Flag for extenal reset 0 No external reset has occured since either the last clear or last power-on reset assertion. 1 An external reset event has occured.

62.4.5 'Functional' Event Reset Disable Register (RGM_FERD)

This register provides dedicated bits to disable 'functional' reset sources. When a 'functional' reset source is disabled, the associated 'functional' event will trigger either a SAFE mode request or an interrupt request (see 'Functional' Event Alternate Request Register (RGM_FEAR)). It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode. Each byte can be written only once after power-on reset.

This register is reset only on power-on and any ‘destructive’ reset.

CAUTION

It is important to clear the **RGM_FES** register before setting any of the bits in the **RGM_FERD** register to ‘1’. Otherwise a redundant ***SAFE*** mode request or interrupt request may occur.

Address: 0h base + 310h offset = 310h

29 D_ST_DONE	**Disable self test completed** 0 A self test completed event triggers a reset sequence.
30–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

62.4.6 'Functional' Event Alternate Request Register (RGM_FEAR)

This register defines an alternate request to be generated when a reset on a 'functional' event has been disabled. The alternate request can be either a ***SAFE*** mode request to MC_ME or an interrupt request to the system. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode.

This register is reset only on power-on and any 'destructive' reset.

Address: 0h base + 320h offset = 320h

28 BE_SOFT_FUNC	**Bidirectional Reset Enable for software 'functional' reset** 0 RESET_B is asserted on a software 'functional' reset event if the reset is enabled. 1 RESET_B is not asserted on a software 'functional' reset event.
29 BE_ST_DONE	**Bidirectional Reset Enable for self test completed** 0 RESET_B is asserted on a self test completed event.
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 BE_EXR	**Bidirectional Reset Enable for external reset** 0 RESET_B is asserted on an external reset event if the reset is enabled.

62.4.8 'Functional' Event Short Sequence Register (RGM_FESS)

This register defines which reset sequence will be done when a 'functional' reset sequence is triggered. The 'functional' reset sequence can either start from ***PHASE1*** or from ***PHASE3***, skipping ***PHASE1*** and ***PHASE2***.

NOTE

This could be useful for fast reset sequence, for example to skip flash reset.

It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read in user mode.

This register is reset only on power-on and any 'destructive' reset.

Address: 0h base + 340h offset = 340h

29 SS_ST_DONE	**Bidirectional Reset Enable for self test completed** 0 RESET_B is asserted on a self test completed event.
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 SS_EXR	**Short Sequence for external reset** 0 The reset sequence triggered by an external reset event will start from ***PHASE1***. 1 The reset sequence triggered by an external reset event if the reset is enabled will start from ***PHASE3***, skipping ***PHASE1*** and ***PHASE2***.

62.4.9 'Functional' Event Short Sequence Register (RGM_FRET)

This register sets the threshold for 'functional' reset escalation to a 'destructive' reset. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode.

Writing a non-zero value to the **FRET** field will enable the 'functional' reset escalation function. Writing any value to this register will reset the 'functional' reset counter. See 'Functional' reset escalation for details on the 'functional' reset escalation function.

This register is reset only on power-on and any 'destructive' reset.

Address: 0h base + 604h offset = 604h

Bit	0	1	2	3	4	5	6	7
Read	0				FRET			
Write								
Reset	0	0	0	0	1	1	1	1

RGM_FRET field descriptions

Field	Description
0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–7 FRET	**'Functional' Reset Escalation Threshold** — If the value of this field is 0, the 'functional' reset escalation function is disabled. Any other value is the number of 'functional' resets which will cause a 'destructive' reset if the **RGM_FRET** register isn't written to beforehand.

62.4.10 Destructive Reset Escalation Threshold Register (RGM_DRET)

This register sets the threshold for 'destructive' reset escalation to keeping the chip in the reset state until the next power-on reset triggers a new reset sequence. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode.RGM_DRET

Writing a non-zero value to the **DRET** field will enable the 'destructive' reset escalation function. Writing any value to this register will reset the 'destructive' reset counter. See 'Destructive' reset escalation for details on the 'destructive' reset escalation function. escalation function.

This register is reset only on power-on.

Address: 0h base + 608h offset = 608h

Bit	0	1	2	3	4	5	6	7
Read	0				DRET			
Write								
Reset	0	0	0	0	0	0	0	0

RGM_DRET field descriptions

0–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–7 DRET	**'Destructive' Reset Escalation Threshold** — If the value of this field is 0, the 'destructive' reset escalation function is disabled. Any other value is the number of 'destructive' resets which will keep the chip in the reset state until the next power-on reset triggers a new reset sequence if the **>RGM_DRET** register isn't written to beforehand.

62.5 Functional description

62.5.1 Reset state machine

The main role of the MC_RGM is the generation of the reset sequence which ensures that the correct parts of the chip are reset based on the reset source event. This is summarized in the following table.

Table 62-1. MC_RGM reset implications

Source	What Gets Reset	External Reset Assertion [1]	Boot Mode Capture
power-on reset	all	yes	yes
'destructive' resets	all except some clock/reset management	yes	yes
external reset	all except some clock/reset management and debug	programmable [2]	yes
'functional' resets	all except some clock/reset management, STCU, FCCU, SSCM and debug	programmable[2]	programmable[3]
shortened external or shortened 'functional' resets[4]	flip-flops except some clock/reset management, STCU, FCCU, SSCM, and debug	programmable[2]	programmable[3]

1. 'external reset assertion' means that the RESET_B pin is asserted by the MC_RGM from the start of the reset sequence until the end of reset ***PHASE3***
2. the assertion of the external reset is controlled via the **RGM_FBRE** register
3. the boot mode is captured if the external reset is asserted
4. the short sequence is enabled via the **RGM_FESS** register

NOTE

JTAG logic has its own independent reset control and is not controlled by the MC_RGM in any way.

The reset sequence is comprised of five phases managed by a state machine, which ensures that all phases are correctly processed through waiting for a minimum duration and until all processes that need to occur during that phase have been completed before proceeding to the next phase.

The state machine used to produce the reset sequence is shown in the following figure.

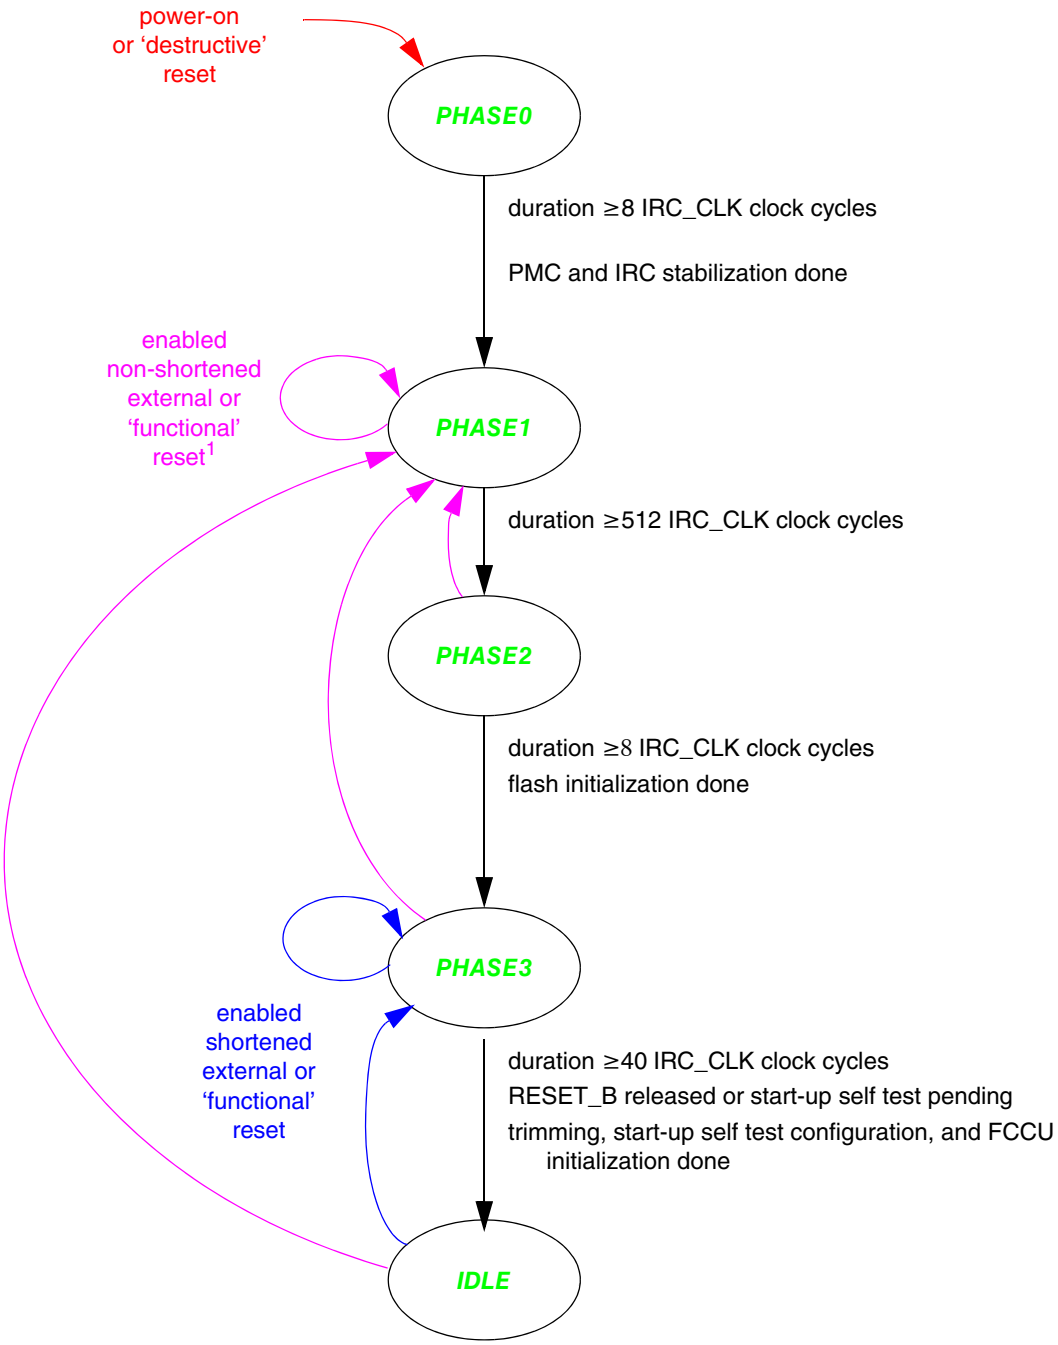

Figure 62-2. MC_RGM State Machine

62.5.1.1 *PHASE0* Phase

This phase is entered immediately from any phase on a power-on or enabled 'destructive' reset event. The reset state machine exits ***PHASE0*** and enters ***PHASE1*** on verification of the following:

- all enabled 'destructive' resets have been processed

- all processes that need to be done in ***PHASE0*** are completed, including PMC and IRC stabilization
- a minimum of 8 IRC_CLK clock cycles have elapsed since power-up completion and the last enabled ‘destructive’ reset event
- the ‘destructive’ reset escalator counter has not reached the value in the DRET field of the RGM_DRET resister

62.5.1.2 *PHASE1* Phase

This phase is entered either on exit from ***PHASE0*** or immediately from ***PHASE2***, ***PHASE3***, or ***IDLE*** on a non-masked external or ‘functional’ reset event if it has not been configured to trigger a ‘short’ sequence. The reset state machine exits ***PHASE1*** and enters ***PHASE2*** on verification of the following:

- all enabled, non-shortened ‘functional’ resets have been processed
- a minimum of 512 IRC_CLK clock cycles have elapsed since the last enabled external or non-shortened ‘functional’ reset event

62.5.1.3 *PHASE2* Phase

This phase is entered on exit from ***PHASE1***. The reset state machine exits ***PHASE2*** and enters ***PHASE3*** on verification of the following:

- all processes that need to be done in ***PHASE2*** are completed flash initialization
- a minimum of 8 IRC_CLK clock cycles have elapsed since entering ***PHASE2***

62.5.1.4 *PHASE3* Phase

This phase is a entered either on exit from ***PHASE2*** or immediately from ***IDLE*** on an enabled, shortened ‘functional’ reset event. The reset state machine exits ***PHASE3*** and enters ***IDLE*** on verification of the following:

- all processes that need to be done in ***PHASE3*** are completed trimming, start-up self test configuration, and FCCU initialization
- a minimum of 40 IRC_CLK clock cycles have elapsed since the last enabled, shortened ‘functional’ reset event

62.5.1.5 *IDLE* Phase

This is the final phase and is entered on exit from ***PHASE3***. When this phase is reached, the MC_RGM releases control of the system to the platform and waits for new reset events that can trigger a reset sequence.

62.5.2 ‘Destructive’ resets

A ‘destructive’ reset indicates that an event has occurred after which critical register or memory content can no longer be guaranteed. Exception to the latter is the software ‘destructive’ reset which does allow the memory content to be preserved if the chip is configured to not execute a self test on power-on, ‘destructive’, and external resets.

The status flag associated with a given ‘destructive’ reset event (**RGM_DES[F_<destructive reset>]** bit) is set when the ‘destructive’ reset is asserted and the power-on reset is not asserted. It is possible for multiple status bits to be set simultaneously, and it is software’s responsibility to determine which reset source is the most critical for the application.

A given ‘destructive’ reset can be optionally disabled by writing bit **RGM_DERD[D_<destructive reset>]**.

NOTE

The **RGM_DERD** register can be written only once between two ‘destructive’ reset events.

The chip’s low-voltage detector threshold ensures that, when 'destructive' voltage out of range (LVD and/or HVD) is enabled, the supply is sufficient to have the ‘destructive’ event correctly propagated through the digital logic. Therefore, if a given ‘destructive’ reset is enabled, the MC_RGM ensures that the associated reset event will be correctly triggered to the full system. However, if the given ‘destructive’ reset is disabled and the voltage goes below the digital functional threshold, functionality can no longer be ensured, and the reset may or may not be asserted.

An enabled ‘destructive’ reset will trigger a reset sequence starting from the beginning of ***PHASE0***.

62.5.3 External reset

The MC_RGM manages the external reset coming from RESET_B. The detection of a falling edge on RESET_B will start the reset sequence.

The status flag associated with the external reset falling edge event (**RGM_FES[F_EXR]** bit) is set when the external reset is asserted and the power-on reset is not asserted.

An enabled external reset will normally trigger a reset sequence starting from the beginning of ***PHASE1***. Nevertheless, the **RGM_FESS** register enables the further configuring of the reset sequence triggered by the external reset. When **RGM_FESS[SS_EXR]** is set, the external reset will trigger a reset sequence starting directly from the beginning of ***PHASE3***, skipping ***PHASE1*** and ***PHASE2***. This can be useful especially when an external reset should not reset the flash.

The MC_RGM may also assert the external reset if the reset sequence was triggered by one of the following:

- a power-on reset
- a ‘destructive’ reset event
- an external reset event if configured via the **RGM_FBRE** register to assert the external reset
- a ‘functional’ reset event configured via the **RGM_FBRE** register to assert the external reset

Glitch filter on RESET_B should not be disabled when using it as a bidi pin

In this case, RESET_B is asserted until all conditions for exiting ***PHASE3*** have been met with the exception of the RESET_B assertion check.In addition, the MC_RGM asserts RESET_B while the start-up self test is being executed.

The RESET_B input is disabled immediately as of the RESET_B output being asserted in order to prevent a falling edge from being detected while the pin is being driven from the chip. The input is then re-enabled 4 µs after the RESET_B output stops being driven by the chip in order to allow the pull-up on the pin to take effect.

If RESET_B is stopped being asserted by the MC_RGM and the 4 µs input mask period expires during the reset ***IDLE*** phase, and now a low value is detected on RESET_B, an external reset falling edge event will not occur, and no new reset sequence will be triggered. For a new reset sequence to trigger, RESET_B must first be deasserted.

62.5.4 ‘Functional’ resets

A ‘functional’ reset indicates that an event has occurred after which it can be guaranteed that critical register and memory content is still intact.

The status flag associated with a given ‘functional’ reset event (**RGM_FES[F_<functional reset>]** bit) is set when the ‘functional’ reset is asserted and the power-on reset is not asserted. It is possible for multiple status bits to be set simultaneously, and it is software’s responsibility to determine which reset source is the most critical for the application.

A given ‘functional’ reset can be optionally disabled by software writing bit **RGM_FERD[D_<functional reset>]**.

NOTE

The **RGM_FERD** register can be written only once between two power-on reset events.

An enabled ‘functional’ reset will normally trigger a reset sequence starting from the beginning of ***PHASE1***. Nevertheless, the **RGM_FESS** register enables the further configuring of the reset sequence triggered by a ‘functional’ reset. When **RGM_FESS[SS_<functional reset>]** is set, the associated ‘functional’ reset will trigger a reset sequence starting directly from the beginning of ***PHASE3***, skipping ***PHASE1*** and ***PHASE2***. This can be useful especially in case a ‘functional’ reset should not reset the flash module.

62.5.5 Alternate event generation

The MC_RGM provides alternative events to be generated on reset source assertion. when a reset source is asserted, the MC_RGM normally enters the reset sequence. alternatively, it is possible for some reset source events to be converted from a reset to either a ***SAFE*** mode request issued to the MC_ME or to an interrupt request issued to the core.

Alternate event selection for a given reset source is made via the **RGM_D/FERD** and **RGM_D/FEAR** registers as shown in the following table.

Table 62-2. MC_RGM Alternate Event Selection

RGM_D/FERD bit value	RGM_D/FEAR bit value	Generated event
0	X	Reset
1	0	***SAFE*** mode request
1	1	Interrupt request

The alternate event is cleared by deasserting the source of the request (i.e., at the reset source that caused the alternate request) and also clearing the appropriate **RGM_D/FES** status bit.

NOTE

SAFE mode requests are generated regardless of whether the system clock is running. Interrupt requests are generated with the system clock, and therefore, if the system clock was disabled at the time of the event, the interrupt request is not asserted until the system clock is re-enabled.

NOTE

If a masked ‘destructive’ reset event which is configured to generate a ***SAFE*** mode/interrupt request occurs during ***PHASE0***, it is ignored, and the MC_RGM will not send any safe mode/interrupt request to the MC_ME.

NOTE

If a masked ‘functional’ reset event which is configured to generate a ***SAFE*** mode/interrupt request occurs during ***PHASE1***, it is ignored, and the MC_RGM will not send any safe mode/interrupt request to the MC_ME.

62.5.6 ‘Functional’ reset escalation

‘Functional’ reset escalation can be used to generate a ‘destructive’ reset if a number of ‘functional’ or external resets has occurred between software writes to the **RGM_FRET** register. This function is enabled by writing a non-zero value to the **FRET** field of this register.

Once ‘functional’ reset escalation has been enabled, the MC_RGM increases a counter on each ‘functional’ or external reset which causes a reset sequence to be initiated (i.e., entrance into PHASE1 or ***PHASE3*** from the ***IDLE*** phase). This counter is cleared on a write of any value to the **RGM_FRET** register and on any power-on or ‘destructive’ reset. If the counter reaches the value in the **RGM_FRET** register’s **FRET** field, the MC_RGM starts a reset sequence at ***PHASE0*** and asserts the **F_EDR** bit in the **RGM_DES** register.

62.5.7 ‘Destructive’ Reset Escalation

‘Destructive’ reset escalation can be used to keep the chip in the reset state until the power-on triggers a reset sequence if a number of ‘destructive’ resets has occurred between software writes to the RGM_DRET register. This function is enabled by writing a non-zero value to the DRET field of this register.

Once ‘destructive’ reset escalation has been enabled, the MC_RGM increases a counter on each ‘destructive’ reset which causes a reset sequence to be initiated (i.e., entrance into PHASE0 from the IDLE phase) or an ongoing reset sequence to restart (i.e., entrance into PHASE0 from PHASE1, PHASE2, or PHASE3). This counter is cleared on a write of any value to the RGM_DRET register and on any power-on reset. If the counter reaches the value in the RGM_DRET register’s DRET field, the MC_RGM enters reset PHASE0 and stays there until the next power-on reset occurs.

On a power-on reset, the dest_rst_escalation output is deasserted. It is asserted by the MC_RGM when the counter reaches the value in the RGM_DRET register's DRET field. It is not deasserted until the next power-on reset.

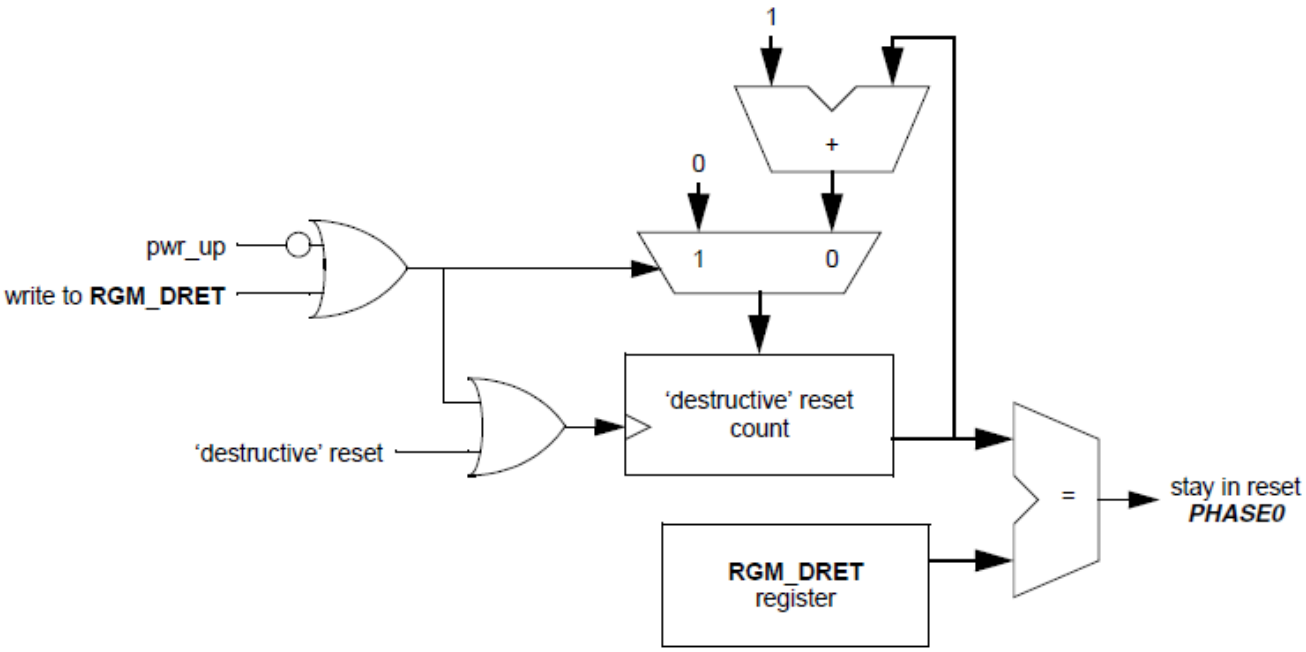

Figure 62-3. MC_RGM 'Destructive ' Reset Escalation to Stay in PHASE0

Chapter 63
System Status and Configuration Module (SSCM)

63.1 Chip-specific SSCM information

63.1.1 System Status and Configuration Module (SSCM) configuration

This section summarizes the System Status and Configuration Module (SSCM) configuration. There is one instance of the SSCM module on the MCU. For a comprehensive description of the SSCM, please reference the SSCM's dedicated chapter.

The SSCM reads the DCF records during boot, and parses this data to see if valid boot code exists.

SSCM_STATUS[NXEN1] indicates status of core 1(z7a) and core 2 (z7b) nexus enable status.

SSCM_STATUS[NXEN0] indicates status of core 0(z4) nexus enable.

The device specific reset value for the SSCM_MEMCONFIG register are shown in the following table.

Table 63-1. SSCM_MEMCONFIG reset value

Field	Field Definition	Value
JPIN	JTAG Part ID	0011011000b
MREV	Minor Revision	0010b
IVLD	Instruction flash memory valid	1b

Table 63-2 shows the address locations that the SSCM uses to search for startup information.

Table 63-2. SSCM startup information addresses

Description	Address
The location at which the SSCM will look for the UTEST records (UTEST_OFFSET)	0x0040_0300h

The SSCM module has a built-in register protection mechanism that affects the behavior of write operations to one or more registers. After software has activated the protection for a register, writes can only be performed in supervisor mode until the protection is either deactivated by software or the device undergoes reset.

See the Register protection (REG_PROT) configuration for a list of affected SSCM registers.

See the Overview for a detailed description of the register protection mechanism.

63.1.2 SSCM User Option Status Register (SSCM_UOPS)

Address offset: 20h

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	BOOT_CORE	0	LOCK_STEP_EN	0											SWT1_EN	SWT0_EN
W																
Reset	*	*	*						*						*	*

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	SEC_BOOT_CONFIG	SEC_BOOT_EN	0	NVM_CFG											
W																
Reset	*	*	*	*						*						

Note Reset value depends on DCF settings in the Flash or DCF configurations. Refer the DCF sheet attached with this document.

Table 63-3. SSCM UOPS register field descriptions

Field	Description
BOOT_CORE	Indicates if boot core is z4 or Z7a. 0 Z4 is the boot core 1 Z7a is the boot core
LOCK_STEP_EN	Indicates status of lock step mode 0 Disabled 1 Enabled
SWT1_EN	Indicates SWT1 status through flash configuration. 0 Disabled 1 Enabled
SWT0_EN	Indicates SWT0 status through flash configuration. 0 Disabled 1 Enabled
SEC_BOOT_CONFIG	Indicates the selected secure boot mode 0 Concurrent Secure boot mode 1 Sequential secure boot mode
SEC_BOOT_EN	Indicates if secure boot status through flash configuration). 0 Disabled 1 Enabled
NVM_CFG	NVM configuration FCCU_CFG[SM], FCCU_CFG[PS], FCCU_CFG[FOM] and FCCU_CFG[FOP]

63.1.3 ECC Error Monitoring

In case of any ECC error during flash memory scanning (such as Life Cycle , RCHW, or DCF records), the application is able to monitor ECC Errors in the Flash (through EER and ADDR) and can choose an appropriate action.

63.2 Introduction

63.2.1 Overview

The System Status and Configuration Module (SSCM) is pictured in the figure below.

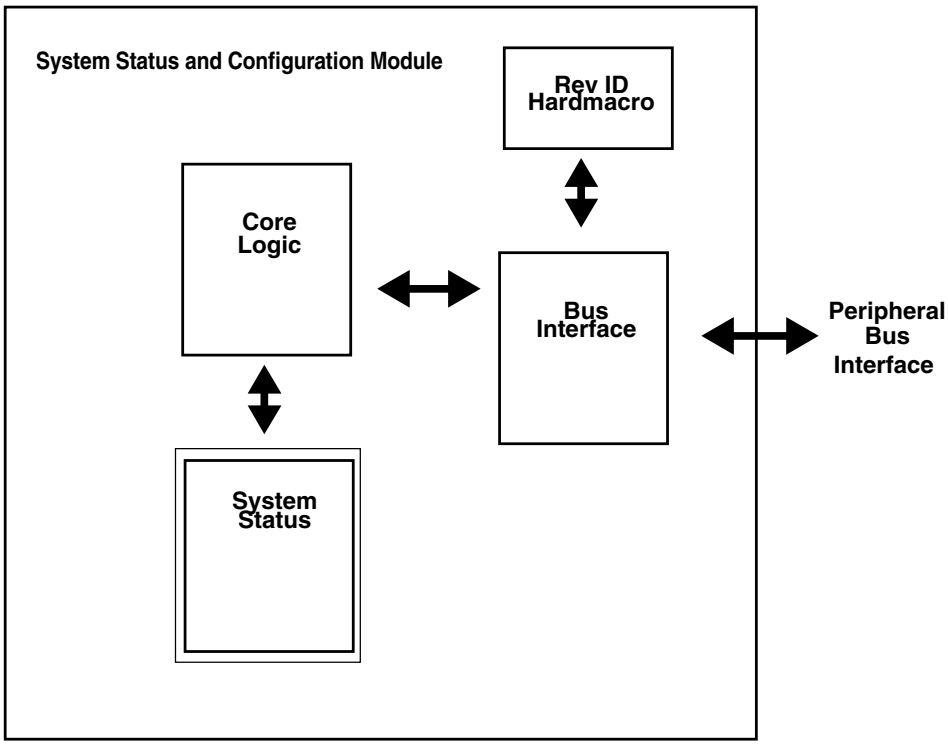

Figure 63-1. SSCM block diagram

63.2.2 Glossary

The table below shows a glossary of terms used through out the text.

Table 63-4. Glossary

Term	Definition
0011b	Binary numbers
0Fh	Hexadecimal numbers
Pin	External physical connection.
Signal	Electronic construct whose state or change in state conveys information.
X	In certain contexts, such as a signal encoding, this indicates a don't care. For example, if a field is binary coded X001b, the state of the first bit is a don't care.
y	y is used for a place holder of 1 hex digit for unknown values.

63.2.3 Features

The SSCM includes these distinct features:

- System Configuration and Status
  - Device Mode and System Status
  - Determine primary boot vector
  - Decodes the Device Life Cycle
- Bus abort enable/disable
- Off-platform Peripheral abort enable/disable

63.2.4 Modes of operation

The SSCM operates identically in all system modes.

63.3 External signal description

The SSCM has no external pins.

63.4 Memory map and register definition

This section provides a detailed description of all memory-mapped registers in the SSCM.

The table below shows the memory map for the SSCM. Note that all addresses are offsets; the absolute address may be calculated by adding the specified offset to the base address of the SSCM.

NOTE

All registers are accessible via 8-bit, 16-bit or 32-bit reads and/or writes. However, 16-bit accesses must be aligned to 16-bit boundaries, and 32-bit accesses must be aligned to 32-bit boundaries. As an example, the STATUS register is accessible by a 16-bit read or write, SSCM Base + 02h, but performing a 16-bit access to SSCM Base + 0003h is illegal (that is, you should not make any transfer that is not aligned to burst size boundary).

NOTE

SSCM does not generate transfer errors in all memory holes.

NOTE

Reserved IPS register access is prohibited.

SSCM memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	SSCM System Status (SSCM_STATUS)	16	R	See section	63.4.1/3320
2	SSCM System Memory and ID Register (SSCM_MEMCONFIG)	16	R	See section	63.4.2/3322
6	SSCM Error Configuration Register (SSCM_ERROR)	16	R/W	0000h	63.4.3/3322
28	Processor Start Address Register (SSCM_PSA)	32	R	See section	63.4.4/3323
34	Life Cycle Status Register (SSCM_LCSTAT)	32	R	See section	63.4.5/3324

63.4.1 SSCM System Status (SSCM_STATUS)

The System Status register reflects the current state of the system.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7
Read	0	CER	CERS	NXEN1	NXEN	1	Reserved	0
Write		w1c	w1c					
Reset	0	0	0	*	*	1	*	0

Bit	8	9	10	11	12	13	14	15
Read	BMODE			1	0	0	0	
Write								
Reset	*	*	*	1	0	0	0	0

* Notes:
- BMODE field: Reset value depends on the device status after leaving reset.
- Reserved field: This field can reset to 0 or 1.
- NXEN field: Reset value depends on the device status after leaving reset.
- NXEN1 field: Reset value depends on the device status after leaving reset..

SSCM_STATUS field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

SSCM_STATUS field descriptions (continued)

Field	Description
1 CER	Configuration Error This field indicates that the SSCM has detected a configuration error during reset while loading initial device configuration. See the chip-specific SSCM information for details about sources of the error. If a non-permanent error is detected, this bit can be cleared by writing a 1. Refer to CERS-DCF Mechanism section. 0 No configuration problem detected by the SSCM 1 Device configuration is not correct
2 CERS	Configuration Error for Safe DCF Clients This field indicates that the SSCM has detected a configuration error during reset while loading the Safe DCF Clients (DCF client with SPRD ADDR enabled, Triple Voting Enabled). If a non-permanent error is detected, this bit can be cleared by writing a 1. Refer to CERS-DCF Mechanism section. 0 No configuration problem detected by the SSCM 1 Device configuration is not correct
3 NXEN1	Processor 1 Nexus enable status 0 Processor 1 Nexus disabled. 1 Processor 1 Nexus enabled
4 NXEN	Processor 0 Nexus enable status 0 Processor 0 Nexus disabled. 1 Processor 0 Nexus enabled
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.

63.4.2 SSCM System Memory and ID Register (SSCM_MEMCONFIG)

The System Memory and ID register is a read-only register which reflects the memory configuration of the system. It also contains the JTAG part ID.

Address: 0h base + 2h offset = 2h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	JPIN										IVLD	MREV				0
Write																
Reset	*	*	*	*	*	*	*	*	*	*	1	*	*	*	*	0

* Notes:
- MREV field: Reset value can be found in the SSCM Configuration section.
- JPIN field: Reset value reflects the JTAG part ID of the device.

SSCM_MEMCONFIG field descriptions

Field	Description
0–9 JPIN	JTAG Part ID Number **NOTE:** Reset value reflects the JTAG part ID of the device.
10 IVLD	Instruction flash memory Valid This bit identifies whether or not the on-chip instruction flash memory is accessible in the system memory map. 0 Instruction Flash is not accessible 1 Instruction Flash is accessible
11–14 MREV	Minor Mask Revision
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

63.4.3 SSCM Error Configuration Register (SSCM_ERROR)

The Error Configuration register is a read-write register that controls the error handling of the system.

Address: 0h base + 6h offset = 6h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Read	0														PAE	RAE
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SSCM_ERROR field descriptions

Field	Description
0–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

14
PAE
	Peripheral Bus Abort Enable.
	
	This bit enables bus aborts on:
	• any access to a peripheral slot that is not used on the device.
	  • This feature is intended to aid in debugging when developing application code.
	• illegal accesses to off-platform peripherals.
	  • On platform peripherals cannot be controlled by SSCM peripheral abort.
	
	0 Illegal accesses to non-existing peripherals do not produce a Prefetch or Data Abort exception
	1 Illegal accesses to non-existing peripherals produce a Prefetch or Data Abort exception

15 RAE	Register Bus Abort Enable. This bit enables bus aborts on illegal accesses to off-platform peripherals. Illegal accesses are defined as reads or writes to reserved addresses within the address space for a particular peripheral. This feature is intended to aid in debugging when developing application code. **NOTE:** Transfers to peripheral bus resources may be aborted even before they reach the peripheral bus (in example, at the AIPS level). In this case, the PAE and RAE register bits have no effect on the abort. 0 Illegal accesses to peripherals do not produce a Prefetch or Data Abort exception 1 Illegal accesses to peripherals produce a Prefetch or Data Abort exception

63.4.4 Processor Start Address Register (SSCM_PSA)

Address: 0h base + 28h offset = 28h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

63.5 Functional description

The primary purpose of the SSCM is to provide information about the current state and configuration of the system that may be useful for configuring application software and for debug of the system.

63.5.1 CERS-DCF Mechanism

The figure below shows that a faulty DCF record has been loaded between the original DCF record set and the final DCF record set. When a faulty DCF record is encountered, the SSCM_STATUS[CERS] field indicates that the device configuration is not correct. In a situation like the one shown below, CERS can be cleared by writing 1 to it, as long as the final DCF record set is correct.

If there is an error in the final set of loaded DCF records, CERS cannot be cleared. This situation indicates that the final DCF record set has at least one error. To fix this, the user should update flash memory after the faulty DCF record with a correct DCF record of the same type. For example, if the faulty DCF record is DCF2, then the correct DCF record should also be DCF2.

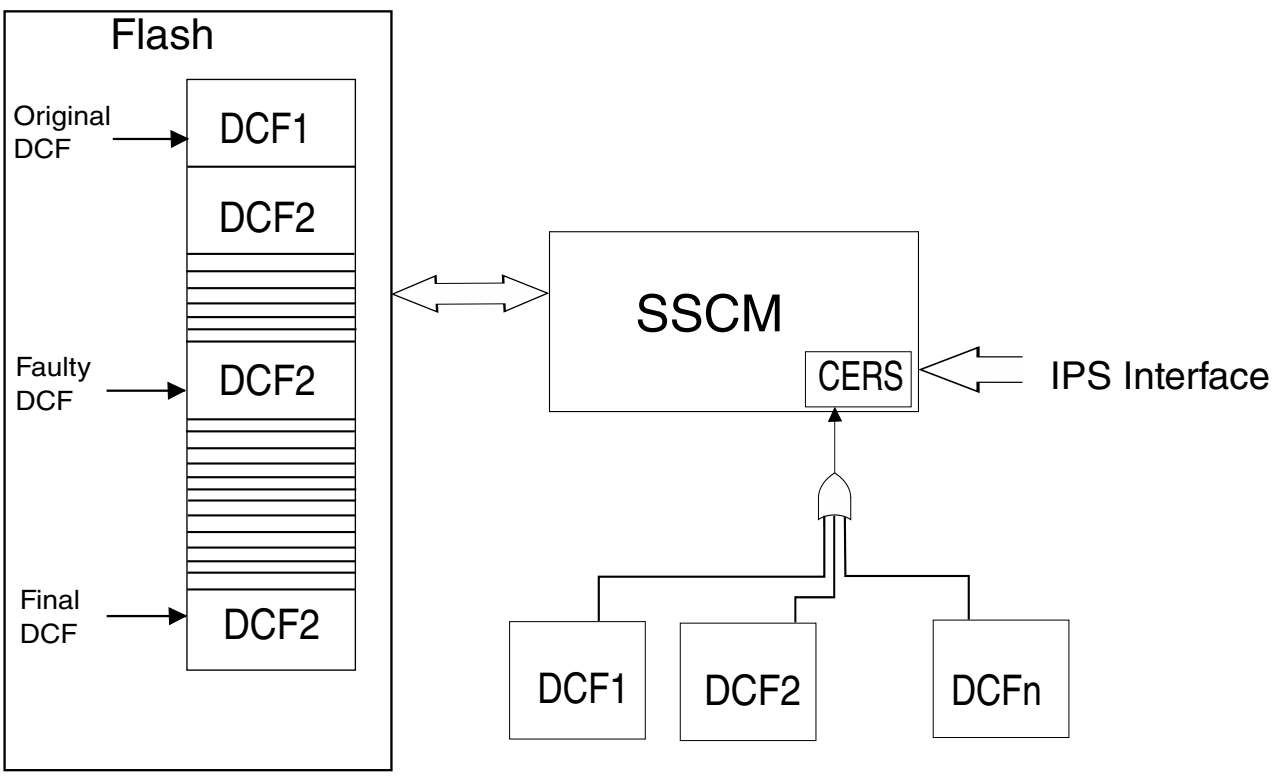

Figure 63-2. DCF Error and CERS Handling

63.5.2 ECC error monitoring

NOTE

During DCF Scanning, if multibit ECC error on DCF start record and DCF start record pattern is corrupted then, SSCM will not be able to identify that as a valid start record and will ignore the flash region as well. In this case, an ECC error address would be logged in . SoC software can monitor for any address of start record. If any start record address found in address log then software should generate a security reset.

Refer to chip-specific SSCM information section for ECC error monitoring and reaction.

63.5.3 Boot mode functionality

The device supports the following boot modes for the main boot core:

- Single Chip (SC) - The device will boot from the first bootable section of the flash memory main array.
- Serial Boot (SBL) - The device will download boot code from either SCI or CAN interface and then execute it.

If booting is not possible with the selected configuration (for example, no Boot ID is found in the selected boot location) then the device will enter static mode.

63.5.4 Hardware configuration

The device will detect the boot mode based on external pins and device status. The following sequence applies:

- If the FAB (Force Alternate Boot Mode) pin is set to boot in serial mode the device can be forced into an Alternate Boot Loader Mode. The type of alternate boot mode is selected according to the ABS (Alternate Boot Selector) pins. For details of the serial boot modes and hardware configuration please refer to the BAM/System Boot chapter.
- If the device identifies a flash memory sector with a valid boot sector, it will boot from the lowest sector. (See Figure 63-3.)
- If none of the flash memory sectors contains a valid boot signature, the device will go into static mode.

63.5.5 Single Chip boot sector search

63.5.5.1 Potential boot sectors

As shown in Figure 63-3 in single chip mode, several locations are searched for a valid boot ID. The lowest sector that starts with a valid boot ID is used to boot the device.

For the flash memory locations that are searched on this device, see the chip-specific details about boot locations in flash memory.

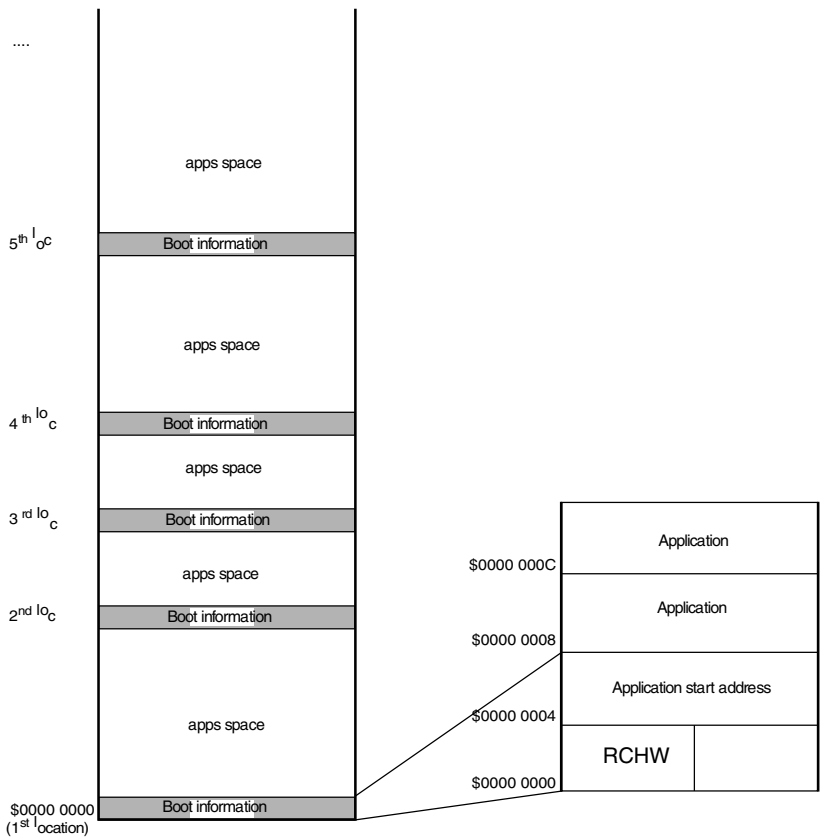

Figure 63-3. Flash memory partitioning and RCHW search

63.5.5.2 Reset Configuration Half-Word

Each boot sector in flash memory contains the Reset Configuration Half-Word (RCHW) at offset 00h. If the RCHW field BOOT_ID holds the value 5Ah then the sector is considered bootable. In addition, there is a flag which indicates that the code is VLE code. All other bits are reserved.

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	VLE	BOOT_ID							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

= Reserved

Once the device detects that it needs to boot from flash memory, and finds a valid BOOT_ID, it will boot from the application start address at offset 04h within the boot sector.

NOTE

When programming any of the locations in the RCHW list, ensure that programming is not interrupted and can complete without error. When erasing any block containing any of the locations in the RCHW list, ensure that the erase is not interrupted (especially by reset or loss of power).

63.5.5.3 Boot and alternate boot sectors

Some applications require an alternate boot sector so that the main boot can be erased and reprogrammed in the field.

When an alternate boot is needed, the user can create two bootable sectors; the lowest sector shall be the main boot sector and the highest shall be the alternate boot sector. The alternate boot sector does not need to be consecutive to the main boot sector.

This scheme ensures that there is always one active boot sector by erasing one of the boot sectors only:

- Sector is activated (that is, program a valid BOOT_ID instead of FFh as initially programmed).
- Sector is deactivated by writing 0 to some bits of the BOOT_ID field (bit 1 and/or bit 3, and/or bit 4, and/or bit 6).

63.5.6 Serial boot loader mode

63.5.6.1 Serial boot loader mode - public password enabled

In Serial Boot Loader Mode, if public serial access is allowed, the MCU executes BAM code which will check for a valid public password on the chosen interface. The interface will be selected via FAB and ABS pins.

- JTAG available
- Boot from BAM

63.5.7 Life Cycle

The SSCM will determine the Life Cycle (LC) of the device by reading the LC slots from the UTEST flash memory. The read operation is done during the reset phase with normal timings and it is protected by operating monitors and ECC check. In addition, a set of sanity checks executed over the LC read data guarantee the integrity of the final LC value.

At the end of the reset phase, the LC can have one of the following values:

- MCU Production
- Customer Delivery
- OEM Production
- In Field
- Failure Analysis

Life cycle can only be moved in the direction shown below:

Figure 63-4. Life cycle sequence

The LC is written into 5 slots, 128 bits each, at fixed locations in the UTEST flash memory block. Each LC slot is read in one single atomic operation and it is organized into two fields:

- the valid field
- the invalid field

Depending on the possible combination of the data programmed into these fields, each LC slot can have one of the possible 4 statuses as seen in Table 63-5.

Table 63-5. LC slot status

LC slots		LC slot value
Valid field (64 bits)	Invalid field (64 bits)	
Erased	Erased	Erased
Marked	Erased	Active
Marked	Marked	Inactive
Any other values		Illegal

"Marked" in this case means that the value has been programmed with the bit pattern 55AA_50AF_55AA_50AFh. "Erased" is detected by the bit pattern FFFF_FFFF_FFFF_FFFFh. Table 63-6 shows how the slots are arranged in memory.

Table 63-6. LC slots in memory

Offset	LC slot word
00h	Valid[31:0]
04h	Valid[63:32]
08h	Invalid[31:0]
0Ch	Invalid[63:32]

The Life Cycle is determined as shown in Table 63-7

NOTE

"Erased" means the slot returns all 1s.

Table 63-7. LC slots

LC slot 0 MCU Production	LC slot 1 Customer Delivery	LC slot 2 OEM Production	LC slot 3 In Field	LC slot 4 Failure Analysis	Resulting life cycle
Active	Erased	Erased	Erased	Erased	MCU Production
Inactive	**Active**	Erased	Erased	Erased	Customer Delivery
Inactive	Inactive	**Active**	Erased	Erased	OEM Production
Inactive	Inactive	Inactive	**Active**	Erased	In Field
Inactive	Inactive	Inactive	Inactive	**Active**	Failure Analysis
Erased	Erased	Erased	Erased	Erased	System Reset
Illegal[1]	Illegal	Illegal	Illegal	Erased	In Field

1. Any value programmed other than shown in table above for Erased, Active, and Inactive would be treated as illegal.

NOTE

When programming Life Cycle, ensure that programming is not interrupted and can complete without error.

NOTE

Any other combination of values will result in a system reset.

NOTE

No one should program “ILLEGAL” even if able to do that.
Device behavior is not guaranteed for these combinations.

63.6 Initialization and application information

63.6.1 Reset

The reset state of each individual bit appears in the detailed register descriptions.

Chapter 64
Power Management Controller block (PMC)

64.1 Chip-specific Power Management Controller (PMC) information

64.1.1 Overview

The device needs a set of digital and analog supplies and the high fidelity analog supplies. The following figure shows how the different supplies are derived.

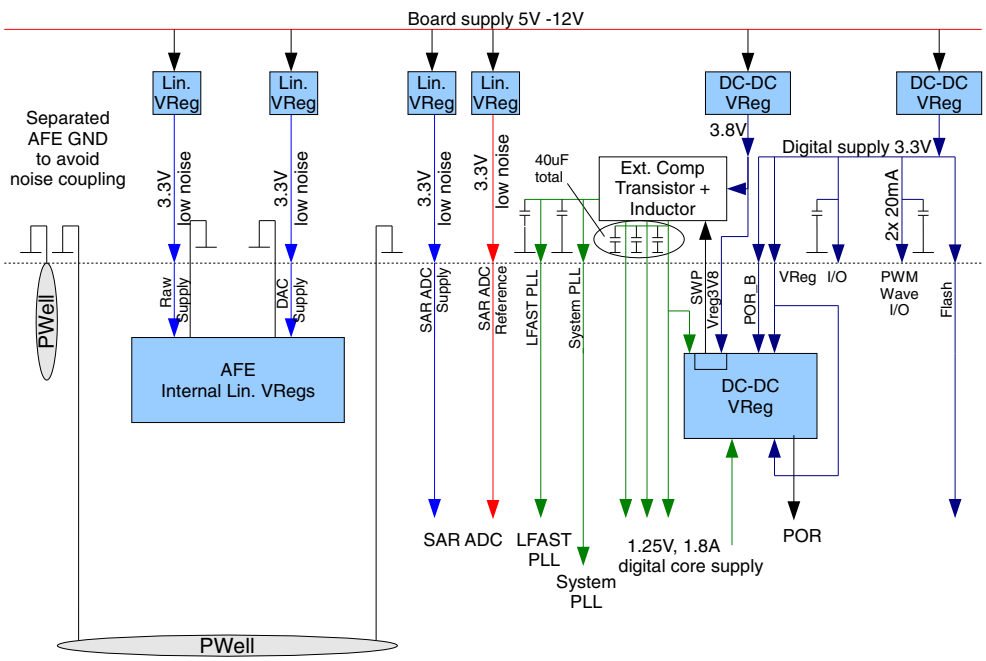

Figure 64-1. Supply Tree

In its standard configuration, the device utilizes the internal DC-DC converter to supply the internal core. This supply is too noisy for supplying the high fidelity analog modules. It might be also required to separate the external 3.3V supplies. For the digital part the HV supply can be derived using a DC-DC converter, while the analog HV supplies shall

be derived from low noise voltage regulators. To avoid spurs in between the high fidelity components via the supply rails, their supplies are separated for the ADC, the clock generation, and the DAC.

In case the high fidelity components are not required to operate in high fidelity mode, the external supply scheme can be simplified to run from a single 3.3V rail.

The digital LV supply at 1.25V can be generated alternatively completely from external. This might make sense in case the external supply is available anyway. In that case the external supply needs to compensate for the internal IR drop.

The following figure shows the case with external core supply and unified 3.3V supply not supporting high fidelity analog processing.

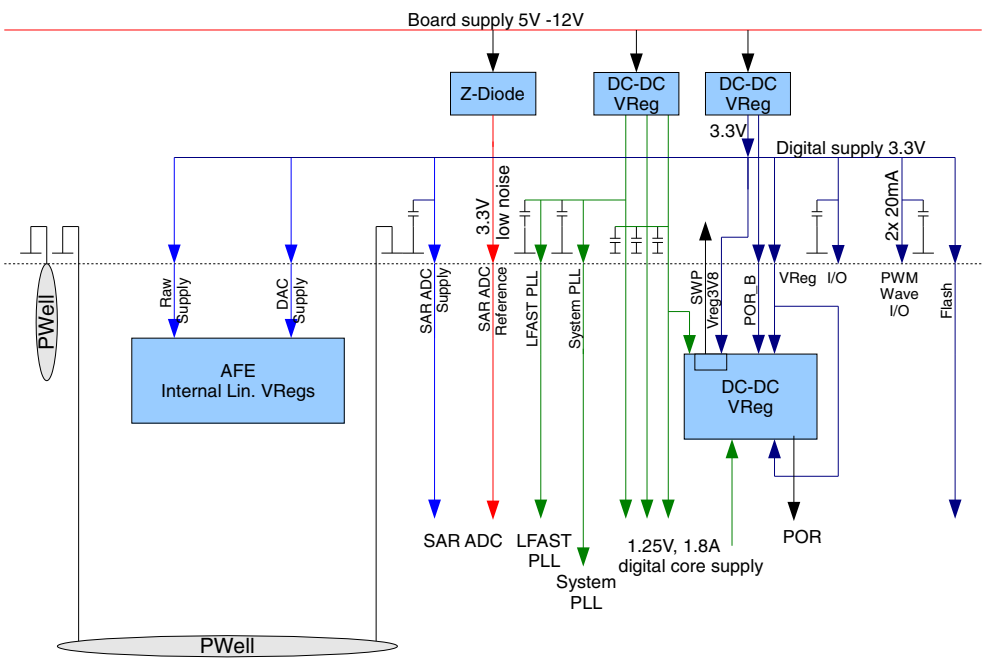

Figure 64-2. Simplified External Supply Tree

When chip is in external regulation mode, the internal POR circuit is disabled. Chip is controlled by POR_B pin. It should be ensured that POR_B should be deasserted only when all supplies are in operating range. LVD and HVD circuit on VDD are disabled by default in external regulation mode. It should be ensured that they are trimmed as per board conditions and only then they are enabled by software or an external LVD/HVD circuit should be used in external regulation.

The following table specifies which LVD/HVD are enabled and disabled in internal and external regulation mode.

Table 64-1. LVD/HVD in internal and external regulation modes

LVD/HVD	Internal Regulation Mode	External Regulation Mode
LVD PMC	Enabled	Enabled
LVD CORE	Enabled	Disabled
HVD CORE	Enabled	Disabled
LVD ADC	Enabled	Enabled
HVD ADC	Enabled	Enabled
LVD Flash	Enabled	Enabled
LVD PLL	Enabled	Enabled
LVD I/O	Enabled	Enabled
LVD MIPI	Disabled	Disabled
1.2V POR	Enabled	Disabled

64.1.2 Power sequencing

Refer device datasheet for power sequencing requirements.

64.1.3 Software-controlled temperature sensor trim adjustment

The SoC provides a feature to update Temperature sensor trims through software. This feature requires an on-chip SAR ADC, this SAR ADC converts the analog voltage provided by temperature sensor into a digital code. The analog voltage provided by temperature sensor is directly proportional to the chip junction temperature. Hence, user should develop a graph of digital ADC code vs. the chip junction temperature reported by corresponding temperature sensor to use this feature. For ADC-TSENS channel details, refer ADC pin muxing.

The following sequence should be used to update temperature sensor trims reliably.

Software sequence for trimming Temperature Sensor 0:

1. Program PMC_REE_TD[TEMP0_0]=0 , PMC_REE_TD[TEMP0_2]=0 to disable reset reaction.
2. Program PMC_TS_IER[TS_EN]=0 to disable temperature sensor interrupt reaction.
3. Program FCCU_NCFS_CFG0[NCFSCx[1:0]] = 00 , to disable FCCU fault reaction.
4. Program PMC_CTL_TD [TS0_DOUT_EN] =0, PMC_CTL_TD[TS0_AOUT_EN]=0 , to disable temperature sensor.
5. Program PMC_CTL_TD [TS0_TRIM_ADJ [4:0]] to update temperature sensor trims to desired value.
6. Wait for 25 us to allow temperature sensor stabilization with new trim values.

7. Program PMC_CTL_TD [TS0_DOUT_EN] =1 , PMC_CTL_TD[TS0_AOUT_EN]=1 , to enable temperature sensor.
8. Check the temperature by performing ADC conversion on Temperature sensor0 ADC channel which is connected to channel no.15 on ADC0.
9. If the temperature is in range (-40°C to 150°C):
   - Clear PMC_ESR_TD[TEMP0_0] and PMC_ESR_TD [TEMP0_2].
   - Program PMC_REE_TD/PMC_TS_IER/ FCCU_NCFS_CFG0 to allow resets, interrupts or fault configuration, respectively.
10. If the temperature is not in range, perform the necessary safety actions for the application to bring the temperature within range.

Software sequence for trimming Temperature Sensor 1:

1. Program PMC_REE_TD[TEMP1_0]=0 , PMC_REE_TD[TEMP1_2]=0 to disable reset reaction.
2. Program PMC_TS_IER[TS_EN]=0 to disable temperature sensor interrupt reaction.
3. Program FCCU_NCFS_CFG0[NCFSCx[1:0]] = 00, to disable FCCU fault reaction.
4. Program PMC_CTL_TD [TS1_DOUT_EN] =0, PMC_CTL_TD[TS1_AOUT_EN]=0, to disable temperature sensor.
5. Program PMC_CTL_TD [TS1_TRIM_ADJ [4:0]] to update temperature sensor trims to desired value.
6. Wait for 25 us to allow temperature sensor stabilization with new trim values.
7. Program PMC_CTL_TD [TS1_DOUT_EN] =1 , PMC_CTL_TD[TS1_AOUT_EN]=1, to enable temperature sensor.
8. Check the temperature by performing ADC conversion on Temperature sensor1 ADC channel which is connected to channel no.15 on ADC1.
9. If the temperature is in range (-40°C to 150°C):
   - Clear PMC_ESR_TD[TEMP1_0] and PMC_ESR_TD [TEMP1_2].
   - Program PMC_REE_TD/PMC_TS_IER/ FCCU_NCFS_CFG0 to allow resets, interrupts or fault configuration, respectively.
10. If the temperature is not in range, perform the necessary safety actions for the application to bring the temperature within range.

NOTE

The temperature sensor flags in PMC_ESR_TD register may get set when ADC supply is varied below LVD level and its LVD destructive reset is masked.

64.1.4 Enabling FCCU faults from PMC

By default, FCCU faults from the PMC block is masked by the DCF. To enable FCCU faults from PMC, dcl_pmc_ree_ctrl dcf client bit 0 must be set to 1. See Device Configuration Format (DCF) Records chapter for general information on DCF records. See the attached spreadsheet for details on the DCF client.

64.2 PMC introduction

NOTE

For the chip-specific implementation details of this module's instances, see the chip configuration information. Also refer to the Hardware Design guide for requirements and recommendations on the external design components.

The power management controller (PMC) consists of two blocks: analog block and a digital block.

The PMC block, shown below, contains all of the registers and digital logic to generate all of the enable signals, trim control bits, power on resets (PORs), and test mode logic for the analog block. The PMC digital logic also controls the PMC analog outputs that are to be sensed by the Analog-to-Digital Converter (ADC) module.

The PMC digital logic also provides the enable signals, trim bits and other registers for the temperature sensors.

Custom interfaces are provided to each of:

- The Reset Generation Module (MC_RGM) block, which receives low voltage detect (LVD) values that are used for phase transition conditions during POR.
- The Flash memory, via the SSCM (and DCF client blocks), provides trim values for use during initial POR.

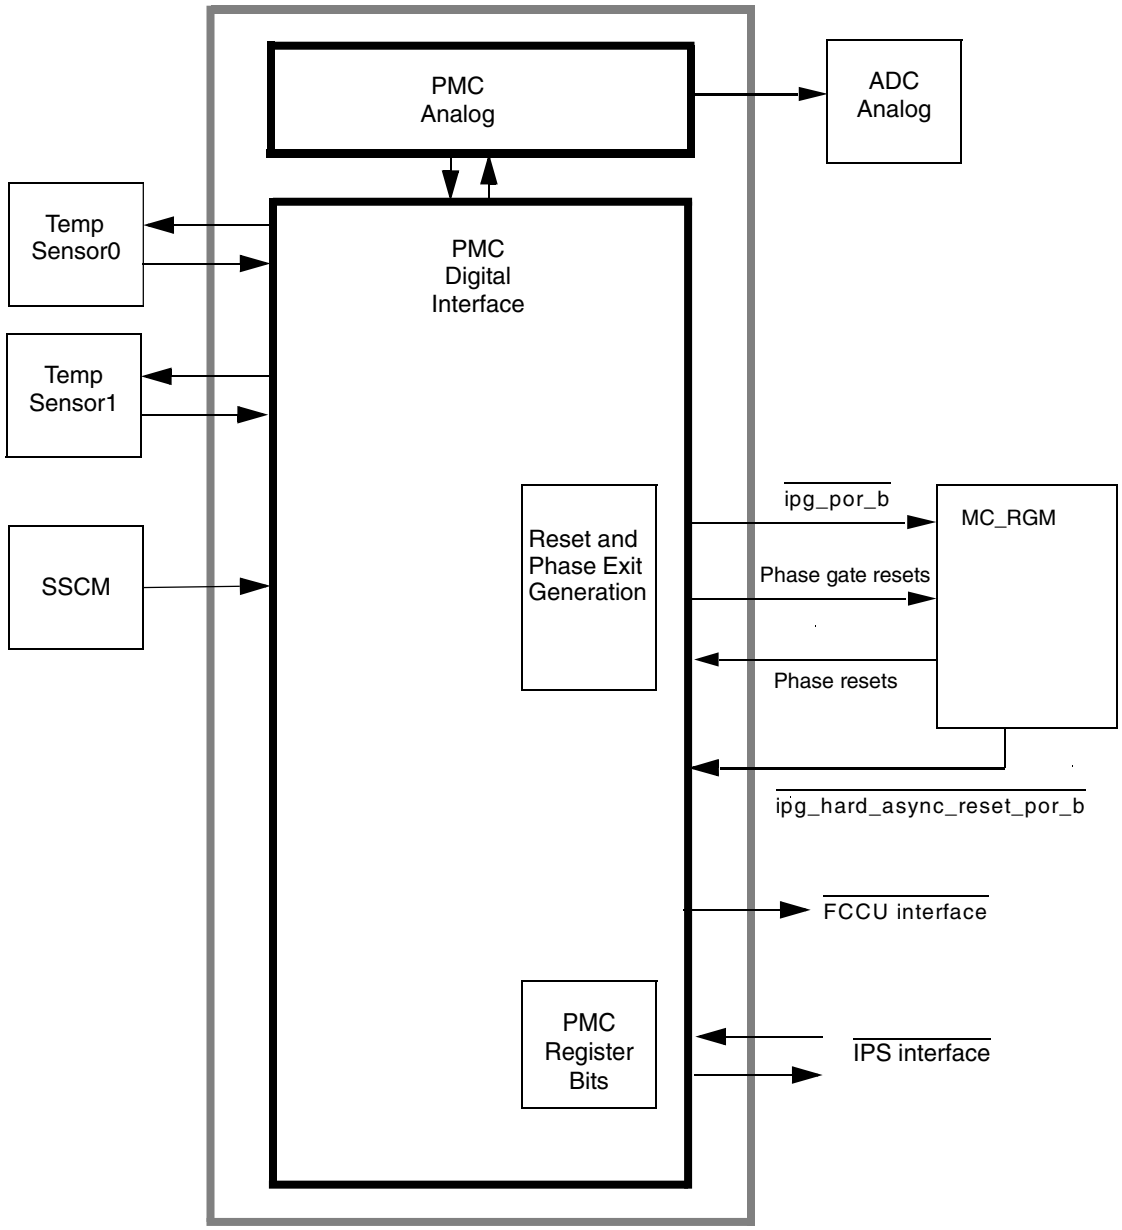

Figure 64-3. Digital PMC block diagram

64.2.1 Features

The PMC module provides:

- Configuration and control information to the analog PMC block.
- Configuration and monitoring of the two temperature sensors.
- Host access, via the IPS bus, to all register controls, configurations, and status.
- Self test logic for the LVDs and HVDs.
- Transfer wait state feature supported on IPS bus access.
- Compatible with 3.3V (analog) operation.

- 1.25 V / 1.8 A output voltage switch-mode power supply (SMPS) asynchronous buck regulator.
- Precision LVD (Low-voltage detection) and HVD (high-voltage detection) for:
  - PMC voltage supply (VDDREG) - LVD
  - VDD core voltage supply - POR/LVD/HVD
  - VDD ADC voltage supply - LVD/HVD
  - Flash memory voltage supply - LVD
  - Oscillators/PLL voltage supply - LVD
  - VDDIO I/O voltage supply - LVD
- Two independent voltage references provide fault tolerance:
  - Voltage monitors and ADC references
  - Core voltage regulator
- DCF Client interface: An interface with Flash memory for retrieval of trim/control information, during POR for:
  - HVDs/ LVDs Regulators
  - Band gap filters
- MC_RGM Interface: Necessary status and indication information to the MC_RGM block during power up.
- FCCU (Fault control and correction Unit): Software Triggered fault injection for LVDs, HVDs, temperature sensors, and LVD self test.

64.3 Memory map and registers

Please note that 8/16 bit register accesses are not supported.

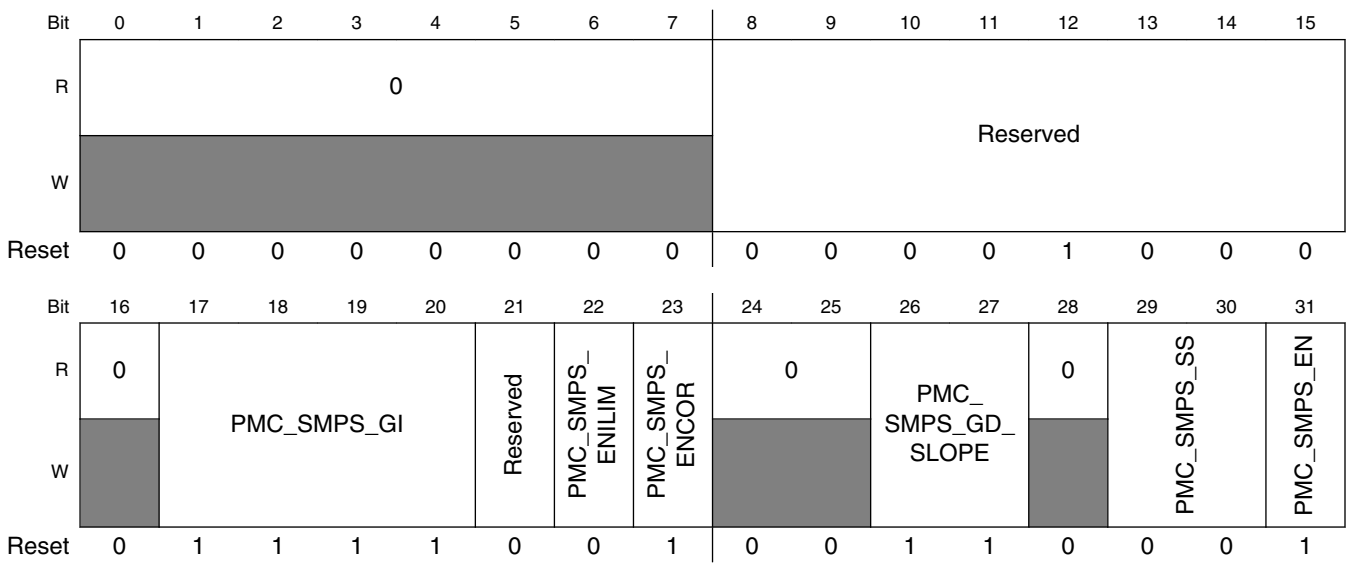
64.3.1 SMPS Control Register (PMC_SMPS_CNTRL)

This register contains the various control settings for the SMPS module.

RESET_B does not reset this register. Only a power-on reset (POR) does.

Address: 0h base + 64h offset = 64h



PMC_SMPS_CNTRL field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–15 Reserved	This field is reserved. These bits should always be set to 8'h08.
16 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
17–20 PMC_SMPS_GI	SMPS Overshoot Current Trimming

Table continues on the next page...

PMC_SMPS_CNTRL field descriptions (continued)

Field	Description
	These trimming bits control the SMPS current limitation feature, when PMC_SMPS_ENLIM = 1. The recommended value is 0110. Please refer to the Hardware Design Guide for more details. This feature is based off of the estimation of the SMPS external inductor current from the RC network connected to vreg_iSENS pin. The RC network is configured such that for a given inductor, the voltage difference between core VDD and vreg_iSENS pin provides an estimate of the inductor current. These trimming bits control the voltage threshold, which in turn selects the max current allowed through the inductor. A 0000 trim setting represents 100mV drop across the intrinsic resistor and each additional count represents an additional 25mV voltage increment. The higher the count of the trim bits, the higher the max current allowed. For a particular external inductor and its associated intrinsic resistance; a particular trim setting is recommended based on current limit required. When the inductor current exceeds the trimmed limit value, the SMPS current limitation loop turns off the external pMOS transistor temporarily. DC loop continues core voltage regulation once inductor current falls within limit.
21 Reserved	This field is reserved. This bit should be programmed to 0.
22 PMC_SMPS_ENILIM	SMPS Inductor Current Limitation Enable This bit enables current limitation feature through the external inductor based on feedback through the ISENS pin. See PMC_SMPS_GI.
23 PMC_SMPS_ENCOR	SMPS Hysteretic Correction Enable ENCOR bit must be turned high after power-up, to limit voltage disturbances during extreme load current transients. It is recommended that the Inductor Current Limitation feature(PMC_SMPS_ENLIM) must be enabled at all times when hysteretic correction is used. 0 Disabled 1 Enabled
24–25 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
26–27 PMC_SMPS_GD_SLOPE	SMPS gate driver strength Controls strength of gate-driver circuit. After power-up minimum strength is selected. By adjusting this field, it is possible to trade efficiency for EMI. Stronger driver will generate more EMI. Recommended settings: 01. 00 100% drive strength 01 Approximately 70% drive strength 10 Approximately 50% drive strength 11 Approximately 35% drive strength
28 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
29–30 PMC_SMPS_SS	SMPS spread spectrum control SMPS frequency modulation control. Allow controller to reduce EMI generated at the switching frequencies and its harmonics. Default settings: 00.

Table continues on the next page...

PMC_SMPS_CNTRL field descriptions (continued)

Field	Description
	00 No modulation 01 15% modulation 10 7.5% modulation 11 30% modulation
31 PMC_SMPS_EN	SMPS controller enable In internal regulation mode, the SMPS controller is enabled by default. When an external regulator is to be used, the external SMPS components must not be populated on the board. In external regulation case, this bit can be de-asserted to disable the SMPS controller after power-up. This will allow the use of the internal power-on-reset even with external regulator. 0 SMPS control is disabled 1 SMPS control is enabled

64.3.2 LVD Self Test Time Window Register (PMC_STTW)

This register configures the Self test Time window for each LVD/HVD.

NOTE

The reset value of STTW register depends upon the value of the dcl_pmc_self_test_time_gap DCF Client. Please refer to Device Configuration Format (DCF) Records for further details.

Address: 0h base + 68h offset = 68h

* Notes:
- If DCF record value is programmed, then reset value will be from DCF, else it will be 0xA0.

PMC_STTW field descriptions

Field	Description
0–19 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
20–31 STTW	Self Test Time Window. These bits are used to control the Time window for the self test for each LVD/HVD. This is based on the clock frequency used. For example, for 21 µs window, with 45 MHz clock, this should be configured with hex value 3E8. **NOTE:** STTW needs to be programmed to attain a window of 21 µs.

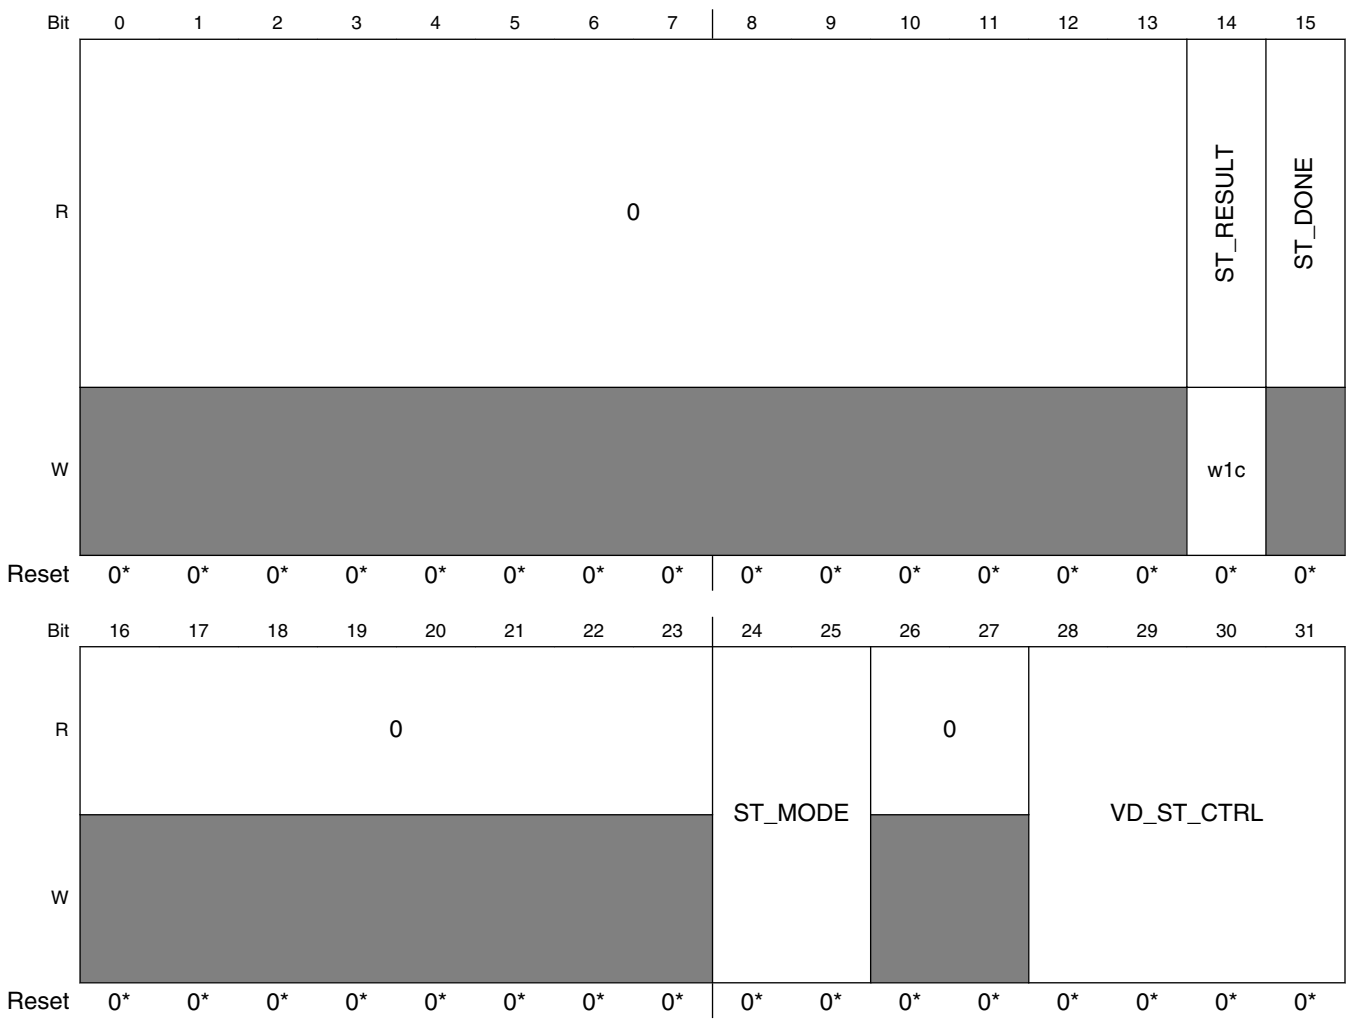
64.3.3 Voltage Detect User Mode Test Register (PMC_SELF_TEST_UM_VD_REG)

This register is used for testing of the LVDs and HVDs during user mode. To clear ST_RESULT field after single VD self test, user should ensure that the ST_CTRL field is also written with 0x0 value along with ST_RESULT = 1 (w1c field).

NOTE

This register is reset on a destructive reset. IPS writes on any register should not be done during running of software self test which is indicated by ST_DONE = 0b0.

Address: 0h base + 6Ch offset = 6Ch



* Notes:

- By default SELF TEST is enabled and by the time the reset value is read, SELF TEST results would be reflected.

PMC_SELF_TEST_UM_VD_REG field descriptions

Field	Description
0–13 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
14 ST_RESULT	ST_RESULT. Self Test result status. ST_RESULT. Self Test result status. (Valid only when ST_DONE is High). It is cleared on reset or writing '1' by the host. 0 Self Test Failed 1 Self Test Passed
15 ST_DONE	Self Test Done status. Self Test completed indication status. **NOTE:** There should be no configuration updates till the time ST_DONE bit is set. 0 Self test running 1 Self test completed.
16–23 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
24–25 ST_MODE	Self Test mode bits for testing of LVDs and HVDs. Mode 01 (software triggered self test) is similar to the default mode, except the user programs the ST_MODE field to start the test. In this mode, all LVD/HVD test modes are executed automatically. Mode 10 (single VD test) executes each test individually. The user sets the test by programming the PMC_SELF_TEST_UM_REG[VD_ST_CTRL] field. If either the default mode or the software triggered self test fail, the user can run the single VD test to determine which LVD/HVD passed and which LVD/HVD failed. 00 Default 01 Software triggered self test. 10 Single VD test as indicated by the VD_ST_CTRL bits. 11 Reserved
26–27 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
28–31 VD_ST_CTRL	Voltage Detect Self Test Control User mode Test bits for testing of LVDs and HVDs. 0000 Functional Mode 0001 Reserved 0010 Core LVD 0011 Core HVD 0100 LVD MIPI 0101 LVD PMC 0110 LVD FLash 0111 LVD ADC

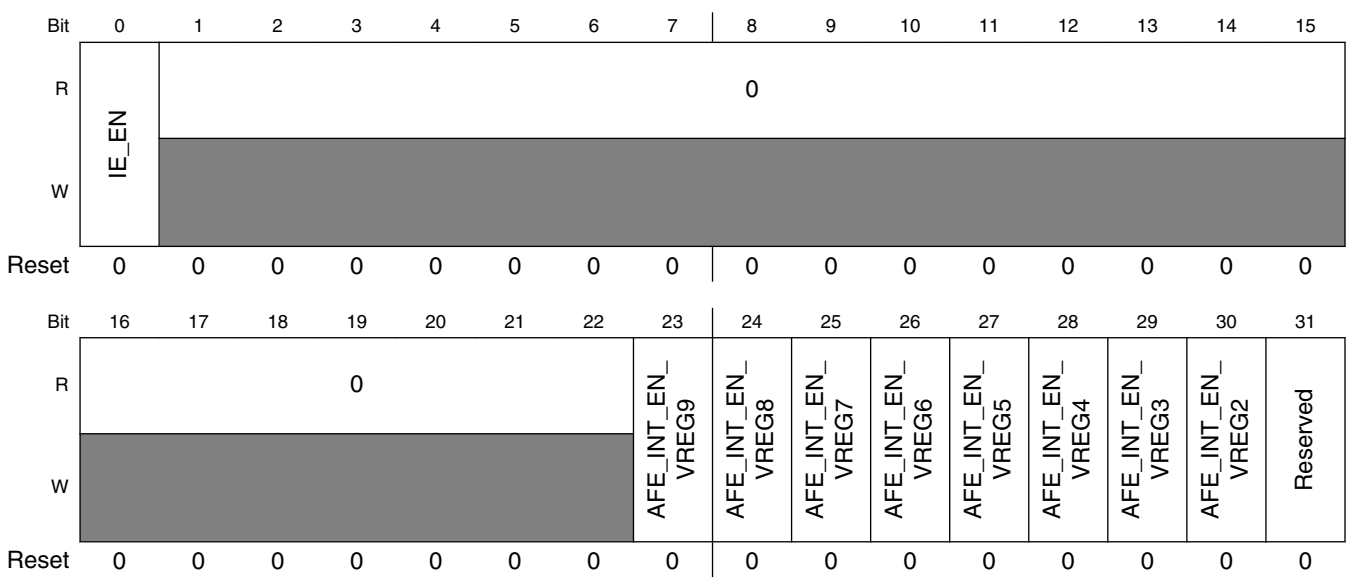
64.3.4 AFE Interrupt Enable Register (PMC_AFE_INTR_ENA)

This configuration register contains a set of AFE Interrupt Enable bits that correspond to each of the AFE Event Status Registers (ESR_0). These bits indicate whether an interrupt occurs when the voltage event is seen. A '0' indicates that no interrupt is to be sent, and a '1' indicates that an interrupt is to occur when the voltage detect event occurs. These bits are enabled via a write of one to the MSB of this register (IE_EN). After this, these bits can be read or written at any time.Please refer to AFE VREGn register descriptions for details.

NOTE

This register is reset on a short functional reset.

Address: 0h base + 78h offset = 78h



PMC_AFE_INTR_ENA field descriptions

Field	Description
0 IE_EN	Interrupt Enable. This bit determines whether any of the Interrupt Enable bits can be written. 0 No interrupt enables can be written. 1 Any interrupt enable can be written.
1–22 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
23 AFE_INT_EN_ VREG9	AFE-9 Interrupt Enable/Disable Control This bit determines whether an interrupt is seen by the system. 0 No interrupt occurs. 1 An interrupt occurs.
24 AFE_INT_EN_ VREG8	AFE-8 Interrupt Enable/Disable Control: This field determines whether an interrupt is seen by the system. 0 No interrupt occurs. 1 An interrupt occurs.
25 AFE_INT_EN_ VREG7	AFE-7 Interrupt Enable/Disable Control This bit determines whether an interrupt is seen by the system. 0 No interrupt occurs. 1 An interrupt occurs.
26 AFE_INT_EN_ VREG6	AFE-6 Interrupt Enable/Disable Control This bit determines whether an interrupt is seen by the system. 0 No interrupt occurs. 1 An interrupt occurs.
27 AFE_INT_EN_ VREG5	AFE-5 Interrupt Enable/Disable Control This bit determines whether an interrupt is seen by the system. 0 No interrupt occurs. 1 An interrupt occurs.
28 AFE_INT_EN_ VREG4	AFE-4 Interrupt Enable/Disable Control This bit determines whether an interrupt is seen by the system. 0 No interrupt occurs. 1 An interrupt occurs.
29 AFE_INT_EN_ VREG3	AFE-3 Interrupt Enable/Disable Control This bit determines whether an interrupt is seen by the system. 0 No interrupt occurs. 1 An interrupt occurs.
30 AFE_INT_EN_ VREG2	AFE-2 Interrupt Enable/Disable Control This bit determines whether an interrupt is seen by the system.

Table continues on the next page...

PMC_AFE_INTR_ENA field descriptions (continued)

Field	Description
	0 No interrupt occurs. 1 An interrupt occurs.
31 Reserved	This field is reserved.

64.3.5 AFE Interrupt Status Register (PMC_AFE_INTR_STATUS)

This configuration register contains a set of Interrupt Status bits that correspond to each of the AFE Interrupt Event Status. These bits indicate whether an AFE interrupt occurs when the voltage event is seen. A '0' indicates that no interrupt event is generated and a '1' indicates that an interrupt has occurred when the voltage detect event occurs. After this, these bits are W1c type

NOTE

Please refer to AFE VREGn register descriptions for details.

NOTE

The value of this register after reset sequences other than power-on-reset (POR) is not deterministic. The value on the status alone do not indicate an LVD has occurred. To ascertain an LVD occurrence, use the corresponding bit in PMC_AFE_INTR_ENA to enable the LVD as an interrupt or MCB_AFE_LVD_MASK to enable the LVD occurrence as a reset source.

PMC_FIR field descriptions

Field	Description
0–27 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
28 STEST_FAULT	A write to this bit sends a FCCU fault (single cycle) for LVD SELF TEST. This is self Clearing bit. 0 No fault is sent 1 Single cycle fault injected.
29 Reserved	Reserved. This field is reserved.
30 HVD_FAULT	High Voltage Detect Fault injection. A write to this bit sends a FCCU fault (single cycle) for HVD. This is self clearing bit. 0 No fault is sent 1 Single cycle fault injected.
31 LVD_FAULT	Low Voltage Detect Fault injection. A write to this bit sends a FCCU fault (single cycle) for LVD. This is self clearing bit. 0 No fault is sent to FCCU 1 Single cycle (one clock cycle) fault is injected to FCCU.

64.3.7 PMC Control Register (PMC_PMCCR)

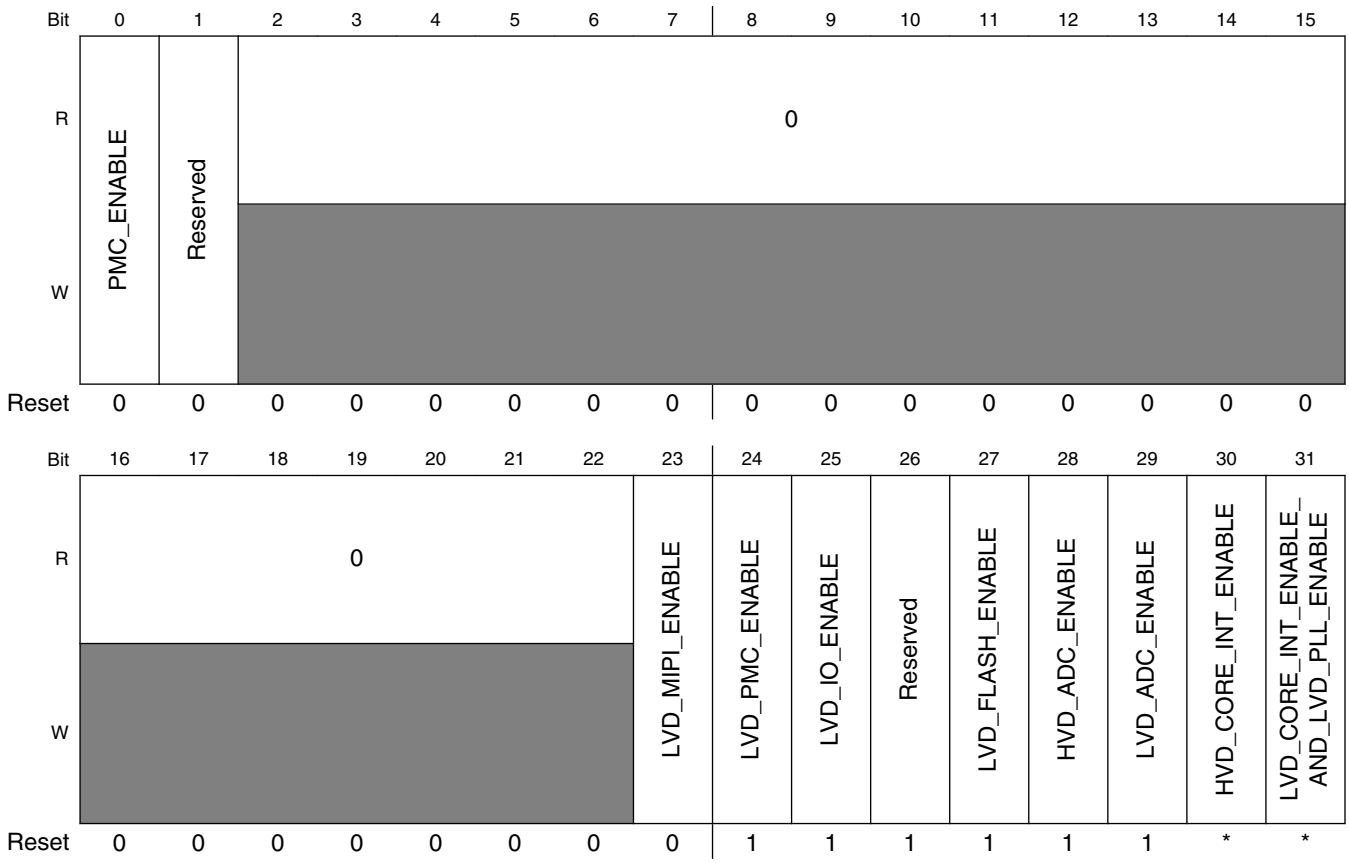
This register contains the various control bits of PMC block.

NOTE

Bits [31:23] of this register gets reset on POR. Bits [1:0] of this register gets reset on destructive reset. Core LVD/HVD are disabled out of reset in external regulation mode. So the value

of bits [31:30] is logic high (1’b1) in internal regulation mode and logic low (1’b0) in external regulation mode out of reset.

Address: 0h base + 94h offset = 94h



* Notes:
- LVD_CORE_INT_ENABLE_AND_LVD_PLL_ENABLE field: See the NOTE above.
- HVD_CORE_INT_ENABLE field: See the NOTE above.

PMC_PMCCR field descriptions

Field	Description
0 PMC_ENABLE	PMC Enable Control This bit determines whether any of the PMC bits can be written or not. 0 No control bit can be written in this(PMC enable control) register. To do a write on this register, first enable this bit and then start writing on other control bits. 1 This Control register can be written.
1 Reserved	Reserved This field is reserved.
2–22 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

PMC_PMCCR field descriptions (continued)

Field	Description
23 LVD_MIPI_ ENABLE	This bit controls the enable/disable on the LVD MIPI supply. 0 LVD_MIPI is disabled. 1 LVD_MIPI is enabled.
24 LVD_PMC_ ENABLE	This bit controls the enable/disable on the LVD PMC supply. 0 LVD_PMC is disabled 1 LVD_PMC is Enabled
25 LVD_IO_ ENABLE	This bit controls the enable/disable on the LVD IO supply. 0 LVD_IO is disabled 1 LVD_IO is Enabled
26 Reserved	This field is reserved.
27 LVD_FLASH_ ENABLE	This bit controls the enable/disable on the LVD FLASH supply. 0 LVD_FLASH is disabled 1 LVD_FLASH is Enabled
28 HVD_ADC_ ENABLE	This bit controls the enable/disable on the HVD ADC supply. 0 HVD_ADC is disabled 1 HVD_ADC is Enabled
29 LVD_ADC_ ENABLE	This bit controls the enable/disable on the LVD ADC supply. 0 LVD_ADC is disabled 1 LVD_ADC is Enabled
30 HVD_CORE_ INT_ENABLE	This bit controls the enable/disable on the HVD Core supply. This bit resets to 0 in external regulation mode and it resets to 1 in internal regulation mode. 0 HVD_CORE is disabled 1 HVD_CORE is Enabled
31 LVD_CORE_ INT_ENABLE_ AND_LVD_PLL_ ENABLE	LVD Core and LVD_PLL Enable Disable control This single bit does the control of LVD_CORE and LVD _PLL. This bit controls the enable/disable on the LVD Core supply and LVD_PLL as well. This bit resets to 0 in external regulation mode and it resets to 1 in internal regulation mode. **NOTE:** In other words, "LVD_CORE_INT_ENABLE" and "LVD_PLL_ENABLE" control are exactly the same. 0 This Single bit does the control of LVD_CORE and LVD _PLL LVD_CORE_INT_ENABLE is disabled. LVD_PLL_ENABLE is disabled. 1 LVD CORE_INT_ENABLE is Enabled. LVD_PLL_ENABLE is Enabled.

64.3.8 Interrupt Enable Register (PMC_TS_IER)

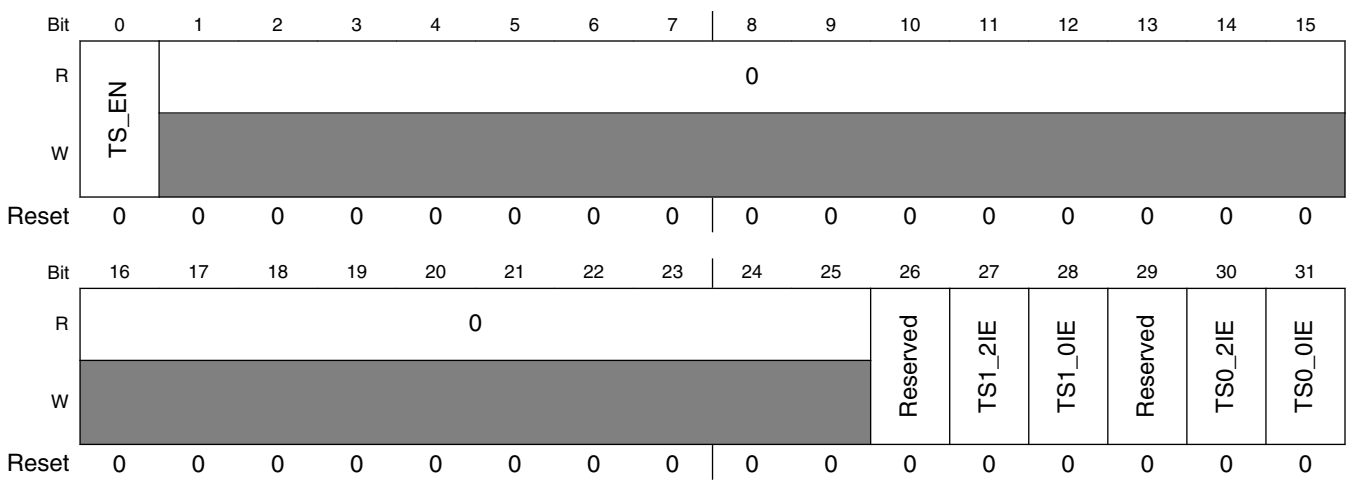
This configuration register contains a set of Interrupt Enable bits that correspond to each of the Temperature Sensor Event Status Registers, ESR_TD (Temperature Event Status register (PMC_ESR_TD)). These bits indicate whether an interrupt occurs when the voltage event is seen. A '0' indicates that no interrupt is to be sent, and a '1' indicates that an interrupt is to occur when the voltage detect event occurs. These bits are enabled via a write of one to the MSB of this register (IE_EN). After this, these bits can be read or written at any time.

NOTE

This register is reset on a short functional reset. For setting up the interrupt if some temperature event occurs:

1. Enable the MSB of this register, i.e., TS_EN.
2. Assert one of the bits, say TS1_2IE, for interrupt to be sent to CPU if over temp. condition is found for TSENS1. This would help to enable/disable the interrupt functionality of the corresponding temperature sensor flag.

Address: 0h base + 98h offset = 98h



PMC_TS_IER field descriptions

Field	Description
0 TS_EN	Temperature Sensor interrupts Enable 0 Temperature sensor interrupts are not enabled. 1 Enable temperature sensor interrupts.
1–25 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

PMC_TS_IER field descriptions (continued)

Field	Description
26 Reserved	This field is reserved. **NOTE:** This field must be programmed to 0. If it is programmed to 1, unintended behavior could result.
27 TS1_2IE	Temperature Sensor 1 input 2 Interrupt Enable. This bit determines whether an interrupt is seen by the system when the temperature rises above its high set threshold (flag1), i.e., 150 C. 0 No interrupt. 1 Interrupt occurs.
28 TS1_0IE	Temperature Sensor 1 input 0 Interrupt Enable. This bit determines whether an interrupt is seen by the system when the temperature falls below its low set threshold, i.e., -40 C. 0 No interrupt. 1 Interrupt occurs.
29 Reserved	This field is reserved. **NOTE:** This field must be programmed to 0. If it is programmed to 1, unintended behavior could result.
30 TS0_2IE	Temperature Sensor 0 input 2 Interrupt Enable. This bit determines whether an interrupt is seen by the system when the temperature rises above its high set threshold (flag1), i.e., 150 C. 0 No interrupt. 1 Interrupt occurs.
31 TS0_0IE	Temperature Sensor 0 input 0 Interrupt Enable. This bit determines whether an interrupt is seen by the system when the temperature falls below its low set threshold, i.e., -40 C. 0 No interrupt. 1 Interrupt occurs.

64.3.9 Temperature Event Status register (PMC_ESR_TD)

This Event Status Register indicates the past state of the two temperature sensor signals. If the temperature event has ever passed the trigger event since the last clearing event, the flag bit is set. In order to clear the flag, a one must be written to the flag bit that needs to be cleared. This register resets on POR.

Address: 0h base + 9Ch offset = 9Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

PMC_ESR_TD field descriptions

Field	Description
0–25 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
26 Reserved	This field is reserved. **NOTE:** This field must be programmed to 0. If it is programmed to 1, unintended behavior could result.
27 TEMP1_2	Temperature sensor 1 status flag 2. This bit is the temperature status flag associated with the temperature for the temperature sensor 1 point (150C). It is asserted when the temperature exceeds its corresponding threshold. It is cleared when one is written to this bit location.

Table continues on the next page...

PMC_ESR_TD field descriptions (continued)

Field	Description
	NOTE: This bit gets cleared even temperature might not have fallen back. This bit is the indication that temperature has crossed its threshold in the past. If the IER[TS1_2IE] bit is also asserted, an interrupt is sent to the CPU. If REE_TD[TEMP1_2} is also asserted, a system reset is generated, which clears IER[TS1_2IE] and negate the interrupt request. If REE_TD[TEMP1_2] is asserted and a destructive reset is selected (via RES_TD[TEMP_2] being 0), then a destructive reset is generated. If RES_TD[TEMP1_2] is set, then a functional reset is generated. 0 Currently no occurrence. 1 Temperature occurrence detected.
28 TEMP1_0	Temperature sensor 1 status flag 0. This bit is the temperature status flag associated with the temperature for the cold temperature sensor 1 point. It is asserted when the temperature exceeds its corresponding threshold. It is cleared when one is written to this bit location. **NOTE:** This bit gets cleared even temperature might not have fallen back. This bit is the indication that temperature has crossed its threshold in the past. If the IER[TS1_0IE] bit is also asserted, an interrupt is sent to the CPU. If REE_TD[TEMP1_0] is also asserted, a system reset is generated, which clears IER[TS1_0IE] and negate the interrupt request. If REE_TD[TEMP1_0] is asserted and a destructive reset is selected (via RES_TD[TEMP_0] being 0), then a destructive reset is generated. If RES_TD[TEMP1_0] is set, then a functional reset is generated. 0 Currently no occurrence. 1 Temperature occurrence detected.
29 Reserved	This field is reserved. **NOTE:** This field must be programmed to 0. If it is programmed to 1, unintended behavior could result.
30 TEMP0_2	Temperature sensor 0 status flag 2. This bit is the temperature status flag associated with the temperature for the temperature sensor point (150C).It is asserted when the temperature exceeds its corresponding threshold. It is cleared when one is written to this bit location. **NOTE:** This bit gets cleared even temperature might not have fallen back. This bit is the indication that temperature has crossed its threshold in the past. If the IER[TS0_2IE] bit is also asserted, an interrupt is sent to the CPU. If REE_TD[TEMP0_2 is also asserted, a system reset is generated, which clears IER[TS0_2IE] and negate the interrupt request. If REE_TD[TEMP0_2] is asserted and a destructive reset is selected (via RES_TD[TEMP0_2] being 0), then a destructive reset is generated. If RES_TD[TEMP_2] is set, then a functional reset is generated. 0 Currently no occurrence. 1 Temperature occurrence detected.
31 TEMP0_0	Temperature sensor 0 status flag 0. This bit is the temperature status flag associated with the temperature for the cold temperature sensor point. It is asserted when the temperature exceeds its corresponding threshold. It is cleared when one is written to this bit location. **NOTE:** This bit gets cleared even temperature might not have fallen back. This bit is the indication that temperature has crossed its threshold in the past. If REE_TD[TEMP0_0] is also asserted, a system reset is generated, which clears IER[TS0_0IE] and negate the interrupt request. If REE_TD[TEMP0_0] is asserted and a destructive reset is selected (via RES_TD[TEMP0_0] being 0), then a destructive reset is generated. If RES_TD[TEMP0_0] is set, then a functional reset is generated.

Table continues on the next page...

PMC_ESR_TD field descriptions (continued)

Field	Description
	0 Currently no occurrence. 1 Temperature occurrence detected.

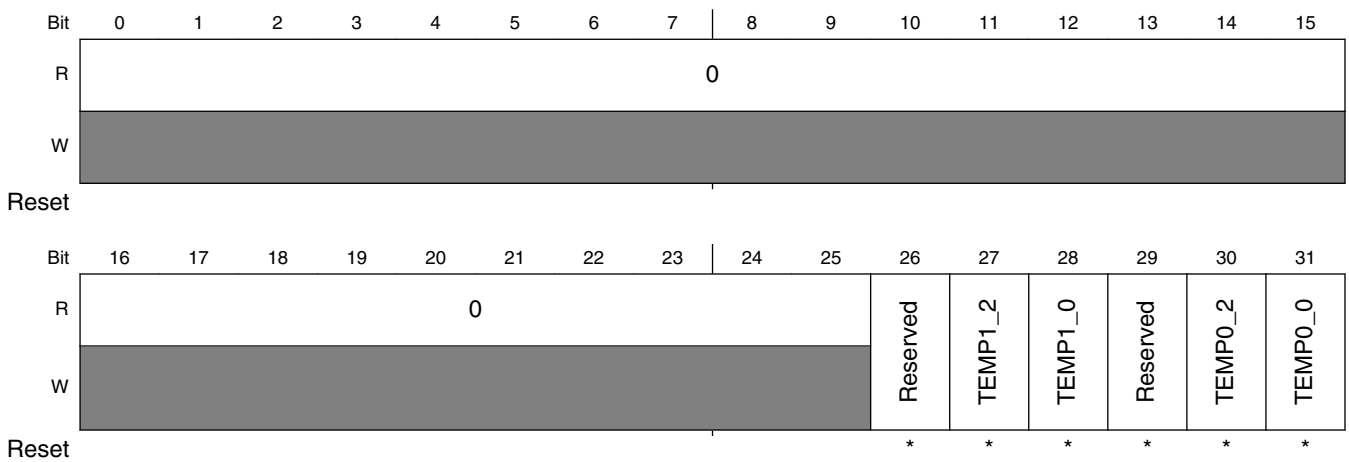
64.3.10 Temperature Reset Event Enable register (PMC_REE_TD)

This Reset Event Enable Register controls whether the temperature detect signal event causes a reset. If the desired flag bit is enabled, the temperature detect event causes a reset to be generated when the selected temperature passes the trigger event.

NOTE

Bits in this register are reset on POR.

Address: 0h base + A0h offset = A0h



* Notes:
- TEMP0_0 field: Reset value is configurable by DCF bits.
- TEMP0_2 field: Reset value is configurable by DCF bits.
- Reserved field: Reset value is configurable by DCF bits.
- TEMP1_0 field: Reset value is configurable by DCF bits.
- TEMP1_2 field: Reset value is configurable by DCF bits.
- Reserved field: Reset value is configurable by DCF bits.

PMC_REE_TD field descriptions

Field	Description
0–25 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
26 Reserved	This field is reserved. **NOTE:** This field must be programmed to 0. If it is programmed to 1, unintended behavior could result.

Table continues on the next page...

PMC_REE_TD field descriptions (continued)

Field	Description
27 TEMP1_2	Temperature sensor 1 detect assertion reset enable 2. This bit defines whether high temperature detect assertion (above 150 C) for TSENS1 will generate a system reset. The RES_TD[TEMP1_2] bit determines whether the reset is functional or destructive.
28 TEMP1_0	Temperature sensor 1 detect assertion reset enable 0. This bit defines whether a temperature detect assertion generates a system reset. The RES_TD[TEMP1_0] bit determines whether high temperature detect assertion (below -40 C) for TSENS1 will generate a system reset.
29 Reserved	This field is reserved. **NOTE:** This field must be programmed to 0. If it is programmed to 1, unintended behavior could result.
30 TEMP0_2	Temperature sensor 0 detect assertion reset enable 2. This bit defines whether a temperature detect assertion generates a system reset. The RES_TD[TEMP0_2] bit determines whether high temperature detect assertion (above 150 C) for TSENS0 will generate a system reset.
31 TEMP0_0	Temperature sensor 0 detect assertion reset enable 0. This bit defines whether a temperature detect assertion generates a system reset. The RES_TD[TEMP0_0] bit determines whether high temperature detect assertion (below -40 C) for TSENS0 will generate a system reset.

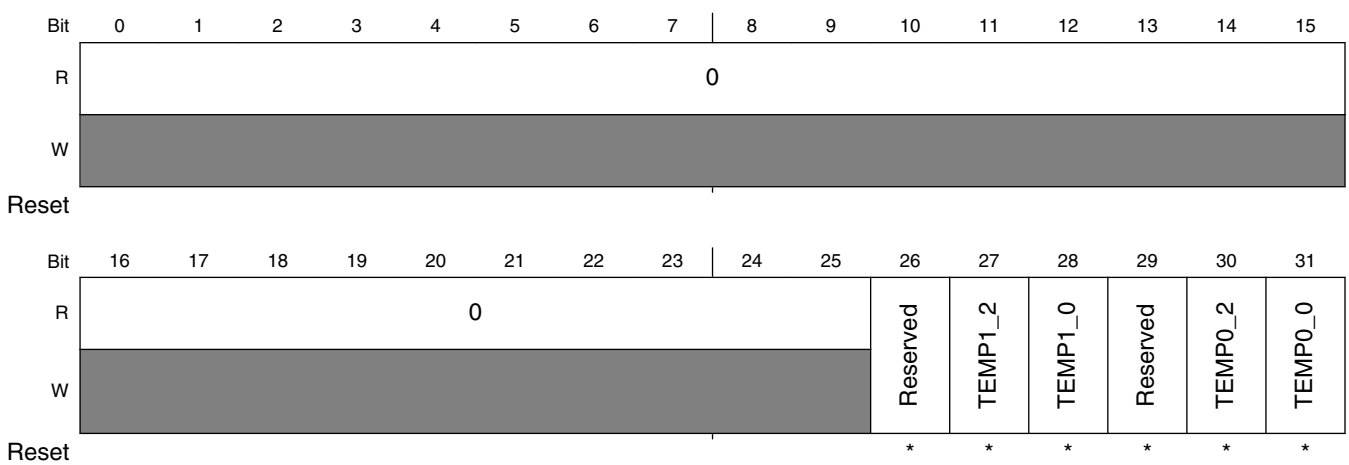
64.3.11 Temperature Reset Event Selection register (PMC_RES_TD)

This Reset Event Select Register controls whether the temperature sensor detect signal event causes a destructive or functional reset. If the desired flag bit is set, then the corresponding temperature sensor event will cause a functional reset to be generated when the selected temperature passes the trigger event else it will cause a destructive reset.

NOTE

Bits in this register are reset on POR.

Address: 0h base + A4h offset = A4h



* Notes:
- TEMP0_0 field: Reset value is configurable by DCF bits.
- TEMP0_2 field: Reset value is configurable by DCF bits.
- Reserved field: Reset value is configurable by DCF bits.
- TEMP1_0 field: Reset value is configurable by DCF bits.
- TEMP1_2 field: Reset value is configurable by DCF bits.
- Reserved field: Reset value is configurable by DCF bits.

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 Reserved	This field is reserved. **NOTE:** This field must be programmed to 0. If it is programmed to 1, unintended behavior could result.
27 TEMP1_2	TEMP1_2 Reset Event Select This bit defines whether high temperature detect assertion (above 150 C) for TSENS1 will generate a system reset. The bit determines whether the reset event is enabled.
28 TEMP1_0	TEMP1_0 Reset Event Select This bit defines whether high temperature detect assertion (below -40 C) for TSENS1 will generate a system reset. The bit determines whether the reset event is enabled.
29 Reserved	This field is reserved. **NOTE:** This field must be programmed to 0. If it is programmed to 1, unintended behavior could result.
30 TEMP0_2	TEMP0_2 Reset Event Select This bit defines whether high temperature detect assertion (above 150 C) for TSENS0 will generate a system reset. The bit determines whether the reset event is enabled.
31 TEMP0_0	TEMP0_0 Reset Event Select This bit defineswhether high temperature detect assertion (below -40 C) for TSENS0 will generate a system reset. The bit determines whether the reset event is enabled.

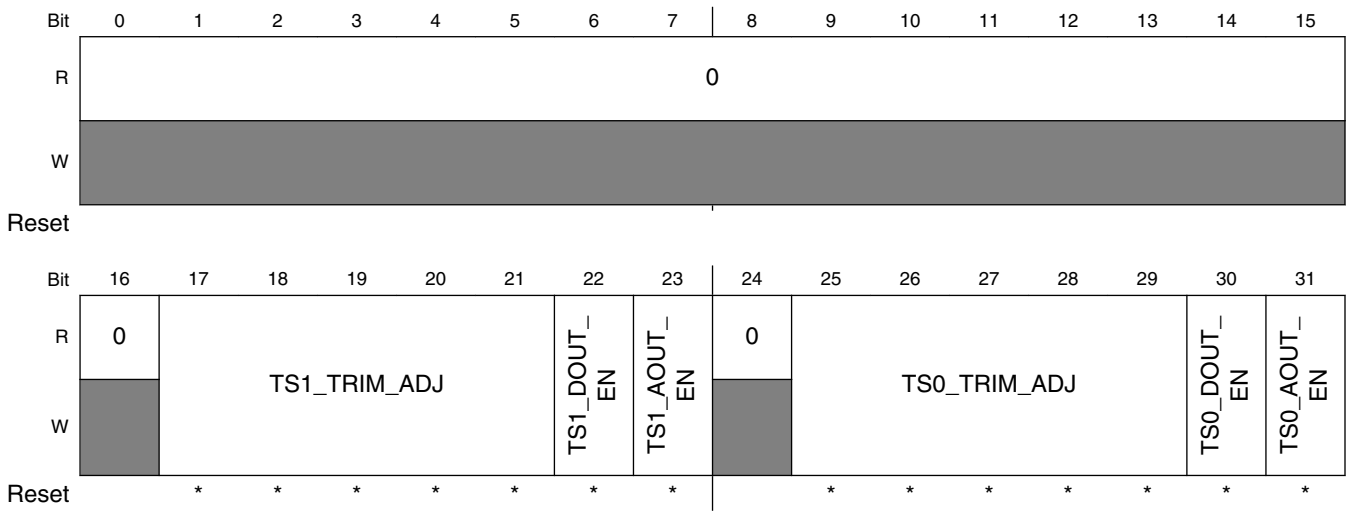
64.3.12 Temperature detector configuration register (PMC_CTL_TD)

This register is reset on functional reset. To disable a temperature sensor, program both TSn_DOUT_EN and TSn_AOUT_EN for that temperature sensor to 0. To enable a temperature sensor, write 1 to both of these fields. Please refer to "Software-controlled Temperature Sensor Trim Adjustment" sub-section in the "Chip-specific Power Management Controller (PMC) information"section.

NOTE

Bits in this register are reset on long functional reset.

Address: 0h base + A8h offset = A8h



* Notes:
- TS0_AOUT_EN field: Reset value is configurable by DCF bits.
- TS0_DOUT_EN field: Reset value is configurable by DCF bits.
- TS0_TRIM_ADJ field: Reset value is configurable by DCF bits.
- TS1_AOUT_EN field: Reset value is configurable by DCF bits.
- TS1_DOUT_EN field: Reset value is configurable by DCF bits.
- TS1_TRIM_ADJ field: Reset value is configurable by DCF bits.

PMC_CTL_TD field descriptions

Field	Description
0–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–21 TS1_TRIM_ADJ	Temperature Sensor 1 Trim Adjust value. Customer adjustable trim register. These bits are a signed binary number that is added to the Temp Sensor Trim Value.
22 TS1_DOUT_EN	Temperature Sensor 1 Digital Output Enable.
23 TS1_AOUT_EN	Temperature Sensor 1 Analog Output Enable. Analog Output Enable.
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–29 TS0_TRIM_ADJ	Temperature Sensor 0 Trim Adjust value. Customer adjustable trim register. These bits are a signed binary number that is added to the Temp Sensor Trim Value.
30 TS0_DOUT_EN	Temperature Sensor 1 Digital Output Enable.
31 TS0_AOUT_EN	Temperature Sensor 1 Analog Output Enable.

64.3.13 Fault Injection Register (PMC_TS_FIR)

This FCCU Fault Injection register enables the user s/w to artificially generate FCCU faults corresponding to TEMP SENS. A write '1' to these bits generates a single cycle pulsed fault to the FCCU block, this bit automatically gets cleared in the next cycle.

NOTE

This register is reset on short functional reset.

Address: 0h base + B4h offset = B4h

31 TSNS_FAULT	Temperature Sensor Fault injection. A write to this bit sends a FCCU fault (single cycle) for TEMP SENSOR.

Table continues on the next page...

PMC_TS_FIR field descriptions (continued)

Field	Description
	0 No fault is sent. 1 Single cycle fault injected.

64.4 Functional description

64.4.1 Analog PMC interface

The digital block uses the analog PMC interface to configure trim values for the regulators and LVDs that are in the analog block.

64.4.2 Temperature sensor interface logic

The digital PMC block provides control and configuration information to the two temperature sensors. This information includes digital and analog enables, and trim values. A user adjustable trim control is also provided to fine tune the trimming (for more details, please refer to Temperature Sensor chapter.

64.4.3 POR MC_RGM phase gates

The interface with the RGM block is used during the power on sequence and startup. It provides various phase gates, thereby enabling the MC_RGM to properly complete the reset sequence.

The temperature sensor provides another reset source, based on the under/over temperature faults and the corresponding REE and RES enables.

64.4.4 Flash interface DCF

During power up, trim values for the regulators, LVDs, and HVDs are read from Flash memory by the SSCM, and are then provided to the digital PMC via the DCF interface.

The reset event enable (REE) configurations that are stored in Flash memory are also provided to the PMC via the DCF interface. These REEs configurations are used, by default, to generate various resets to the RGM. Please refer to "Device Configuration Format (DCF) Records" chapter for more details.

64.4.5 FCCU interface

The digital block generates various fault indications to the FCCU block:

- Separate corresponding, active-high, fault indications are generated whenever an LVD or HVD defect is detected in the analog block.
- A fault indication is generated when a self test task results in a failure.
- A fault condition is generated whenever over-temperature or under-temperature events occur in the temperature sensor.

The figures below show the exact logic for the generation fault indications to FCCU block.

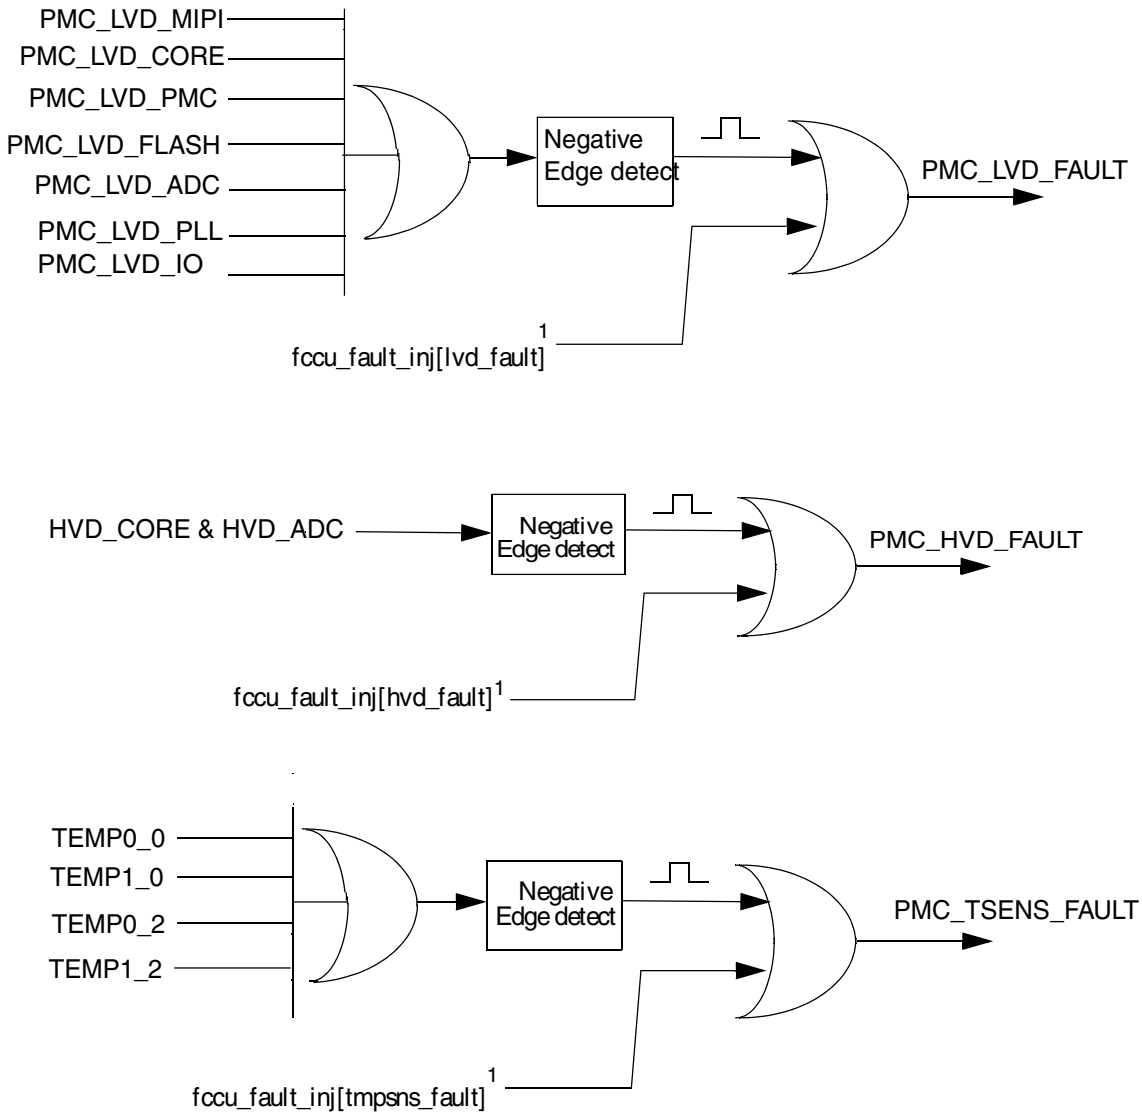

Figure 64-4. Fault generation to FCCU

:

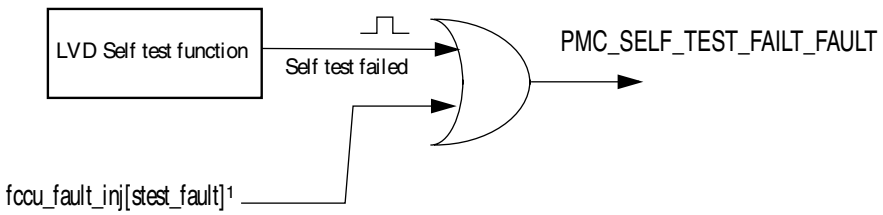

Figure 64-5. FCCU_fault_gen_LVD_Self_Test

[1] See “FCCU Fault Injection Register 0(FIR) for details.

64.4.6 SMPS interface

The digital block has an SMPS Interface:

- The PMC provides an SMPS regulator controlled to be used in conjunction with external components to provide the core supply voltage. The regulator is an asynchronous buck regulator with nominal switching frequency of 1MHz. This frequency can be modulated to improve the EMI generated by the regulator. The start-up behavior of the switching regulator is controlled by the Soft-Start module, that guarantees a controlled increase of the core supply voltage.

64.4.7 LVD and HVD self test mechanism

The PMC implements an LVD/HVD self test mechanism for use in satisfying reliability and robustness goals. The digital block assists and controls the analog block during it's performance of the self test.

Currently, three self test modes (described in the following sections) are supported by the analog block (based on the mode specified by the VD_UTST[ST_MODE] register bit).

The self test status and result are provided in the VD_UTST[ST_DONE, ST_RESULT] register fields, respectively.

64.4.7.1 Default mode

The self test is always performed during start up (i.e power on) or after a destructive reset event. The self test starts during the phase 3 RGM state, when the SSCM has completed reads from the Flash memory.

Meanwhile, the LVD/HVD indication from the analog block is latched in the VD_UTST register. At the end of the self test (i.e. when all of the LVDs/HVDs have been tested), the VD_UTST[ST_DONE] status bit is set to '1' and all of the bits in the VD_UTST register are checked for ‘1’. One or more bits not set to '1' generates a fault indication to the FCCU block, and the VD_UTST[ST_RESULT] register bit is set to ‘0’. In the case where all of the register bits are set to '1', the test is considered to be PASSED, the VD_UTST[ST_RESULT] register bit is set to ‘1’, and no fault indications are provided to the FCCU.

This startup self test function also provides gating of the reset phase3 exit in RGM. This means the RGM will not be able to exit from phase3 until the self test is successfully completed.

64.4.7.2 Software triggered self test

This mode is entered by software by writing '01' to the VD_UTST[ST_MODE] register 2-bit field. The complete self test, as is performed in default mode, is repeated. The difference is that the self test in this mode is initiated by the host while the self test in default mode is started automatically during power on.

NOTE

The LVD self test Time Window Register (STTW) has to be configured appropriately (based on the clock frequency used), before initiating software triggered self test. For example, the configuration (in decimal) for a 66 MHz PMC clock and a 21 us window could be calculated using the following formula:

Freq in MHz x window in us = Decimal value (used to program the counter value in the register).

64.4.7.3 Single voltage detection test

This mode is entered by software writing '10' to the VD_ST_CTRL[ST_MODE] register 2-bit field. The test completes after the prescribed time gap has elapsed. The PASS/FAIL result is then updated based on the corresponding LVD output tripping, or not.

NOTE

The LVD Self Test Time Window Register (STTW) must to be configured appropriately as in Software triggered self test mode.

NOTE

During the running of the LVD self test, the LVD or HVD output, which corresponds to the LVD or HVD monitor on which self test is running, is masked. Therefore, they will have no effect on POR generation, or in any reset and/or fault generation, when self test is running on that particular monitor. Also, it is possible to mask all the LVDs and HVDs during self test (configurable through DCF sheet). Please refer to device-specific RM on this.

Chapter 65
Power Control Unit (MC_PCU)

65.1 Introduction

65.1.1 Overview

The power control unit (MC_PCU) acts as a bridge for mapping the PMC peripheral to the MC_PCU address space.

The following figure depicts the MC_PCU block diagram.

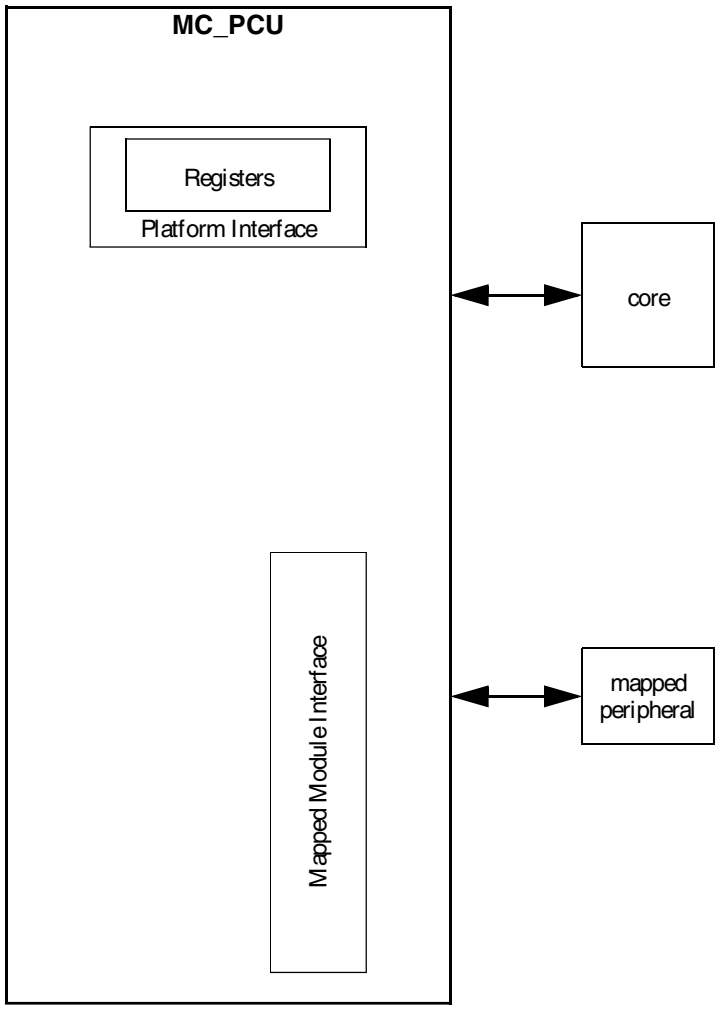

Figure 65-1. MC_PCU block diagram

65.1.2 Features

The MC_PCU maps the PMC registers to the MC_PCU address space.

65.2 External signal description

The MC_PCU has no connections to any external pins.

65.3 Memory Map and Registers

Any access to unused registers as well as write accesses to read-only registers:

- Does not change register content
- Cause a transfer error

All registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian.

MC_PCU memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

31 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.

Chapter 66
Mode Entry Module (MC_ME)

66.1 Introduction

66.1.1 Overview

The MC_ME controls the chip mode and mode transition sequences in all functional states. It also contains configuration, control and status registers accessible for the application.

The following figure shows the MC_ME block diagram.

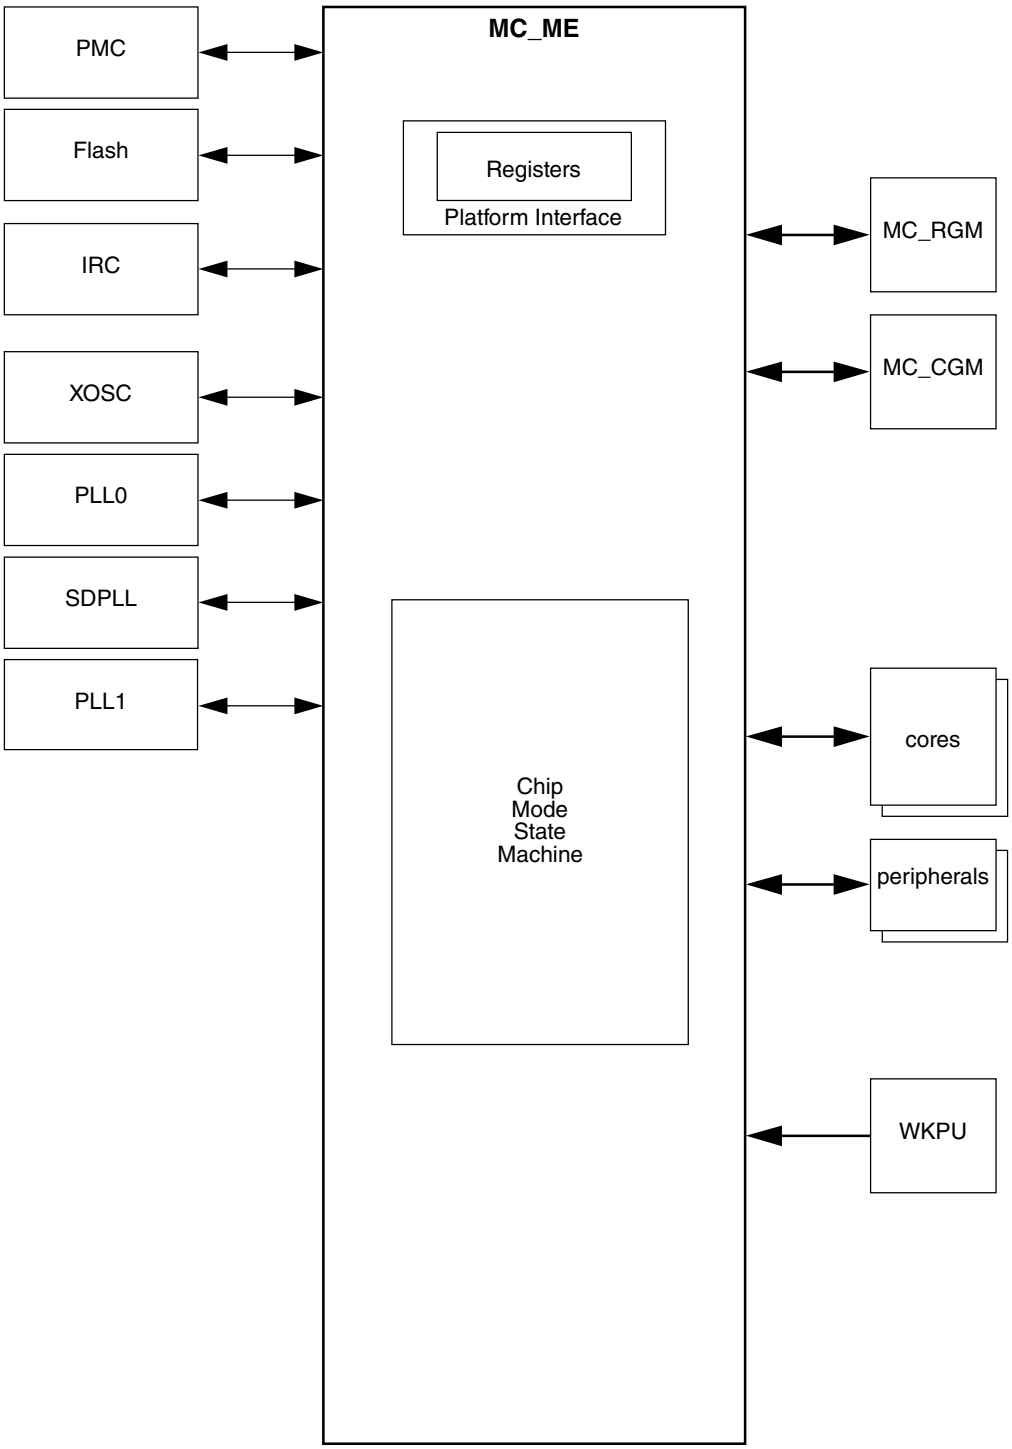

Figure 66-1. MC_ME Block Diagram

66.1.2 Features

The MC_ME includes the following features:

- control of the available modes by the ME_ME register
- definition of various chip mode configurations by the ME_<mode>_MC registers
- control of the actual chip mode by the ME_MCTL register for:
  - switching between software-running modes
  - switching from software-running modes to low-power modes
  - switching to a mode to run diagnostics after a failure has been detected
  - triggering a device ‘functional’ reset which does not cause a start-up self test to run
  - triggering a device ‘destructive’ reset which may cause a start-up self test to run
- capture of the current mode and various resource status within the contents of the ME_GS register
- optional generation of various mode transition interrupts
- status bits for each cause of invalid mode transitions
- peripheral clock gating control based on the ME_RUN_PC0…7, ME_LP_PC0…7, and ME_PCTLn registers
- additional core clock gating and boot address control based on the ME_CCTLn and ME_CADDRn registers
- capture of current peripheral and additional core clock gated/enabled status
- progressive system clock switching when transitioning from a lower power consumption mode to a higher power consumption mode, and vice versa

66.1.3 Modes of Operation

The MC_ME is based on several chip modes corresponding to different usage models of the chip. Each mode is configurable and can define a policy for energy and processing power management to fit particular system requirements. An application can easily switch from one mode to another depending on the current needs of the system. The operating modes controlled by the MC_ME are divided into system and user modes. The system modes are modes such as RESET, DRUN, SAFE, and TEST. These modes aim to ease the configuration and monitoring of the system. The user modes are modes such as RUN0…3, HALT0, and STOP0 which can be configured to meet the application requirements in terms of energy management and available processing power. The modes DRUN, SAFE, TEST, and RUN0…3 are the chip software running modes.

The following table describes the MC_ME modes.

Table 66-1. MC_ME Mode Descriptions

Name	Description	Entry	Exit
RESET	This is a chip-wide virtual mode during which the application is not active. The system remains in this mode until all resources are available for the embedded software to take control of the chip. It manages hardware initialization of chip configuration, voltage regulators, clock sources, and flash modules.	system reset assertion from MC_RGM	system reset deassertion from MC_RGM
DRUN	This is the entry mode for the embedded software. It provides full accessibility to the system and enables the configuration of the system at startup. It provides the unique gate to enter user modes. BAM when present is executed in DRUN mode.	system reset deassertion from MC_RGM, software request from SAFE, TEST and RUN0…3	system reset assertion, RUN0…3, TEST via software, SAFE via software or hardware failure.
SAFE	This is a chip-wide service mode which may be entered on the detection of a recoverable error. It forces the system into a pre-defined safe configuration from which the system may try to recover.	hardware failure, software request from DRUN, TEST, and RUN0…3	system reset assertion, DRUN via software
TEST	This is a chip-wide service mode which is intended to provide a control environment for chip software testing.	software request from DRUN	system reset assertion, SAFE via software or hardware failure, DRUN via software
RUN0…3	These are software running modes where most processing activity is done. These various run modes allow to enable different clock & power configurations of the system with respect to each other.	software request from DRUN or other RUN0…3, interrupt event from HALT0, interrupt or wakeup event from STOP0	system reset assertion, SAFE via software or hardware failure, other RUN0…3 modes, HALT0, STOP0 via software
HALT0	This is a reduced-activity low-power mode during which the clock to the core is disabled[1]. It can be configured to switch off analog peripherals like clock sources, flash, main regulator, etc. for efficient power management at the cost of higher wakeup latency.	software request from RUN0…3	system reset assertion, SAFE on hardware failure, RUN0…3 on interrupt event
STOP0	This is an advanced low-power mode during which the clock to the core is disabled[1]. It may be configured to switch off most of the peripherals including clock sources for efficient power management at the cost of higher wakeup latency.	software request from RUN0…3	system reset assertion, SAFE on hardware failure, RUN0…3 on interrupt event or wakeup event

1. Along with the Cores, clocks to the below peripherals are also disabled in HALT0 and STOP0 modes.
   - Core_0/1/2 related TCM and DMEM logic
   - SWT_0/1/2
   - STM_0/1/2
   - SMPU_0/1
   - EIM
   - PCM
   - AXBS_0/1
   - XBIC_0/1
   - AIPS_0/1
   - CMU_11
   - SEMA42
   - CSE
   - TDM
   - PFLASH/c55fmc
   - PRAMC
   - DMA and related interface to AXBS

- SPT-AHB/SIPI-AHB/FEC-AHB/Flexray-AHB interface
- NAL/NPC/NXMC_0/1/2

66.2 External Signal Description

The MC_ME has no connections to any external pins.

66.3 Memory Map and Registers

The MC_ME contains registers for:

- mode selection and status reporting
- mode configuration
- mode transition interrupts status and mask control
- scalable number of peripheral sub-mode selection and status reporting
- scalable number of additional core enabling and disabling control and status reporting

Any access to unused registers as well as write accesses to read-only registers will:

- not change register content
- cause a transfer error

Unless otherwise noted, all registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the ME_RUN_PC0 register may be accessed as a word at address 0x080, as a half-word at address 0x082, or as a byte at address 0x083.

Some fields may be read-only, and their reset value of '1' or '0' and the corresponding behavior cannot be changed.

NOTE

All registers are read only in user mode

4 S_MTRANS	Mode transition status 0 Mode transition process is not active 1 Mode transition is ongoing
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 S_PDO	Output power-down status - This bit specifies output power-down status of I/Os. This bit is asserted whenever outputs of pads are forced to high impedance state or the pads power sequence driver is switched off.

Table continues on the next page...

MC_ME_GS field descriptions (continued)

Field	Description
	0 No automatic safe gating of I/Os used and pads power sequence driver is enabled 1 In SAFE/TEST modes, outputs of pads are forced to high impedance state and the pads power sequence driver is disabled. The inputs are level unchanged. In STOP0 mode, only the pad power sequence driver is disabled, but the state of the output remains functional.
9–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 S_MVR	Main voltage regulator status 0 Main voltage regulator is not ready 1 Main voltage regulator is ready for use
12–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–15 S_FLA	Flash availability status 00 Reserved 01 Reserved 10 Reserved 11 Flash is in normal mode and available for use
16–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 S_SDPLL	SDPLL status 0 SDPLL is not stable 1 SDPLL is providing a stable clock
24 S_PLL1	PLL1 status 0 PLL1 is not stable 1 PLL1 is providing a stable clock
25 S_PLL0	PLL0 status 0 PLL0 is not stable 1 PLL0 is providing a stable clock
26 S_XOSC	XOSC status **NOTE:** S_XOSC alone should not be relied on. To get the current status of XOSC also check CMU0_ISR[OLRI] flag. XOSC is stable when MC_ME_GS[S_XOSC] is 1 and OLRI flag = 0 0 XOSC is not stable 1 XOSC is providing a stable clock
27 S_IRC	IRC status 0 IRC is not stable 1 IRC is providing a stable clock
28–31 S_SYSCLK	System clock switch status - These bits specify the system clock currently used by the system. 0000 IRC_CLK 0001 XOSC_CLK 0010 PLL0_PHI_CLK 0011 reserved

Table continues on the next page...

MC_ME_GS field descriptions (continued)

Field	Description
	0100 PLL1_PHI_CLK 0101 reserved 0110 reserved 0111 reserved 1000 reserved 1001 reserved 1010 reserved 1011 reserved 1100 reserved 1101 reserved 1110 reserved 1111 system clock is disabled

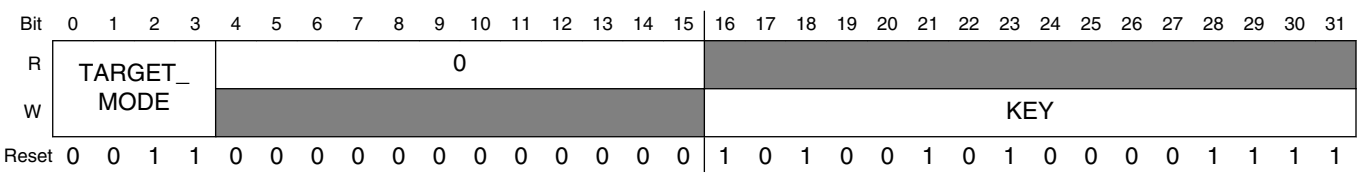
66.3.2 Mode Control Register (MC_ME_MCTL)

This register is used to trigger software-controlled mode changes. Depending on the modes as enabled by ME_ME register bits, configurations corresponding to unavailable modes are reserved and access to ME_<mode>_MC registers must respect this for successful mode requests.

NOTE

Byte and half-word write accesses are not allowed for this register as a predefined key is required to change its value.

Address: 0h base + 4h offset = 4h



MC_ME_MCTL field descriptions

Field	Description
0–3 TARGET_MODE	Target chip mode - These bits provide the target chip mode to be entered by software programming. The mechanism to enter into any mode by software requires the write operation twice: first time with key, and second time with inverted key. These bits are automatically updated by hardware while entering SAFE on hardware request. Also, while exiting from the HALT0 and STOP0 modes on hardware exit events, these are updated with the appropriate RUN0…3 mode value. 0000 RESET (triggers a 'functional' reset event) 0001 TEST 0010 SAFE 0011 DRUN 0100 RUN0

Table continues on the next page...

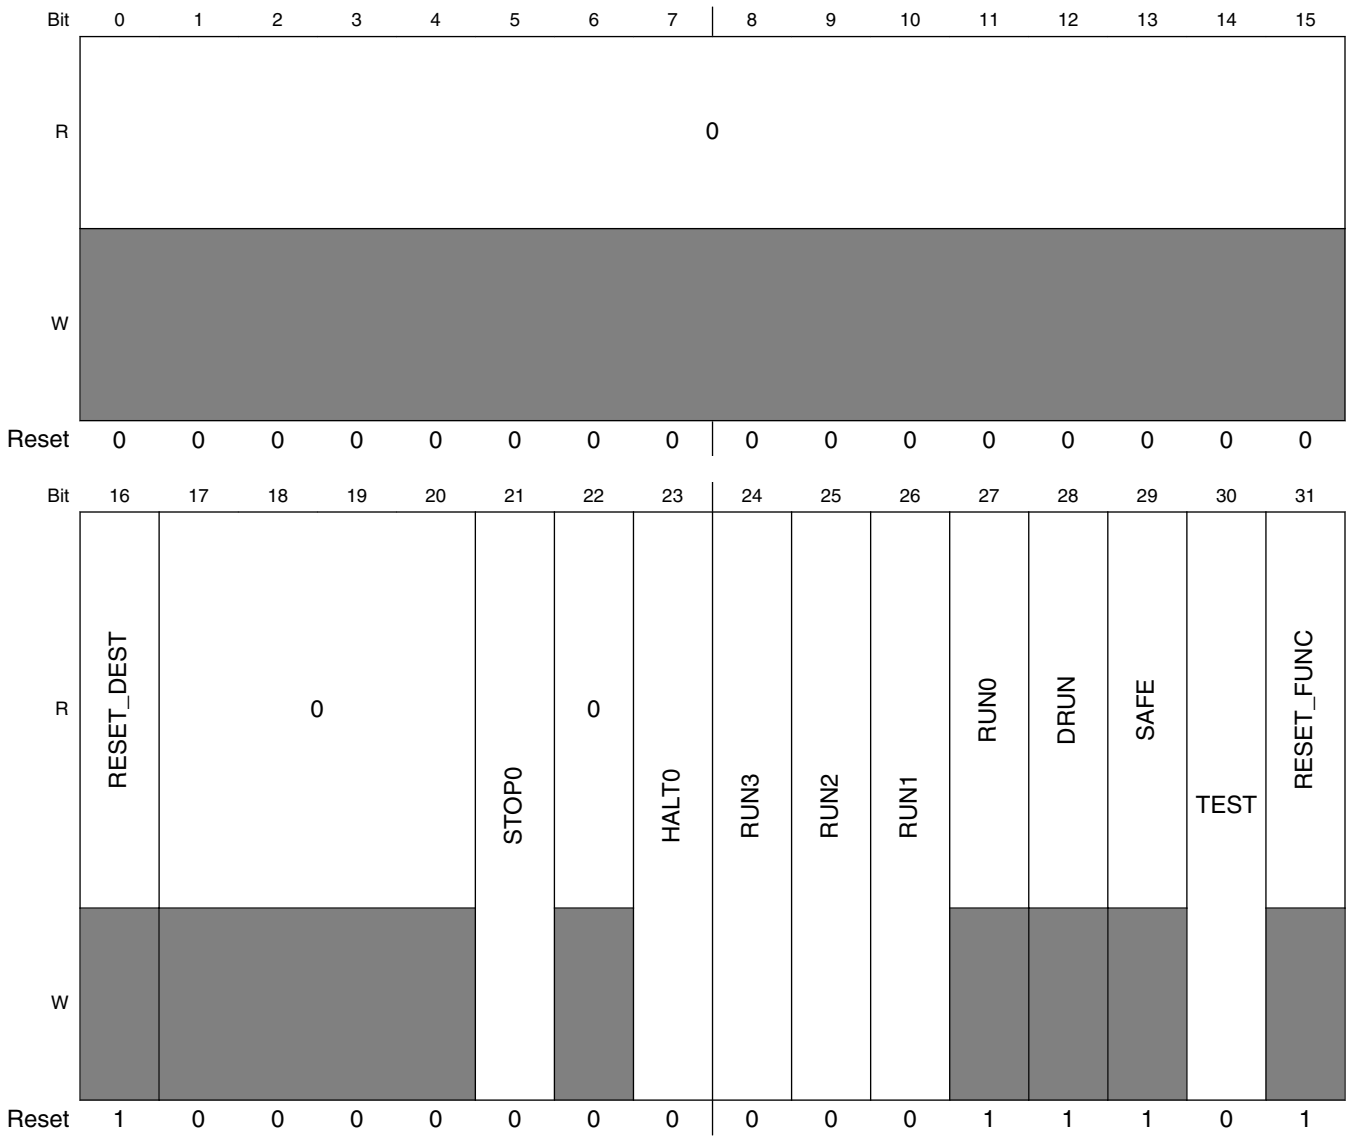
MC_ME_MCTL field descriptions (continued)

Field	Description
	0101 RUN1 0110 RUN2 0111 RUN3 1000 HALT0 1001 reserved 1010 STOP0 1011 reserved 1100 reserved 1101 reserved 1110 reserved 1111 RESET (triggers a 'destructive' reset event)
4–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 KEY	Control key - These bits enable write access to this register. Any write access to the register with a value different from the keys is ignored. Read access will always return inverted key. KEY: 0101101011110000 (0x5AF0) INVERTED KEY: 1010010100001111 (0xA50F)

66.3.3 Mode Enable Register (MC_ME_ME)

This register allows a way to disable the chip modes which are not required for a given chip. RESET_FUNC, SAFE, DRUN, RUN0, and RESET_DEST modes are always enabled.

Address: 0h base + 8h offset = 8h



MC_ME_ME field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

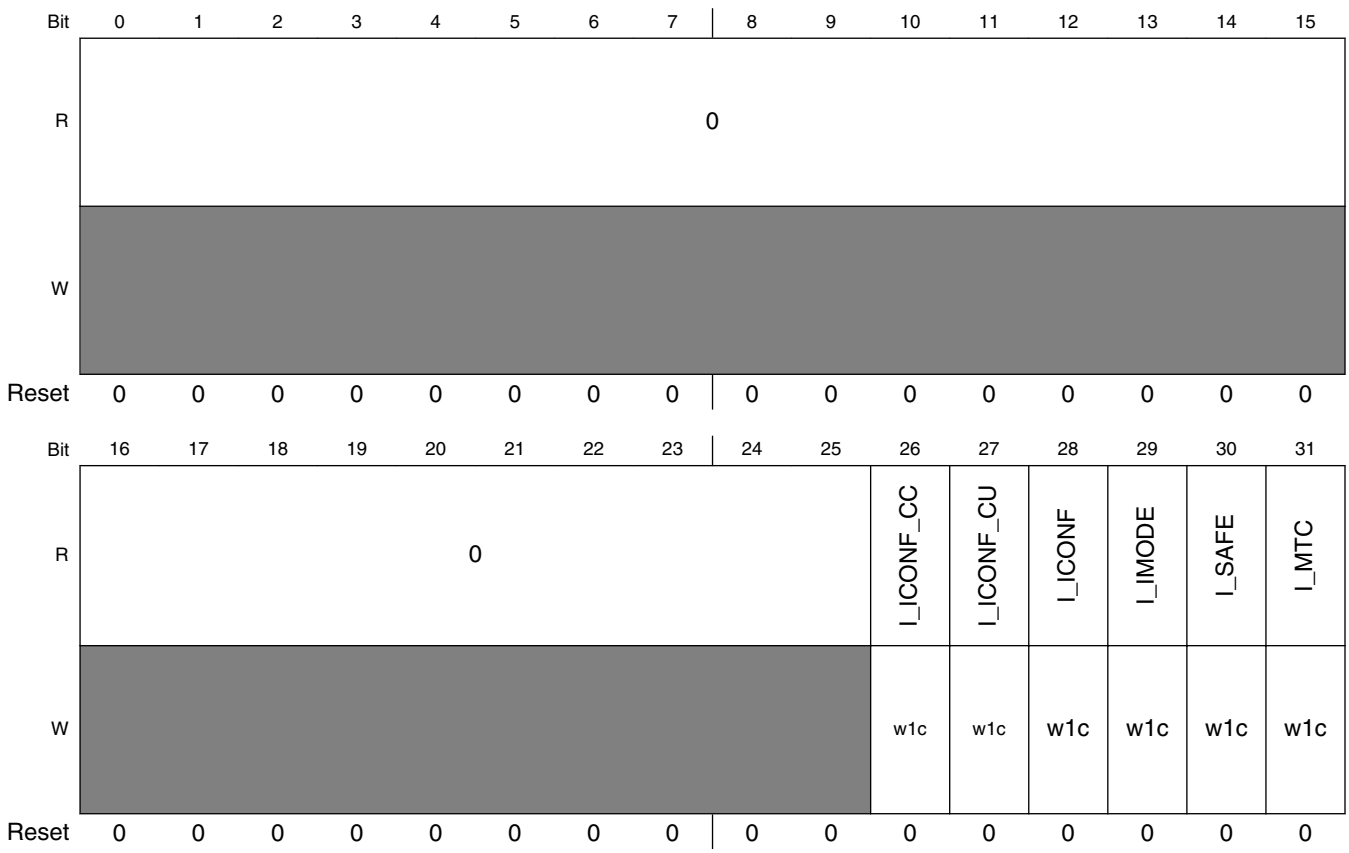
MC_ME_ME field descriptions (continued)

Field	Description
16 RESET_DEST	'destructive' RESET mode enable 1 'destructive' RESET mode is enabled
17–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 STOP0	STOP0 mode enable 0 STOP0 mode is disabled 1 STOP0 mode is enabled
22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 HALT0	HALT0 mode enable 0 HALT0 mode is disabled 1 HALT0 mode is enabled
24 RUN3	RUN3 mode enable 0 RUN3 mode is disabled 1 RUN3 mode is enabled
25 RUN2	RUN2 mode enable 0 RUN2 mode is disabled 1 RUN2 mode is enabled
26 RUN1	RUN1 mode enable 0 RUN1 mode is disabled 1 RUN1 mode is enabled
27 RUN0	RUN0 mode enable 1 RUN0 mode is enabled
28 DRUN	DRUN mode enable 1 DRUN mode is enabled
29 SAFE	SAFE mode enable 1 SAFE mode is enabled
30 TEST	TEST mode enable 0 TEST mode is disabled 1 TEST mode is enabled
31 RESET_FUNC	'functional' RESET mode enable 1 'functional' RESET mode is enabled

66.3.4 Interrupt Status Register (MC_ME_IS)

This register provides the current interrupt status.

Address: 0h base + Ch offset = Ch



MC_ME_IS field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 I_ICONF_CC	Invalid mode configuration interrupt (core configuration) - This bit is set if a write access to one of the ME_CADDRn registers is attempted while a mode transition is in progress. 0 No write to an ME_CADDRn register was attempted during an ongoing mode transition 1 A write to an ME_CADDRn register was attempted during an ongoing mode transition
27 I_ICONF_CU	Invalid mode configuration interrupt (Clock Usage) - This bit is set during a mode transition if a clock which is required to be on by an enabled peripheral is configured to be turned off. It is cleared by writing a '1' to this bit. 0 No invalid mode configuration (clock usage) interrupt occurred 1 Invalid mode configuration (clock usage) interrupt is pending

Table continues on the next page...

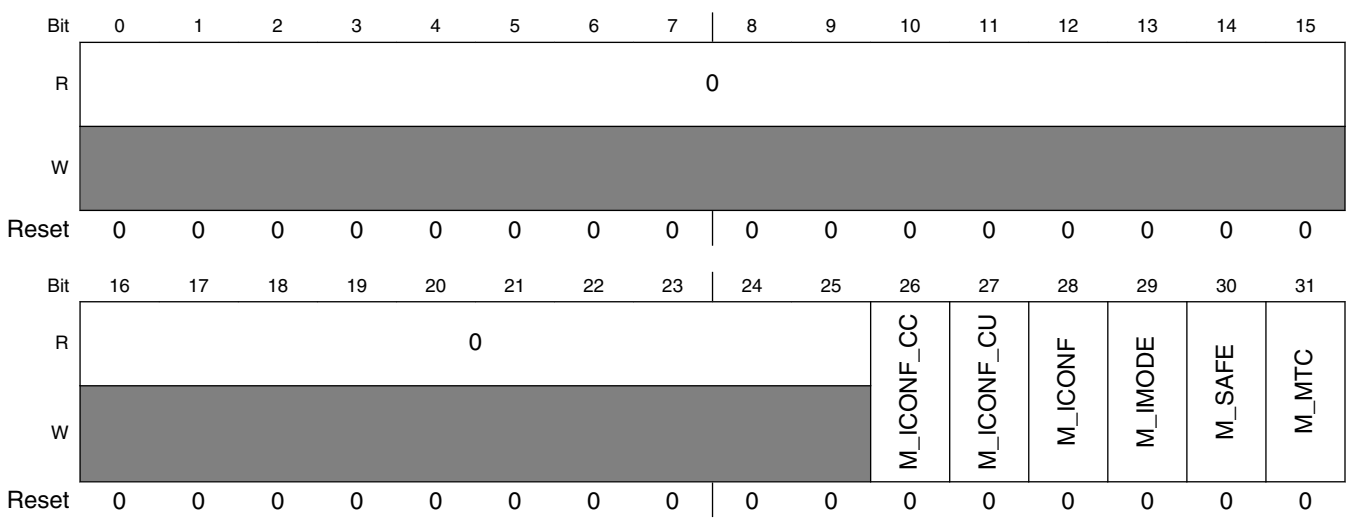
MC_ME_IS field descriptions (continued)

Field	Description
28 I_ICONF	Invalid mode configuration interrupt - This bit is set whenever a write operation to ME_<mode>_MC registers with invalid mode configuration is attempted. It is cleared by writing a '1' to this bit. 0 No invalid mode configuration interrupt occurred 1 Invalid mode configuration interrupt is pending
29 I_IMODE	Invalid mode interrupt - This bit is set whenever an invalid mode transition is requested. It is cleared by writing a '1' to this bit. 0 No invalid mode interrupt occurred 1 Invalid mode interrupt is pending
30 I_SAFE	SAFE mode interrupt - This bit is set whenever the chip enters SAFE mode on hardware requests generated in the system. It is cleared by writing a '1' to this bit. 0 No SAFE mode interrupt occurred 1 SAFE mode interrupt is pending
31 I_MTC	Mode transition complete interrupt - This bit is set whenever the mode transition process completes (S_MTRANS transits from 1 to 0). It is cleared by writing a '1' to this bit. This mode transition interrupt bit will not be set while entering low-power modes HALT0, or STOP0. 0 No mode transition complete interrupt occurred 1 Mode transition complete interrupt is pending

66.3.5 Interrupt Mask Register (MC_ME_IM)

This register controls whether an event generates an interrupt or not.

Address: 0h base + 10h offset = 10h



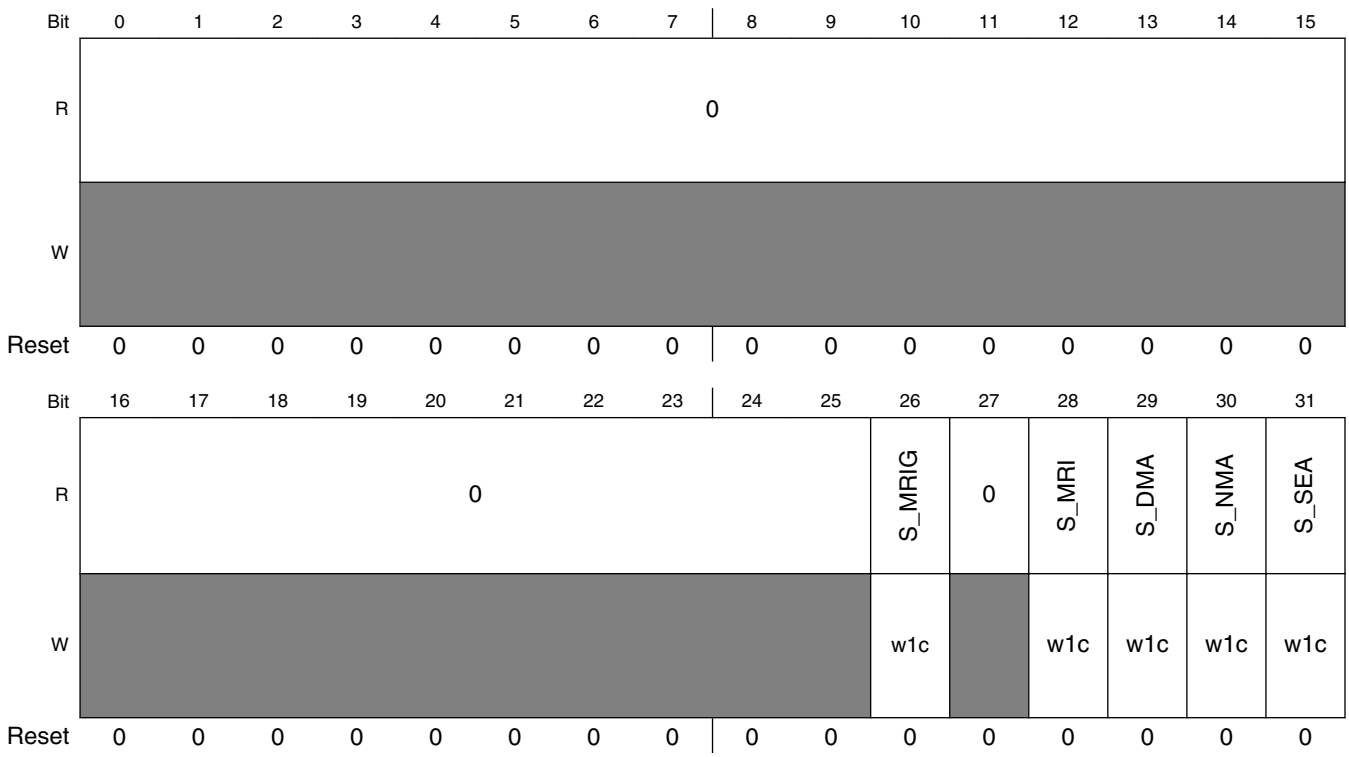
MC_ME_IM field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 M_ICONF_CC	Invalid mode configuration (core configuration) interrupt mask 0 Invalid mode interrupt is masked 1 Invalid mode interrupt is enabled
27 M_ICONF_CU	Invalid mode configuration (clock usage) interrupt mask 0 Invalid mode interrupt is masked 1 Invalid mode interrupt is enabled
28 M_ICONF	Invalid mode configuration interrupt mask 0 Invalid mode interrupt is masked 1 Invalid mode interrupt is enabled
29 M_IMODE	Invalid mode interrupt mask 0 Invalid mode interrupt is masked 1 Invalid mode interrupt is enabled
30 M_SAFE	SAFE mode interrupt mask 0 SAFE mode interrupt is masked 1 SAFE mode interrupt is enabled
31 M_MTC	Mode transition complete interrupt mask 0 Mode transition complete interrupt is masked 1 Mode transition complete interrupt is enabled

66.3.6 Invalid Mode Transition Status Register (MC_ME_IMTS)

This register provides the status bits for the possible causes of an invalid mode interrupt.

Address: 0h base + 14h offset = 14h



MC_ME_IMTS field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 S_MRIG	S_MRIG Mode Request Ignored status — This bit is set whenever a new mode is requested while a transition to the SAFE mode is in progress. It is cleared by writing a ‘1' to this bit. 0 Mode transition requested is not illegal 1 Mode transition requested is illegal This bit is also set if a transition to STOP/HALT mode is requested when a wakeup is active.
27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 S_MRI	Mode Request Illegal status - This bit is set whenever the target mode requested is not a valid mode with respect to current mode. It is cleared by writing a '1' to this bit. 0 Target mode requested is not illegal with respect to current mode 1 Target mode requested is illegal with respect to current mode

Table continues on the next page...

MC_ME_IMTS field descriptions (continued)

Field	Description
29 S_DMA	Disabled Mode Access status - This bit is set whenever the target mode requested is one of those disabled modes determined by ME_ME register. It is cleared by writing a '1' to this bit. 0 Target mode requested is not a disabled mode 1 Target mode requested is a disabled mode
30 S_NMA	Non-existing Mode Access status - This bit is set whenever the target mode requested is one of those non existing modes determined by ME_ME register. It is cleared by writing a '1' to this bit. 0 Target mode requested is an existing mode 1 Target mode requested is a non-existing mode
31 S_SEA	SAFE Event Active status - This bit is set whenever the chip is in SAFE mode, SAFE event bit is pending and a new mode requested other than RESET/SAFE modes. It is cleared by writing a '1' to this bit. 0 No new mode requested other than RESET/SAFE while SAFE event is pending 1 New mode requested other than RESET/SAFE while SAFE event is pending

66.3.7 Debug Mode Transition Status Register (MC_ME_DMTS)

This register provides the status of different factors which influence mode transitions. It is used to give an indication of why a mode transition indicated by ME_GS.S_MTRANS may be taking longer than expected.

NOTE

The ME_DMTS register does not indicate whether a mode transition is ongoing. Therefore, some ME_DMTS bits may still be asserted after the mode transition has completed.

Address: 0h base + 18h offset = 18h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MC_ME_DMTS field descriptions

Field	Description
0–3 PREVIOUS_ MODE	Previous chip mode - These bits show the mode in which the chip was prior to the latest change to the current mode. 0000 RESET 0001 TEST 0010 SAFE 0011 DRUN 0100 RUN0 0101 RUN1 0110 RUN2 0111 RUN3 1000 HALT0 1001 reserved 1010 STOP0 1011 reserved 1100 reserved 1101 reserved 1110 reserved 1111 reserved
4–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 MPH_BUSY	MC_ME/MC_PCU Handshake Busy indicator - This bit is set if the MC_ME has requested a mode change from the MC_PCU and the MC_PCU has not yet completed its handshake. 0 Handshake is not busy 1 Handshake is busy
9–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 PMC_PROG	MC_PCU Mode Change in Progress indicator - This bit is set if the MC_PCU is in the process of powering up or down power domains. It is cleared when all power-up/down processes have completed. 0 Power-up/down transition is not in progress 1 Power-up/down transition is in progress
12 DBG_MODE	Debug mode indicator - This bit is set while the chip is in debug mode. 0 The chip is not in debug mode 1 The chip is in debug mode
13 CCKL_PROG	Core Clock Enable/Disable in Progress - This bit is set while any core's clock is in the process of being enabled or disabled. 0 No core clock is being enabled or disabled 1 A core clock is being enabled or disabled
14 PCS_PROG	Progressive System Clock Switching in Progress - This bit is set while the progressive system clock switching process is in progress. 0 PCS is not in progress 1 PCS is in progress
15 SMR	SAFE mode request from MC_RGM is active indicator - This bit is set if a hardware SAFE mode request has been triggered. It is cleared when the hardware SAFE mode request has been cleared.

Table continues on the next page...

MC_ME_DMTS field descriptions (continued)

Field	Description
	0 A SAFE mode request is not active 1 A SAFE mode request is active
16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 VREG_CSRC_SC	Main VREG dependent Clock Source State Change during mode transition indicator - This bit is set when a clock source which depends on the main voltage regulator to be powered-up is requested to change its power up/down state. It is cleared when the clock source has completed its state change. 0 No state change is taking place 1 A state change is taking place
18 CSRC_CSRC_SC	(Other) Clock Source dependent Clock Source State Change during mode transition indicator - This bit is set when a clock source which depends on another clock source to be powered-up is requested to change its power up/down state. It is cleared when the clock source has completed its state change. 0 No state change is taking place 1 A state change is taking place
19 IRC_SC	IRC State Change during mode transition indicator - This bit is set when the IRC is requested to change its power up/down state. It is cleared when the IRC has completed its state change. 0 No state change is taking place 1 A state change is taking place
20 SCSRC_SC	Secondary Clock Sources State Change during mode transition indicator - This bit is set when a secondary clock source is requested to change its power up/down state. It is cleared when all secondary system clock sources have completed their state changes. (A 'secondary clock source' is a clock source other than IRC.) 0 No state change is taking place 1 A state change is taking place
21 SYSCLK_SW	System Clock Switching pending status - 0 No system clock source switching is pending 1 A system clock source switching is pending
22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 CDP_PRPH_224_255	Clock Disable Process Pending status for Peripherals 224...255[1] - This bit is set when any peripheral has been requested to have its clock disabled. It is cleared when all the peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
25 CDP_PRPH_192_223	Clock Disable Process Pending status for Peripherals 192...223 - This bit is set when any peripheral appearing in ME_PS6 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral

Table continues on the next page...

MC_ME_DMTS field descriptions (continued)

Field	Description
26 CDP_PRPH_ 160_191	Clock Disable Process Pending status for Peripherals 160...191 - This bit is set when any peripheral appearing in ME_PS5 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
27 CDP_PRPH_ 128_159	Clock Disable Process Pending status for Peripherals 128...159 - This bit is set when any peripheral appearing in ME_PS4 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
28 CDP_PRPH_96_ 127	Clock Disable Process Pending status for Peripherals 96...127 - This bit is set when any peripheral appearing in ME_PS3 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
29 CDP_PRPH_64_ 95	Clock Disable Process Pending status for Peripherals 64...95 - This bit is set when any peripheral appearing in ME_PS2 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
30 CDP_PRPH_32_ 63	Clock Disable Process Pending status for Peripherals 32...63 - This bit is set when any peripheral appearing in ME_PS1 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
31 CDP_PRPH_0_ 31	Clock Disable Process Pending status for Peripherals 0...31 - This bit is set when any peripheral appearing in ME_PS0 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral

1. Peripheral n corresponds to the ME_PCTLn register. Please refer to the module memory map for the ME_PCTLn locations actually occupied, which in turn indicates which peripherals are reported in the ME_DMTS register.

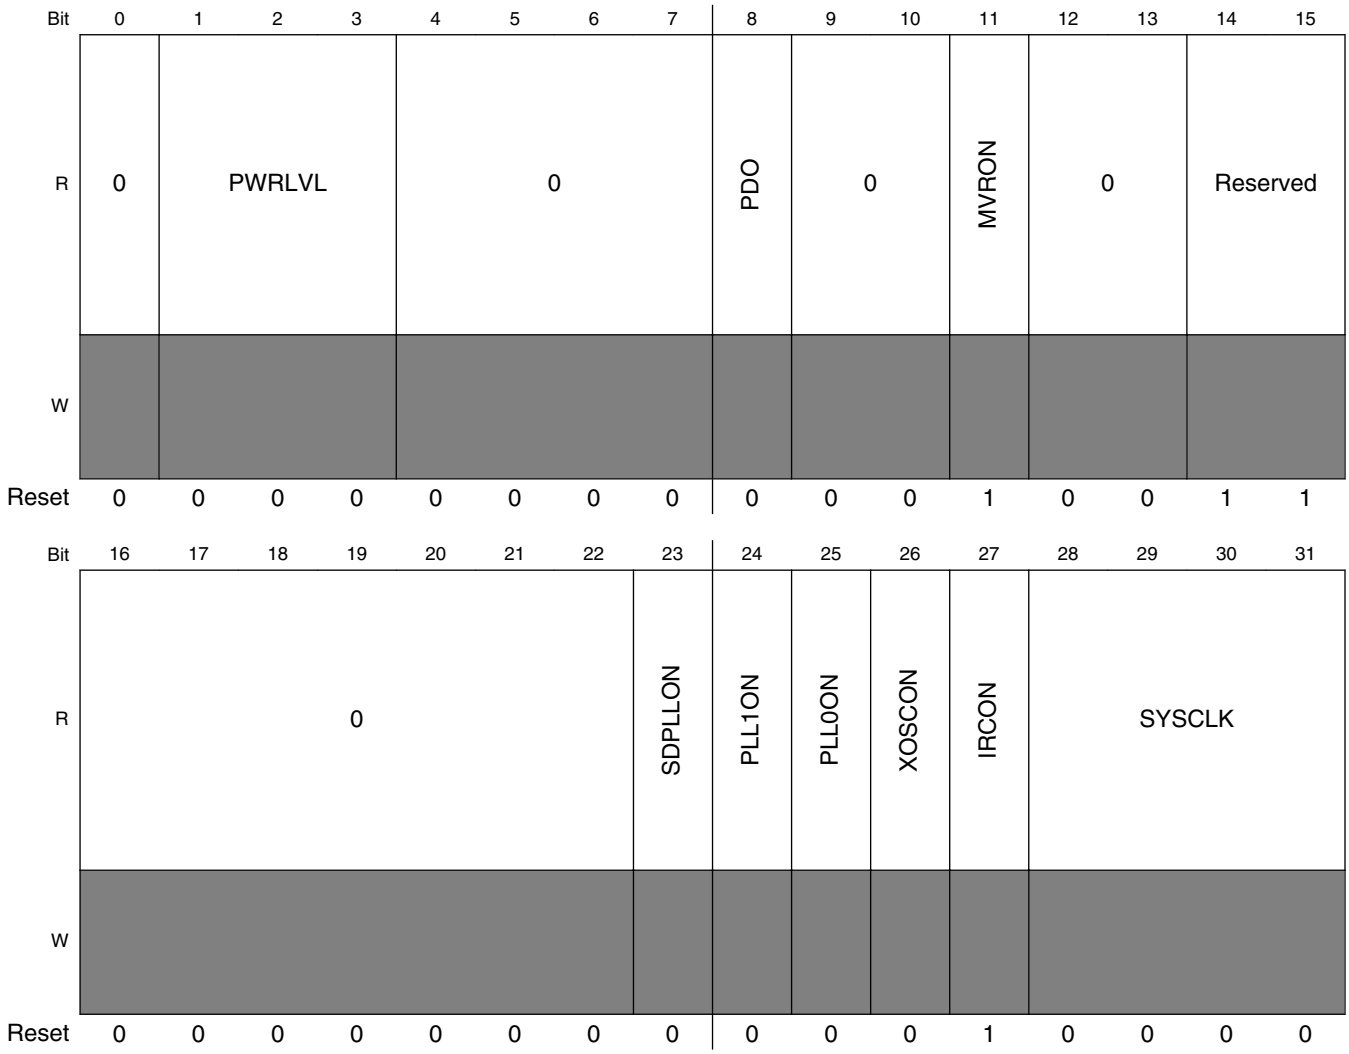
66.3.8 RESET Mode Configuration Register (MC_ME_RESET_MC)

This register configures system behavior during RESET mode.

NOTE

The following configuration values are set according to the chip configuration: XOSCON

Address: 0h base + 20h offset = 20h



MC_ME_RESET_MC field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–3 PWRLVL	Power level - These bits indicate the relative power consumption level of this mode with respect to that of other modes. When switching between two modes with differing power levels, system clock progressive switching is enabled.
4–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 PDO	I/O output power-down control-This bit controls the output power-down of I/Os. 0 No automatic safe gating of I/Os used and pads power sequence driver is enabled

Table continues on the next page...

MC_ME_RESET_MC field descriptions (continued)

Field	Description
9–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 MVRON	Main voltage regulator control - This bit specifies whether main voltage regulator is switched off or not while entering this mode. 1 Main voltage regulator is switched on
12–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–15 Reserved	This field is reserved. — 11 Flash is in normal mode

MC_ME_DRUN_MC field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–3 PWRLVL	Power level - These bits indicate the relative power consumption level of this mode with respect to that of other modes. When switching between two modes with differing power levels, system clock progressive switching is enabled.
4–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 PDO	I/O output power-down control - This bit controls the output power-down of I/Os. 0 No automatic safe gating of I/Os used and pads power sequence driver is enabled 1 In SAFE/TEST modes, outputs of pads are forced to high impedance state and pads power sequence driver is disabled. The inputs are level unchanged. In STOP0 mode, only the pad power sequence driver is disabled, but the state of the output remains functional.
9–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 MVRON	Main voltage regulator control - This bit specifies whether main voltage regulator is switched off or not while entering this mode. 1 Main voltage regulator is switched on
12–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 1.
16–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 SDPLLON	SDPLL control 0 SDPLL is switched off 1 SDPLL is switched on
24 PLL1ON	PLL1 control

Table continues on the next page...

MC_ME_DRUN_MC field descriptions (continued)

Field	Description
	0 PLL1 is switched off 1 PLL1 is switched on
25 PLL0ON	PLL0 control 0 PLL0 is switched off 1 PLL0 is switched on
26 XOSCON	XOSC control 0 XOSC is switched off 1 XOSC is switched on
27 IRCON	IRC control 0 IRC is switched off 1 IRC is switched on
28–31 SYSCLK	System clock switch control - These bits specify the system clock to be used by the system. 0000 IRC_CLK 0001 XOSC_CLK 0010 PLL0_PHI_CLK 0011 reserved 0100 PLL1_PHI_CLK 0101 reserved 0110 reserved 0111 reserved 1000 reserved 1001 reserved 1010 reserved 1011 reserved 1100 reserved 1101 reserved 1110 reserved 1111 system clock is disabled in TEST mode, reserved in all other modes

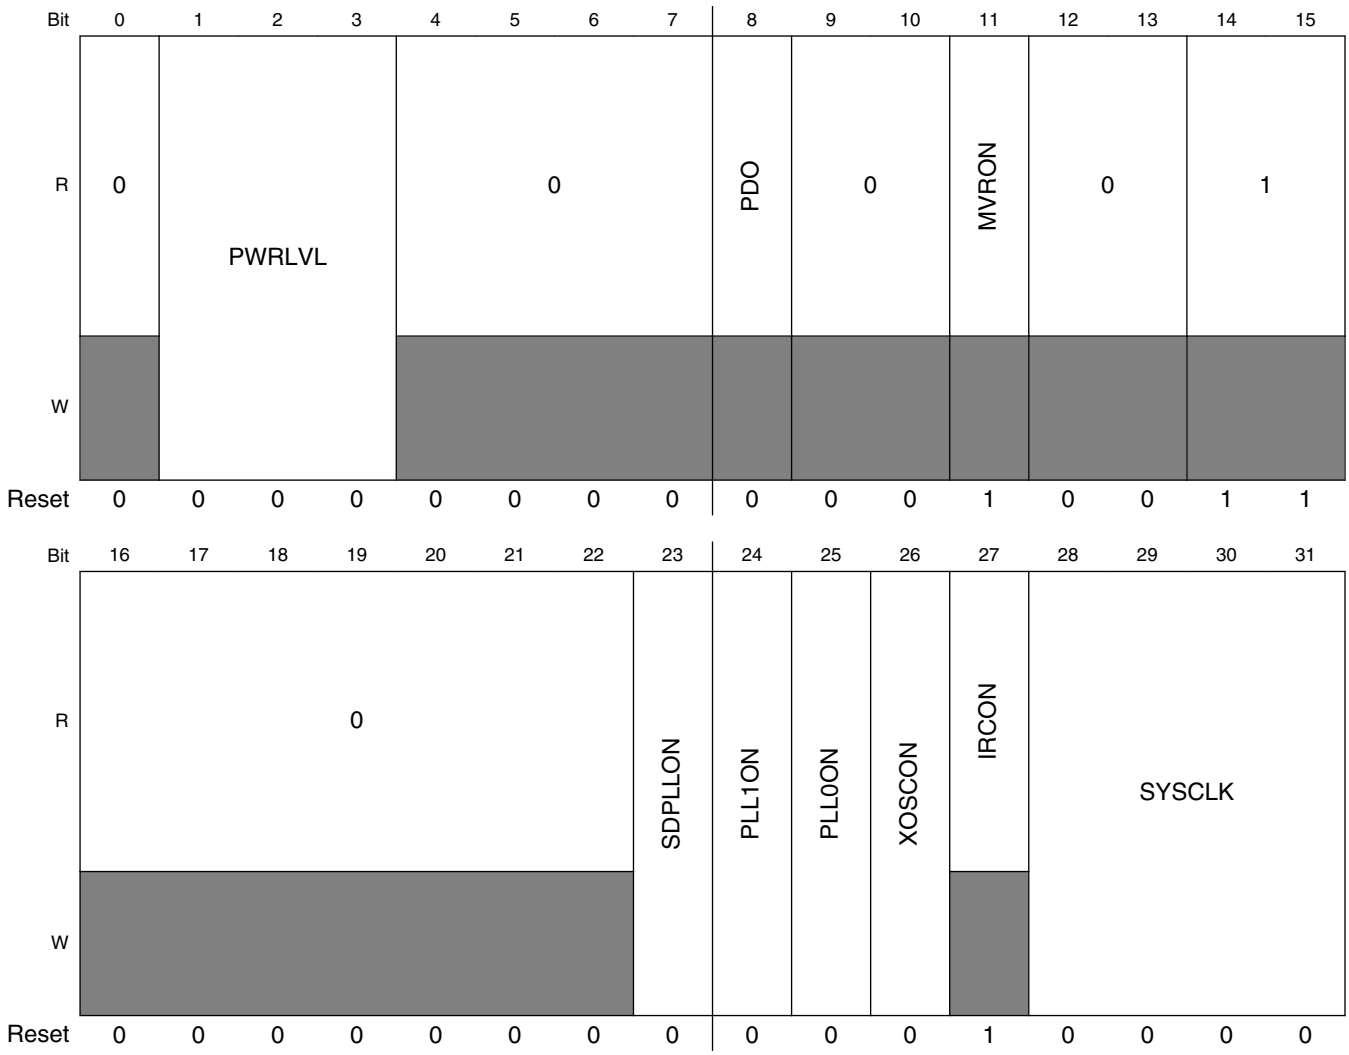
66.3.12 RUN0 3 Mode Configuration Register (MC_ME_RUN*n*_MC)

This register configures system behavior during RUN0…3 modes.

NOTE

Byte write accesses are not allowed to this register.

Address: 0h base + 30h offset + (4d × i), where i=0d to 3d



MC_ME_RUN*n*_MC field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–3 PWRLVL	Power level - These bits indicate the relative power consumption level of this mode with respect to that of other modes. When switching between two modes with differing power levels, system clock progressive switching is enabled.

Field	Description
	0 Peripheral is frozen with clock gated 1 Peripheral is active
27 RUN0	Peripheral control during RUN0 0 Peripheral is frozen with clock gated 1 Peripheral is active
28 DRUN	Peripheral control during DRUN 0 Peripheral is frozen with clock gated 1 Peripheral is active
29 SAFE	Peripheral control during SAFE 0 Peripheral is frozen with clock gated 1 Peripheral is active
30 TEST	Peripheral control during TEST 0 Peripheral is frozen with clock gated 1 Peripheral is active
31 RESET	Peripheral control during RESET 0 Peripheral is frozen with clock gated 1 Peripheral is active

66.3.24 Low-Power Peripheral Configuration Register (MC_ME_LP_PC*n*)

These registers configure eight different types of peripheral behavior during non-run modes.

Address: 0h base + A0h offset + (4d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0					STOP0	0	HALT0	0							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MC_ME_LP_PC*n* field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 STOP0	Peripheral control during STOP0 0 Peripheral is frozen with clock gated 1 Peripheral is active
22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 HALT0	Peripheral control during HALT0 0 Peripheral is frozen with clock gated 1 Peripheral is active
24–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

66.3.25 LFAST_0 Peripheral Control Register (MC_ME_PCTL9)

These registers select the configurations during run and non-run modes for each peripheral.

Address: 0h base + C9h offset = C9h

Bit	0	1	2	3	4	5	6	7
Read	0	DBG_F	LP_CFG			RUN_CFG		
Write								
Reset	0	0	0	0	0	0	0	0

MC_ME_PCTL9 field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 DBG_F	Peripheral control in debug mode - This bit controls the state of the peripheral in debug mode **NOTE:** This feature is useful to freeze the peripheral state while entering debug. For example, this may be used to prevent a reference timer from running while making a debug accesses. 0 Peripheral state depends on RUN_CFG/LP_CFG bits and the chip mode 1 Peripheral is frozen if not already frozen in chip modes.
2–4 LP_CFG	Peripheral configuration select for non-run modes - These bits associate a configuration as defined in the ME_LP_PC0…7 registers to the peripheral. 000 Selects ME_LP_PC0 configuration 001 Selects ME_LP_PC1 configuration 010 Selects ME_LP_PC2 configuration

Field	Description
	0 z7a is disabled 1 z7a is running
30 S_CORE1	Core 1 status - This bits specifies the current status of z4a which is controlled by the ME_CCTL1 register. 0 z4a is disabled 1 z4a is running
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

66.3.56 Core Control Register (MC_ME_CCTL1)

This register controls whether z4a is disabled or running during run modes.

This register cannot be written after a mode change request has been made until the mode transition has completed (i.e., while the S_MTRANS bit of the ME_GS register = '1'). A write access to this register during this time will result in the ICONF_CC flag in the ME_IS register being asserted.

When secondary cores are enabled by using CCTL register in target mode for the first time without setting RMC bit, it starts booting from the BAM location which causes SRAM initialization. If the secondary core is enabled for the first time, the user should always program the CADDR register and set RMC bit before making transition to target mode.

NOTE

Whenever the Z4 core is doing a mode transition from clock enabled to clock enabled mode or from clock disable to clock enabled mode with RMC bit set, the lockstep disablement NCF, NCF[64], will be set. Software should ignore this and take appropriate action to clear it.

66.4 Functional Description

66.4.1 Mode Transition Request

The transition from one mode to another mode is normally handled by software by accessing the mode control register ME_MCTL. But the in case of special events, the mode transition can be automatically managed by hardware. In order to switch from one mode to another, the application should access the ME_MCTL register twice by writing

- the first time with the value of the key (0x5AF0) into the KEY bit field and the required target mode into the TARGET_MODE bit field,
- and the second time with the inverted value of the key (0xA50F) into the KEY bit field and the required target mode into the TARGET_MODE bit field.

Once a valid mode transition request is detected, the target mode configuration information is loaded from the corresponding ME_<mode>_MC register.The mode transition request may require a number of cycles depending on the programmed configuration, and software should check the S_CURRENT_MODE bit field and the S_MTRANS bit of the global status register ME_GS to verify when the mode has been correctly entered and the transition process has completed. For a description of valid mode requests, please refer to Mode Transition Interrupts.

Any modification of the mode configuration register of the currently selected mode will not be taken into account immediately but on the next request to enter this mode. This means that transition requests such as RUN0…3 -> RUN0…3, DRUN -> DRUN, SAFE -> SAFE, and TEST -> TEST are considered valid mode transition requests. As soon as the mode request is accepted as valid, the S_MTRANS bit is set till the status in the ME_GS register matches the configuration programmed in the respective ME_<mode>_MC register.

Note

It is recommended that software polls the S_MTRANS bit in the ME_GS register after requesting a transition to HALT0 or STOP0 modes.

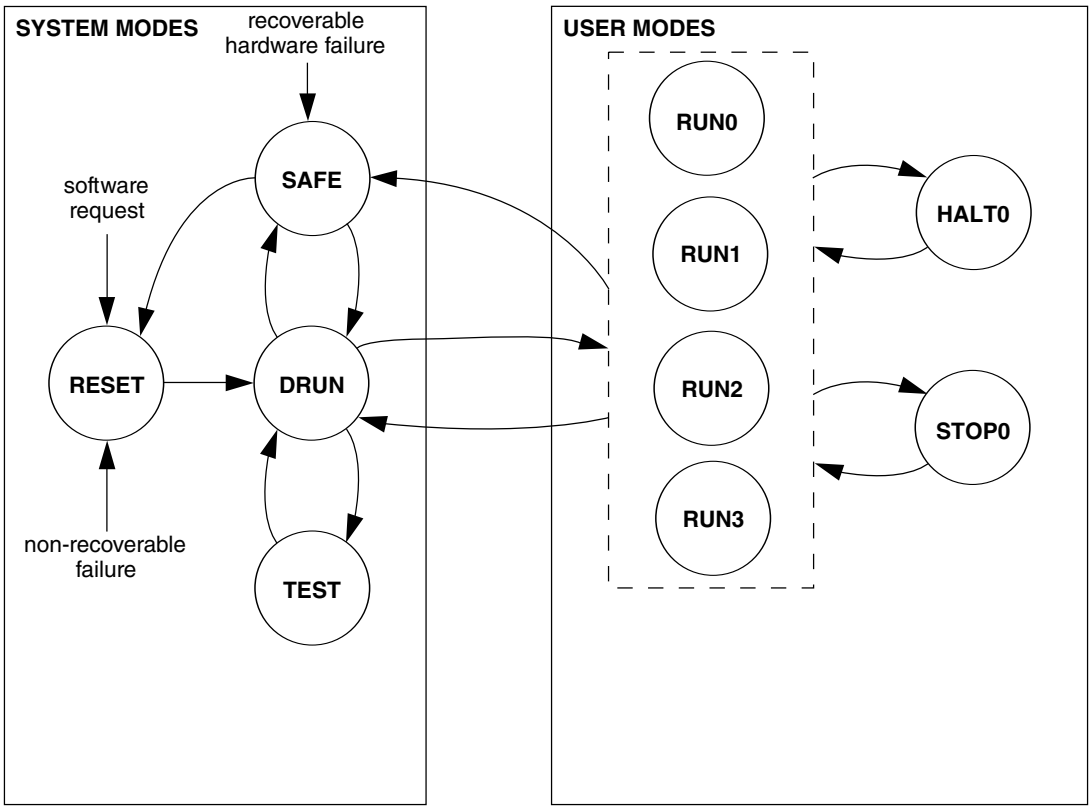

Figure 66-2. MC_ME Mode Diagram

66.4.2 Modes Details

66.4.2.1 RESET Mode

The chip enters this mode on the following events:

- from SAFE, DRUN, RUN0…3, or TEST mode when the TARGET_MODE bit field of the ME_MCTL register is written with either "0000" for a 'functional' reset or "1111" for a 'destructive' reset
- from any mode due to a system reset by the MC_RGM because of some non-recoverable hardware failure in the system (see the MC_RGM chapter for details)

Transition to this mode is instantaneous, and the system remains in this mode until the reset sequence is finished. The mode configuration information for this mode is provided by the ME_RESET_MC register. This mode has a pre-defined configuration, and the IRC_CLK is selected as the system clock.

66.4.2.2 DRUN Mode

The chip enters this mode on the following events:

- automatically from RESET mode after completion of the reset sequence
- from RUN0…3, SAFE, or TEST mode when the TARGET_MODE bit field of the ME_MCTL register is written with "0011"

As soon as any of the above events has occurred, a DRUN mode transition request is generated. The mode configuration information for this mode is provided by the ME_DRUN_MC register. In this mode, the flash, all clock sources, and the system clock configuration can be controlled by software as required. After system reset, the software execution starts with the default configuration selecting the IRC_CLK as the system clock. The clock source configuration except system clock source 0 can be chosen by preloaded information in flash memory. This information is loaded into the ME_DRUN_MC register during PHASE3 of the reset sequence.

This mode is intended to be used by software

- to initialize all registers as per the system needs

Note

Software must ensure that the code executes from RAM before changing to this mode if the flash is configured to be in the low-power or power-down state in this mode.

66.4.2.3 SAFE Mode

The chip enters this mode on the following events:

- from any mode except RESET when the TARGET_MODE bit field of the ME_MCTL register is written with "0010"
- from any mode except RESET due to a SAFE mode request generated by the MC_RGM because of some potentially recoverable hardware failure in the system (see the MC_RGM chapter for details)

Note

If a hardware SAFE mode request occurs during RESET, depending on the timing of the SAFE mode request, SAFE mode may be entered immediately after the normal completion of the reset sequence or several system clock cycles after DRUN entry. The SAFE mode request does not have any influence on the execution of the reset sequence itself.

As soon as any of the above events has occurred, a SAFE mode transition request is generated. The mode configuration information for this mode is provided by the ME_SAFE_MC register. This mode has a pre-defined configuration, and the IRC_CLK is selected as the system clock.

If the SAFE mode is requested by software while some other mode transition process is ongoing, the new target mode becomes the SAFE mode regardless of other pending requests or new requests during the mode transition. No new mode request made during a transition to the SAFE mode will cause an invalid mode interrupt.

Note

If software requests to change to the SAFE mode and then requests to change back to the parent mode before the mode transition is completed, the chip's final mode after mode transition will be the SAFE mode, and an invalid mode transition interrupt will be generated.

As long as a SAFE event is active, the system remains in the SAFE mode, and any software mode request during this time is ignored and lost.

This mode is intended to be used by software

- to assess the severity of the cause of failure and then to either
  - re-initialize the chip via the DRUN mode, or
  - completely reset the chip via the RESET mode.

If the outputs of the system I/Os need to be forced to a high impedance state upon entering this mode, the PDO bit of the ME_SAFE_MC register should be set. The input levels remain unchanged.

66.4.2.4 TEST Mode

The chip enters this mode on the following events:

- from the DRUN mode when the TARGET_MODE bit field of the ME_MCTL register is written with "0001"

As soon as any of the above events has occurred, a TEST mode transition request is generated. The mode configuration information for this mode is provided by the ME_TEST_MC register. Except for the main voltage regulator, all resources of the system are configurable in this mode. The system clock to the whole system can be stopped by programming the SYSCLK bit field to "1111", and in this case, the only way to exit this mode is via a chip reset.

This mode is intended to be used by software

- to execute software test routines

Note

Software must ensure that the code executes from RAM before changing to this mode if the flash is configured to be in the low-power or power-down state in this mode.

66.4.2.5 RUN0…3 Modes

The chip enters one of these modes on the following events:

- from the DRUN, SAFE, or another RUN0…3 mode when the TARGET_MODE bit field of the ME_MCTL register is written with "0100…0111"
- from the HALT0 mode due to an interrupt event
- from the STOP0 mode due to an interrupt or wakeup event

As soon as any of the above events has occurred, a RUN0…3 mode transition request is generated. The mode configuration information for these modes is provided by the ME_RUN0…3_MC registers. In these modes, the flash, all clock sources, and the system clock configuration can be controlled by software as required.

These modes are intended to be used by software

- to execute application routines

Note

Software must ensure that the code executes from RAM before changing to this mode if the flash is configured to be in the low-power or power-down state in this mode.

66.4.2.6 HALT0 Mode

The chip enters this mode on the following events:

- from one of the RUN0…3 modes when the TARGET_MODE bit field of the ME_MCTL register is written with "1000".

As soon as any of the above events has occurred, a HALT0 mode transition request is generated. The mode configuration information for this mode is provided by ME_HALT0_MC register. This mode is quite configurable, and the ME_HALT0_MC register should be programmed according to the system needs. If there is a HALT0 mode request while an interrupt request is active, the transition to HALT0 is aborted with the resultant mode being the current mode, SAFE (on SAFE mode request), or DRUN (on reset), and an invalid mode interrupt is not generated.

This mode is intended as a first-level low-power mode with

- the core clocks frozen
- the additional core clocks frozen
- only a few peripherals running

and to be used by software

- to wait until it is required to do something and then to react quickly (i.e., within a few system clock cycles of an interrupt event)

Note

It is good practice for software to ensure that the S_MTRANS bit in the ME_GS register has been cleared on HALT0 mode exit to ensure that the previous RUN0…3 mode configuratoin has been fully restored before executing critical code.

66.4.2.7 STOP0 Mode

The chip enters this mode on the following events:

- from one of the RUN0…3 modes when the TARGET_MODE bit field of the ME_MCTL register is written with "1010".

As soon as any of the above events has occurred, a STOP0 mode transition request is generated. The mode configuration information for this mode is provided by the ME_STOP0_MC register. This mode is fully configurable, and the ME_STOP0_MC register should be programmed according to the system needs. The following clock sources are switched off in this mode:

- the PLL1
- the PLL0
- the SDPLL

If there is a STOP0 mode request while any interrupt or wakeup event is active, the transition to STOP0 is aborted with the resultant mode being the current mode, SAFE (on SAFE mode request), or DRUN (on reset), and an invalid mode interrupt is not generated.

This mode is intended as an advanced low-power mode with

- the core clock frozen
- the additional core clocks frozen
- almost all peripherals stopped

and to be used by software

- to wait until it is required to do something with no need to react quickly (e.g., allow for system clock source to be re-started)

This mode can be used to stop all clock sources except IRC. When exiting the STOP0 mode, the IRC clock is selected as the system clock until the target clock is available.

Note

It is good practice for software to ensure that the S_MTRANS bit in the ME_GS register has been cleared on STOP0 mode exit to ensure that the previous RUN0…3 mode configuration has been fully restored before executing critical code.

NOTE

All interrupts that are masked in INTC should be disabled in the modules as well. Otherwise a hang situation can occur as follows:

- Module issues an interrupt and STOP_ACK to MC_ME is gated.
- MC_ME does not retract and wait for STOP_ACK.
- This interrupt is not available at INTC so the core cannot service it, which causes a hang.

NOTE

A potential system hang scenario may occur if a stop/halt mode request is generated when the interrupts are enabled in active modules and interrupts appears when the MC_ME is transitioning to stop/halt mode.

User needs to adhere to some software guidelines:

- Disable Interrupts before requesting a stop/halt mode change.
- If the previous guideline is not possible ensure any interrupt are finished before stop/halt mode change.
- The wake-up from stop mode should always be done by using external wake-up and not from internal interrupts.

66.4.3 Mode Transition Process

The process of mode transition follows the following steps in a pre-defined manner depending on the current chip mode and the requested target mode. In many cases of mode transition, not all steps need to be executed based on the mode control information, and some steps may not be applicable according to the mode definition itself.

66.4.3.1 Target Mode Request

The target mode is requested by accessing the ME_MCTL register with the required keys. This mode transition request by software must be a valid request satisfying a set of pre-defined rules to initiate the process. If the request fails to satisfy these rules, it is ignored, and the TARGET_MODE bit field is not updated. An optional interrupt can be generated for invalid mode requests. Refer to Mode Transition Interrupts for details.

In the case of mode transitions occurring because of hardware events such as a reset, a SAFE mode request, or interrupt requests and wakeup events to exit from low-power modes, the TARGET_MODE bit field of the ME_MCTL register is automatically updated with the appropriate target mode. The mode change process start is indicated by the setting of the mode transition status bit S_MTRANS of the ME_GS register.

A RESET mode requested via the ME_MCTL register is passed to the MC_RGM, which generates a global system reset and initiates the reset sequence. The RESET mode request has the highest priority, and the MC_ME is kept in the RESET mode during the entire reset sequence.

The SAFE mode request has the next highest priority after reset. It can be generated either by software via the ME_MCTL register from all software running modes or by the MC_RGM after the detection of system hardware failures, which may occur in any mode.

66.4.3.2 Target Mode Configuration Loading

On completion of the Target Mode Request step, the target mode configuration from the ME_<target mode>_MC register is loaded to start the resources (voltage sources, clock sources, flash, pads, etc.) control process.

An overview of resource control possibilities for each mode is shown in the following table. A ' √' indicates that a given resource is configurable for a given mode.

Table 66-2. MC_ME Resource Control Overview

Resource	Mode						
	RESET	TEST	SAFE	DRUN	RUN0...3	HALT0	STOP0
IRC		√					
	on	on	on	on	on	on	on
XOSC		√		√	√	√	√
	off	off	off	off	off	off	off
PLL0		√		√	√	√	
	off	off	off	off	off	off	off

Table continues on the next page...

Table 66-2. MC_ME Resource Control Overview (continued)

Resource	Mode						
	RESET	TEST	SAFE	DRUN	RUN0…3	HALT0	STOP0
SDPLL		√		√	√	√	
	off	off	off	off	off	off	off

	off	off	off	off	off	off	off
MVREG	on	on	on	on	on	on	on
PDO		√	√				√
	off	off	on	off	off	off	off

66.4.3.3 Peripheral Clocks Disable

On completion of the Target Mode Request step and the system clock frequency ramp-down of the System Clock Switching step, the MC_ME requests each peripheral to enter its stop mode when:

- the peripheral is configured to be disabled via the target mode, the peripheral configuration registers ME_RUN_PC0…7 and ME_LP_PC0…7, and the peripheral control registers ME_PCTLn

Note

The MC_ME automatically requests peripherals to enter their stop modes if the power domains in which they are residing are to be turned off due to a mode change. However, it is good practice for software to ensure that those peripherals that are to be powered down are configured in the MC_ME to be frozen.

Each peripheral acknowledges its stop mode request after closing its internal activity. The MC_ME then disables the corresponding clock(s) to this peripheral.

In the case of a SAFE mode transition request, the MC_ME does not wait for the peripherals to acknowledge the stop requests. The SAFE mode clock gating configuration is applied immediately regardless of the status of the peripherals' stop acknowledges.

Please refer to Peripheral Clock Gating for more details.

Each peripheral that may block or disrupt a communication bus to which it is connected ensures that these outputs are forced to a safe or recessive state when the chip enters the SAFE mode.

66.4.3.4 Processor Low-Power Mode Entry

If, on completion of the Peripheral Clocks Disable step, the mode transition is to the HALT0,STOP0 mode, the MC_ME requests each processor to enter its stopped state. Each processor acknowledges its stop state request bit after completing all outstanding bus transactions.

If, on completion of the Peripheral Clocks Disable step, the mode transition is from a non-low-power mode to another non-low-power mode, the MC_ME requests each processor which is configured in the ME_CCTLn registers to be disabled to enter its stopped state. The processor acknowledges its stop state request bit after completing all outstanding bus transactions.

66.4.3.5 Processor Clocks Disable

If, on completion of the Processor Low-Power Mode Entry step, and all processors which are configured in the ME_CCTLn registers to be disabled are in their appropriate stopped state, the MC_ME disables the applicable processor clocks bits to achieve further power saving.

The clocks to processors which are configured to be running in both the current and target modes or disabled in both the current and target modes are unaffected while transitioning between non-low-power modes.

warning

Clocks to the whole chip including the processor and system memory can be disabled in TEST mode.

66.4.3.6 System Clock Disable

If, on completion of the Processor Clocks Disable step, all processor clocks have been disabled, the system clock used for non-processor system functions and memory is disabled.

66.4.3.7 Clock Sources Switch-On

On completion of the Processor Low-Power Mode Entry step, the MC_ME switches on all clock sources based on the <clock source>ON bits of the ME_<current mode>_MC and ME_<target mode>_MC registers. The following clock sources are switched on at this step:

- the IRC
- the XOSC
- the PLL1
- the PLL0
- the SDPLL

The clock sources that are required by the target mode are switched on. The duration required for the output clocks to be stable depends on the type of source, and all further steps of mode transition depending on one or more of these clocks waits for the stable status of the respective clocks. The availability status of these clocks is updated in the S_<clock source> bits of ME_GS register.

The clock sources which need to be switched off are unaffected during this process in order to not disturb the system clock which might require one of these clocks before switching to a different target clock.

66.4.3.8 Pad Outputs-On

On completion of the step, if the PDO bit of the ME_<target mode>_MC register is cleared, then

- all pad outputs are enabled to return to their previous state
- the slew rate control mechanism is switched on

66.4.3.9 Peripheral Clocks Enable

Based on the current and target chip modes, the peripheral configuration registers ME_RUN_PC0…7, ME_LP_PC0…7, and the peripheral control registers ME_PCTLn, the MC_ME enables the clocks for selected modules as required. This step is executed only after the process is completed, and if the value of the PWRLVL field of the ME_<target mode>_MC register is process is completed.

66.4.3.10 System and Processor Clocks Enable

The MC_ME enables the non-processor system clock and the clocks of all processors which are configured in the ME_CCTLn registers to be disabled in the current mode and to be running in the target mode.

The MC_ME initiates the resetting of all processors which are configured in the ME_CCTLn registers to be running in the target mode and which have their RMC bits in the ME_CADDRn registers set to '1'. The core_rst_b outputs remain asserted until the end of the mode transition as indicated by the S_MTRANS bit of the ME_GS register at which time they are deasserted.

If the value of the PWRLVL field of the ME_<target mode>_MC register is different from that of the ME_<current mode>_MC register's, the mode change handshake will not be initiated until after the system clock frequency ramp-down step of the System Clock Switching process is completed.

66.4.3.11 Processor Low-Power Mode Exit

On completion of the System and Processor Clocks Enable step, the MC_ME requests all processors which are configured in the ME_CCTLn registers to be disabled in the current mode and to be running in the target mode.

66.4.3.12 System Clock Switching

Based on the SYSCLK bit field of the ME_<current mode>_MC and ME_<target mode>_MC registers, if the target and current system clock configurations differ, the following method is implemented for clock switching.

- The target clock configuration for the IRC_CLK takes effect only after the S_IRC bit of the ME_GS register is set by hardware (i.e., the IRC has stabilized).

- The target clock configuration for the XOSC_CLK takes effect only after the S_XOSC bit of the ME_GS register is set by hardware (i.e., the XOSC has stabilized).
- The target clock configuration for the PLL1_PHI_CLK takes effect only after the S_PLL1 bit of the ME_GS register is set by hardware (i.e., the PLL1 has stabilized).
- The target clock configuration for the PLL0_PHI_CLK takes effect only after the S_PLL0 bit of the ME_GS register is set by hardware (i.e., the PLL0 has stabilized)
- If the clock is to be disabled, the SYSCLK bit field should be programmed with "1111". This is possible only in theTEST mode.

If the value of the PWRLVL field of the ME_<target mode>_MC register not equal to that of the ME_<current mode>_MC register's, a progresive clock switching is performed.

The current system clock configuration can be observed by reading the S_SYSCLK bit field of the ME_GS register, which is updated after every system clock switching. Until the target clock is available, the system uses the previous clock configuration.

System clock switching starts only after

- the Clock Sources Switch-On process has completed if the target system clock source is one of the following:
  - the IRC
  - the XOSC
  - the PLL1
  - the PLL0
- the Peripheral Clocks Disable process has completed in order not to change the system clock frequency before peripherals close their internal activities
- the Peripheral Clocks Enable process has completed

An overview of system clock source selection possibilities for each mode is shown in the following table. A '√' indicates that a given clock source is selectable for a given mode.

Table 66-3. MC_ME System Clock Selection Overview

System Clock Source	Mode						
	RESET	TEST	SAFE	DRUN	RUN0...3	HALT0	STOP0
IRC_CLK	√	√	√	√	√	√	√

Table continues on the next page...

Table 66-3. MC_ME System Clock Selection Overview (continued)

System Clock Source	Mode						
	RESET	TEST	SAFE	DRUN	RUN0...3	HALT0	STOP0
	(default)	(default)	(default)	(default)	(default)	(default)	(default)
XOSC_CLK		√		√	√	√	
PLL1_PHI_CLK		√		√	√	√	
PLL0_PHI_CLK		√		√	√	√	
system clock is disabled		√[1]					

1. disabling the system clock during TEST mode will require a reset in order to exit TEST mode

66.4.3.13 Pad Switch-Off

If the PDO bit of the ME_<target mode>_MC register is '1' then

- the outputs of the pads are forced to the high impedance state if the target mode is SAFE or TEST

This step is executed only after the Peripheral Clocks Disable process has completed.

66.4.3.14 Clock Sources Switch-Off

Based on the chip mode and the <clock source>ON bits of the ME_<mode>_MC registers, if a given clock source is to be switched off, the MC_ME requests the clock source to power down and updates its availability status bit S_<clock source> of the ME_GS register to '0'. The following clock sources switched off at this step:

- the IRC
- the XOSC
- the PLL1

- the PLL0
- the SDPLL

For the clock sources related to the sytem clock, this step is executed only after the System Clock Switching process has completed.

66.4.3.15 Current Mode Update

The current mode status bit field S_CURRENT_MODE of the ME_GS register is updated with the target mode bit field TARGET_MODE of the ME_MCTL register when :

- all the updated status bits in the ME_GS register match the configuration specified in the ME_<target mode>_MC register
- power sequences are done
- clock disable/enable process is finished
- processor low-power mode (stop) entry and exit processes are finished

Note

SAFE mode entry does not wait for the clock disable/enable process to finish. It only waits for the ME_GS.S_RC bit to be set. This is to ensure that the SAFE mode is entered as quickly as possible.

Software can monitor the mode transition status by reading the S_MTRANS bit of the ME_GS register. The mode transition latency can differ from one mode to another depending on the resources' availability before the new mode request and the target mode's requirements.

If a mode transition is taking longer to complete than is expected, the ME_DMTS register can indicate which process is still in progress.

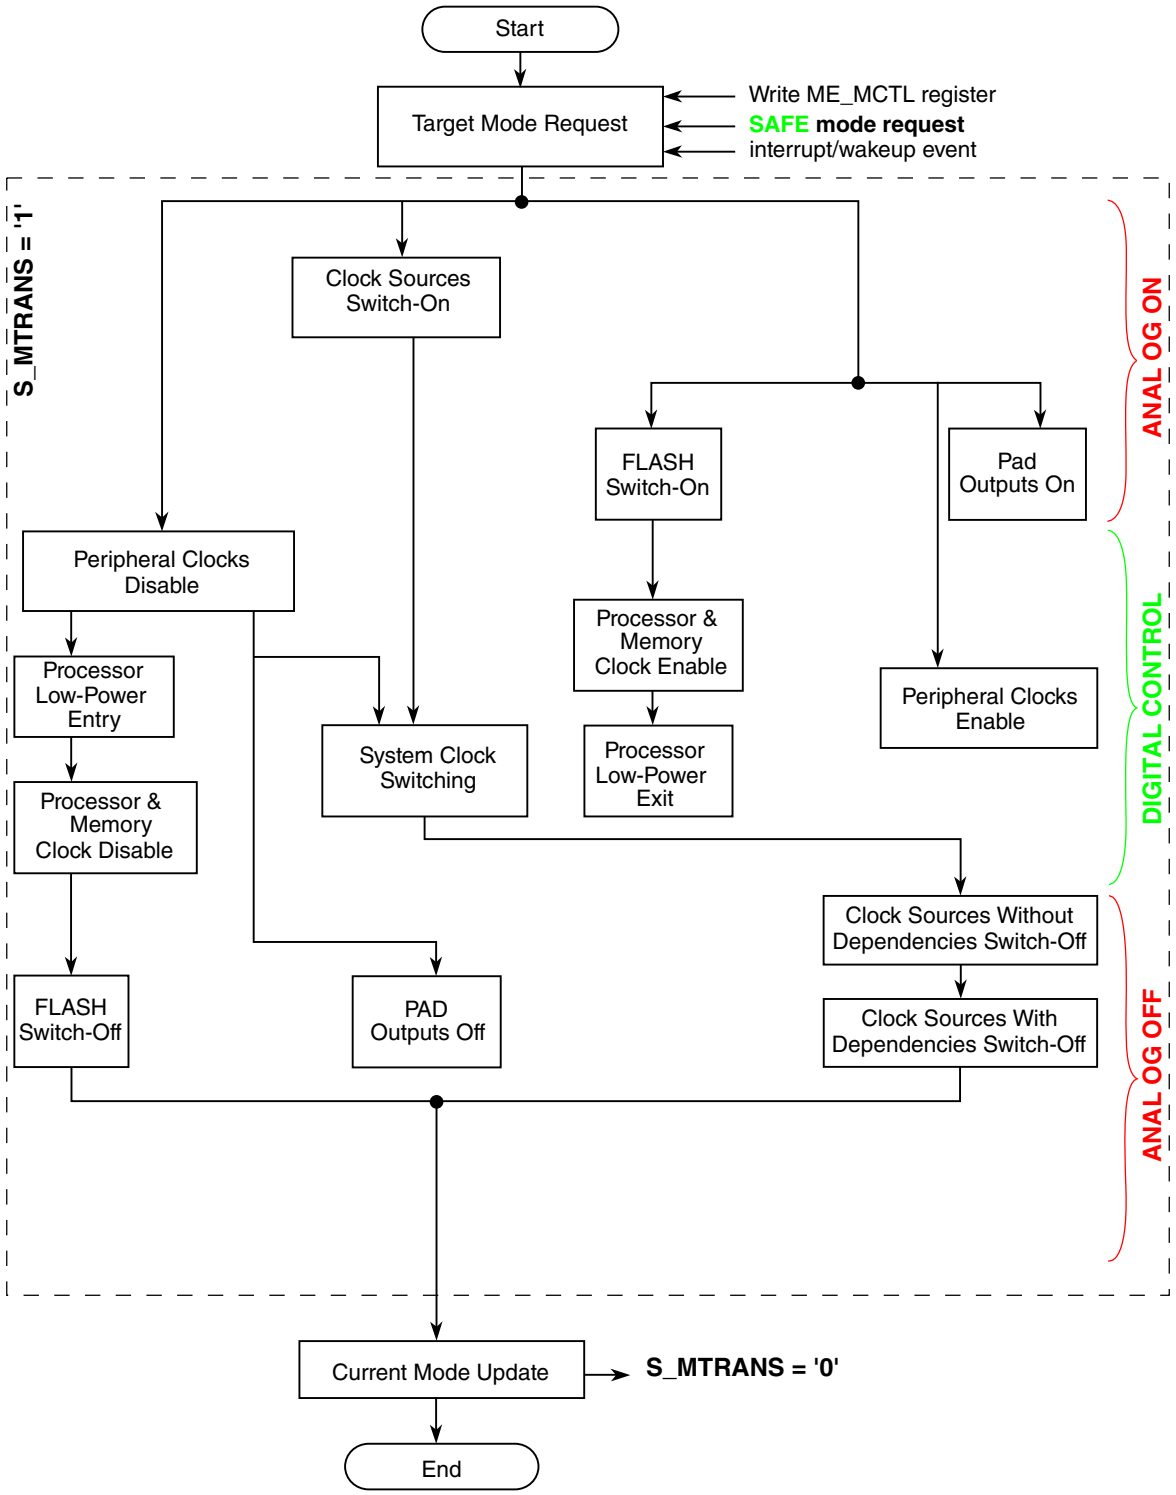

Figure 66-3. MC_ME Transition Diagram

66.4.4 Mode transition and progressive clock switching

The MC_ME initiates a progressive clock switching via MC_CGM whenever the **ME_<current mode>_MC.PWRLVL** field is different from **ME_<target mode>_MC.PWRLVL** bit field. Broadly, the mode transition process can be divided into three steps with respect to progressive cclock switching - RAMP DOWN, LOAD CHANGE and RAMP UP. One or more of these steps may not be needed based on the current and target mode configirations. The clock switching (from current system clock source to target system clock source) can happen before or after the LOAD CHANGE step.

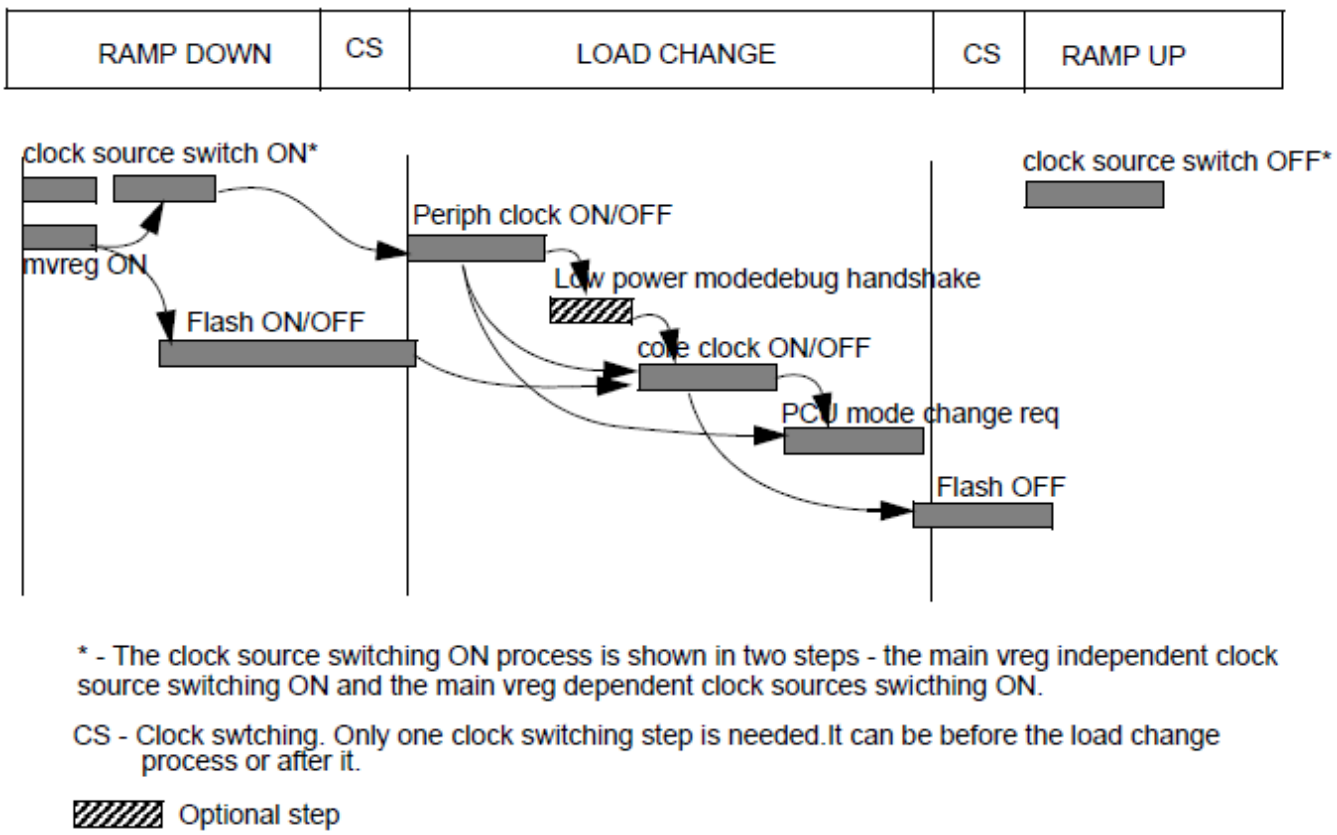

Figure 66-4. MC_ME mode transition process with PCS

The table below shows the different ways the mode transition process can complete.

Table 66-4. Mode transition steps

Pwrlvl	Source clock	Target clock	Mode transition steps
Same	IRC	Non-IRC	LoadChange -> ClockSwitch
	IRC	IRC	LoadChange
	Non-IRC	IRC	LoadChange -> ClockSwitch

Table continues on the next page...

Table 66-4. Mode transition steps (continued)

Pwrlvl	Source clock	Target clock	Mode transition steps
	Non-IRC	Non-IRC	LoadChange -> ClockSwitch
Different	IRC	Non-IRC	LoadChange -> ClockSwitch -> RampUp
	IRC	IRC	LoadChange
	Non-IRC	IRC	RampDown -> ClockSwitch -> LoadChange
	Non-IRC	Non-IRC	RampDown -> ClockSwitch -> LoadChange -> RampUp

66.4.5 Protection of Mode Configuration Registers

While programming the mode configuration registers ME_<mode>_MC, the following rules must be respected. Otherwise, the write operation is ignored and an invalid mode configuration interrupt may be generated.

- If the IRC_CLK is selected as the system clock, IRC must be on.
- If the XOSC_CLK clock is selected as the system clock, XOSC must be on.
- If the PLL1_PHI_CLK clock is selected as the system clock, PLL must be on.
- If the PLL0_PHI_CLK clock is selected as the system clock, PLL0 must be on.

Note

Software must ensure that clock sources with dependencies other than those mentioned above are switched on as needed. There is no automatic protection mechanism to check this in the MC_ME.

- Configuration "00" for the FLAON bit field is reserved.
- System clock configurations marked as 'reserved' may not be selected.
- Configuration "1111" for the SYSCLK bit field is allowed only for theTEST mode, and only in this case may all system clock sources be turned off.

warning

If the system clock is stopped during TEST mode, the chip can exit only via a system reset.

66.4.6 Mode Transition Interrupts

The MC_ME provides interrupts for incorrectly configuring a mode, requesting an invalid mode transition, indicating a SAFE mode transition not due to a software request, and indicating when a mode transition has completed.

66.4.6.1 Invalid Mode Configuration Interrupt

Whenever a write operation is attempted to the ME_<mode>_MC registers violating the protection rules mentioned in the Protection of Mode Configuration Registers, the interrupt pending bit I_ICONF of the ME_IS register is set and an interrupt request is generated if the mask bit M_ICONF of the ME_IM register is '1'.

In addition, during a mode transition, if a clock source has been configured in the ME_<target mode>_MC register to be off and a peripheral requiring this clock source to be on has been enabled via the ME_RUN_PC0…7/ME_LP_PC0…7 and ME_PCTLn registers, the interrupt pending bit I_ICONF_CU of the ME_IS register is set and an interrupt request is generated if the mask bit M_ICONF_CU of the ME_IM register is '1'.

If an attempt to write to ME_CADDRn registers is made after a mode change request has been made via the second write to the ME_CTL register and before the completion of that mode transition as indicated by the S_MTRANS bit in the ME_GS register deasserting, the interrupt pending bit I_ICONF_CC of the ME_IS register is set and an interrupt request is generated if the mask bit M_ICONF_CC of the ME_IM register is '1'.

NOTE

In case of illegal clock configuration in low power mode, low power mode entry hangs. The software needs to take care that peripherals enabled in low power mode have their clocks enabled in it.

66.4.6.2 Invalid Mode Transition Interrupt

The mode transition request is considered invalid under the following conditions:

- If the system is in the SAFE mode and the SAFE mode request from MC_RGM is active, and if the target mode requested is other than RESET or SAFE, then this new mode request is considered to be invalid, and the S_SEA bit of the ME_IMTS register is set.
- If the TARGET_MODE bit field of the ME_MCTL register is written with a value different from the specified mode values (i.e., a non-existing mode), an invalid mode transition event is generated. When such a non existing mode is requested, the S_NMA bit of the ME_IMTS register is set. This condition is detected regardless of whether the proper key mechanism is followed while writing the ME_MCTL register.
- If some of the chip modes are disabled as programmed in the ME_ME register, their respective configurations are considered reserved, and any access to the ME_MCTL register with those values results in an invalid mode transition request. When such a disabled mode is requested, the S_DMA bit of the ME_IMTS register is set. This condition is detected regardless of whether the proper key mechanism is followed while writing the ME_MCTL register.
- If the target mode is not a valid mode with respect to the current mode, the mode request illegal status bit S_MRI of the ME_IMTS register is set. This condition is detected only when the proper key mechanism is followed while writing the ME_MCTL register. Otherwise, the write operation is ignored.
- If a new mode request occurs while a mode transition to the SAFE mode is in progress (the S_MTRANS bit of the ME_GS register is '1'), the mode request ignored status bit S_MRIG of the ME_IMTS register is set. This condition is detected only when the proper key mechanism is followed while writing the ME_MCTL register. Otherwise, the write operation is ignored.

Note

As the causes of invalid mode transitions may overlap at the same time, the priority implemented for invalid mode transition status bits of the ME_IMTS register in the order from highest to lowest is S_SEA, S_NMA, S_DMA and S_MRI.

As an exception, the mode transition request is not considered as invalid under the following conditions:

- A new request is allowed to enter the RESET or SAFE mode irrespective of the mode transition status.

- As the exit of HALT0 and STOP0 modes depends on the interrupts of the system which can occur at any instant, these requests to return to RUN0…3 modes are always valid.
- In order to avoid any unwanted lockup of the chip modes, software can abort a mode transition by requesting the parent mode if, for example, the mode transition has not completed after a software determined 'reasonable' amount of time for whatever reason. The parent mode is the chip mode before a valid mode request was made.
- Self-transition requests (e.g., RUN0 → RUN0) are not considered as invalid even when the mode transition process is active (i.e., S_MTRANS is '1'). During the low-power mode exit process, if the system is not able to enter the respective RUN0…3 mode properly (i.e., all status bits of the ME_GS register match with configuration bits in the ME_<mode>_MC register), then software can only request the SAFE or RESET mode. It is not possible to request any other mode or to go back to the low-power mode again.

Whenever an invalid mode request is detected, the interrupt pending bit I_IMODE of the ME_IS register is set, and an interrupt request is generated if the mask bit M_IMODE of the ME_IM register is '1'.

66.4.6.3 SAFE Mode Transition Interrupt

Whenever the system enters the SAFE mode as a result of a SAFE mode request from the MC_RGM due to a hardware failure, the interrupt pending bit I_SAFE of the ME_IS register is set, and an interrupt is generated if the mask bit M_SAFE of ME_IM register is '1' .

The SAFE mode interrupt pending bit can be cleared only when the SAFE mode request is deasserted by the MC_RGM (see the MC_RGM chapter for details on how to clear a SAFE mode request). If the system is already in SAFE mode, any new SAFE mode request by the MC_RGM also sets the interrupt pending bit I_SAFE. However, the SAFE mode interrupt pending bit is not set when the SAFE mode is entered by a software request (i.e., programming of ME_MCTL register).

66.4.6.4 Mode Transition Complete interrupt

Whenever the system fully completes a mode transition (i.e., the S_MTRANS bit of ME_GS register transits from '1' to '0'), the interrupt pending bit I_MTC of the ME_IS register is set, and an interrupt request is generated if the mask bit M_MTC of the ME_IM register is '1'. The interrupt bit I_MTC is not set when entering low-power modes HALT0 and STOP0 in order to avoid the same event requesting the immediate exit of these low-power modes.

66.4.7 Peripheral Clock Gating

During all chip modes, each peripheral can be associated with a particular clock gating policy determined by two groups of peripheral configuration registers.

The run peripheral configuration registers ME_RUN_PC0…7 are chosen only during the software running modes DRUN, TEST, SAFE, and RUN0…3. All configurations are programmable by software according to the needs of the application. Each configuration register contains a mode bit which determines whether or not a peripheral clock is to be gated. Run configuration selection for each peripheral is done by the RUN_CFG bit field of the ME_PCTLn registers.

The low-power peripheral configuration registers ME_LP_PC0…7 are chosen only during the low-power modes HALT0 and STOP0. All configurations are programmable by software according to the needs of the application. Each configuration register contains a mode bit which determines whether or not a peripheral clock is to be gated. Low-power configuration selection for each peripheral is done by the LP_CFG bit field of the ME_PCTLn registers.

Any modifications to the ME_RUN_PC0…7, ME_LP_PC0…7, and ME_PCTLn registers do not affect the clock gating behavior until a new mode transition request is generated.

Whenever the chip enters a debug session during any mode, the following occurs for each peripheral:

- The clock is gated if the DBG_F bit of the associated ME_PCTLn register is set. Otherwise, the peripheral clock gating status depends on the RUN_CFG and LP_CFG bits.

66.4.8 Application Example

The following figure shows an example application flow for requesting a mode change and then waiting until the mode transition has completed.

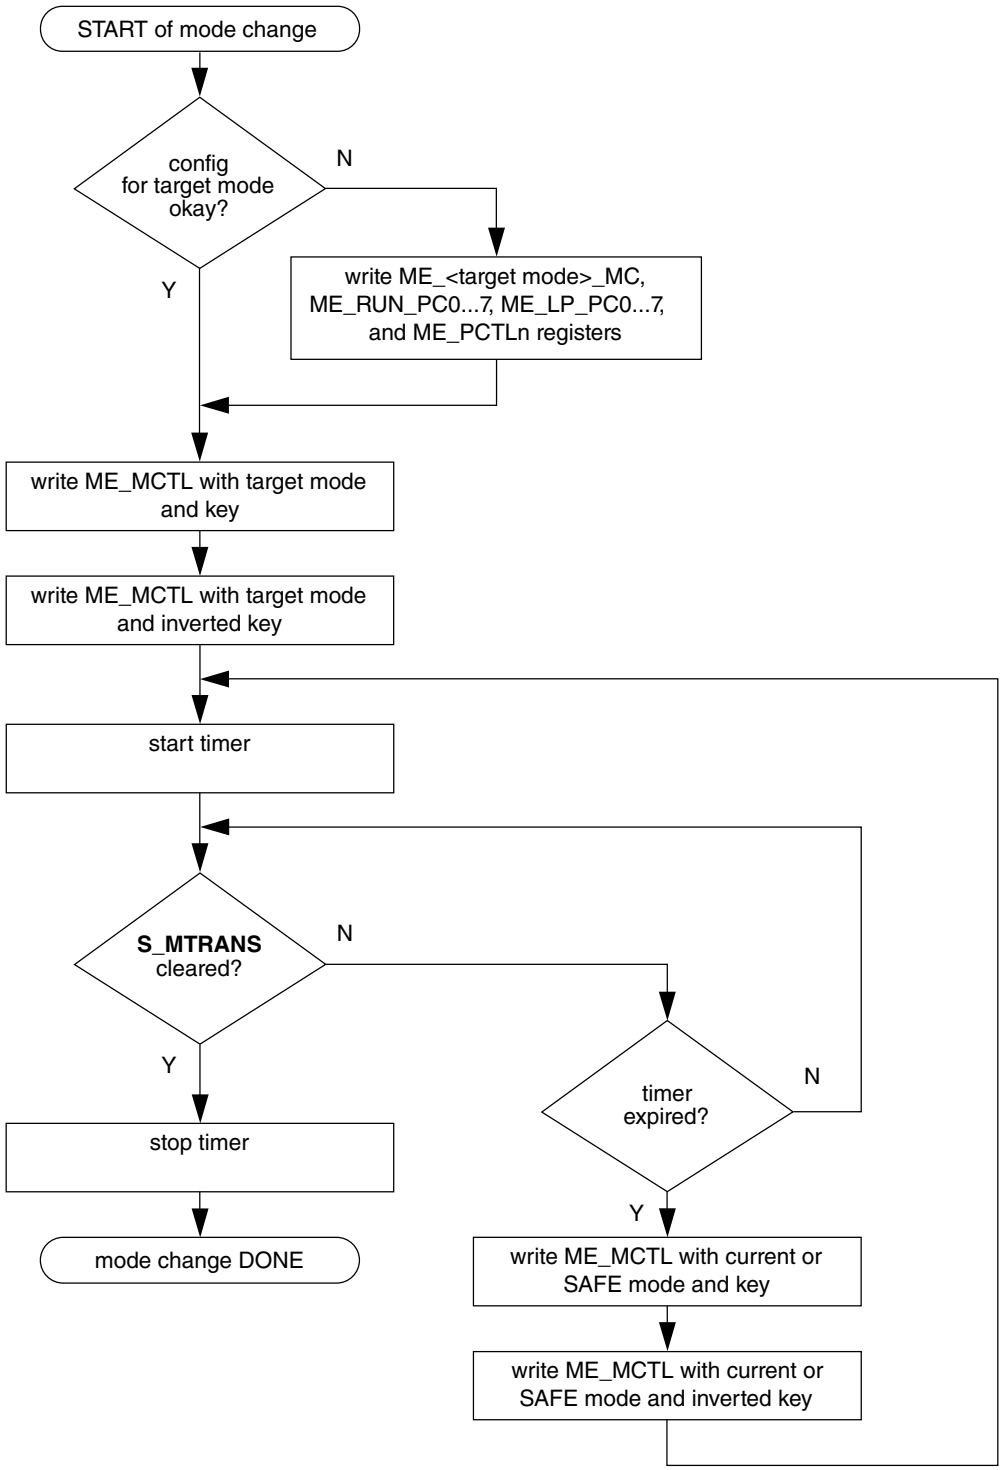

Figure 66-5. MC_ME Application Example Flow Diagram

Chapter 67
Nexus Crossbar Multi-Master Client (NXMC)

67.1 Chip-specific NXMC information

67.1.1 NXMC block connections

To provide Nexus data trace messaging from bus masters on the master ports of the crossbar (XBAR) that do not inherently have a trace client, a Nexus Crossbar Multi-Master Client (NXMC) monitors traffic into the master port of the XBAR. Trace messages transmitted over the Nexus interface (or stored in trace memory) include which NXMC generated the message as well as an identifier for the pre-concentrator source of the message.

The following figure shows a block diagram illustrating the NXMC integration.

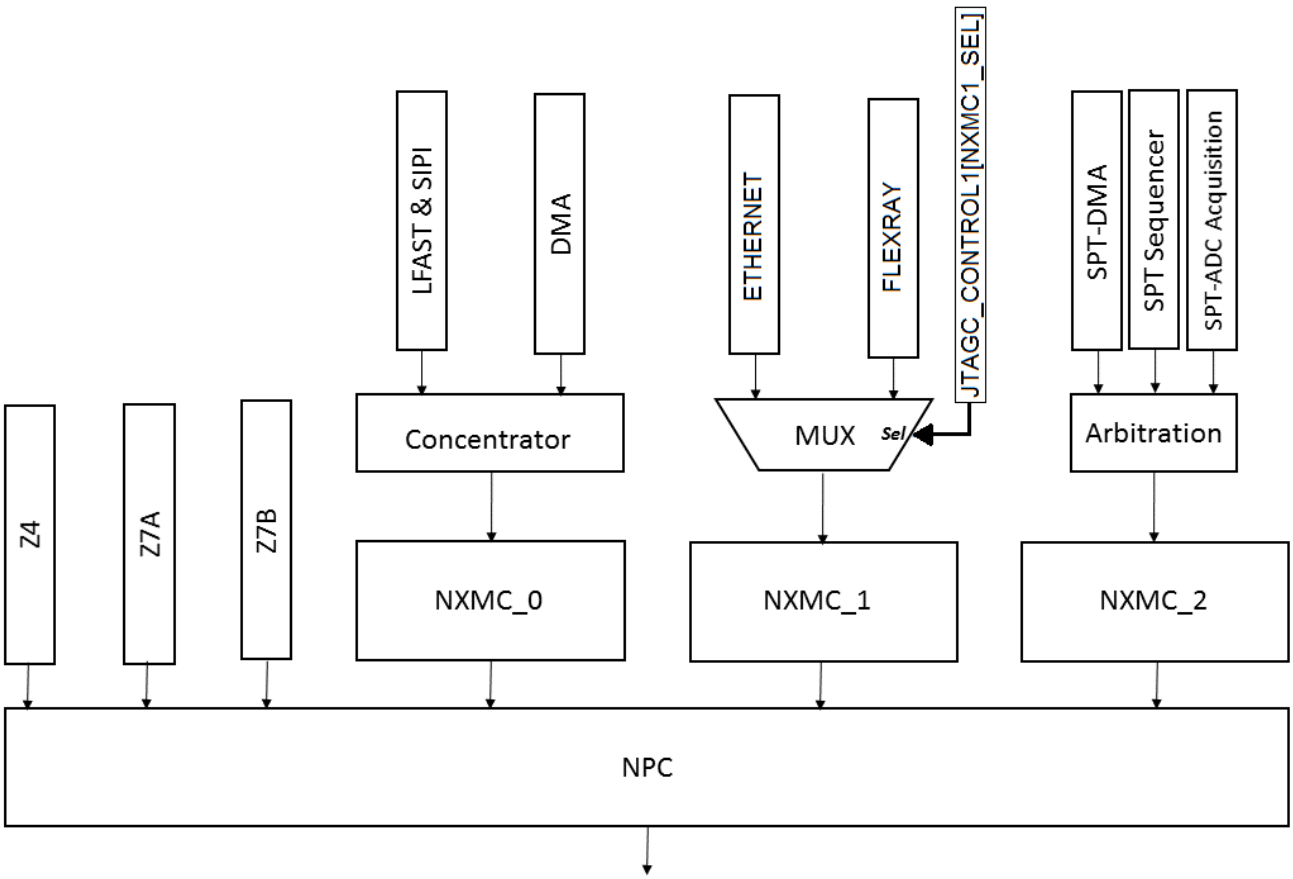

Figure 67-1. NXMC integration block diagram

The values of the trace master ID or in-circuit client ID, along with the Nexus message source identifier for the different clients are shown in the following table.

Table 67-1. NXMC source and master client IDs

Nexus Client	Trace Master	Nexus trace source ID (SRC)	Trace master ID or In-circuit trace client ID (MASTER)
NXMC0	DMA	0b1100	0b0010
	SIPI/LFAST		0b0100
NXMC1	FlexRay	0b1101	0b0011
	Ethernet		0b0101
NXMC2	SPT-DMA (PDMA)	0b1110	0b0110
	SPT-MIPICSI2 Acquisition (bypass SDMA)		0b1010[1]
	SPT-Sequencer (Command Sequencer DMA)		0b1101
	SPT-ADC/MIPICSI2-Acquisition(Main SDMA)		0b1110[1]

1. See SPT_SDMA_CTRL1[HMASTER_ENC_DIS] for control of Nexus trace MASTER ID for SPT-ADC-Acquisition (SDMA). This register field controls the trace master id contain in the MID field of the Nexus message. The NXMC2 either sends the SPT-ADC-Acquisition ID or it sends an SD ADC identifier depending on the HMASTER_ENC_DIS setting.

67.1.2 Avoiding trace overflows

For preventing the trace overflows the following configurations can be programmed.

- DMA – FIFO watermark level(MCB_NPC_SPECIAL_ENABLE.WATERMARK[3:0]), NPC NAL FIFO EXTENSION_MODE, DMA Bandwidth Control (DMA_TCDn_CSR.BWC[1:0]).
- SPT – FIFO watermark level, NPC NAL FIFO EXTENSION_MODE, SPT Throttle Control (MCB_MISC2.SPT_NEXUS_THROTTLE_CONTROL) and NXMC_2_FIFO_EN.
- All other masters - FIFO watermark level, NPC NAL FIFO EXTENSION_MODE.

The FIFO watermark level can be used to throttle trace from various nexus sources inside chip. Its default value is 0x3 and can be programmed maximum upto 0x7. On increasing the value from 0x3 to 0x7, it is seen that the fifo-full error messages in traces are decreased.

In the NPC NAL FIFO EXTENSION_MODE, the FIFO mentioned above can be extended to be 0xF deep. Please follow the guidelines in register description of MCB_NPC_SPECIAL_ENABLE[NPC_NAL_FIFO_EXTENSION_MODE], when using this mode. Trace overflows will be further reduced when using this mode.

For DMA, in the TCD, a BWC field can be programmed, which puts empty cycles between DMA transfers, thereby reducing the throughput and chances of trace overflows.

For SPT, SPT_NEXUS_THROTTLE_CONTROL can be programmed. Making this value ‘0’, will cause SPT to give full-performance. Increasing this value, will decrease the SPT traffic throughput. So, the NXMC-fifo-overflows in case of SPT can also be managed by this configuration. In addition to this, the SPT also takes NXMC-fifo-watermark-level into consideration. SPT traffic is stalled when this watermark level crosses half-full threshold. SPT traffic restarts once the watermark level comes below the half-full threshold mark. Since the SPT is taking NXMC-fifo-watermark-level into consideration, any stall in the trace path will stall the SPT traffic as well. If 'Aurora clock' limitation documented in System clock frequency limitations is not met ,then NAL-fifo stall will happen which will cause NXMC2-fifo to stall and that in turn will cause SPT operation to stall.

While tracing SPT, NXMC_2_FIFO can be enabled by programming MCB_MISC2[NXMC_2_FIFO_EN]. This FIFO between SPT and NXMC can handle intermittent bursts of data, but if the amount of data traced is very large (for eg, if both CSDMA and PDMA traces are enabled at full throughput) then this FIFO will show overflow (MCB_NEX_FIFO_STATUS[31])

67.1.3 Nexus Message Timestamp

The Nexus message TSTAMP field is a timestamp value provided by a counter clocked by SYS_CLK. Trace messages generated by the e200z420 core and e200z760 cores capture a 30-bit timestamp from the counter. Trace masters that interface through a Nexus Crossbar Multi-Master Client module (LFAST/SIPI, DMA, ENET, FlexRay, SPT-PDMA, SPT Command Sequencer, SPT-SDMA) capture a 16-bit timestamp value from this counter. Thus, the timestamp for these trace masters will roll-over to zero before the timestamps from e200zx core trace masters.

67.2 Introduction

The Nexus Crossbar Multi-master Client (NXMC) module provides real-time trace capabilities in compliance with the IEEE-ISTO Nexus 5001-2012 standard. This module provides development support capabilities for devices without requiring address and data pins for internal visibility. A portion of the pin interface is also compliant with the IEEE 1149.1 JTAG standard. The IEEE-ISTO 5001 standard defines an extensible auxiliary port which is used in conjunction with the JTAG port.

Many bus masters start accesses to internal address locations via the system bus. The NXMC module monitors the system bus and provides real-time trace information to debug or development tools.

67.2.1 Features

The NXMC module is compliant with the IEEE-ISTO 5001-2012 standard. The following features are implemented:

- Data trace via Data Write Messaging (DWM) and Data Read Messaging (DRM). This provides the capability for the development tool to trace reads and/or writes to (selected) internal memory resources.
- Multi-master tracing capability for multiple master accesses
- Watchpoint messaging based on internal/external triggers, via the auxiliary pins
- Watchpoint trigger events out based on internal/external triggers
- Watchpoint trigger enable of data trace messaging
- Start or stop of Tracing (Data Trace, Watchpoint Trace) based on internal triggers.
- Nexus Auxiliary port for higher data throughput
  - One $\overline{\text{EVTO}}$ (Watchpoint Event) pin
  - One $\overline{\text{EVTI}}$ (Event In) pin

- Registers for data trace, watchpoint generation, and watchpoint trigger
- All features controllable and configurable via the JTAG port

67.3 External signal description

This section details information regarding the standard ports and protocol. The NXMC pin interface provides the function of transmitting messages from the messages queues to NPC. It is also responsible for handshaking with the message queues.

The NXMC module implements the following signals:

- One $\overline{\text{EVTI}}$
- One $\overline{\text{EVTO}}$

These pins are described in Table 67-3.

All NXMC input functionality is controlled through the JTAG port in compliance with IEEE 1149.1 (see IEEE 1149.1 (JTAG) Test Access Port for details). A separate JTAG TAP controller is instantiated within the NXMC. The following table describes the JTAG pins.

Table 67-2. JTAG pins for NXMC

JTAG port	Input/ output	Description
TDO	O	The Test Data Output (TDO) pin is the serial output for test instructions and data. TDO is three-stateable and is actively driven in the shift-IR and shift-DR controller states. TDO changes on the falling edge of TCK.
TDI	I	The Test Data Input (TDI) pin receives serial test instruction and data. TDI is sampled on the rising edge of TCK and has an internal pull-up resistor.
TMS	I	The Test Mode Select (TMS) input pin is used to sequence the JTAG test controllers' state machine. TMS is sampled on the rising edge of TCK and has an internal pull-up resistor.
TCK	I	The Test Clock (TCK) input pin is used to synchronize the test logic, and control register access through the JTAG port.
TRST	I	The Test Reset ($\overline{\text{TRST}}$) input pin is used to asynchronously initialize the JTAG controller. The $\overline{\text{TRST}}$ pin has an internal pull-down resistor.

Table 67-3. NXMC Auxiliary pins

Auxiliary port	Input/ output	Description
EVTO	O	Event Out ($\overline{\text{EVTO}}$) is an output which, when asserted, indicates one of two events has occurred based on the EOC bits in the DC Register: • one of the internal or external watchpoints has occurred and EOC = 2'b00 • system-level debug mode was entered (ipg_debug) and EOC = 2'b01

Table continues on the next page...

Table 67-3. NXMC Auxiliary pins (continued)

Auxiliary port	Input/ output	Description
		$\overline{\text{EVTO}}$ is held asserted for one cycle.
EVTI	I	Event In ($\overline{\text{EVTI}}$) is an input which initiates synchronization messages. If the Nexus module is enabled at reset, (see Enabling NXMC operation), assertion initiates data trace synchronization messages (provided data trace is enabled).

67.4 Supported messages and TCODEs

The NXMC pins allow for flexible transfer operations via public messages. A TCODE defines the transfer format, the number and/or size of the packets to be transferred, and the purpose of each packet. The IEEE-ISTO 5001-2012 standard defines a set of public messages. The NXMC block supports the public TCODEs listed in the following table. The SRC and MASTER field values are described in the device-specific chapter that describes how the modules are configured.

Table 67-4. Supported public TCODEs

Message name	Min packet size (bits)	Max packet size (bits)	Packet name	Packet type	Packet description
Data Trace - Data Write Message	6	6	TCODE	fixed	TCODE number = 58
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (See Table 67-5)
	1	32	U-ADDR	variable	Unique portion of the data write address
	8	64	DATA	fixed	Data write value (size fixed based on DSZ field)
Data Trace - Data Read Message	6	6	TCODE	fixed	TCODE number = 59
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (See Table 67-5)
	1	32	U-ADDR	variable	Unique portion of the data read address
	8	64	DATA	fixed	Data read value (size fixed based on DSZ field)
Error Message	6	6	TCODE	fixed	TCODE number = 8
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	ETYPE	fixed	Error type (See Table 67-6)

Table continues on the next page...

Table 67-4. Supported public TCODEs (continued)

Message name	Min packet size (bits)	Max packet size (bits)	Packet name	Packet type	Packet description
	14	14	ECODE	fixed	Error code (See Table 67-7)
Data Trace - Data Write Message w/ Sync	6	6	TCODE	fixed	TCODE number = 60
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (See Table 67-5)
	1	32	F-ADDR	variable	Full access address (leading zero (0) truncated)
	8	64	DATA	fixed	Data write value (size fixed based on DSZ field)
Data Trace - Data Read Message w/ Sync	6	6	TCODE	fixed	TCODE number = 61
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (See Table 67-5)
	1	32	F-ADDR	variable	Full access address (leading zero (0) truncated)
	8	64	DATA	fixed	Data read value (size fixed based on DSZ field)
Watchpoint Message	6	6	TCODE	fixed	TCODE number = 15
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	1	8	WPHIT	variable	Watchpoint source(s) number (See Table 67-23)

Table 67-5. Data trace size (DSZ) encodings (TCODE = 58, 59, 60, 61)

DSZ	Transfer size
001	8-bit
010	16-bit
011	32-bit
100	64-bit
000, 101-111	Reserved

Table 67-6. Error Type (ETYPE) encodings (applicable to all error messages)

ETYPE	Description
0000	Queue overrun caused message (one or more) to be lost
0001	Contention with higher priority message caused message(s) to be lost

Table continues on the next page...

Table 67-6. Error Type (ETYPE) encodings (applicable to all error messages) (continued)

ETYPE	Description
0010	Reserved
0011	Reserved
0100	Reserved
0101	Invalid access opcode (Nexus register unimplemented)
0110–1111	Reserved

Table 67-7. Error Code (ECODE) encodings (applicable based on error source)

ECODE		Description[1]
13 to 8	7 to 0	
Source (SRC)		
000000	XXXXXXX1	Watchpoint Message(s) lost
000000	XXXXXX1X	Data Trace Message(s) lost

CKSRCn	1XXXXXXX	Reserved

1. The SRC field values are described in the device-specific chapter that describes how the modules are configured.

67.5 Register description

This section describes the NXMC register definition. Nexus registers are accessed using the JTAG port in compliance with IEEE 1149.1. See IEEE 1149.1 (JTAG) Test Access Port for details. The complete list of registers is shown in this table.

Table 67-8. NXMC registers

Nexus register	Nexus access opcode (hex)	Read/ write	Read address (hex)	Write address (hex)
Development Control 1 (DC1)	2	R/W	04	05
Development Control 2 (DC2)	3	R/W	06	07
Watchpoint Trigger (WT)	B	R/W	16	17
Data Trace Control (DTC)	D	R/W	1A	1B
Data Trace Start Address1 (DTSA1)	E	R/W	1C	1D
Data Trace Start Address2 (DTSA2)	F	R/W	1E	1F
Data Trace End Address1 (DTEA1)	12	R/W	24	25
Data Trace End Address2 (DTEA2)	13	R/W	26	27
Breakpoint/Watchpoint Control Register1 (BWC1)	16	R/W	2C	2D
Breakpoint/Watchpoint Control Register2 (BWC2)	17	R/W	2E	2F
Breakpoint/Watchpoint Address Register1 (BWA1)	1E	R/W	3C	3D
Breakpoint/Watchpoint Address Register2 (BWA2)	1F	R/W	3E	3F

67.5.1 Development control register 1 (DC1)

The Development Control Registers control the basic development features of the NXMC module. This table shows the format of the DC1.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

23:1	Reserved for future functionality (read as 0)	
0	Reserved for future functionality (Read/Write – default values must not be changed for normal operation)	

1. The EOC bits in DC1 must be programmed to trigger EVTO on watchpoint occurrence for the EWC bits to have any effect.

67.5.3 Watchpoint trigger register (WT)

The Watchpoint Trigger Register allows the watchpoints defined either internally to the NXMC module or by an external module to trigger actions. These watchpoints can control data trace enable and disable.

The WT bits can be used to produce an address related window for triggering trace messages. This table shows the format of the WT register.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

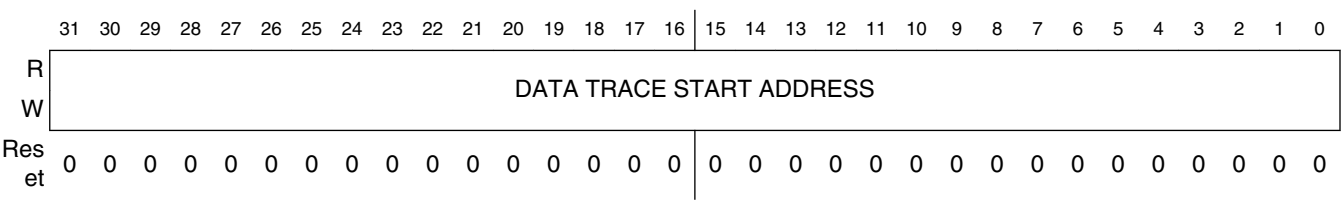
23:20	Reserved for future functionality
19:16 MID	ID of the system bus Master to be traced[1]
15:8	Reserved for future functionality
7 RC1	Range Control 1. 0 Condition trace on address within range (endpoints inclusive) 1 Condition trace on address outside of range (endpoints exclusive)
6 RC2	Range Control 2. 0 Condition trace on address within range (endpoints inclusive) 1 Condition trace on address outside of range (endpoints exclusive)
5:0	Reserved for future functionality

1. The MASTER field values are described in the device-specific chapter that describes how the modules are configured.

67.5.5 Data trace start address registers 1 and 2 (DTSA1 and DTSA2)

The Data Trace Start Address Registers define the start addresses for each trace channel. This table shows the format of the DTSA1 and DTSA2 registers.



67.5.6 Data trace end address registers 1 and 2 (DTEA1 and DTEA2)

The Data Trace End Address Registers define the end addresses for each Trace channel. This table shows the format of the DTEA1 and DTEA2 registers.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DATA TRACE END ADDRESS																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This table illustrates the range that are selected for data trace for various cases of DTSA being less than, greater than, or equal to DTEA.

Table 67-13. Data trace address range options

Programmed values	Range control bit value	Range selected
DTSA ≤ DTEA	0	DTSA -> <- DTEA
DTSA ≤ DTEA	1	<- DTSA DTEA ->
DTSA > DTEA	N/A	Invalid range—no trace

Note

DTSA must be less than (or equal to) DTEA in order to guarantee correct data write/read traces.

When the range control bit is 0 (internal range), accesses to DTSA and DTEA addresses are traced. When the range control bit is 1 (external range), accesses to DTSA and DTEA are not traced.

67.5.7 Breakpoint/watchpoint control register 1 (BWC1)

Breakpoint/watchpoint control register 1 controls the attributes for generation of NXMC watchpoint#1. This table shows the format of the BWC1 register.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	BWE1		BRW1		0	0	0	0	0	0	0	0	0	0	BWR1		BWT1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

67.5.9 Breakpoint/watchpoint address registers 1 and 2 (BWA1 and BWA2)

The Breakpoint/Watchpoint Address Registers are compared with system bus addresses in order to generate internal watchpoints. This table shows the format of the BWA1 and BWA2 registers.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	BREAKPOINT / WATCHPOINT ADDRESS																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

67.5.10 Unimplemented registers

Unimplemented registers are those with client select and index value combinations other than those listed in Table 67-8. For unimplemented registers, the NXMC module drives TDO to zero during the SHIFT-DR state. It also transmits an error message with the invalid access opcode encoding (ETYPE = 0101).

67.6 Programming considerations (RESET)

If NXMC register configuration is to occur during system reset (as opposed to debug mode), all NXMC configuration should be completed between the negation of $\overline{\text{TRST}}$ and system reset de-assertion. The JTAG ID register should be read by the tool after negation of $\overline{\text{TRST}}$ and should be programmed before deassertion of system reset.

67.6.1 IEEE 1149.1 (JTAG) Test Access Port

The NXMC module uses the IEEE 1149.1 TAP controller for accessing Nexus resources. The JTAG signals themselves are shared by all TAP controllers on the device. The NXMC module implements a 4-bit Instruction Register (IR). The valid instructions and method for register access are outlined in NXMC register access via JTAG.

67.6.2 Enabling NXMC operation

The Nexus module is enabled by loading a single instruction into the JTAG Instruction Register (IR). Once enabled, the module is ready to accept control input via the JTAG pins.

The Nexus module is disabled when the JTAG state machine reaches the Test-Logic-Reset state. This state can be reached by the assertion of the $\overline{\text{TRST}}$ pin or by cycling through the state machine using the TMS pin. The Nexus module is also disabled if a Power-on-Reset (POR) event occurs.

If the NXMC module is disabled, no trace output is provided. Nexus registers are not available for reads or writes.

67.6.3 Enabling NXMC TAP controller

Assertion of a Power-on-Reset signal or assertion of the $\overline{\text{TRST}}$ pin resets all TAP controllers. Upon exit from the Test-Logic-Reset state, the IR value is loaded with the JTAG ID. When the NXMC TAP is accessed, this information helps the development tool obtain information about the Nexus module it is accessing, such as version, sequence, feature set, etc.

67.6.4 NXMC register access via JTAG

Access to Nexus register resources is enabled by loading a single instruction into the JTAG Instruction Register (IR).

Once the JTAG NEXUS-ACCESS instruction has been loaded, the JTAG port allows tool/target communications with all Nexus registers according to the map in Table 67-8.

Reading/writing of a Nexus register then requires two passes through the Data-Scan (DR) path of the JTAG state machine.

1. The first pass through the DR selects the Nexus register to be accessed by providing an index (see Table 67-8), and the direction (read/write). This is achieved by loading an 8-bit value into the JTAG Data Register (DR). This register has the format shown below.

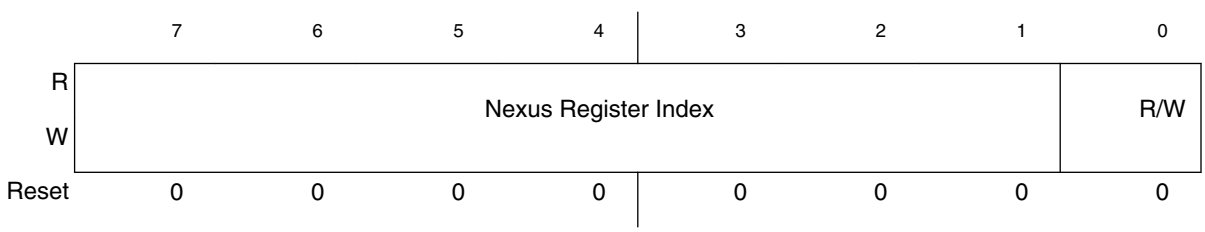

Table 67-16. JTAG DR field description for Nexus register access

Field	Description
Nexus Register Index	Selected from values in Table 67-8
Read/Write (R/W)	0 Read 1 Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.

a. During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the Capture-DR state.

b. During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the Update-DR state.

67.7 Functional description

The following sections describe the functionality of the NXMC module.

67.7.1 Data trace

This section describes the data trace mechanism supported by the NXMC module. Data trace is implemented via Data Write Messaging (DWM) and Data Read Messaging (DRM), as per the IEEE-ISTO 5001-2012 standard.

67.7.1.1 Data trace messaging (DTM)

NXMC data trace messaging is accomplished by snooping the system bus and storing the information for qualifying accesses (based on enabled features and matching target addresses). The NXMC module traces all data access that meet the selected range and attributes.

67.7.1.2 DTM message formats

The NXMC block supports five types of DTM messages:

- Data write
- Data read
- Data write synchronization
- Data read synchronization
- Error messages

67.7.1.2.1 Data write and data read messages

The data write and data read messages contain the data write/read value and the address of the write/read access, relative to the previous data trace message. The DATA field is considered fixed based on the DSZ encodings to either 8, 16, 32 , 64. Data write message and data read message information is messaged out in the format shown in the following figure. The SRC field values are described in the device-specific chapter that describes how the modules are configured.

Table 67-17. DTM message format for DATA width = 64 bits

8/16/32/64 bits	1–32 bits	3 bits	4 bits	4 bits	6 bits
DATA	U-ADDR	DSZ	MASTER	SRC	TCODE (111010 or 111011)

67.7.1.2.2 Data trace with non-contiguous byte strobes asserted

The v6 extensions to AMBA 2.0 allow system bus transfers with bytes non-asserted byte strobes in between asserted byte strobes. The NXMC does not support transfers with non-contiguous byte strobes asserted. In such a condition, the invalid bytes in the DATA packet are driven to the value of 0xFF.

67.7.1.2.3 DTM overflow error messages

An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards incoming messages until it has completely emptied the queue. Once emptied, an error message is queued. The error encoding indicates which type(s) of messages attempted to be queued while the FIFO was being emptied.

If only a data trace message attempts to enter the queue while it is being emptied, the error message incorporates the data trace only error encoding (ECODE = 00000000000010). If a watchpoint also attempts to be queued while the FIFO is being emptied, then the error message incorporates error encoding (ECODE = 00000000000011).

Error information is messaged out in the format shown in this figure. The SRC field values are described in the device-specific chapter that describes how the modules are configured.

Table 67-18. DTM error message format (fixed length = 28 bits)

14 bits	4 bits	4 bits	6 bits
ECODE	ETYPE	SRC	TCODE (001000)

NOTE

The internal queue FIFO is very small. This causes FIFO overflows whenever Trace is enabled on any of the AHB clients and the AHB master module generates >4 burst accesses. If the customer is experiencing a lot of overflow error messages the amount of data snooped by the NXMC should be reduced.

67.7.1.2.4 Data trace synchronization messages

A data trace write/read with synchronization message is messaged via the auxiliary port (provided data trace is enabled) for the following conditions (see Table 67-20):

- Initial data trace message upon exit from system reset or whenever data trace is enabled is a synchronization message.
- Upon returning from a low power state, the first data trace message is a synchronization message.
- Upon returning from debug mode, the first data trace message is a synchronization message.
- After occurrence of queue overrun (can be caused by any trace message), the first data trace message is a synchronization message.
- After the periodic data trace counter has expired indicating 255 without-sync data trace messages have occurred since the last with-sync message occurred.
- Upon assertion of the event in (EVTI) pin, the first data trace message is a synchronization message if the EIC bits of the DC Register have enabled this feature.
- Upon data trace write/read after the previous DTM Message was lost due to a collision while entering the FIFO between the DTM message and any of the following: error message, or watchpoint message or peripheral message. This is a very rare occurrence and possible only in case of continuous burst on the system bus as well as watchpoint events which is unrealistic.

Data trace synchronization messages provide the full address (without leading zeros) and ensure that development tools fully synchronize with data trace regularly. Synchronization messages provide a reference address for subsequent DTMs, in which only the unique portion of the data trace address is transmitted. The format for data trace write/read with synchronization messages is shown in the following figure. The SRC and MASTER field values are described in the device-specific chapter that describes how the modules are configured.

Table 67-19. Data write/read with synchronization message format

8-64 bits	1–32 bits	3 bits	4 bits	4 bits	6 bits
DATA	F-ADDR	DSZ	MASTER	SRC	TCODE (111100 or 111101)

Exception conditions that result in data trace synchronization are summarized in this table.

Table 67-20. Data trace exception summary

Exception condition	Exception handling
System Reset Negation	At the negation of JTAG reset ($\overline{\text{TRST}}$), queue pointers, counters, state machines, and registers within the NXMC module are reset. If data trace is enabled, the first data trace message is a data write/read with synchronization message.
Data Trace Enabled	The first data trace message (after data trace has been enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a low power mode or debug mode the next data trace message is converted to a data write/read with synchronization message.
Queue Overrun	An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards messages until it has completely emptied the queue. Once emptied, an error message is queued. The error encoding indicates which type(s) of messages attempted to be queued while the FIFO was being emptied. The next DTM message in the queue is a data write/read with synchronization message.
Periodic Data Trace Synchronization	A forced synchronization occurs periodically after 255 data trace messages have been queued. A data write/read with synchronization message is queued. The periodic data trace message counter then resets.
Event In	If the Nexus module is enabled, an $\overline{\text{EVTI}}$ assertion initiates a data write/read with synchronization message upon the next data write/read (if data trace is enabled and the EIC bits of the DC Register have enabled this feature).
Collision Priority	All messages have the following priority: Error > WPM > DTM. Although a very rare occurrence, during simultaneous burst lower priority messages can be lost due to burst of high priority messages. Proper error messages are generated and in case of DTM lost a subsequent read/write queues a data write/read with synchronization message.

67.7.1.3 Enabling data trace messaging operation

Data trace messaging can be enabled in one of three ways:

- Setting the TM field of the DC Register via JTAG to enable data trace (DC[1]).

- Using the DTS field of the WT Register to enable data trace on watchpoint hits (either watchpoints configured within the NXMC module or external watchpoint inputs controlled by the device).
- By toggling the external start control, which in turn sets the TM field of the DC register to enable data trace. (The TM bit clears and hence the data tracing stops on the toggle of external stop control. In case of conflict between JTAG write and external start/stop control, JTAG write takes precedence.

Note

When enabling the DTM, either via JTAG or external start/stop control, it is important to make sure that all the other controls (i.e. DTC, DTSA/E1/2 and WT register fields) are correctly configured to ensure correct DTM functionality.

67.7.1.4 DTM queueing

The NXMC implements a programmable depth queue for queuing all messages. Messages that enter the queue are transmitted via the auxiliary pins in the order in which they are queued.

Note

If multiple trace messages need to be queued at the same time, watchpoint messages have the highest priority (WPM > DTM).

67.7.1.5 Relative addressing

The relative address feature is compliant with IEEE-ISTO 5001-2012 and is designed to reduce the number of bits transmitted for addresses of data trace messages. The address transmitted is relative to the address of the previous data trace message. It is generated by XORing the new address with the previous address, and then using only the results up to the most significant 1 in the result. To recreate this address, an XOR of the (most-significant 0-padded) message address with the previously decoded address gives the current address.

For example, if the previous address (A1) = 0x0003FC01, the new address (A2) = 0x0003F365 as shown in this figure.

Message Generation:

A1 = 0000 0000 0000 0011 1111 1100 0000 0001
A2 = 0000 0000 0000 0011 1111 0011 0110 0101

A1 ⊕ A2 = 0000 0000 0000 0000 0000 1111 0110 0100

Address Message (M1) = 1111 0110 0100

Address Re-creation:

A1 ⊕ M1 = A2
A1 = 0000 0000 0000 0011 1111 1100 0000 0001
M1 = 0000 0000 0000 0000 0000 1111 0110 0100

A2 = 0000 0000 0000 0011 1111 0011 0110 0101

Figure 67-2. Relative addressing example

67.7.1.6 Data trace windowing

Data write/read messages are enabled via the RWT1(2) field in the Data Trace Control Register (DTC) for each DTM channel. Data trace windowing is achieved via the address range defined by the DTEA and DTSA Registers and by the RC1(2) field in the DTC. All system bus DMA initiated read/write accesses which fall inside or outside these address ranges, as programmed, are candidates to be traced.

67.7.1.7 System bus cycle special cases

The system bus cycle special cases are shown in this table.

Table 67-21. System Bus cycle special cases

Special case	Action
System bus cycle with data error	Data trace message discarded
System bus cycle completed without error	Cycle captured and transmitted
System bus cycle is an instruction fetch	Cycle ignored

67.7.1.8 System bus multi-master tracing

DTM tracing can be done either for all the masters or for a single master (indicated by the MID field of the DTC register) based on the DTC register MME field. In case of single master, the correct value needs to be configured in the MID register before enabling the data trace operation.

The MASTER field of the DTM message (see figure in Data write and data read messages for an example) indicates the system bus master for which the trace has been generated. For each masters (0 to 15) there is a parameter associated (MSID0-15) for indicating its actual ID, which finally gets inserted in the MASTER field. The MASTER field values are described in the device-specific chapter that describes how the modules are configured.

67.7.2 Watchpoint support

The NXMC module provides watchpoint messaging via the auxiliary pins, as defined by IEEE-ISTO 5001-2012. Watchpoint messages can be generated by either using the NXMC defined internal watchpoints or by externally defined watchpoint signals.

67.7.2.1 Watchpoint messaging

Enabling watchpoint messaging is accomplished by setting the WEN bit in the DC Register. This bit is set either via JTAG write 1 access or external start indication, and cleared via JTAG write 0 access or external start indication. In case of conflict between JTAG write and external start/stop control, JTAG write takes precedence.

Note

In case of enabling the watchpoint messaging, either via JTAG or external start/stop control, it is important to make sure that all the other Watch Point Message (WPM) controls (i.e. BWC1/2, BWA1/2 register fields) are configured with the correct values in order to ensure correct WPM operation.

Watchpoint setting is supported through two methods:

- Internal watchpoints—Using the BWC1(2) registers, two independently controlled internal watchpoints can be initialized. When a system bus access address matches on BWA1(2), a watchpoint message is transmitted. The system bus multi-master or single master controls applies here too as explained for DTM (in System bus multi-master tracing).
- External watchpoints—The NXMC module supports two external watchpoint inputs. The optional logic to generate these watchpoint signals is implemented at the device level. The watchpoints are described in the device-specific chapter that describes how the modules are configured. If either of these signals asserts (i.e, on 0-to-1 transition), a watchpoint message is transmitted.

The Nexus module provides watchpoint messaging using the IEEE-ISTO 5001 defined TCODE. When any of the four possible watchpoint sources asserts, a message is sent to the queue to be messaged out. This message indicates the watchpoint number as shown in Table 67-22 and Table 67-23.

Table 67-22. Watchpoint message format (fixed length = 18 bits)

8 bits	4 bits	6 bits
WPHIT (RRRRXXXX)	SRC	TCODE (001111)

Table 67-23. Watchpoint source description

Watchpoint source (8-bits)	Watchpoint description
RRRRXXX1[1]	External Watchpoint #1(device defined)
RRRRXX1X	External Watchpoint #2 (device defined)
RRRRX1XX	Internal Watchpoint #1 (BWA1 match)
RRRR1XXX	Internal Watchpoint #2 (BWA2 match)

1. R = reserved for future use (insert 0s).

67.7.2.2 Watchpoint error message

An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards messages until it has completely emptied the queue. Once emptied, an error message is queued. The error encoding indicates which type(s) of messages attempted to be queued while the FIFO was being emptied.

If only a watchpoint message attempts to enter the queue while it is being emptied, the error message incorporates the watchpoint only error encoding (ECODE = 00000000000001). If a data trace message also attempts to enter the queue while it is being emptied, the error message incorporates error encoding (00000000000011). Error information is messaged out in the format shown in this figure.

Table 67-24. Error message format (fixed length = 28 bits)

14 bits	4 bits	4 bits	6 bits
ECODE	ETYPE	SRC	TCODE (001000)

Chapter 68
Nexus Port Controller (NPC)

68.1 Chip-specific NPC information

68.1.1 EVTO sharing - Pulse time

In this device, whenever a Nexus client drives EVTO input of NPC for one SYS_CLK period, the NPC drives EVTO on pad for one SYS_CLK period on the following clock.

68.1.2 Trace messages for transactions with error responses

For transactions of trace clients which result in error responses, traces may or may not be generated. Such transactions will be reported to MEMU.

The Nexus clients in this device do not perform speculative execution. When speculative execution is done, a trace message may be output before it is known whether the branch was actually taken. Since the Nexus clients in this device do not support it, the CANCEL field is not present in the trace messages of this device.

68.1.3 Trace loss during resets

NOTE

Whenever reset occurs (reset which breaks debugger trace connection) and nexus tracing is ON, debug trace data stored in internal fifo corresponding to instructions executed before reset instruction will be lost.

68.1.4 EVTI_IN pin

EVTI_IN is an active low signal. The NPC Port Configuration Register's EVT_EN bit configures the EVTI_IN and EVTO_B pins for EVTI/EVTO port functionality. If it is chosen by the user to not use this configuration and to use the SIUL_MSCR configuration register for this purpose, then it is recommended that the user also sets the PUE and PUS bits to 1 along with setting the IBE and SSS configurations. Otherwise, a 0 event may be seen in EVTI_IN which will trigger the EVTI functions in chip.

68.2 Introduction

The following figure is a block diagram of the Nexus Port Controller (NPC) block.

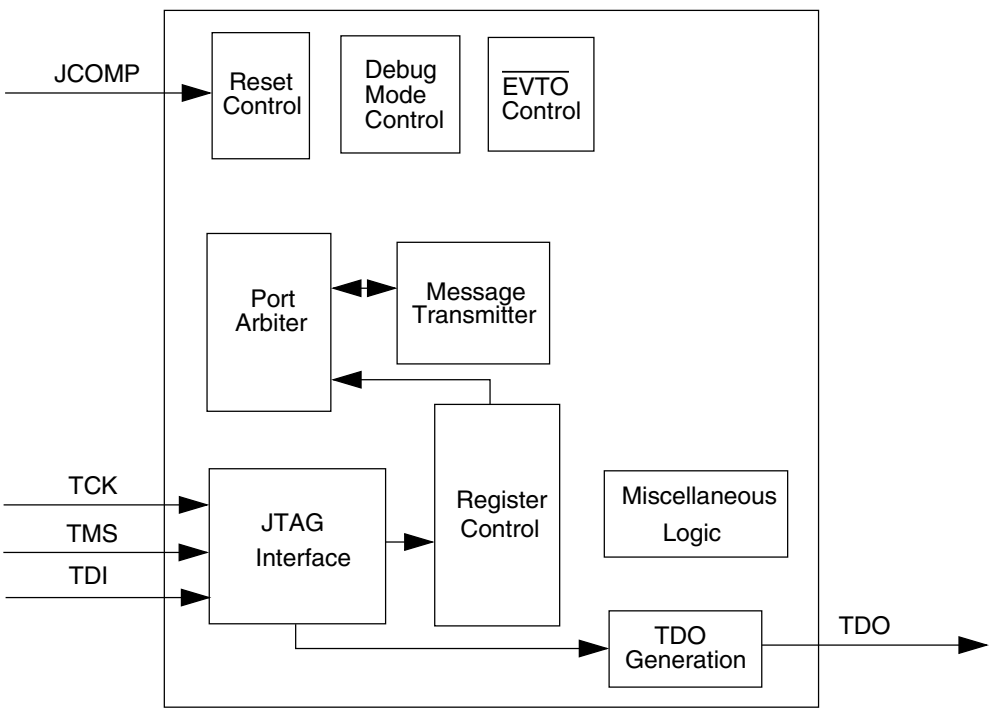

Figure 68-1. Nexus Port Controller Block Diagram

68.2.1 Overview

On a system-on-a-chip device, there are often multiple blocks that require development support. Each of these blocks implements a development interface based on the IEEE-ISTO 5001-2001 standard. The blocks share input and output ports that interface with the

development tool. The NPC controls the usage of the input and output port in a manner that allows all the individual development interface blocks to share the port, and appear to the development tool to be a single block.

68.2.2 Features

The NPC block performs the following functions:

- Nexus Device Identification Register and Messaging
- Generates MCKO enable and frequency division control signals
- Controls sharing of $\overline{\text{EVTO}}$
- Control of the device-wide debug mode
- Generates asynchronous reset signal for Nexus blocks based on JCOMP input, and power-on reset status
- Selectable mode for transmission of processor status information on MDO Auxiliary Output Port pins
- Controls arbitration for ownership of the Nexus Aurora Link (NAL) in Aurora Link mode

68.2.3 Modes of operation

The NPC block uses the JCOMP input, and an internal power-on reset indication as its primary reset signals. Upon exit of reset, the mode of operation is determined by the Port Configuration Register (PCR) settings.

68.2.3.1 Reset

The NPC block is asynchronously placed in reset when either power-on reset is asserted, JCOMP is not set for Nexus access or the TAP controller state machine is in the Test-Logic-Reset state. Holding TMS high for 5 consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Following negation of power-on reset, the NPC remains in reset until the system clock achieves lock. The NPC is unaffected by other sources of reset. While in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state
- The output port pins are negated
- The TDI, TMS, and TCK TAP inputs are ignored (when in power-on reset or JCOMP not set for NPC operation only
- Registers default back to their reset values

68.2.3.2 Disabled-Port Mode

In disabled-port mode, output pin port enable signals are negated, thereby disabling message transmission. Any debug feature that generates messages can not be used. The primary features available are class 1 features and read/write access to the registers. Class 1 features include the ability to trigger a breakpoint event indication through $\overline{\text{EVTO}}$.

68.2.3.3 Aurora Link Mode

In Aurora Link mode, trace data is transmitted through the Nexus Aurora Link (NAL). For SoCs that support a Nexus Aurora Link, the FPM bit in the PCR functions as the Aurora Link enable. Aurora Link Mode is enabled by setting the MCKO_EN and FPM bits and selecting a non-zero value for the ALC_NUM_LN bits in the PCR. The MCKO_DIV value should be set to select a clock frequency equal to the system clock frequency (MCKO_DIV = 000).

68.3 External signal description

68.3.1 Overview

The NPC pin interface provides for the transmission of messages from Nexus blocks to the external development tools and for access to Nexus client registers. The NPC pin definition is outlined in the following table. Pull information for the JTAG signals can be found in the JTAG chapter.

Table 68-1. NPC Signal Properties

Name	Port	Function	Reset State
EVTO_B	Nexus	Event Out pin	0b1
JCOMP	JTAG	JTAG Compliancy and TAP Sharing Control	—

Table continues on the next page...

Table 68-1. NPC Signal Properties (continued)

Name	Port	Function	Reset State
TCK	JTAG	Test Clock Input	—
TDI	JTAG	Test Data Input	—
TDO	JTAG	Test Data Output	High Z[1]
TMS	JTAG	Test Mode Select Input	—

1. TDO output buffer enable is negated when the NPC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented on TDO at the SoC level.

68.3.2 Detailed signal descriptions

This section describes each of the signals listed in Table 68-1 in more detail. Note that the JTAG test clock (TCK) input from the pin is not a direct input to the NPC. The NPC requires two separate input clocks for TCK clocked logic, one for posedge (rising edge TCK) logic and one for negedge (falling edge TCK) logic. Both clocks are derived from the pin TCK, and generated external to the NPC.

68.3.2.1 EVTO_B — Event Out

Event Out ($\overline{\text{EVTO}}$) is an output pin that is asserted upon breakpoint occurrence to provide breakpoint status indication. The $\overline{\text{EVTO}}$ output of the NPC is generated based on the values of the individual $\overline{\text{EVTO}}$ signals from all Nexus blocks that implement the signal.

68.3.2.2 JCOMP — JTAG Compliancy

The JCOMP signal provides the ability to share the TAP. The NPC TAP controller remains in reset until it is enabled using the JCOMP signal.

68.3.2.3 TCK — Test Clock Input

Test Clock Input (TCK) pin is used to synchronize the test logic and control register access through the JTAG port.

68.3.2.4 TDI — Test Data Input

Test Data Input (TDI) pin receives serial test instruction and data. TDI is sampled on the rising edge of TCK.

68.3.2.5 TDO — Nexus Test Data Output

Test Data Output (TDO) pin transmits serial output for instructions and data. TDO is three-stateable and is actively driven in the SHIFT-IR and SHIFT-DR controller states. TDO is updated on the falling edge of TCK and sampled by the development tool on the rising edge of TCK.

68.3.2.6 TMS — Test Mode Select

Test Mode Select Input (TMS) pin is used to sequence the IEEE 1149.1-2001 TAP controller state machine. TMS is sampled on the rising edge of TCK.

68.4 Register definition

This section provides a detailed description of the NPC registers accessible to the end user. Individual bit-level descriptions and reset states of the registers are included.

The following table shows the NPC registers by index values. The registers are not memory-mapped and can only be accessed via the TAP. The NPC block does not implement the client select control register because the value does not matter when accessing the registers.

Note that the bypass and instruction registers have no index values. These registers are not accessed in the same manner as Nexus client registers. Refer to the individual register descriptions for more detail.

Table 68-2. NPC registers

Index	Register
0	Device ID Register (DID)
126	Aurora Configuration Register (ACR)
127	Port Configuration Register (PCR)

68.4.1 Register descriptions

This section consists of NPC register descriptions.

68.4.1.1 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the BYPASS instruction or any unimplemented instructions are active. After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

68.4.1.2 Instruction register

The NPC block uses a 4-bit instruction register as shown in the following table. The instruction register is accessed via the SELECT_IR_SCAN path of the tap controller state machine, and allows instructions to be loaded into the block to enable the NPC for register access (NEXUS_ENABLE) or select the bypass register as the shift path from TDI to TDO (BYPASS or unimplemented instructions).

Instructions are shifted in through TDI while the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states. Synchronous entry into the Test-Logic-Reset state results in synchronous loading of the BYPASS instruction. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the BYPASS instruction. During the Capture-IR TAP controller state, the instruction register is loaded with the value of the previously executed instruction, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

	3	2	1	0
R	Previous Instruction Opcode			
W	Instruction Opcode			
Reset:	BYPASS Instruction Opcode (0xF)			

68.4.1.3 Nexus Device ID (DID) Register

The device identification register, shown in the following figure, allows the part revision number, design center, part identification number, and manufacturer identity code of the part to be determined through the output port.

Register index: 0

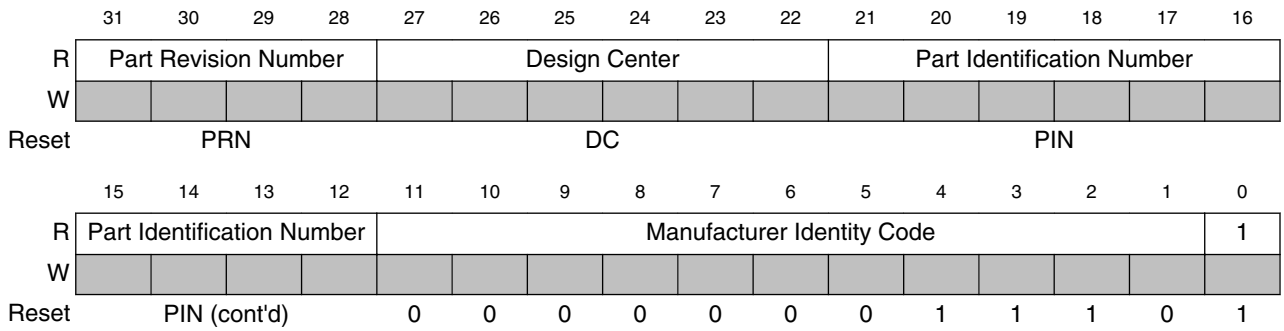

Table 68-5. DID field descriptions

Bit	Name	Description
31:28	PRN	Part Revision Number These bits contain the revision number of the part
27:22	DC	Design Center These bits indicate the device design center
21:12	PIN	Part Identification Number These bits contain the part number of the device
11:1	MIC	Manufacturer Identity Code These bits contain the reduced Joint Electron Device Engineering Council (JEDEC) ID for NXP, 0xE.
0	Bit [0]	IDCODE Register ID Bit [0] identifies this register as the device identification register and not the bypass register

68.4.1.4 Port Configuration Register (PCR)

Register index: 127

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	FPM	Reserved	MCKO_EN	MCKO_DIV			EVT_EN	Reserved	Reserved	0	0	0	ALC_NUM_LN		0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved	0	0	0	0	0	Reserved	Reserved	0	0	0	0	0	0	0	PSTAT_EN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The PCR, shown in the figure above, is used to select the NPC mode of operation, enable MCKO and select the MCKO frequency, and enable or disable MCKO gating. This register should be configured as soon as the NPC is enabled.

NOTE

The mode or clock division must not be modified after MCKO has been enabled. Changing the mode or clock division while MCKO is enabled can produce unpredictable results.

Table 68-7. PCR field descriptions

Bit	Name	Description
31	FPM	Full Port Mode The value of the FPM bit determines if Nexus Aurora mode is enabled. 0 Nexus Aurora mode disabled 1 Nexus Aurora mode enabled
30	Reserved	
29	MCKO_EN	The value of the MCKO_EN bit determines if Nexus Aurora mode is enabled. 0 Nexus Aurora mode disabled 1 Nexus Aurora mode enabled
28:26	MCKO_DIV	MCKO Division Factor The value of this signal determines the frequency of MCKO relative to the system clock frequency when MCKO_EN is asserted. Set to 000 when Nexus Aurora mode is enabled.
25	EVT_EN	EVTO/EVTI Enable This bit enables the EVTO/EVTI port functions. 0 EVTO/EVTI port disabled 1 EVTO/EVTI port enabled

Table continues on the next page...

Table 68-7. PCR field descriptions (continued)

Bit	Name	Description
24	Reserved	
23	Reserved	
19:18	ALC_NUM_LN	Aurora Lane Control, Number of Lanes The value of this bit determines how many high-speed Aurora lanes are enabled 00 0 Lanes Enabled 01 2 Lanes Enabled 10 4 Lanes Enabled 11 Reserved
15	Reserved	
9	Reserved	
8	Reserved	
0	PSTAT_EN	Processor Status Mode Enable[1] This bit enables processor status (PSTAT) mode. In PSTAT mode, all auxiliary output port MDO pins are used to transmit processor status information, and Nexus messaging is unavailable. 0 PSTAT disabled 1 PSTAT mode enabled

1. PSTAT Mode is intended for factory processor debug only. The PSTAT_EN bit should be written to disable PSTAT mode if Nexus messaging is desired. No Nexus messages are transmitted under any circumstances when PSTAT mode is enabled.

68.4.1.5 Aurora Configuration Register (ACR)

Register index: 126

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	LVDS_RXOPT[3:0]				0	0	0	0	LVDS_TXOPT[7:0]							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The ACR, shown in the figure above, is used to configure the RXOPT and TXOPT settings of the LVDS receive and transmit pads.

Table 68-9. ACR Field Descriptions

Bit	Name	Description
15:12	LVDS_RXOPT[3:0]	Configures LVDS receive pad options rxopt3, rxopt2, rxopt1, rxopt0
7:0	LVDS_TXOPT[7:0]	Configures LVDS transmit pad options txopt7, txopt6, txopt5, txopt4, txopt3, txopt2, txopt1, txopt0

68.5 Functional Description

68.5.1 NPC reset configuration

The NPC is placed in disabled mode upon exit of reset. If message transmission via the output port is desired, a write to the PCR is then required to enable the NPC and select the mode of operation.

For SoCs that support message transmission via the Nexus Aurora Link, asserting the MCKO_EN and FPM bits and setting the NUM_ALC_LN bits to a non-zero value enables NAL data transmission.

The following table describes the NPC reset configuration options.

Table 68-10. NPC reset configuration options

Power On Reset status asserted?	JCOMP asserted high	MCKO_EN bit of the Port Configuration Register	FPM bit of the Port Configuration Register[1]	NUM_ALC_LN bits of the PCR > 0	Configuration
yes	X	X	X	X	Reset
no	no	X	X	X	Reset
no	yes	0	X	X	Disabled
no	yes	1	0	X	Reduced Port Mode

1. This bit is not available

68.5.2 IEEE 1149.1-2001 (JTAG) TAP

The NPC block uses the IEEE 1149.1-2001 test access port (TAP) for accessing registers. Each of the individual Nexus blocks on the device implements a TAP controller for accessing its registers as well. TAP signals include TCK, TDI, TMS, and TDO. There may also be other blocks on the MCU that use the TAP and implement a TAP controller.

Refer to the IEEE 1149.1-2001 specification for further detail on electrical and pin protocol compliance requirements.

The NPC implements a Nexus controller state machine that transitions based on the state of the IEEE 1149.1-2001 state machine shown in Figure 68-3 . The Nexus controller state machine is defined by the IEEE-ISTO 5001-2001 standard. It is shown in Figure 68-4.

The instructions implemented by the NPC TAP controller are listed in the following table. The value of the NEXUS-ENABLE instruction is 0b0000. Each unimplemented instruction acts like the BYPASS instruction. The size of the NPC instruction register is 4 bits.

Table 68-11. Implemented Instructions

Instruction Name	Private/Public	Opcode	Description
NEXUS-ENABLE	public	0x0	Activate Nexus controller state machine to read and write NPC registers.
BYPASS	private	0xF	NPC BYPASS instruction. Also the value loaded into the NPC IR upon exit of reset.

Data is shifted between TDI and TDO starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register and all Nexus tool-mapped registers.

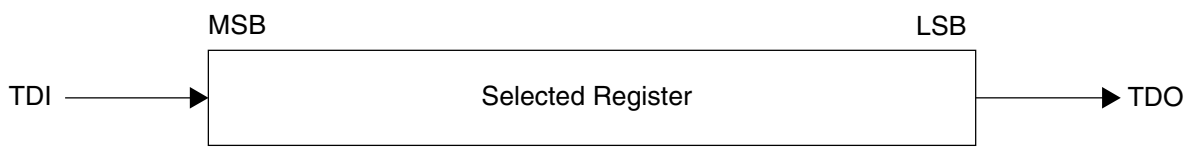

Figure 68-2. Shifting Data Into Register

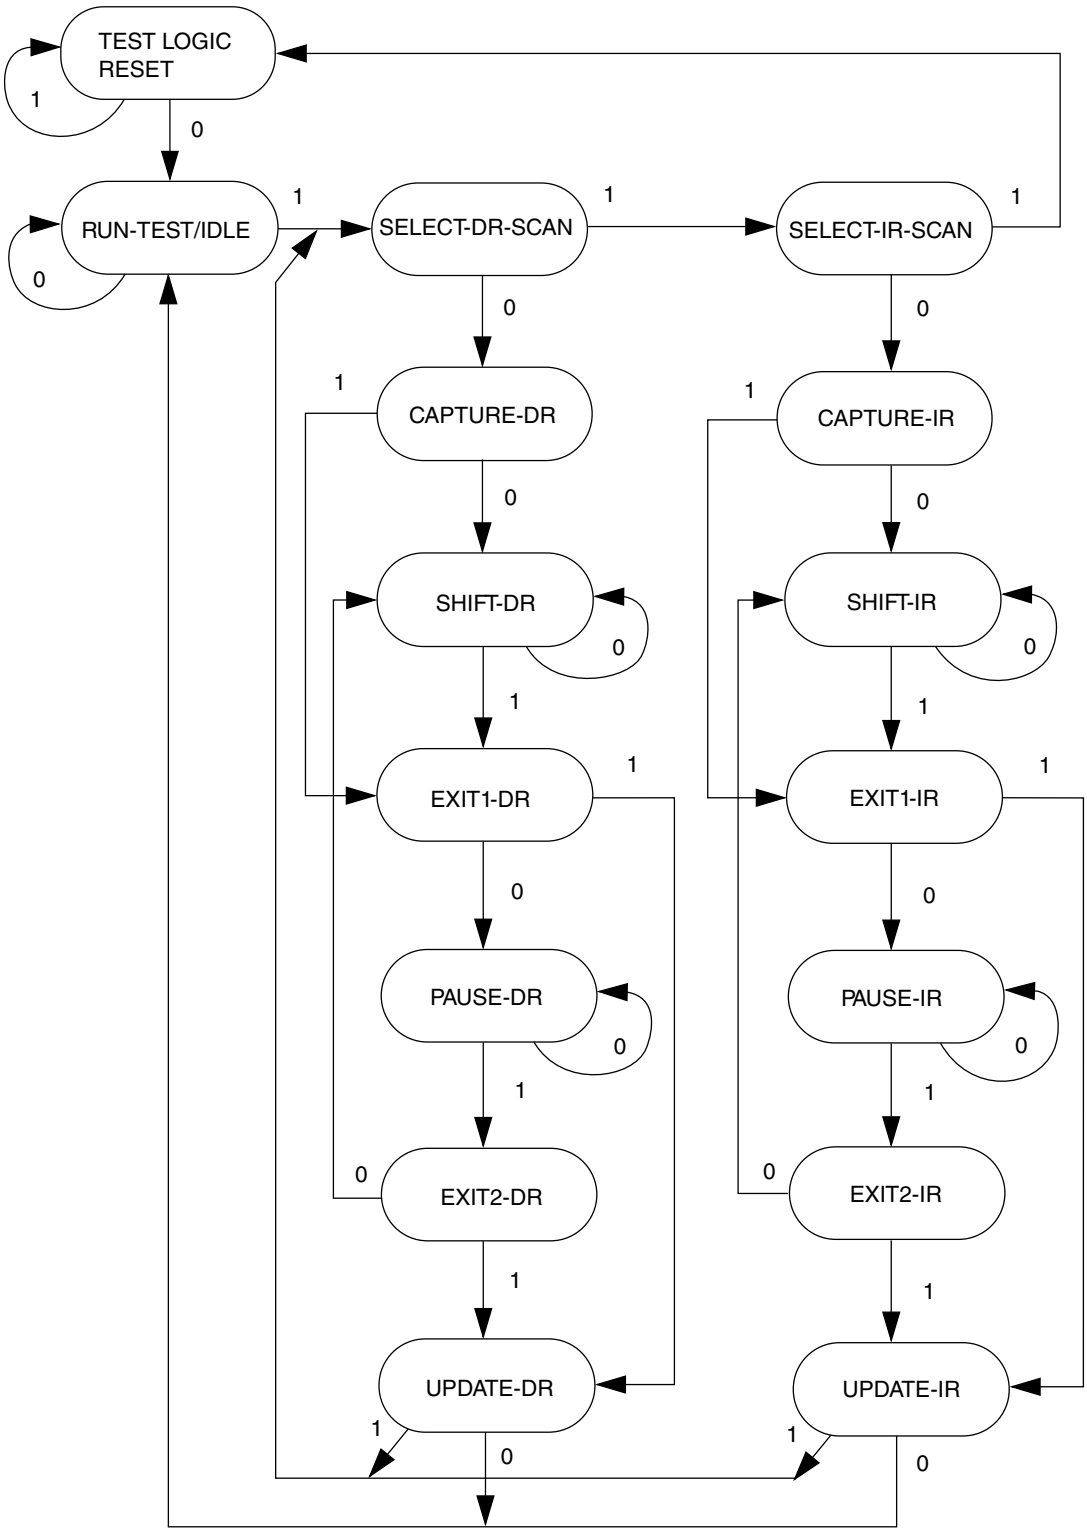
68.5.2.1 Enabling the NPC TAP controller

Assertion of the power-on reset signal or setting JCOMP to a value other than the NPC enable encoding resets the NPC TAP controller. When not in power-on reset, the NPC TAP controller is enabled by driving JCOMP with the NPC enable value and exiting the Test-Logic-Reset state. Loading the NEXUS-ENABLE instruction then grants access to Nexus debug.



NOTE: The value shown adjacent to each state transition in this figure represents the value of TMS at the time of a rising edge of TCK.

Figure 68-3. IEEE 1149.1-2001 TAP Controller State Machine

68.5.2.2 Retrieving device IDCODE

The Nexus TAP controller does not implement the IDCODE instruction. However, the device identification message can be output by the NPC through the output port or shifted out serially by accessing the Nexus Device ID register through the TAP.

Transmission of the device identification message serially via the TAP is achieved by performing a read of the register contents as described in Selecting a Nexus Client Register. The device identification message is not transmitted on the Aurora Link in Aurora Link mode, and it can be retrieved only via the TAP in that mode.

68.5.2.3 Loading NEXUS-ENABLE Instruction

Access to the NPC registers is enabled when the TAP controller instruction register is loaded with the NEXUS-ENABLE instruction. This instruction is shifted in via the SELECT-IR-SCAN path and loaded in the UPDATE-IR state. At this point, the Nexus controller state machine, shown in Figure 68-4, transitions to the REG_SELECT state. The Nexus controller has three states: idle, register select, and data access. Table 68-12 illustrates the IEEE 1149.1 sequence to load the NEXUS-ENABLE instruction.

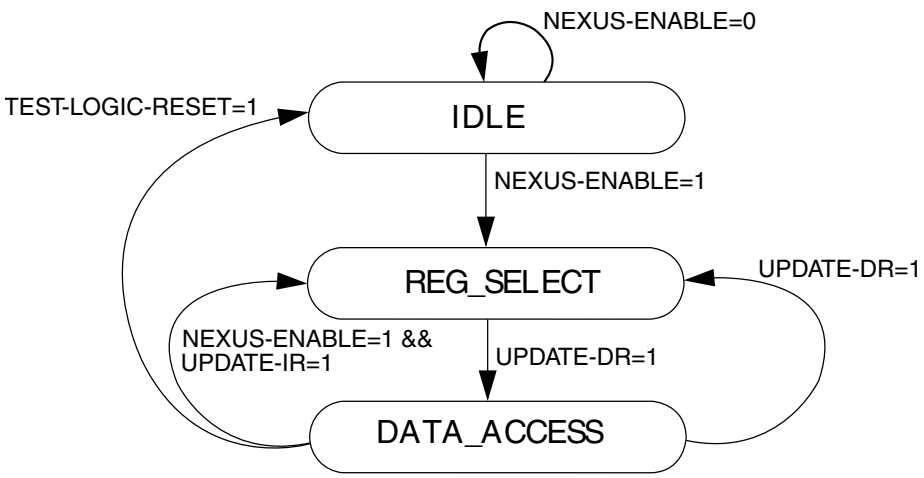


Figure 68-4. NEXUS Controller State Machine

Table 68-12. Loading NEXUS-ENABLE instruction

Clock	TMS	IEEE 1149.1 State	Nexus State	Description
0	0	RUN-TEST/IDLE	IDLE	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	IDLE	Transitional state
2	1	SELECT-IR-SCAN	IDLE	Transitional state
3	0	CAPTURE-IR	IDLE	Internal shifter loaded with current instruction

Table continues on the next page...

Table 68-12. Loading NEXUS-ENABLE instruction (continued)

Clock	TMS	IEEE 1149.1 State	Nexus State	Description
4	0	SHIFT-IR	IDLE	TDO becomes active, and the IEEE 1149.1-2001 shifter is ready. Shift in all but the last bit of the NEXUS_ENABLE instruction.
3 TCKS				
8	1	EXIT1-IR	IDLE	Last bit of instruction shifted in
9	1	UPDATE-IR	IDLE	NEXUS-ENABLE loaded into instruction register
10	0	RUN-TEST/IDLE	REG_SELECT	Ready to be read/write Nexus registers

68.5.2.4 Selecting a Nexus Client Register

When the NEXUS-ENABLE instruction is decoded by the TAP controller, the input port allows development tool access to all Nexus registers. Each register has a 7-bit address index.

All register access is performed via the SELECT-DR-SCAN path. The Nexus Controller defaults to the REG_SELECT state when enabled. Accessing a register requires two passes through the SELECT-DR-SCAN path: one pass to select the register and the second pass to read/write the register.

The first pass through the SELECT-DR-SCAN path is used to enter an 8-bit Nexus command consisting of a read/write control bit in the LSB followed by a 7-bit register address index, as illustrated in the following table. The read/write control bit is set to 1 for writes and 0 for reads.

MSB	LSB
7-bit register index	R/W

Figure 68-5. IEEE 1149.1 Controller Command Input

The second pass through the SELECT-DR-SCAN path is used to read or write the register data by shifting in the data (LSB first) during the SHIFT-DR state. When reading a register, the register value is loaded into the JTAG shifter during the CAPTURE-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the UPDATE-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

The following table illustrates a sequence which writes a 32-bit value to a register.

Table 68-13. Write to a 32-Bit Nexus Client Register

Clock	TMS	IEEE 1149.1 State	Nexus State	Description
0	0	RUN-TEST/IDLE	REG_SELECT	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	REG_SELECT	First pass through SELECT-DR-SCAN path
2	0	CAPTURE-DR	REG_SELECT	Internal shifter loaded with current value of controller command input.
3	0	SHIFT-DR	REG_SELECT	TDO becomes active, and write bit and 6 bits of register index shifted in.
7 TCKs				
11	1	EXIT1-DR	REG_SELECT	Last bit of register index shifted into TDI
12	1	UPDATE-DR	REG_SELECT	Controller decodes and selects register
13	1	SELECT-DR-SCAN	DATA_ACCESS	Second pass through SELECT-DR-SCAN path
14	0	CAPTURE-DR	DATA_ACCESS	Internal shifter loaded with current value of register
15	0	SHIFT-DR	DATA_ACCESS	TDO becomes active, and outputs current value of register while new value is shifted in through TDI
31 TCKs				
47	1	EXIT1-DR	DATA_ACCESS	Last bit of current value shifted out TDO. Last bit of new value shifted in TDI.
48	1	UPDATE-DR	DATA_ACCESS	Value written to register
49	0	RUN-TEST/IDLE	REG_SELECT	Controller returned to idle state. It could also return to SELECT-DR-SCAN to write another register.

68.5.3 Nexus JTAG Port Sharing

Each of the individual Nexus blocks on the device implements a TAP controller for accessing its registers. When Nexus has ownership of the TAP, only the block whose NEXUS-ENABLE instruction is loaded has control of the TAP. This allows the interface to all of these individual TAP controllers to appear to be a single port from outside the device. If no register is selected as the shift path for a Nexus block, that block acts like a single-bit shift register, or bypass register.

68.5.4 $\overline{\text{EVTO}}$ Sharing

The NPC block controls sharing of the $\overline{\text{EVTO}}$ output between all Nexus clients that produce an $\overline{\text{EVTO}}$ signal. The NPC assumes incoming $\overline{\text{EVTO}}$ signals will be asserted for one system clock period. After receiving a single clock period of asserted $\overline{\text{EVTO}}$ from any Nexus client, the NPC latches the result, and drives $\overline{\text{EVTO}}$ for one MCKO period on the following clock. When there is no active MCKO, such as in disabled mode, the NPC drives $\overline{\text{EVTO}}$ for two system clock periods. $\overline{\text{EVTO}}$ sharing is active as long as the NPC is not in reset.

68.5.5 Nexus Reset Control

The JCOMP input that is used as the primary reset signal for the NPC is also used by the NPC to generate a single-bit reset signal for other Nexus blocks. If JCOMP is negated, an internal reset is asserted, indicating that all Nexus modules should be held in reset.

68.5.6 Data Transmission via Nexus Aurora Link

The NPC supports data transmission over a high-speed serial Nexus Aurora Link (NAL). The NPC's role in Aurora Link data transmission is to route trace data to the NAL while continuing to manage arbitration between Nexus clients for the right to transmit data. In addition, the NPC monitors the NAL transmit queue and will halt further data transmission from Nexus clients if the queue is in danger of an overrun condition. In the event of an overrun condition, the NPC transmits a standard Nexus error message.

Once the PCR is configured for Aurora Link Mode (MCKO_EN bit set, FPM bit set, ALC_NUM_LN set to non-zero value), the NPC waits for the NAL to acknowledge it is ready to receive data before starting data transmission. All data transmitted in Aurora Link mode is transmitted in frames, with each frame consisting of 8192 bytes of data. The first beat of each frame is accompanied by the assertion of the start of frame control signal, and the last beat of each frame is accompanied by the assertion of the end of frame control signal. Each beat of valid NAL data from the NPC is also accompanied by the assertion of the NAL data valid message signal.

Data received by the NAL is held in a FIFO until it can be sent out on the Aurora Link. The NPC keeps track of the NAL FIFO fill level. To help prevent an overrun of the NAL FIFO, the NPC holds off further grants to all clients if the NAL FIFO is filled above the watermark level. In the event that the NAL FIFO is overrun with data, the NPC transmits its FIFO overrun error message.

68.6 Initialization/Application Information

68.6.1 Accessing NPC tool-mapped registers

To initialize the TAP for Nexus register accesses, the following sequence is required:

1. Enable the Nexus TAP controller
2. Load the TAP controller with the NEXUS-ENABLE instruction

To write control data to NPC tool-mapped registers, the following sequence is required:

1. Write the 7-bit register index and set the write bit to select the register with a pass through the SELECT-DR-SCAN path in the TAP controller state machine.
2. Write the register value with a second pass through the SELECT-DR-SCAN path. Note that the prior value of this register is shifted out during the write.

To read status and control data from NPC tool-mapped registers, the following sequence is required:

1. Write the 7-bit register index and clear the write bit to select register with a pass through SELECT-DR-SCAN path in the TAP controller state machine.
2. Read the register value with a second pass through the SELECT-DR-SCAN path. Data shifted in is ignored.

See the IEEE-ISTO 5001-2001 standard for more detail.

Chapter 69
Nexus Aurora Link (NAL)

69.1 Chip-specific NAL information

On this chip, the reset value of NAL General Status Register (NAL_GSR) is 0x0000_2400h.

69.2 Introduction

The Aurora Protocol is used to send debug information over a high-speed serial link out of the device. The Nexus Aurora Link (NAL) consists of all the logic on the MCU needed to implement the connection up to the physical-layer SerDes and transceivers; it includes Aurora control and data multiplexing, data-encoding and striping, and the Physical Coding Sublayer (PCS) portion of the protocol. The following figure details the NAL block diagram. The number of lanes, n, is 4.

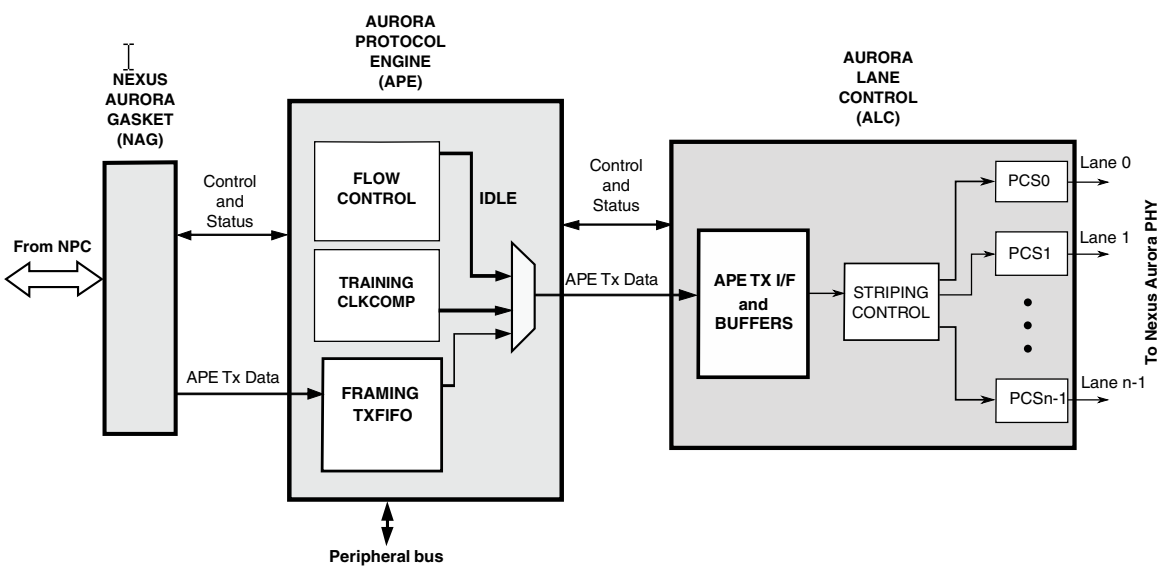

Figure 69-1. NAL block diagram

Debug data in the Nexus format from multiple clients is collected by the Nexus Port Controller (NPC) ; messages are then packetized and sent across an asynchronous clock boundary-crossing gasket to the Aurora Protocol Engine, which performs all the logical layer functions and flow control; data from the protocol engine is sent on to the Aurora Lane Control (ALC) block, which performs data-striping and sizing, based on the number of lanes selected for debug; it also performs the PCS functions of the link. The PCS drives the Nexus Aurora Physical (NAP) interface. The NAP, in conjunction with the NAL, supports one-way simplex high-speed serial communication with an external debugger.

The NAL is composed of three main blocks: the NPC/Aurora Gasket, the Aurora Protocol Engine, and Aurora Lane Control. The table below lists NAL functionality by block and lists the high level features for the Nexus Aurora PHY.

Table 69-1. NAL and NAP feature summary

Sub-Component	Feature
NPC Aurora Gasket (NAG)	• Transmit FIFO to buffer data as it crosses the NPC/NAL clock-domain boundary and Transmit FIFO space available indication to NPC. The NPC uses Transmit FIFO space available indication(s) to determine if data can be sent to the NAL. • Platform to Domain clock domain crossing. The NPC is on the core clock domain while the NAP is on a domain sourced from the external PHY clock input signals.
Aurora Protocol Engine (APE)	• Link training • Per the Aurora Protocol specification, clock-compensation, and data framing
Aurora Link Control (ALC)	• Striping of data stream from the Aurora core across all available lanes in two-byte chunks • PCS functionality for NAL
Nexus Aurora PHY (NAP)	• Physical transmission of serial data to device pins • External clock source for SerDes clock domain

69.3 Transmit operation

During transmit operation, the NPC collects debug data from Nexus clients over a 32-bit interface: 30 bits are used for MDO and 2 bits are used for MSEO information. The NPC places MDO data into a payload (maximum payload size depends on the number of lanes, each lane has a maximum of 7424 symbols before terminating the payload) and adds the following:

- 16-bit start symbol
- 16-bit end symbol

Each payload is transferred from the NPC to the NPC/NAL gasket, through the Aurora Protocol Engine, the Aurora Lane Control and finally out to the device SerDes/LVDS pins through the NAP.

After each end symbol packet transfer, the NAL adds a clock compensation sequence needed for downstream SerDes devices to remain synchronized to the MCU.

NOTE

Symbol counting for clock compensation starts just prior to the verification symbols; therefore, training symbols are excluded when counting.

69.4 Nexus Aurora formatting

The Aurora physical interface is the transport mechanism for Nexus messages. The Nexus messages are formatted by the Aurora formatter and striped into Aurora lanes. The Nexus messages themselves encapsulated into a virtual Nexus port that consists of a 30-bit Message Data Output (MDO) port and a 2-bit Message Start/End Output (MSEO) signal. The MSEO portion of the port is the two least significant bits (LSB) of the 32-bit Aurora message. The rest of the 32-bit Aurora frame consists of 30 MDO bits that are added LSB first.

69.5 Static training

The NAL supports static training. The NAL performs Static training by using programmable timers to determine how long to stay in each stage of the training process. In static training, there is no communication between the channel partners to exchange training status; rather the NAL sends the align/bond/verify sequence to its partner for a set amount of time sufficient for the receive partner to complete the training stage.

Note

Prior to initialization, the NAL must be reset to its POR state; to do this, assert the block reset. See the RST bit field description in the NAL General Control Register (NAL_GCR).

The following steps enable static training:

1. Write 80000000h to NAL_GCR
2. Write 00000000h to NAL_GCR
3. Write 80783C0Fh to NAL_TCR
4. Write 80000000h to NAL_GCR

5. Write 00000000h to NAL_GCR
6. Write A0080000h to NPC_PCR

This resets the channel and start the training routine. The time spent in each stage can range from 16 to 3072 cycles; once a counter times out, a counter time-out signal is asserted to the Aurora Protocol Engine (APE) to prompt it to move to the next stage. Additionally, it is possible to hold the training procedure in any of the stages indefinitely, by setting one of the three hold bits (AHD/BHD/VHD). When set, these bits cause the channel to sit in Align/Bond/Verify until unset, allowing a user to interactively step through the training procedure by monitoring the status at the debugger side and then stepping the device side to the next stage.

During the Aurora training sequence, the NAL generates a specific set of character sequences per the Aurora protocol specification which are to be transmitted simultaneously on all lanes.

69.6 Clock compensation considerations

The Aurora Protocol Specification describes clock compensation as a means for the link to compensate for clock rate differences between the transmitter and receiver. The specification requires that a clock compensation be inserted at a minimum every 10,000 symbol pairs. This allows the link to accommodate up to a 200 ppm difference in clock rates. The GCR[CCOEN] field sets the default clock compensation time out at 7424 cycles. However, due to the fact that the NAL is restricted to only inserting clock compensation sequences after an end-of-frame, it may not be possible to always meet the Aurora specification requirement.

Since the NPC always operates in framed mode, there is one scenario that can prevent an adequate number of clock compensation sequences from being generated: the sparse data case. In the sparse data case, there are long periods of time when no data is flowing through the link; no data means no frames. The NAL could end up transmitting idles for an undetermined number of cycles while waiting for the NPC to provide new data. However, a user can get around this problem by insuring that the NPC always has at least some minimal amount of data to send. In extreme sparse data cases where clock compensation is required, the receiver could reset the NPC or use a periodic watchpoint to force data transmission, and therefore force and end-of-frame to complete clock compensation.

69.7 Programmable registers

The Nexus Aurora Link (NAL) module provides a Nexus parallel to Aurora formatting for the MCU trace information. These registers are not memory-mapped and can only be accessed via the JTAG interface.

Table 69-2. NAL memory map

Offset	Register name	Width (in bits)	Access	Reset value
0h	NAL General Status Register (NAL_GSR)	32	R	See section
8h	NAL General Control Register (NAL_GCR)	32	R/W	0000_0000h
Ch	NAL Training Control Register (NAL_TCR)	32	R/W	0000_0000h

69.7.1 Nexus Aurora Link General Status Register (NAL_GSR)

The NAL_GSR is a read only register that describes the status of the NAL. See the chip-specific NAL information for the NAL_GSR reset value.

Chapter 70
Nexus Aurora PHY (NAP)

70.1 Introduction

The Nexus Aurora PHY (NAP), in conjunction with the Nexus Aurora Link (NAL), supports one-way simplex high-speed serial communication with an external debugger. Configuration settings in the Nexus Port Controller (NPC) Port Configuration Register (NPC_PCR) specify the NAP and NAL lane configuration. The NAL performs all logical layer functions, flow control, data-striping and sizing based on the number of data lanes available for use, and physical coding sublayer functions on the data being sent to the NAP for transmission. The NAP receives 8b/10b encoded data from the NAL then serializes and transmits this data through a given PHY lane's Low Voltage Differential Signaling (LVDS) buffers to an external debugger.

Each NAP lane consists of a data symbol character accumulator which registers the 10-bit character for that lane from the NAL on the rising edge of the NAL clock. Next, a serializer takes the 10-bit character and serializes it into the individual data bits that are then transmitted at the PHY clock rate via the LVDS output drivers to the external debugger receive channel.

Note

The NAL performs static link training for an attached debugger's PHY. The NAP is not directly aware of the link training operation, since it merely transmits the data presented to it by the NAL.

On the receive side of the external debugger, it is the responsibility of the external debugger to perform elastic buffering, symbol detection, symbol locking (called Lane Alignment in Aurora terminology), 10b/8b decoding, decode and disparity error tracking in the received data stream.

The following figure shows a high level block diagram of the High Speed Nexus Interface and the NAP.

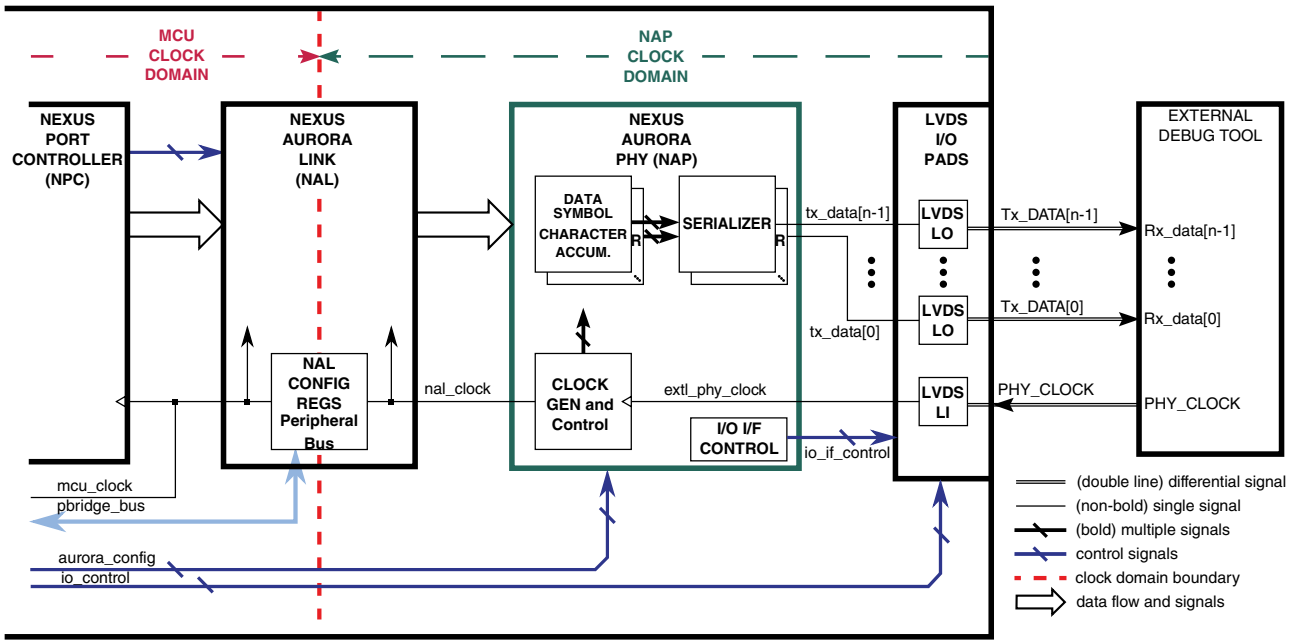

Figure 70-1. High speed Nexus interface block diagram

70.1.1 Features

The features of the NAP are as follows:

- Xilinx Aurora Protocol Specification V2.x compliant
- 1Gb/s per channel trace data payload bandwidth with 1.25 GHz clock
- Simplex mode with static (timer-based) channel training

70.1.2 Modes of operation

The operating mode of the NAP is determined by the device control signals. The functional configuration is determined by the NPC_PCR setting; functional operation is enabled by the NPC.

70.1.2.1 Reset

During Nexus Reset all internal NAP resources are reset, all output ports are disabled, and all inputs are ignored. Since there is no device clock domain logic in the NAP itself, the NAP is unaffected by device system reset. Depending on the NAP configuration settings, the NAP may activate upon exiting Nexus Reset if any Aurora lanes are enabled during this reset mode, else it remains disabled and inactive.

70.1.2.2 Link training

Before beginning trace output mode operation, the Aurora Link must go through a training process conducted by the NAL to ensure that an external debugger can correctly reconstruct the transmitted data stream. Training proceeds once the link powers up, and must complete successfully before data transmission can occur.

The NAL initializes and trains the Aurora Link in a simplex configuration using a timer based static-training method. The initialization and training sequence described in Aurora Protocol Specification progresses from one step to the next via the use of programmable timers contained in the NAL. A timer is programmed for each stage of training and as each timer expires, the training sequence proceeds to the next stage until complete. The NAP is not directly aware of the link training operation, since it merely transmits the data presented to it by the NAL.

70.1.2.3 Transmit

During Nexus trace output operation, it is the responsibility of the NPC to push data into the Aurora Link at a sufficiently high rate to ensure that the link does not become data-starved. The NAL and NAP support up to transmit lanes. The Aurora encapsulated data is modified by the NAL to ensure the appropriate number of symbols are transmitted through the NAP.

70.2 External signal description

The external signals of the NAP are listed in the following table. Each of the NAP signals consists of a positive and negative differential pair.

Table 70-1. NAP signals

Signal Name	Direction	Description
PHY_CLOCK (CLKP/CLKN)	Input	NAP clock input from external debug tool

Table continues on the next page...

Table 70-1. NAP signals (continued)

Signal Name	Direction	Description
TX Data0 (TX0P/TX0N)	Output	NAP Tx data for lane 0
TX Data1 (TX1P/TX1N)	Output	NAP Tx data for lane 1
TX Data2 (TX2P/TX2N)	Output	NAP Tx data for lane 2
TX Data3 (TX3P/TX3N)	Output	NAP Tx data for lane 3

70.3 Memory map and register definition

There are no control, configuration or status registers within the NAP. All control, configuration and status options for number of lanes and LVDS pads are handled in the NPC_PCR which is described in the NPC Chapter.

70.4 Functional description

High-level descriptions of the operation of the NAP and its main functional blocks are given in the following sections.

70.4.1 Data symbol character accumulator

The data symbol character accumulator portion of the NAP for each lane is made up of a symbol character register whose inputs are connected to the 10-bit NAL character bus. The data symbol character accumulator essentially registers a 10-bit character for that lane simultaneous with the rising edge of the NAL clock and presents the 10-bit quantity to the serializer at the appropriate times.

70.4.2 Serializer

The serializer portion of the NAP for each lane takes the data captured by that lane's Data Symbol Character Accumulator and demuxes the data to provide a single serial stream of symbol data to be output by the LVDS LO buffer for that lane at the PHY clock rate.

The following figure shows a high level timing diagram that demonstrates the operation of the serializer for a NAP lane, where S0–S9 represents a 10-bit symbol, S10–S19 represent the next symbol, and so on.

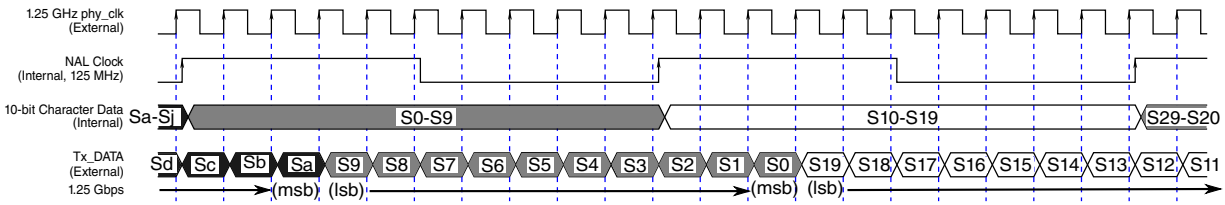

Figure 70-2. Serializer timing diagram

70.4.3 Clock generation and control

The Clock Generation and Control block is responsible for generating the necessary clocks and state signals needed by the rest of the NAP. The Data Symbol Character Accumulators and serializers are the main consumers of the signals generated by the Clock Generation and Control block.

70.5 Initialization information

The NAP does not require initialization other than the Nexus Reset and programming of the NPC_PCR to configure the number of lanes and LVDS pads.

JTAG Controller (JTAGC)

71.1 Chip-specific JTAGC information

71.1.1 JTAGC ACCESS_AUX block instructions

This table shows the ACCESS_AUX JTAGC instructions.

Table 71-1. ACCESS_AUX 5-bit JTAG instructions

Instruction	Code[4:0]	Instruction Summary
ACCESS_AUX_x	10000–11110	Grants one of the auxiliary TAP controllers ownership of the TAP as shown in the cells below.
ACCESS_AUX_NPC	10000	Enables access to the NPC TAP controller
ACCESS_AUX_z7a	10001	Enables access to Core z7a ONCE
ACCESS_AUX_z7b	10010	Enables access to Core z7b OnCE
ACCESS_AUX_ALL_CORES	10011	Enables DAISY Chained access to the Cores
Reserved	10100	Reserved
Reserved	10101	Reserved
Reserved	10110	Reserved
ACCESS_AUX_NXMC0	10111	Enables access to the Nexus XBAR Slave 0 TAP controller
ACCESS_AUX_NXMC1	11000	Enables access to the Nexus XBAR Slave 1 TAP controller
ACCESS_AUX_NXMC2	11001	Enables access to the Nexus XBAR Slave 2 TAP controller
ACCESS_AUX_OnCE	11010	Enables access to Core z4 OnCE.
Reserved	11011	Reserved
Reserved	11100	Reserved
Reserved	11101	Reserved
ACCESS_AUX_NAL	11110	Enables access to NAL

71.1.1.1 JTAG ID reset value

JTAG ID reset value for the device is 0x298D801D

71.1.2 Control 1 register

The Control 1 register is a 32-bit shift register path from TDI to TDO selected when the ENABLE_CONTROL1 instruction is active. The default reset value of the Control 1 register is 0. The Control 1 register transfers its value to a parallel hold register on the rising edge of TCK when the TAP controller state machine is in the Update-DR state.

71.2 Introduction

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format.

71.2.1 Block diagram

The following is a simplified block diagram of the JTAG Controller (JTAGC) block. Refer to Register description for more information about the JTAGC registers.

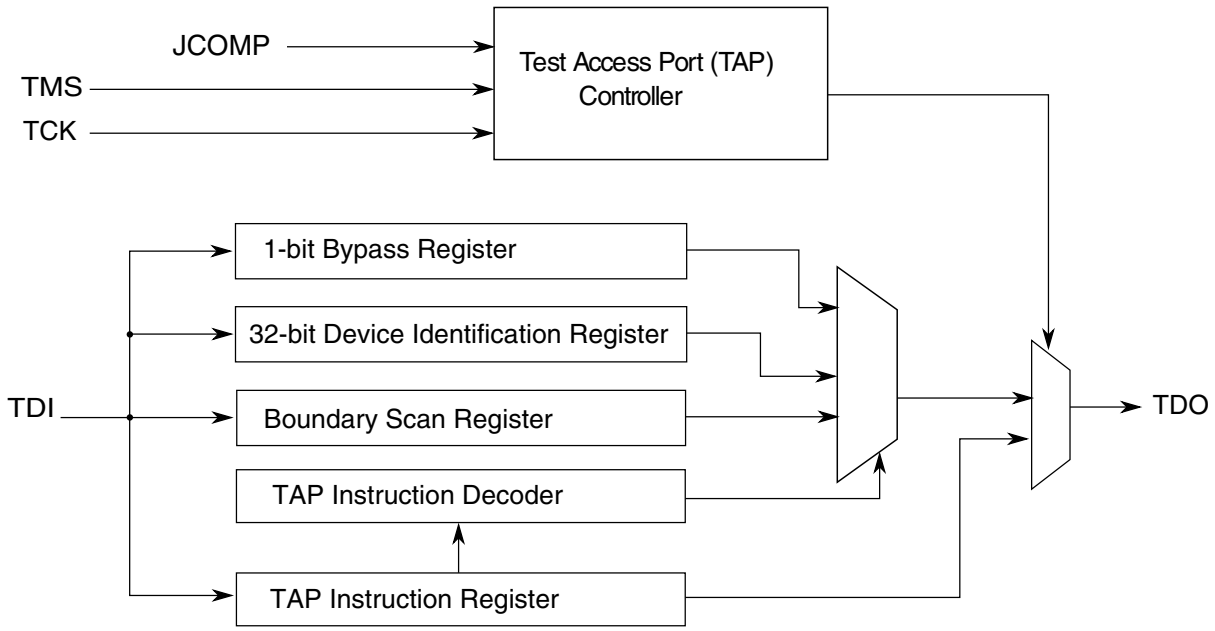

Figure 71-1. JTAG (IEEE 1149.1) block diagram

71.2.2 Features

The JTAGC block is compliant with the IEEE 1149.1-2001 standard, and supports the following features:

- IEEE 1149.1-2001 Test Access Port (TAP) interface
  - 4 pins (TDI, TMS, TCK, and TDO)
- JCOMP input that provides reset control
- Instruction register that supports several IEEE 1149.1-2001 defined instructions as well as several public and private device-specific instructions. Refer to Table 71-6 for a list of supported instructions.
- Sharing of the TAP with other TAP controllers via ACCESS_AUX_x instructions
- JTAG_PASSWORD register
- Control 1 register

- Bypass register, boundary scan register, and device identification register.
- TAP controller state machine that controls the operation of the data registers, instruction register and associated circuitry.

71.2.3 Modes of operation

The JTAGC block uses JCOMP and a power-on reset indication as its primary reset signals. Several IEEE 1149.1-2001 defined test modes are supported, as well as a bypass mode.

71.2.3.1 Reset

The JTAGC block is placed in reset when either power-on reset is asserted, JCOMP is negated, or the TMS input is held high for enough consecutive rising edges of TCK to sequence the TAP controller state machine into the Test-Logic-Reset state. Holding TMS high for five consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Asserting power-on reset or setting JCOMP to a value other than the value required to enable the JTAGC block results in asynchronous entry into the reset state. While in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state, thereby disabling the test logic and allowing normal operation of the on-chip system logic to continue unhindered
- The instruction register is loaded with the IDCODE instruction

71.2.3.2 IEEE 1149.1-2001 defined test modes

The JTAGC block supports several IEEE 1149.1-2001 defined test modes. A test mode is selected by loading the appropriate instruction into the instruction register while the JTAGC is enabled. Supported test instructions include EXTEST, HIGHZ, CLAMP, SAMPLE and SAMPLE/PRELOAD. Each instruction defines the set of data register(s) that may operate and interact with the on-chip system logic while the instruction is current. Only one test data register path is enabled to shift data between TDI and TDO for each instruction.

The boundary scan register is enabled for serial access between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. The single-bit bypass register shift stage is enabled for serial access between TDI and TDO when the BYPASS, HIGHZ, CLAMP or reserved instructions are active. The functionality of each test mode is explained in more detail in JTAGC block instructions.

71.2.3.3 Bypass mode

When no test operation is required, the BYPASS instruction can be loaded to place the JTAGC block into bypass mode. While in bypass mode, the single-bit bypass shift register is used to provide a minimum-length serial path to shift data between TDI and TDO.

71.3 External signal description

The JTAGC consists of a set of signals that connect to off chip development tools and allow access to test support functions. The JTAGC signals are outlined in the following table and described in the following sections.

Table 71-3. JTAG signal properties

Name	I/O	Function	Reset State
TCK	Input	Test Clock	Weak pullup
TDI	Input	Test Data In	Weak pullup
TDO	Output	Test Data Out	High Z[1]
TMS	Input	Test Mode Select	Weak pullup
JCOMP	Input	JTAG Compliancy	Weak pulldown

1. TDO output buffer enable is negated when the JTAGC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented at the TDO pad for use when JTAGC is inactive.

71.3.1 TCK—Test clock input

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the TAP.

71.3.2 TDI—Test data input

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

71.3.3 TDO—Test data output

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is three-stateable and is actively driven only in the Shift-IR and Shift-DR states of the TAP controller state machine, which is described in TAP controller state machine.

71.3.4 TMS—Test mode select

Test Mode Select (TMS) is an input pin used to sequence the IEEE 1149.1-2001 test control state machine. TMS is sampled on the rising edge of TCK.

71.3.5 JCOMP—JTAG compliancy

The JCOMP signal provides IEEE 1149.1-2001 compatibility and provides the ability to share the TAP. The JTAGC TAP controller is enabled when JCOMP is set to the JTAGC enable encoding, otherwise the JTAGC TAP controller remains in reset.

71.4 Register description

This section provides a detailed description of the JTAGC block registers accessible through the TAP interface, including data registers and the instruction register. Individual bit-level descriptions and reset states of each register are included. These registers are not memory-mapped and can only be accessed through the TAP.

71.4.1 Instruction register

The JTAGC block uses a 5-bit instruction register as shown in the following figure. The instruction register allows instructions to be loaded into the block to select the test to be performed or the test data register to be accessed or both. Instructions are shifted in through TDI while the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in

the Update-IR and Test-Logic-Reset TAP controller states. Synchronous entry into the Test-Logic-Reset state results in the IDCODE instruction being loaded on the falling edge of TCK. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the IDCODE instruction. During the Capture-IR TAP controller state, the instruction shift register is loaded with the value 00001b , making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

	4	3	2	1	0
R	0	0	0	0	1
W	Instruction Code				
Reset:	0	0	0	0	1

Figure 71-2. Instruction register

71.4.2 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the BYPASS, CLAMP, HIGHZ or reserve instructions are active. After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

71.4.3 Device identification register

The device identification (JTAG ID) register, shown in the following figure, allows the revision number, part number, manufacturer, and design center responsible for the design of the part to be determined through the TAP. The device identification register is selected for serial data transfer between TDI and TDO when the IDCODE instruction is active. Entry into the Capture-DR state while the device identification register is selected loads the IDCODE into the shift register to be shifted out on TDO in the Shift-DR state. No action occurs in the Update-DR state.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Part Revision Number				Design Center						Part Identification Number

R	Part Identification Number				Manufacturer Identity Code											1
W																
Reset	PIN (contd.)				MIC											1

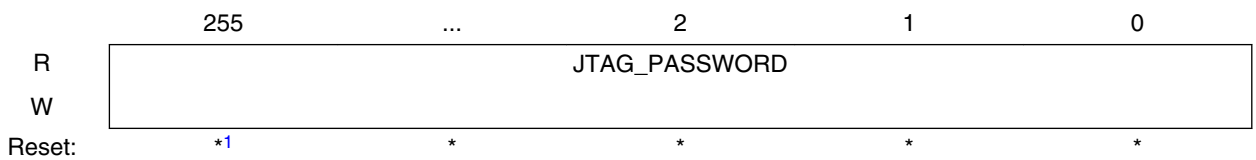
The following table describes the device identification register functions.

Table 71-4. Device identification register field descriptions

Field	Description
PRN	Part Revision Number. Contains the revision number of the part. Value is 0x0.
DC	Design Center. Indicates the design center. Value is 0x26.
PIN	Part Identification Number. Contains the part number of the device. 0011011000b.
MIC	Manufacturer Identity Code. Contains the reduced Joint Electron Device Engineering Council (JEDEC) ID. Value is 0x00E.
IDCODE ID	IDCODE Register ID. Identifies this register as the device identification register and not the bypass register. Always set to 1.

71.4.4 JTAG_PASSWORD register

The JTAG_PASSWORD register is a 256-bit shift register path from TDI to TDO selected when the ENABLE_JTAG_PASSWORD instruction is active. The default reset value of the JTAG_PASSWORD register is 256'b0. The JTAG_PASSWORD register transfers its value to a parallel hold register on the rising edge of TCK when the TAP controller state machine is in the Update-DR state. Once the ENABLE_JTAG_PASSWORD instruction is executed, the register value remains valid until a JTAG reset occurs. The operation of this register is described in the security documentation.



1. The reset value of JTAG_PASSWORD is 256 'b0.

The following table describes the JTAG_PASSWORD register functions.

Table 71-5. JTAG_PASSWORD register field descriptions

Field	Description
JTAG_PASSWORD	JTAG Password. The JTAG_PASSWORD bits are used to provide the JTAG password for security.

71.4.5 Boundary scan register

The boundary scan register is connected between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. It is used to capture input pin data, force fixed values on output pins, and select a logic value and direction for

bidirectional pins. Each bit of the boundary scan register represents a separate boundary scan register cell, as described in the IEEE 1149.1-2001 standard and discussed in Boundary scan. The size of the boundary scan register and bit ordering is device-dependent and can be found in the device BSDL file.

71.5 Functional description

This section explains the JTAGC functional description.

71.5.1 JTAGC reset configuration

While in reset, the TAP controller is forced into the Test-Logic-Reset state, thus disabling the test logic and allowing normal operation of the on-chip system logic. In addition, the instruction register is loaded with the IDCODE instruction.

71.5.2 IEEE 1149.1-2001 (JTAG) Test Access Port

The JTAGC block uses the IEEE 1149.1-2001 TAP for accessing registers. This port can be shared with other TAP controllers on the MCU. Ownership of the port is determined by the value of the currently loaded instruction. For more detail on TAP sharing via JTAGC instructions refer to ACCESS_AUX_x instructions.

Data is shifted between TDI and TDO though the selected register starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register, test data registers, and the bypass register.

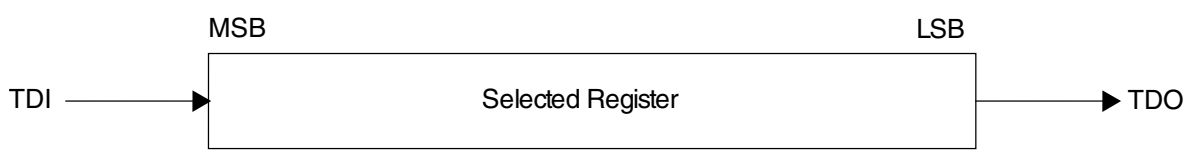


Figure 71-3. Shifting data through a register

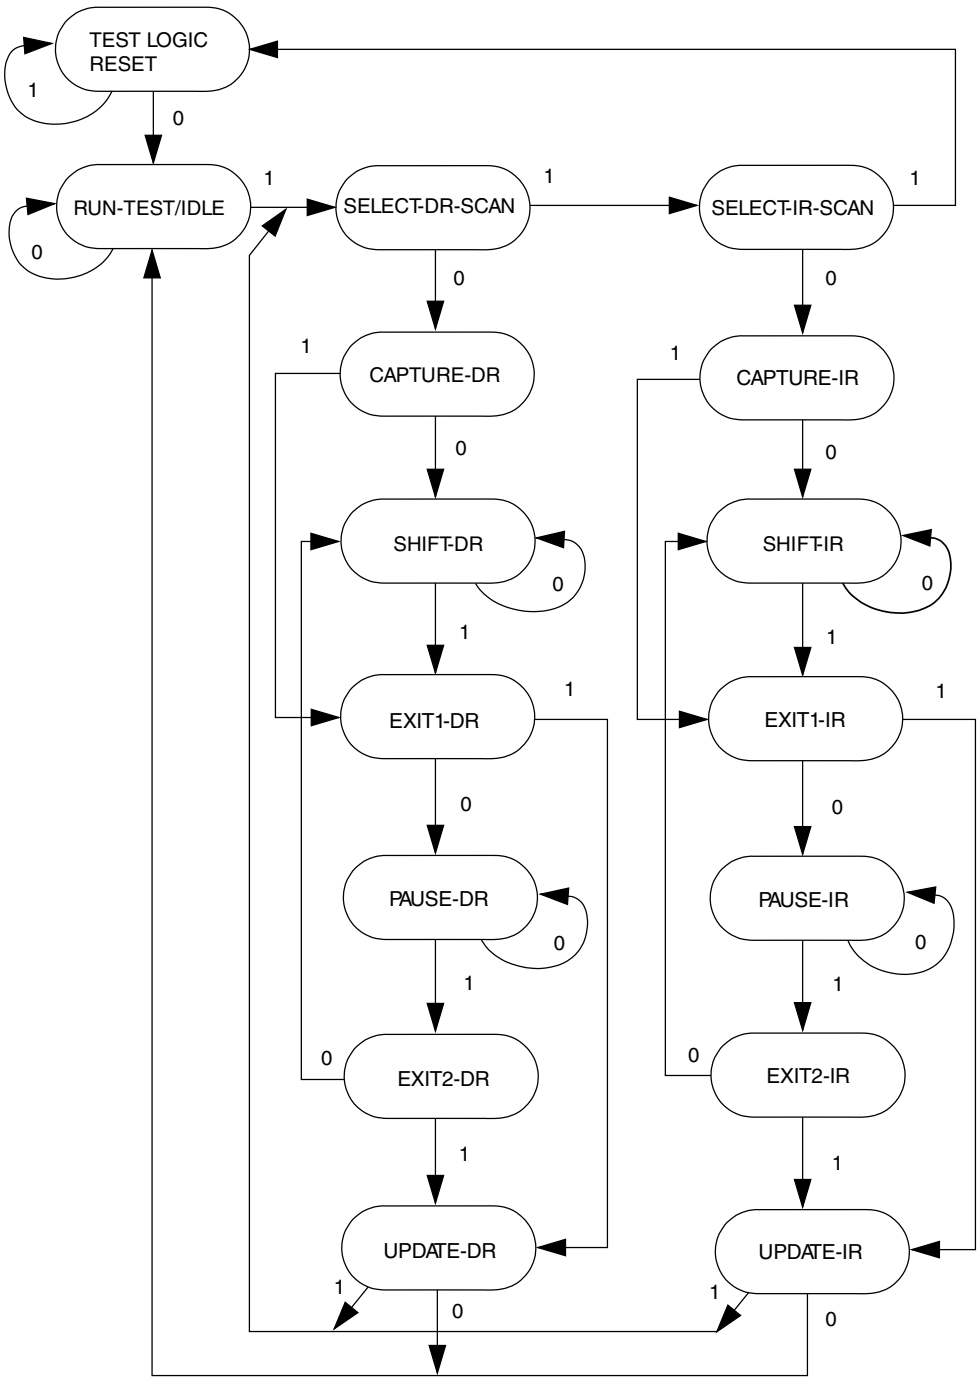
71.5.3 TAP controller state machine

The TAP controller is a synchronous state machine that interprets the sequence of logical values on the TMS pin. The following figure shows the machine's states. The value shown next to each state is the value of the TMS signal sampled on the rising edge of the

TCK signal. As the following figure shows, holding TMS at logic 1 while clocking TCK through a sufficient number of rising edges also causes the state machine to enter the Test-Logic-Reset state.



The value shown adjacent to each state transition in this figure represents the value of TMS at the time of a rising edge of TCK.

Figure 71-4. IEEE 1149.1-2001 TAP controller finite state machine

71.5.3.1 Enabling the TAP controller

The JTAGC TAP controller is enabled by setting JCOMP to a logic 1 value.

71.5.3.2 Selecting an IEEE 1149.1-2001 register

Access to the JTAGC data registers is achieved by loading the instruction register with any of the JTAGC block instructions while the JTAGC is enabled. Instructions are shifted in via the Select-IR-Scan path and loaded in the Update-IR state. At this point, all data register access is performed via the Select-DR-Scan path.

The Select-DR-Scan path is used to read or write the register data by shifting in the data (LSB first) during the Shift-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the Capture-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the Update-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

71.5.4 JTAGC block instructions

The JTAGC block implements the IEEE 1149.1-2001 defined instructions listed in the following table. This section gives an overview of each instruction; refer to the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

Table 71-6. General 5-bit JTAG instructions

Instruction	Code[4:0]	Instruction Summary
IDCODE	00001	Selects device identification register for shift
SAMPLE/PRELOAD	00010	Selects boundary scan register for shifting, sampling, and preloading without disturbing functional operation
SAMPLE	00011	Selects boundary scan register for shifting and sampling without disturbing functional operation
EXTEST	00100	Selects boundary scan register and applies preloaded values to output pins. **NOTE:** Execution of this instruction asserts functional reset.
Factory debug reserved	00101	Intended for factory debug only
Factory debug reserved	00110	Intended for factory debug only
ENABLE_JTAG_PASSWORD	00111	Selects JTAG_PASSWORD register
HIGHZ	01001	Selects bypass register and three-states all output pins. **NOTE:** Execution of this instruction asserts functional reset.
Factory debug reserved	01010	Intended for factory debug only

Table continues on the next page...

Table 71-6. General 5-bit JTAG instructions (continued)

Instruction	Code[4:0]	Instruction Summary
CLAMP	01100	Selects bypass register and applies preloaded values to output pins. **NOTE:** Execution of this instruction asserts functional reset.
ENABLE_CONTROL1	01110	Selects Control 1 register
Factory debug reserved	01111	Intended for factory debug only
BYPASS	11111	Selects bypass register for data operations
Reserved[1]	All other opcodes	Decoded to select bypass register

1. The manufacturer reserves the right to change the decoding of reserved instruction codes in the future

The ACCESS_AUX instructions are described in the chip configuration debug information.

71.5.4.1 IDCODE instruction

IDCODE selects the 32-bit device identification register as the shift path between TDI and TDO. This instruction allows interrogation of the MCU to determine its version number and other part identification data. IDCODE is the instruction placed into the instruction register when the JTAGC block is reset.

71.5.4.2 SAMPLE/PRELOAD instruction

The SAMPLE/PRELOAD instruction has two functions:

- The SAMPLE portion of the instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE/PRELOAD instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. Both the data capture and the shift operation are transparent to system operation.
- The PRELOAD portion of the instruction initializes the boundary scan register cells before selecting the EXTEST or CLAMP instructions to perform boundary scan tests. This is achieved by shifting in initialization data to the boundary scan register during the Shift-DR state. The initialization data is transferred to the parallel outputs of the boundary scan register cells on the falling edge of TCK in the Update-DR state. The data is applied to the external output pins by the EXTEST or CLAMP instruction. System operation is not affected.

71.5.4.3 SAMPLE instruction

The SAMPLE instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. There is no defined action in the Update-DR state. Both the data capture and the shift operation are transparent to system operation.

71.5.4.4 EXTEST External test instruction

EXTEST selects the boundary scan register as the shift path between TDI and TDO. It allows testing of off-chip circuitry and board-level interconnections by driving preloaded data contained in the boundary scan register onto the system output pins. Typically, the preloaded data is loaded into the boundary scan register using the SAMPLE/PRELOAD instruction before the selection of EXTEST. EXTEST asserts the internal system reset for the MCU to force a predictable internal state while performing external boundary scan operations.

71.5.4.5 ENABLE_JTAG_PASSWORD instruction

The ENABLE_JTAG_PASSWORD instruction selects the JTAG_PASSWORD register for connection as the shift path between TDI and TDO.

71.5.4.6 ENABLE_CONTROL1 instruction

The ENABLE_CONTROL1 instruction selects the Control 1 register for connection as the shift path between TDI and TDO.

71.5.4.7 HIGHZ instruction

HIGHZ selects the bypass register as the shift path between TDI and TDO. While HIGHZ is active all output drivers are placed in an inactive drive state (e.g., high impedance). HIGHZ also asserts the internal system reset for the MCU to force a predictable internal state.

71.5.4.8 CLAMP instruction

CLAMP allows the state of signals driven from MCU pins to be determined from the boundary scan register while the bypass register is selected as the serial path between TDI and TDO. CLAMP enhances test efficiency by reducing the overall shift path to a single bit (the bypass register) while conducting an EXTEST type of instruction through the boundary scan register. CLAMP also asserts the internal system reset for the MCU to force a predictable internal state.

71.5.4.9 ACCESS_AUX_x instructions

The JTAGC is configurable to allow other TAP controllers on the device to share the port with it. This is done by providing ACCESS_AUX_x instructions for each of these TAP controllers. When this instruction is loaded, control of the JTAG pins are transferred to the selected TAP controller. Any data input via TDI and TMS is passed to the selected TAP controller, and any TDO output from the selected TAP controller is sent back to the JTAGC to be output on the pins. The JTAGC regains control of the JTAG port during the UPDATE-DR state if the PAUSE-DR state was entered. Auxiliary TAP controllers are held in RUN-TEST/IDLE while they are inactive. Instructions not used to access an auxiliary TAP controller on a device are treated like the BYPASS instruction.

71.5.4.10 BYPASS instruction

BYPASS selects the bypass register, creating a single-bit shift register path between TDI and TDO. BYPASS enhances test efficiency by reducing the overall shift path when no test operation of the MCU is required. This allows more rapid movement of test data to and from other components on a board that are required to perform test functions. While the BYPASS instruction is active the system logic operates normally.

71.5.5 Boundary scan

The boundary scan technique allows signals at component boundaries to be controlled and observed through the shift-register stage associated with each pad. Each stage is part of a larger boundary scan register cell, and cells for each pad are interconnected serially to form a shift-register chain around the border of the design. The boundary scan register consists of this shift-register chain, and is connected between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are loaded. The shift-register chain contains a serial input and serial output, as well as clock and control signals.

71.6 Initialization/Application information

The test logic is a static logic design, and TCK can be stopped in either a high or low state without loss of data. However, the system clock is not synchronized to TCK internally. Any mixed operation using both the test logic and the system functional logic requires external synchronization.

To initialize the JTAGC block and enable access to registers, the following sequence is required:

1. Set the JCOMP signal to the JTAGC enable value, thereby enabling the JTAGC TAP controller
2. Load the appropriate instruction for the test or action to be performed

72.3 Introduction

The CJTAG module implements parts of the IEEE 1149.7 standard for test and debug capabilities. IEEE 1149.7 defines enhanced test and debug capabilities which are backwards compatible with IEEE P1149.1. This standard is also known as "Compact JTAG" or "CJTAG".

The module implements the following parts of the IEEE 1149.7 standard:

- IEEE 1149.1 compliant behavior while allowing multiple on-chip TAP controllers
- Ability to assert test reset
- Improved system scan performance with one-bit IR and DR chip bypass paths

- Physical connection of a Debug and Test System (external tool) to a running system without corrupting its operation
- Operation with both 4-pin and 2-pin scan topologies

72.3.1 Types of operation

The 1149.7 standard provides a scalable and flexible solution to meet the needs of varied component and system complexities. There are three types of operation:

- **Compliant**
  - Compliant with the IEEE 1149.1 standard
  - Four-pin operation using the "Standard Protocol" — IEEE 1149.1 signaling where TCK, TMS, TDI and TDO signals transfer control/data information
  - More than one TAPC may be associated with the TAP (once made visible by private instructions)
- **Extended**
  - Compatible with the IEEE 1149.1 standard
  - Four-pin operation using the "Standard Protocol" — IEEE 1149.1 signaling where TCK, TMS, TDI(C) and TDO(C) signals transfer control/data information
  - Additional test/debug functions
- **Advanced**
  - Two-pin operation using the "Advanced Protocol" — signaling where TCK(C) and TMS(C) signals transfer control/data information
  - The TMS(C) signal is operated in a bidirectional manner with the TMS, TDI and TDO TAP information serialized and transferred via this signal

72.3.2 Deployment by class

The TAP.7 capabilities are deployed using five capability classes (T0–T4), each matching the needs of certain scan topologies and mixes of 1149.1 TAPs and 1149.7 TAPs. The classes provide the following capability:

- **Compliant Operation** – provides behavior compliant with the IEEE 1149.1-2001 standard:
  - **Class T0** – 1149.1 compliance when multiple TAPs are used on the same chip.
- **Extended Operation** – extends the capabilities of the IEEE 1149.1-2001 standard:
  - **Class T1** – T0 + Test access port power management, functional reset, and test reset.
  - **Class T2** – T1 + Chip bypass (1-bit) for IR/DR Scans + hot-connection with no errors..
  - **Class T3** – T2 + Star operation (TAPs are paralleled) with series equivalent scans for test.
- **Advanced Operation** – adds capabilities addressing test and debug needs in complex environments:
  - **Class T4** – T3 + Scan with two pins with the Advanced Protocol. A number of protocol optimizations maximize scan performance. TDI(C)/TDO(C) pins are optional and may have programmable function when implemented.

72.3.3 1149.7 TAP signals

The TAP signals for the T0–T4 TAP.7 classes are listed in the following table. Signal names that end in “C” are associated with expanded functionality (beyond the functionality provided by the IEEE 1149.1 standard).

The table uses the following notation:

- M = Mandatory signal
- MC = Mandatory signal with expanded functionality
- O = Optional signal
- OC = Optional signal with expanded functionality

The CJTAG module provides T4 capability and implements the following pins:

- TCKC
- TDIC
- TDOC
- TMSC

Table 72-2. TAP.7 signal list

Signal name	Description	Class				
		T4	T3	T2	T1	T0
TCK/TCKC	Test clock	MC	M	M	M	M
TMS/TMSC	Test mode select	MC	M	M	M	M
TDI/TDIC	Test data input	OC	MC	M	M	M
TDO/TDOC	Test data output	OC	MC	M	M	M
Mandatory signal count (minimum)		2	4	4	4	4

72.3.4 TAP.7 architecture

The TAP.7 hardware architecture is shown in the following figure. It is described with the hardware layers listed below:

- **STL – System Test Logic** – Logic with 1149.1 compliant behavior and underlying TAP hierarchy (T0 capabilities). Provides an IEEE 1149.1 interface for the T0 TAP. 7. This logic is outside the CJTAG module.
- **RSU – Reset and Selection Unit** – A hardware layer that is placed between the APU, EPU, or STL and the TAP.7 signals (Added as an option to support the use of the Control Protocol) Provides reset and TAP.7 Controller selection services.
- **EPU – Extended Protocol Unit** – A hardware layer that is placed between the STL and the TAP.7 signals. (Added for T1, T2, and T3 capabilities). Provides an IEEE 1149.1 interface for the T1–T3 TAP.7s.
- **APU – Advanced Protocol Unit** – A hardware layer that is placed between the STL/EPU and the TAP.7 signals (added for T4 capabilities). Provides a T4 TAP.7 interface that is either narrow or wide, with the wide version providing an IEEE 1149.1 interface.

The CJTAG module supports T4 functionality that includes STL, RSU, EPU, and APU hardware layers.

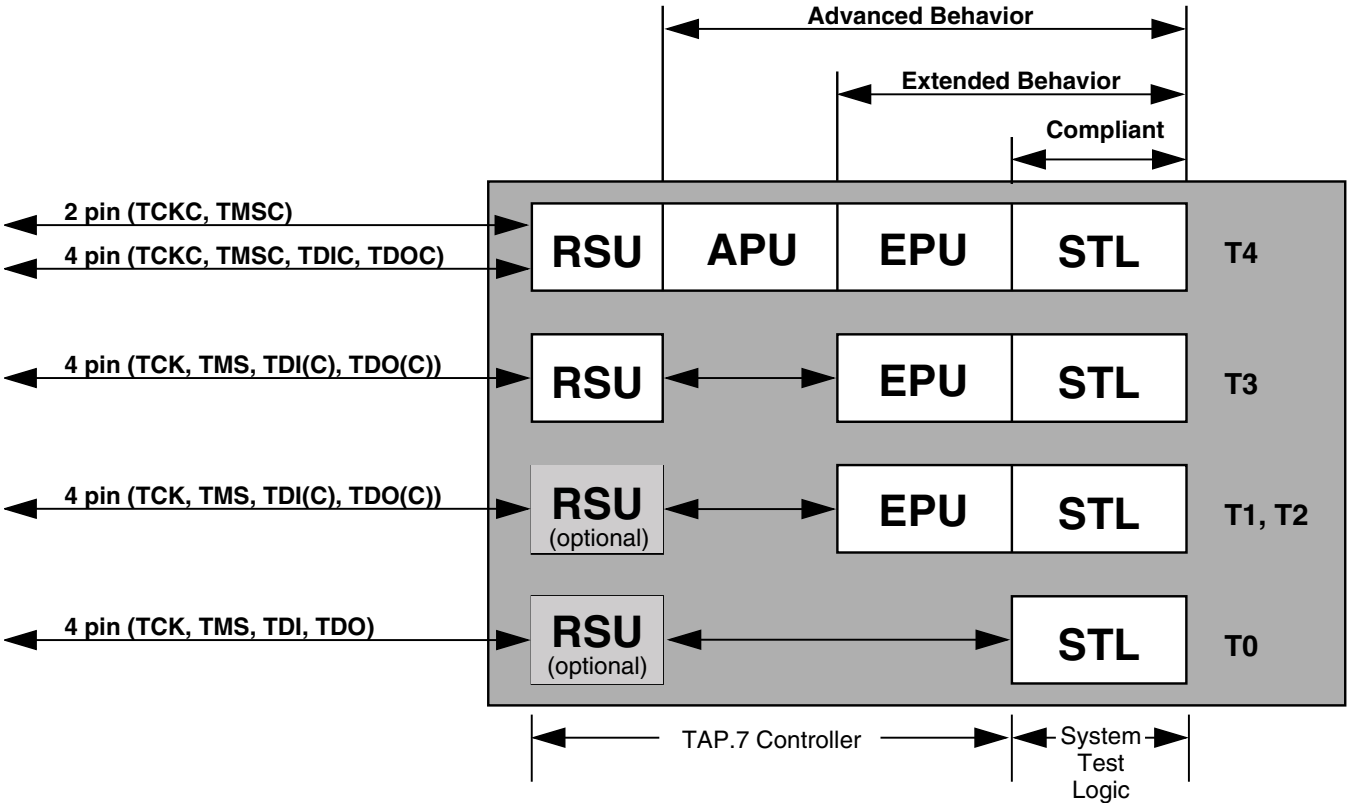

Figure 72-1. TAP.7 Controller Architecture

72.3.5 Protocols

The TAP.7 architecture utilizes the three protocols shown in the following figure.

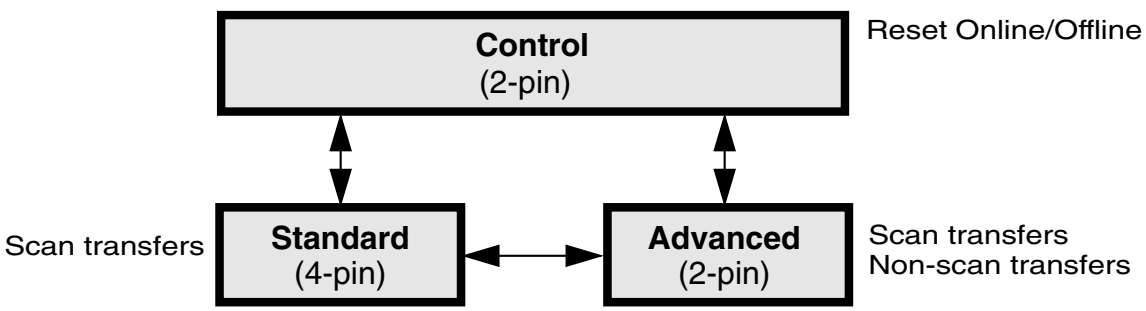

Figure 72-2. TAP.7 Behaviors

The Standard Protocol transfers data with the TMS(C) signal value being sampled with a TCK(C) edge. The Advanced and Control Protocols use both data transferred with the TMS(C) signal value being sampled with a TCK(C) signal edge and escape sequences. The Standard Protocol may be used to switch to the use of the Advanced Protocol and

vice versa. The Control Protocol can also be used to switch between the use of the Standard and the Advanced Protocol. The mandatory and optional deployment of these protocols with the TAP.7 classes is shown in the following table.

Table 72-3. Class/protocol relationship

Class	Protocol		
	Standard	Control	Advanced
T0 – T2	Mandatory	Optional	N/A
T3	Mandatory	Mandatory	N/A
T4	Mandatory	Mandatory	Mandatory

The CJTAG module implements T4 functionality and supports the Standard, Advanced, and Control Protocols.

72.3.5.1 Standard Protocol

The Standard Protocol is the signaling defined by the IEEE 1149.1 standard. This protocol is also used to implement TAP.7 commands using only the TCK(C) and TMS(C) signals in a manner that does not require either TAP.7 controller instruction or data registers. The TAP.7 controller does not add bits to the scan paths of underlying technology. The Standard Protocol can be used to manage the TAP.7 controller functionality independent of the function associated with the availability of the TDI and TDO signals. The Standard Protocol supports STL data transfers only when these signals are present and provide the 1149.1 functionality defined by the IEEE 1149.1 standard.

72.3.5.2 Advanced Protocol

The Advanced Protocol supports both STL data transfers and management of the TAP.7 controller functionality with both the 2-signal (narrow) and 4-signal (wide) configurations. The Advanced Protocol serializes the TMS, TDI, and TDO information used with the Standard Protocol using only the TCK(C) and TMS(C) signals. A number of additional scan formats provide bit sequences optimized for specific use cases. Each of these additional scan formats affects the TMSC signaling sequences.

72.3.5.3 Control Protocol

The Control Protocol uses Escape sequences to reset the TAP.7 controller, place a TAP.7 controller offline or online, and indicate End of Transmission (EOT) with the Advanced Protocol. The characteristics of this protocol provide Hot-Connect-Protection by requiring a preamble of alternating ones and zeroes preceding a selection escape when a TAP controller is started up offline.

72.4 Operating models

The following figure illustrates a simplified view of the CJTAG operating model.

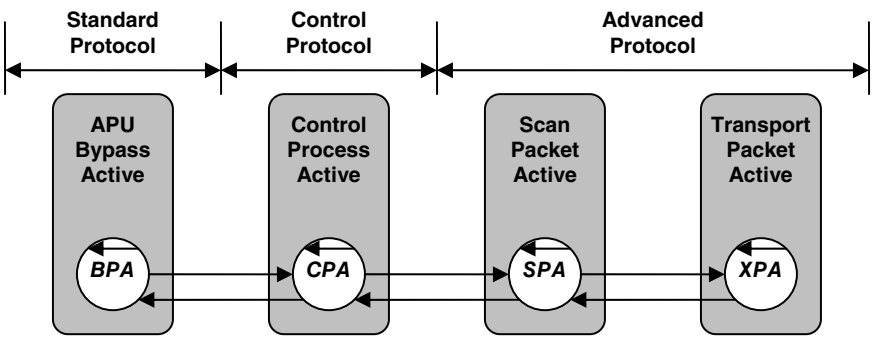

Figure 72-3. CJTAG operating model

72.5 CJTAG implementation summary

The CJTAG module is a T4 TAP.7 controller that implements the following functions.

72.5.1 T0 functions

- IDCODE. - implemented in chip level TAPC (JTAGC module)
- 1149.1 Compliance at start-up
- Isolating / Excluding of embedded TAPs – implemented in chip level TAPC (JTAGC module)
- Operation with other technologies and scan topologies
- Multiple embedded TAPs

72.5.2 T1 functions

- EPU Command processing
- EPU Class-Specific Registers
- Asserting a test reset to the STL (TRESET Register)

72.5.3 T2 functions

- "Super Bypass" function – JScan0, JScan1, JScan2 scan formats. Allows the STL to be coupled or decoupled.

72.5.4 T3 functions

- Generation of a TAP.7 controller reset with a Reset Escape Sequence
- JScan3 Scan Format

72.5.5 T4 functions

- TMSC sampling on rising edge or falling edge of TCKC
- MScan (For test and debug)
- OScan 0-7
- TDIC and TDOC / Alternate pin function multiplexing (wide 4 only)

72.6 Ancillary services

72.6.1 Overview

Ancillary services are pertinent to any TAP.7 controller implemented with an RSU, such as the CJTAG module.

Ancillary services include:

- Resets
- Start-up options

- Escape sequences
- TAPC state machine

72.6.2 Resets

The TAP.7 controller reset function expands the reset function provided by the IEEE 1149.1 standard to provide additional reset types. It supports six reset types, Type-0 – Type-5, listed below. It can be implemented with as few as two reset types (Type-2 and Type-4), or as many as six reset types (all types) of reset inputs: This is determined by the class and options implemented.

The CJTAG module utilizes Type-0, Type-2, Type-3, Type-4, and Type-5 resets.

- **Type-0** – Reset of the TAP.7 by power management logic (power-on reset)
- **Type-1** – Chip level generated Test Reset. (equivalent to Type-2)
- **Type-2** – Externally generated Test Reset (nTRST/nTRST_PD pin)
- **Type-3** – TAP.7 controller generated reset
- **Type-4** – *Test-Logic-Reset* state
- **Type-5** – TAP.7 Controller TReset Register reset of the CLTAPC.

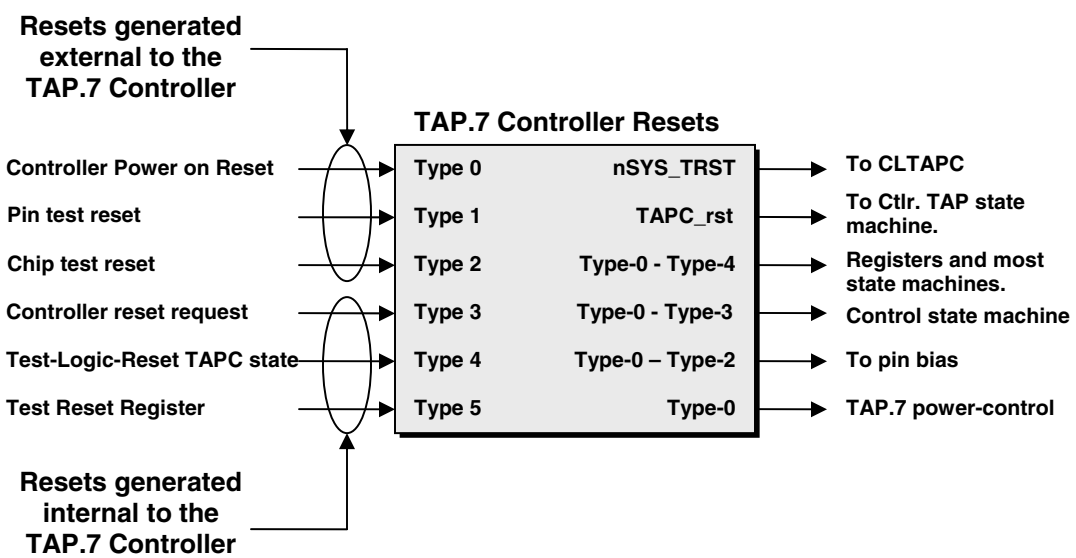

Figure 72-4. Conceptual view of the EPU reset logic and state machines

72.6.2.1 Type 5 reset

A Type-5 reset affects only the STL via the nSYS_TRST pin. It is asserted when the TRESET Register value is a logic 1. This register is set to its inactive state by reset Types 0-4.

72.6.2.2 Type 4 reset

A Type-4 reset is created by the *Test-Logic-Reset* state. It does not affect the TAP.7 TAPC state machine state as this state is the source of this reset, nor does it cause the assertion of the nSYS_TRST signal. It does however affect the coupling and decoupling of the STL. The Type-4 reset initializes the TAP.7 registers and most controller state machines. It affects but does not initialize the control state machine managing TAP.7 controller selection. It also establishes the default operating conditions.

72.6.2.3 Type 3 reset

A Type-3 reset is created by reset requests generated by the TAP.7 controller. A Type-3 reset performs the functions associated with a Type-4 reset and creates the *Test-Logic-Reset* state.

A Type-3 reset is generated in response to reset requests generated by EPU and APU logic

- A reset escape sequence
- Reset protocol sequences (delay packet directive, check packet directive)

A Type-3 reset request is generated with a reset escape sequence. This function is similar to but not the same as the reset function generated by a test reset pin. The Advanced Protocol includes certain bit patterns that initiate Type-3 resets. These bit patterns assist in the initialization of the TAP.7 controller when the TCKC signal is sourced by the TS and the external tool/TS connection is broken. The external tool may also generate these sequences, if desired, while the external tool/TS connection remains intact. These reset requests cause a Type-3 reset that is one clock wide.

With this being the case, consideration may be given to integrating the CJTAG module without the use of the Test Reset signal (nTRST/nTRST_PD pin).

72.6.2.4 Type 2 reset

A Type-2 reset is created by chip level logic to initialize the TAP.7 controller when TAP.7 power control is not implemented. It is unimplemented otherwise. It performs all of the functions of the Type-3 reset in addition to initializing the escape sequence detection logic.

72.6.2.5 Type 1 reset

A Type-1 reset is created with either the nTRST or nTRST_PD pin. It is not created when neither of these pins is implemented. It performs all of the functions of the Type-2 reset. It initiates TAP.7 controller power down provided the TAP.7 power control mode permits power down.

72.6.2.6 Type 0 reset

A Type-0 reset is implemented when TAP.7 controller power down is implemented. It performs all of the functions of a Type-1 reset and also initializes the TAP.7 power control logic.

72.6.2.7 Reset State Machine

The Reset State Machine assists in the translation of the reset inputs to the reset outputs. It handles Type-3 reset controller reset requests. The state machine state assures Type-0, Type-1, and Type-2 resets are forwarded to the STL without modifying their duration.

This state machine allows a Type-3 reset only when its state is “T3 Reset” (two TCK(C) falling edges have occurred in the absence of a Type-0, Type-1, and Type-2 reset).

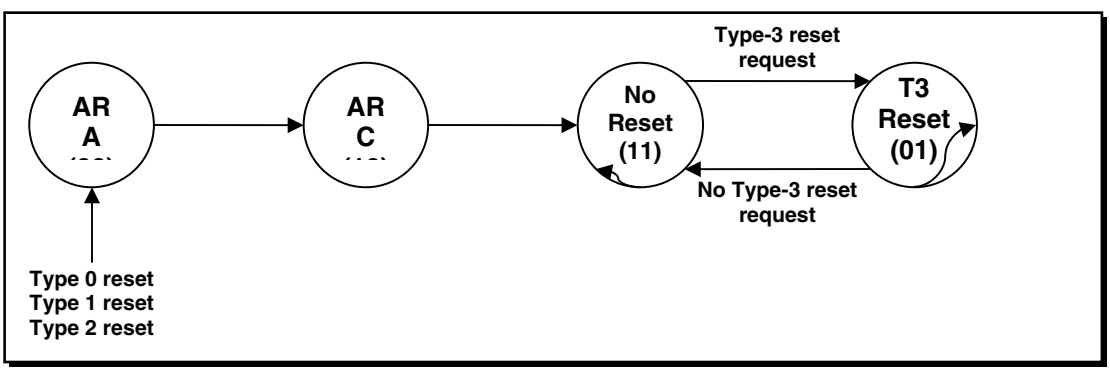

Figure 72-5. Reset state machine

Table 72-4. Reset state descriptions

Reset state		Description
ARA	Async. Reset Asserted	An async. reset has occurred or is occurring
ARC	Async. Reset Completed	An async. reset has occurred and has been released
No Reset	No Reset	No Reset
T3 Reset	Type-3 Reset	A Type-3 reset request has been processed.

Type-0, Type-1, and Type-2 resets are fully asynchronous. These resets are passed directly to nSYS_TRST without modification. The Type-3, Type-4, and Type-5 resets are fully synchronous.

The effects of the TAP.7 controller reset types are shown in the following table.

Table 72-5. Reset effects

Reset	CLTAPC	Pin-Hi-Z	State Machines other than CSM	Control State Machine (CSM)	TAPC SM State	Escape Sequence Detection	Power Control State
Type-5	Yes	–	–	–	–	–	–
Type-4	–	Yes	Yes	–	–	–	–
Type-3	Yes	Yes	Yes	Yes	Yes	–	–
Type-2	Yes	Yes	Yes	Yes	Yes	Yes	–
Type-1	Yes	Yes	Yes	Yes	Yes	Yes	–
Type-0	Yes	Yes	Yes	Yes	Yes	Yes	Yes

72.6.3 Start-up Options

72.6.3.1 Overview

The TAP.7 start-up options are shown in the following table. The only startup option currently supported by the CJTAG module is 1149.1 Compliant.

Table 72-6. Start-up Options

Start-up Option	Description
1149.1 Compliant	TAP.1 signal functionality, the CLTAPC is coupled
1149.1 Compatible	TAP.7 signal functionality, the CLTAPC is decoupled

Table continues on the next page...

Table 72-6. Start-up Options (continued)

Start-up Option	Description
1149.1 Protocol Compatible	No, or alternate TDIC/TDOC signal functionality, the CLTAPC is decoupled.
Offline-at-Start-up (Dormant)	The TAP.7 controller is offline and awaits synchronization to external tool operation so as to be placed online, the CLTAPC is decoupled after its state is moved to *Run-Test/Idle*

72.6.3.2 1149.1 Compliant start-up

Start-up behavior with the 1149.1 Compliant behavior start-up option:

- 1149.1-specific behavior / Standard protocol
- The TAPC finite state machine operated in lock step with the CLTAPC finite state machine.
- The TDIC and TDOC pins are present and provide the TDI and TDO function.
- The CLTAPC is coupled at start-up.

With this start-up option, the TAP.7 controller may be programmed and the scan topology may be interrogated. If the scan topology is known to be the Series Scan Topology at power-up, the TAP.7 can be operated as though it is a TAP.1.

Table 72-7. Reset values for TAP.7 startup options

Start-up Option	Type-0 – Type-3 Reset?	Default TAP.7 and TAP.7 controller characteristics				
		TAP.7 Controller online	CLTAPC Coupled	SGC Reg. == 1	SCNFMT	Initial TMSC pin bias
1149.1 Compliant	x	Yes	Yes	Yes	JScan0	PU

72.6.4 RSU operation

The RSU uses TCKC and TMSC with the control protocol for configuration control.

72.6.4.1 General Operation

From a very high level, the RSU enables the remainder of the TAP.7 functionality when the TAP.7 controller is Online and disables the remainder of the TAP.7 functionality otherwise. The RSU either consumes or discards the TMS(C) information while the TAP. 7 controller is Offline. The relationship of the escape sequence detection, technology selection logic, and the underlying technology is shown in the following figure.

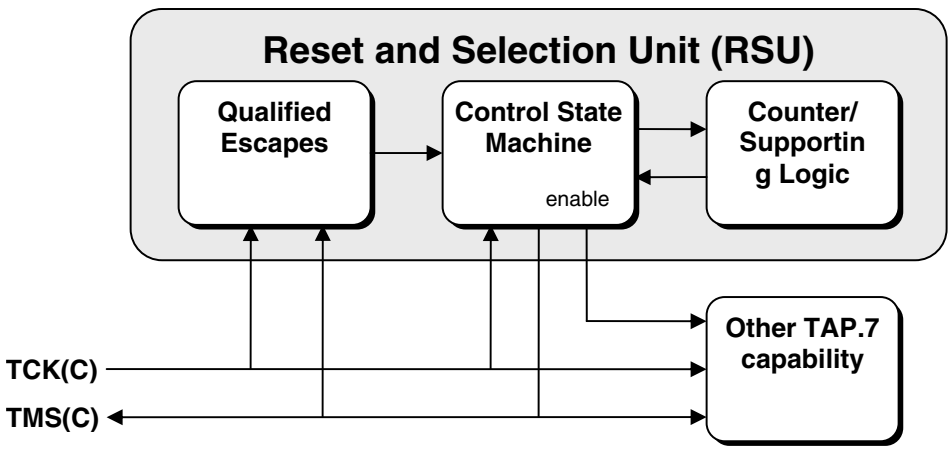

Figure 72-6. Conceptual view of technology selection mechanism

72.6.4.2 Common Signaling Across Technologies

With the TAP.7 architecture, the signaling conventions chosen for technology selection is multiple data transitions of the TMS(C) signal while the TCK(C) signal is a logic 1. The common signaling space is available when the external tool sources the TCK(C) signal as it is capable of creating these signaling conventions. It is unavailable when the TS sources the TCK(C) signal as the external tool cannot stop the TCKC signal at a logic 1 to create these signaling conventions.

72.6.4.3 Escape Sequence Detection

TAP.7 TAPC interprets the count of the number of TMS(C) edges while TCK(C) is a logic 1 as one of four escape sequences. Each escape sequence has a different function and TMSC edge count. These escape sequences, their edge counts, and their functions are described below:

- **Custom** (2 or 3 edges) – Ends scan and transport transfers with a TAP.7 controller, may be used for other purposes with another technology.
- **Reset** (> 7 edges) – Resets all technologies (generates a Type-3 TAP.7 TAPC reset)

The external tool creates an escape sequence by generating one or more TMS(C) edge pairs while the TCK(C) signal is a logic 1 value. Even and odd TMS(C) edge counts beginning with two are given the same meaning.

An escape sequence:

- Can be detected only when a Type-0, Type-1 or Type-2 reset is **not** asserted.
- Begins and ends while the TCK(C) is a logic 1.
- Uses TMS(C) as a clock while the TCK(C) is a logic 1.
- Overlays additional control information onto the normal information that is transferred with the TCK(C) and the TMS(C) without changing the normal information.
- Must be detected when TCK(C) is a logic 1 regardless of the TCK(C) and TMS(C) drive histories.

72.6.4.3.1 Custom escape sequence

An online technology can use the custom escape sequence in any manner it chooses. It is used as the End of Transmission (EOT) of certain data types (formats OScan4-7) with T4 and above TAP.7s.

72.6.4.3.2 Reset escape sequences

A reset event initializes all technologies sharing the TCK(C) and TMS(C) connectivity. A reset escape sequence resets the technology. It is recommended that this reset occur with the falling edge of TCKC. With a TAP.7 controller a reset escape sequence generates a Type-3 reset beginning with the falling edge of TCK(C) following the asynchronous detection of the event.

72.6.5 TAPC State Machine

T1 and above TAP.7s require knowledge of the TAPC state machine state. With T2 and above TAPs this knowledge must be developed independently of the CLTAPC. This is generally accomplished by implementing a TAPC state machine within the EPU. This TAPC state machine provides the function of the state machine within a standard 1149.1 TAPC. It is recommended that this state machine is implemented to change state on the falling edge of TCK(C) as this has numerous advantages to a TAP.7 controller. The EPU does not contain 1149.1 Instruction or Data Registers. The APU controls the state changes of this TAPC state machine with T4 and above TAP.7s.

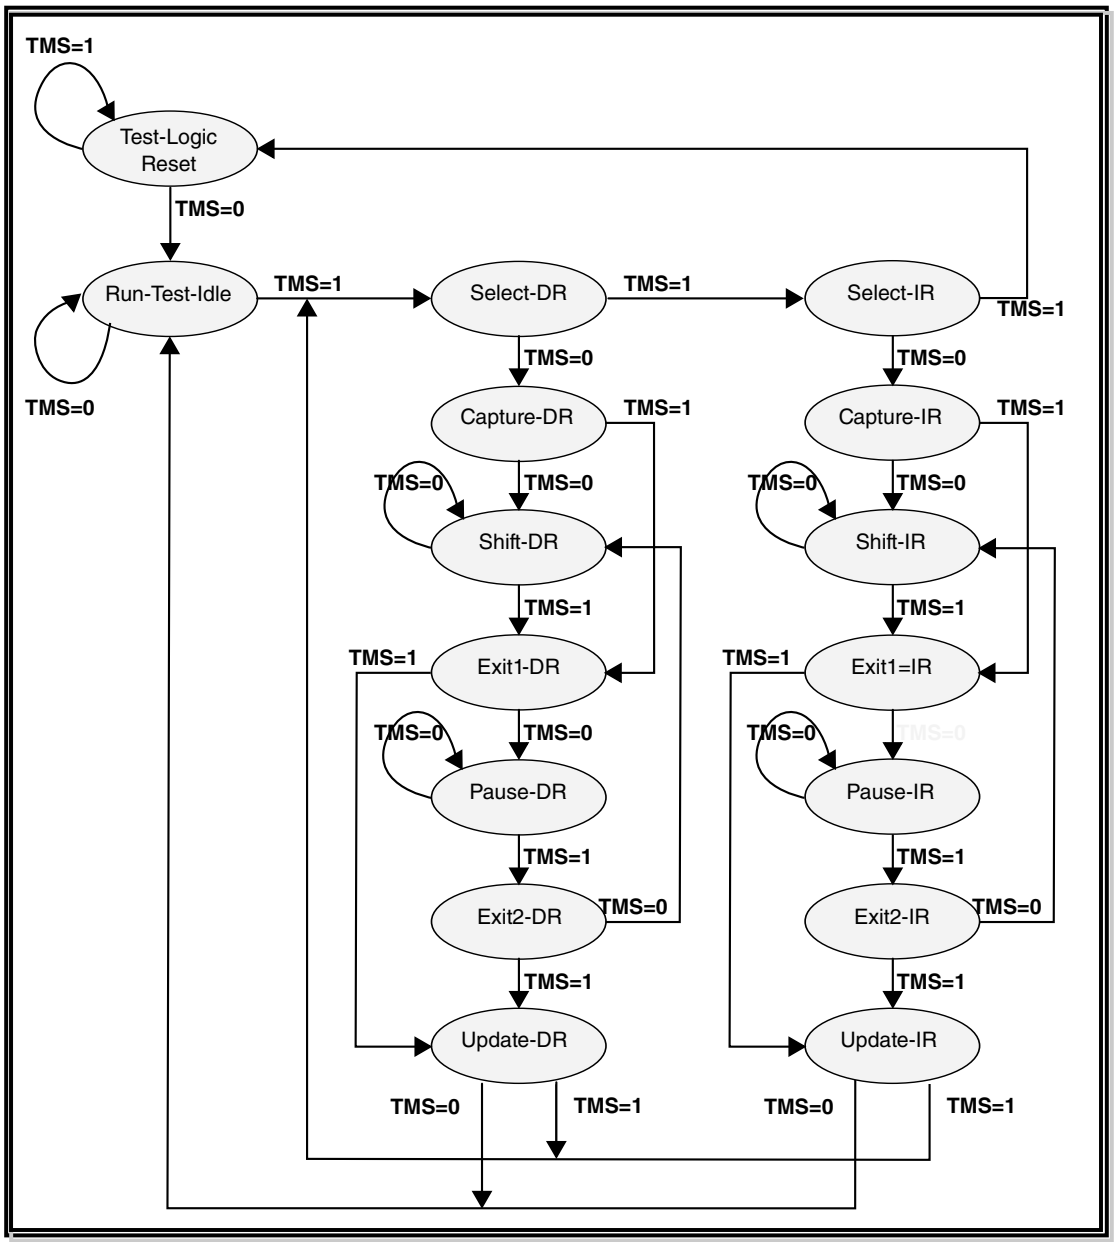

Figure 72-7. Falling edge TAP controller state machine

72.7 EPU (Extended Protocol Unit) Operation

72.7.1 EPU Operation

The EPU adds functionality to the BYPASS and IDCODE instructions.

72.7.1.1 Zero-bit DR-Scans (ZBS)

A zero-bit DR-Scan (ZBS) is a TAPC-state sequence that begins with the *Select-DR-Scan* state and ends with an exit from the *Update-DR* state without an intervening *Shift-DR* state. The external tool controls the EPU using ZBSs.

The use of ZBSs can begin immediately following the *Test-Logic-Reset* state since this state initializes the Instruction Registers of TAPs with either the *BYPASS* or *IDCODE* instructions.

72.7.1.2 Utilizing ZBSs for TAP.7 Controller Functionality

Beginning with a ZBS count of zero, the ZBS count is incremented with each consecutive occurrence of a ZBS without encountering a *Shift-DR* state. This count cannot be incremented past seven. *Run-Test/Idle* is the only state that may occur between consecutive occurrences of ZBSs without terminating the count of consecutive ZBSs.

72.7.1.3 Locking the ZBS Count

When a DR-Scan containing a *Shift-DR* state occurs, and the ZBS count is greater than zero, the ZBS count is not incremented when the *Update-DR* state is reached. It is instead locked at its current value. ZBSs occurring after locking the ZBS count do not affect the locked ZBS count. Locking the ZBS count is the equivalent of storing the count for subsequent use.

72.7.1.4 Control levels

Locking the ZBS count activates a control level that is equal to the locked ZBS count (1-7) when ZBSs are being used for TAP.7 functionality and merely locks the ZBS count otherwise.

1. ZBSs may be used by the STL or another function
2. TAP.7 command generation
3. Reserved control level
4. Accesses to optional TAP.7 scan paths
5. Accesses to optional TAP.7 scan paths

6. Force offline operation (optional)
7. External tool uses

Control level one may be used by the STL since there is no TAP.7 controller functionality associated with this control level.

Control level two enables DR-Scans to create TAP.7 commands. A portfolio of these commands supports the deployment of TAP.7 controllers in the Series or Star Scan Topologies. These commands manage TAP.7 controller registers and perform other functions.

Control level three is reserved for use with a subsequent specification revision.

Control levels four and five provide access to custom (private) scan paths when access to these paths is permitted by a TAP.7 register bit used for this purpose. The EPU provides a 1-bit scan path otherwise. No other EPU functionality is associated with these control levels. The CJTAG module does not support the use of this control level.

Control level six may be optionally used to force offline operation with a TAP.7 controller that supports this capability. The EPU provides a 1-bit scan path for this control level. The CJTAG module does not support the use of this control level.

Control level seven is reserved for external tool use. With this control level, external tool capabilities may be managed using the same infrastructure used to manage TAP.7 controller capability. The EPU provides a 1-bit scan path for this control levels.

72.7.1.5 Exiting a Control Level

A control level is exited when one of the following occurs:

- The *Select-IR-Scan* TAP.7 controller state
- The *Test-Logic-Reset* state
- Certain TAP.7 controller commands (Exit Control Level – ECL register bit)
- An event that synchronizes the operation of TAP.7 controllers

72.7.1.6 Zeroing the ZBS Count

Events causing an exit from a control level also zero the ZBS count. Scan Selection Directives (SSDs) associated with T3 and above TAP.7s zero the ZBS count when the control level has not been locked.

72.7.1.7 Utilizing ZBSs within the STL

After the *Test-Logic-Reset* state, ZBSs are used for basic EPU control. ZBSs that are intended for TAP.7 use are henceforth called "***TAP.7 ZBSs***". ZBSs that are intended for other uses are henceforth called "***Other ZBSs***". Two TAP.7 registers enable the STL's use of ZBSs. Storing these registers causes a control level exit, zeroes the ZBS count, and enables the use of Other ZBSs. Storing the Suspend Register (**SUSPEND**) suspends the use of control levels. Storing the ZBS Inhibit Register (**ZBSINH**) inhibits ZBS detection.

When either of these methods is used, the *Test-Logic-Reset* state enables the use of TAP. 7 ZBSs in addition to initializing the TAP.7 controller.

The operation of the TAP.7 controller changes with the use of these two paths.

When the System Path is used:

- A count of eight consecutive ZBSs is used to create a logic 0 SUSPEND Register value.
- The CLTAPC supplies the TAP.7 scan path and controls the drive of TDO(C), provided it is not bypasses.
- The EPU supplies the TAP.7 scan path (a one bit bypass) when the CLTAPC is bypassed.
- Functions supporting Boundary Scan in a Star Scan Topology are enabled.

When the EPU Path is used:

- When the control level has not been locked, the TDO(C) signal remains high-impedance.
- The command control level may be created
- When commands are used, the TDO(C) signal remains high-impedance except during *Shift-DR* states within CR-Scans, and remains high impedance at other times.
- Auxiliary scan paths may be accessed with control levels four and five.

72.7.2 EPU Registers

72.7.2.1 Global

A global register is a register whose value is stored at the same time and with the same value as registers with the same name in all TAP.7 TAPCs sharing an external tool connection. They are stored using TAP.7 TAPC commands dedicated for this purpose. These commands store a single global register. Global registers manage TAP.7 TAPC functions that affect the synchronized operation of a TAP.7 TAPC. An example of a global register is the Scan Format (SCN_FMT) Register used to define the TAPC signal protocol.

A second means of storing all global registers is available. The selection of the TAP.7 TAPC with the technology selection function stores either the Scan Format register value (short form) or all global registers (long form). Storing all global registers provides a simple means to synchronize the values of all global registers when Technology Selection causes a non-operating TAP.7 TAPC to become operational while other TAPCs are operational.

72.7.2.2 Local

Local registers manage TAP.7 TAPC functions that do not affect the synchronized operation of TAP.7 TAPCs. Local registers are conditionally stored using TAP.7 controller commands dedicated for this purpose. These commands provide for changing the value of these registers one a time with a unique value in a Series Scan Topology based on the TAPC's position on the scan chain. Local registers are stored with a unique value in a Star Scan Topology based on a TAPC address assigned to the TAPC.

Registers programmed with commands are described in this section. The CJTAG module implements all mandatory T4 registers as well as the optional APFC, TRESET, and RDBACK0 registers.There are 16 mandatory and 10 optional registers that can be grouped in classes as shown in Read-only – Configuration and register read back..

- **Control** – TAP.7 controller behaviors and characteristics.
- **Options** – Control of optional functions.
- **Select** – Controls the selection of a TAP.7 for Scan and execution of conditional commands.
- **Read-only** – Configuration and register read back.

Table 72-8. TAP.7 controller register list (managed with commands)

Register type	Global/local	Width	Register mnemonic	Name
Control	Global	1	ECL	Exit Control Level
		1	SUSPEND	Suspend
		1	ZBSINH	ZBS Detect Inhibit
		5	SCNFMT	Scan Format
		1	SSDE	SSD Enable
		2	DLYC	Delay control
		2	RDYC	Ready Control
Options	Local	1	TRESET	Test Reset
		2	APFC	Aux. Pin Func. Cntl.
Select	Local	1	CGM	Cond. Group Member
		1	SGC	Scan Group Candidate
		1	SEDGE	Sampling Edge
Read-only	Local	32	RDBACK0	Read-back 0
		32	RDBACK1	Read-back 1
		32	CNFG0	Configuration Register 0

M = Mandatory register

O = Optional register

72.7.2.3 Register Descriptions

72.7.2.3.1 Exit Control Level (ECL)

Storing this register zeroes the ZBS count and unlocks the control level.

This register is set using the STMC command. It remains logic 1 only momentarily before immediately returning to logic 0.

This register is cleared by a global register load.

72.7.2.3.2 Suspend (SUSPEND)

Setting this register suspends the use of control levels. When this register is a logic 1, the "System Path" (STL) is used.

1 – Suspend use of control levels. Enables "System Path."

0 – Enable use of control levels.

SUSPEND is set with the STMC command.

This register is cleared when 8 consecutive ZBSs are detected without the locking of the ZBS count.

This register is cleared by a global register load.

72.7.2.3.3 ZBS Inhibit (ZBSINH)

Storing to ZBSINH inhibits ZBS detection.

1 – Inhibit ZBS detection.

0 – Enable ZBS detection.

ZBSINH is set with the STMC command.

This register is cleared by a global register load.

72.7.2.3.4 Scan Format (SCNFMT[4:0])

Set using Store Scan Format (STFMT) command.

Read using Scan String (SCNS) command.

Table 72-9. Scan Format Register Values

TAPC.7 Class	SCNFMT	Description
T2–T4	00000	**JScan0:** • 1149.1 Compliant Operation. • Requests the coupling of the CLTAPC when the Run-Test/Idle state is reached.
	00001	**JScan1:** • 1149.1 Compatible Operation • Requests the decoupling of the CLTAPC when the Run-Test/Idle state is reached.
	00010	**JScan2:** • 1149.1 Compatible Operation. • Requests the coupling or decoupling of the CLTAPC when the Run-Test/Idle state is reached based on the value of the CACT register
T3–T4	00011	**JScan3:**

Table continues on the next page...

Table 72-9. Scan Format Register Values (continued)

TAPC.7 Class	SCNFMT	Description
		• Non-compatible 1149.1 Operation • Allows the detection of a T2 TAP.7 controller that is deployed in a Star-4 topology. • Enables TDOC signal behavior that prevents drive conflicts in a Star-4 Scan Topology. • Enables the use of SSDs
T4	01000	**OScan0** • Data rate dependent components • Single TAP.7 communication • Debug and Test applications
	01001	**OScan1** • TAP.1 components • Single/Multi-TAP.7 communication • Debug and Test applications
	01010	**OScan2** • TAP.1 components • No TDI or TDO in non-shift states • Debug applications
	01011	**OScan3** • TAP.1 components • No TDI in non-shift states • No TDO in any state
T4	01100	**OScan4** • Data rate dependent components • Single TAP.7 communication • Debug and Test applications
	01101	**OScan5** • TAP.1 components • Single/Multi-TAP.7 communication • Debug and Test applications
	01110	**OScan6** • TAP.1 components • No TDI or TDO in non-shift states • Debug applications

Table continues on the next page...

Table 72-9. Scan Format Register Values (continued)

TAPC.7 Class	SCNFMT	Description
	01111	**OScan7** • TAP.1 components • No TDI in non-shift states • No TDO in any state
	10000	**MScan** • Data rate dependent components • Multi TAP.7 communication • Directed CID assignment • Virtually any IP with compliant or non-compliant 1149.1 behavior
	10001 – 11111	**Reserved**

The use of a Scan Format value other than 00000b – 10000 shall not change the value of the SCNFMT Register.

72.7.2.3.5 Scan Selection Directive Enable (SSDE)

This register specifies whether the Scan Selection State may be managed using the scan selection directives.

0 – Scan selection directives are not enabled.

1 – Scan selection directives are enabled.

This register is set using the STMC command.

This register is read using SCNS (Scan String), RDBACK0.

72.7.2.3.6 Delay Control (DLYC[1:0])

The Delay Control register provides a means for the external tool to delay the completion of an SP. This delay is essentially an external tool stall. This delay may be zero, one, two, or n TCKC periods. This delay is especially useful when the TCKC is sourced by the TS and a Standard-to-Advanced Protocol adapter is added to an external tool supporting only the Standard Protocol. It allows an external tool design additional time to receive TDO, advance the external tool TAPC state, receive TMS and TDI information, and begin generation of a new SP payload. The DLYC register should be programmed before the use of the Advanced Protocol begins after the use of the Standard Protocol.

Set using the STMC command.

Read using SCNS, RDBACK0

Bits 18-17 of the "Global Register."

72.7.2.3.7 Ready Control (RDYC[1:0])

The Ready Control register defines behavior exhibited in the SP payload output bit frames when the STL stall opportunities (RDY bits) are included as control information. This register defines the number of additional bits inserted in these bit frames. These bits provide more time for a high-performance external tool to ascertain whether the TAP.7 controller is ready to complete the SP payload. The use of these bits makes a high-performance external tool design easier as input and output buffer delays play less of a role in limiting the TAP.7 controller performance. The RDYC register should be programmed before the use of the Advanced Protocol begins.

Set using the STMC command.

Read using SCNS, RDBACK0.

Bits 18-17 of the Global register state.

72.7.2.3.8 Test Reset (TRESET)

Asserts a test reset to the STL.

0 – The nSYS_TRST and SYS_TMS signals presented to the STL is not influenced by this bit.

1 – The nSYS_TRST presented to the STL is asserted and the SYS_TMS signal is a logic 1.

Set using the STC1 command.

The effects of the TRESET Register may be modified by a private TAP.7 controller register. When this private register is unimplemented or has a value of zero, the TRESET register causes the maximum initialization of the STL with nSYS_TRST and the SYS_TMS logic 1 value. Otherwise, the value of the private register may modify the function of the TRESET Register bit.

When the TRESET Register is a logic 1, the STL scan path appears broken as the state of CLTAPC remains *Test-Logic-Reset* while the EPUTAPC state progression continues. When the operation of the EPUTAPC and CLTAPC controllers is coupled, as with a T1 TAP.7, the state of these two TAPCs may be resynchronized to the *Run-Test/Idle* state by:

- An STC1 Command that sets the TRESET Register value to a logic 0.
- A stay in the Run-Test/Idle state of two or more SYS_TCK periods immediately following the Update-DR state of this command

A failure to follow the guidelines is considered a programming error and will result in erroneous system operation. The EPUTAPC and CLTAPC states will not be synchronized as they progress through the state diagram.

72.7.2.3.9 Auxiliary Pin Function Control (APFC[1:0])

This register enables TDI and TDO alternate functions when 2-pin TAP.7 operation is selected.

0x – TDI and TDO have JTAG function.

1x – TDI and TDO have alternate function.

Set using STC2 command.

Read using SCNS, RDBACK0.

72.7.2.3.10 Conditional Group Member (CGM)

Used by STC1, STC2, STTESTM, and EXC3 – EXC0 commands as the “condition” for updating registers.

Set and cleared using MCM and SCNB commands.

Read using SCNS, RDBACK0.

72.7.2.3.11 Scan Group Candidate (SGC)

This register determines whether the STL is coupled when the *Run-Test/Idle* state is reached when scan formats other than JScan0 and JScan1 are used.

- **0** – Decoupling action.
- **1** – Coupling action.

Set and cleared using STMC, MSC, and SCNB commands.

Read using SCNS, RDBACK0.

72.7.2.3.12 Sampling Edge (SEDGE)

The Sampling Edge register defines the TCKC edge used to sample the TMSC input.

- **0** – Sample TMSC on the TCKC falling edge.
- **1** – Sample TMSC on the TCKC rising edge.

Set and cleared using STC1 command.

Read using SCNS, RDBACK0

72.7.2.3.13 Read Back 0 (RDBACK0)

Non-transport related register information.

Read using SCNS command.

Unimplemented registers shall read back as "0".

Table 72-10. RDBACK register format

DT = Default Topology

DP = Default Pin Function

72.7.3 EPU Commands

There are two command types:

- Two Part Commands
- Three Part Commands

Any number of two-part and three part commands may be issued in any combination before the command control level is exited. If the command control level is exited before a two- or three-part command is completed, the command is aborted and becomes a NOP.

72.7.3.1 Two Part Commands

TAP.7 controller commands are 10-bit values. The 10-bit commands are created by two consecutive DR-Scans when the control level is locked at the command control level (two). The first DR-Scan provides a five-bit command opcode. The second DR-Scan provides a five-bit operand. These two scans are called the command part one (CP1) and command part two (CP2), respectively. A command created entirely with these two scans is called a two-part command.

72.7.3.2 Three Part Commands

Some commands are used to send and/or receive data values other than values embedded in the command's operand. These commands are called three-part commands. With these commands, CP1 and CP2 are followed by an additional DR-Scan to transport a data value to or from an EPU scan path. When used for this purpose, the DR-Scan is called a Control Register Scan (CR-Scan). The CR-Scan is a minimum of zero bits in length with there being no maximum length. The CR-Scan path is described in SECTION.

72.7.3.3 Command Sequence

The two 5-bit values concatenated to create the 10-bit command represent the number of Shift-DR states between the *Capture-DR* and *Update-DR* states of CP1 and CP2. The count within CP1 creates the MSBs of the command while the count within CP2 creates the LSBs of the command. The command is decoded when the *Update-DR* state of the second DR-Scan is reached. A determination as to whether the command is a two- or three-part command is made at this point. The command format is shown in the following figure.

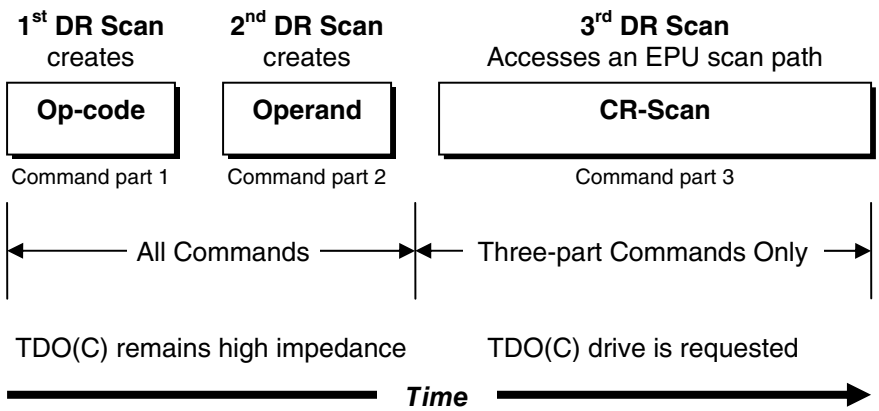

Figure 72-8. DR_Scan sequence used for command creation

The 10-bit command created by CP1 and CP2 determines the command's function and whether the command is a two- or three-part command. If the command is a two part command, the function specified by the command is performed when command part 2 completes. If the command is a three-part command, the DR-Scan following CP2 performs a TAP.7 controller function designated by the 10-bit controller command. This DR-Scan is called a ***Control-Register Scan*** (CR-Scan) and can be any length. A CR-Scan has many of the attributes of the DR-Scan as it moves data between the external tool and TAP.7 controller and accesses various EPU scan paths. There are many two part commands, but only three three-part commands, each having a special purpose.

72.7.3.4 Commands

There are 11 mandatory and 5 optional commands that can be grouped in classes as shown in the following list:

- Store – The operand is stored in a register or causes an action.
- Select – Controls participation of Scan and conditional command execution.
- Scan – Inputs and outputs with a CR-Scan.
- Enumerate – Controller ID allocation and de-allocation.
- Private – Commands available for chip-specific definition.

The definition of the commands with their operands is shown in the following table.

Table 72-13. – TAP.7 controller command list

Command class	Opcode count	Mnemonic	Name	TAP.7 class			
				1	2	3	4
Store	0x00	STMC	Store Miscellaneous Control	M	M	M	M
	0x01	STC1	Store Conditional 1-bit	M	M	M	M
	0x02	STC2	Store Conditional 2-bit	M	M	M	M
	0x03	STFMT	Store Format	-	M	M	M
	0x04	STDCST	Store Data Channel State	-	-	-	-
Select	0x06	MCM	Make Cond. Group Member	M	M	M	M
	0x07	MSC	Make Scan Group Candidate	-	M	M	M
Scan	0x08	SCNB	Scan Bit	M	M	M	M
	0x09	SCNS	Scan String	M	M	M	M
Enumerate[1]	0x0A	CIDA	Allocate Controller ID	-	-	M	M
	0x0B	CIDD	De-allocate Controller ID	-	-	M	M
Reserved	0x0C–0x1F	Reserved	Reserved	-	-	-	-

1. Enumerate commands are not currently supported by the CJTAG module.

72.7.3.4.1 Store Commands

Store commands are two-part commands that are available in both Star and Series Scan Topologies. The Store Miscellaneous Control (STMC) Command performs control functions that affect all TAP.7 controllers sharing an external tool connection. It stores values in one-bit and two-bit registers.

The Store Conditional 1 bit (STC1) and Store Conditional 2 bit (STC2) Commands store one-bit and two-bit values in registers, respectively. These commands operate two ways:

1. Unconditionally storing registers in all TAP.7 controllers or
2. Storing registers in only the TAP.7 controllers that have a logic 1 Conditional Group Member (CGM) Register value.

The Store Format (STFMT) Command unconditionally stores a five-bit Scan Format value.

The Store Data Channel State (STDCST) Command stores a five-bit value identifying the states supporting transport.

72.7.3.4.2 Select Commands

Select commands are two-part commands that are available in both Star and Series Scan Topologies. Their primary use is to select TAP.7 controllers of interest in a Star Scan Topology. These commands define the TAP.7 controller(s) participating in scans and the TAP.7 controllers that conditionally execute STC1 and STC2 Commands.

The Make Conditional Group Member (MCM) Command specifies which TAP.7 controllers execute store conditional commands as it manages the Command and Path Enable (CAPE) Register. This register also affects the execution of private commands and is utilized in EPU scan path selection.

The Make Scan Group Candidate (MSC) command manages the SGC register. This register determines whether the STL is coupled when the *Run-Test/Idle* state is reached when scan formats other than JScan0 and JScan1 are used. Select commands execute only when the CIDI Register is a logic 0, indicating the TAP.7 controller's CID is valid, and are treated as no operations otherwise.

72.7.3.4.3 Scan Commands

Scan commands are three-part commands that are available in both Star and Series Scan Topologies. The CR-Scan portion of Scan Bit (SCNB) and Scan String (SCNS) Commands is used to set and test bits (SCNB) or transfer strings of bits (SCNS). The commands may be used to access both public and private registers.

72.7.3.5 Command Definitions

72.7.3.5.1 Store Commands

72.7.3.5.1.1 Store Miscellaneous Control Command (STMC)

STFMT		Store Scan Format
Opcode	Operand	
00011	nnnnn	SCNFMT = nnnnn

72.7.3.5.2 Select Commands

This section describes the select commands with their operands.

72.7.3.5.2.1 Make Conditional Group Member (MCM)

This command operates as a no operation when the CIDI Register is a logic 1 (The Controllers CID is invalid). Otherwise it sets the CGM bit in a TAP.7 controller that has a valid CID and the CID matches the operand CID field (iiii). The CGM Register is also stored with the STMC and SCNB commands.

Table 72-18. Make Conditional Group Member (MCM)

MCM		Conditional Group Member	
Opcode	Operand	m	Description
00110	m iiii	0	CGM bit of the non-targeted controller is cleared
		1	CGM bit of the targeted controller is set. CGM bit of a non-targeted controller is unaffected.

72.7.3.5.2.2 Make Scan Group Candidate (MSC)

This command operates as a no operation when the CIDI Register is a logic 1 (The Controllers CID is invalid). Otherwise it sets the SGC bit in a TAP.7 controller that has a valid CID and the CID matches the operand CID field (iiii). The SGC Register is also stored with the STMC and SCNB commands.

Table 72-19. Make Scan Group Candidate (MSC)

MSC		Make Scan Group Candidate	
Opcode	**Operand**	**m**	**Description**
00111	m iiii	0	SGC bit of the non-targeted controller is cleared
		1	SGC bit of the targeted controller is set. SGC bit of a non-targeted controller is unaffected.

72.7.3.5.3 Scan Commands

72.7.3.5.3.1 Scan Bit (SCNB)

This is a 3-part command. The operand chooses the bit to be read or written by the CR-Scan.

Table 72-20. Scan Bit (SCNB)

SCNB			Scan Bit		
Opcode	**Operand**	**CR-Scan**	**yyyyy**	**Description**	**R/W**
01000	yyyyy	-	0	Scan Group Candidate (SGC)	Write only
		-	1	Conditional Group Member (CGM)	Write only
		-	2	CNFG[0]	Read only
		-	3	CNFG[1] (not implemented)	Read only
		-	4	CNFG[2] (not implemented)	Read only
		-	5	CNFG[3] (not implemented)	Read only
		-	6	Functional reset requested (FRESETR) (not implemented)	Read only
		-	7	Series topology detect	Write only
		-	15 – 8	Reserved	Read only

72.7.3.5.3.2 Scan String (SCNS)

This is a 3-part command. The operand chooses the string to be read or written by the CR-Scan.

Table 72-21. Scan String (SCNS)

SCNS			Scan String		
Opcode	**Operand**	**CR-Scan**	**yyyyy**	**Description**	**R/W**
01001	yyyyy	-	0	RDBACK[0] Register [31:0]	Read only

Table continues on the next page...

Table 72-21. Scan String (SCNS) (continued)

SCNS			Scan String		
Opcode	Operand	CR-Scan	yyyyy	Description	R/W
		-	1	RDBACK[1] Register [31:0] (not implemented)	Read only
		-	2	CNFG[0] Register [31:0]	Read only
		-	3	CNFG[1] Register [31:0] (not implemented)	Read only
		-	4	CNFG[2] Register [31:0] (not implemented)	Read only
		-	5	CNFG[3] Register [31:0] (not implemented)	Read only
		-	6 - 7	Reserved (read logic 0)	Read only
		-	31 - 8	Private – available for customization	

72.7.4 EPU operating states

The TAP.7 controller and STL share the use of ZBSs. The EPU has three operating states as shown in the following figure:

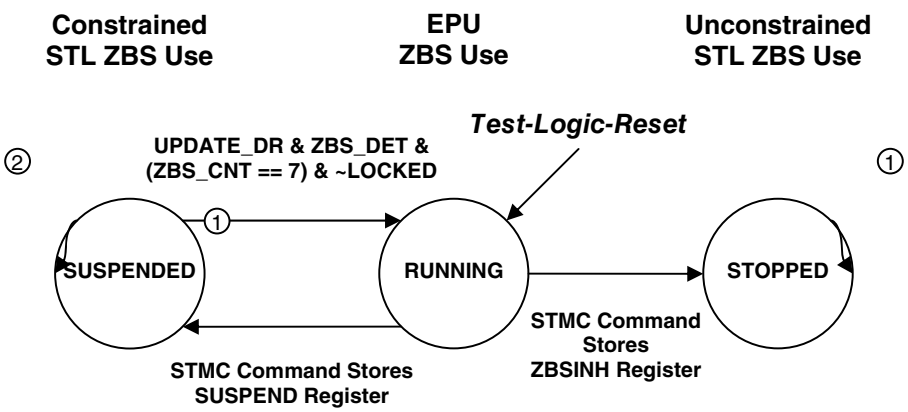

Figure 72-9. EPU operating states

The values of the SUSPEND and ZBSINH Registers determine the type of operation as shown in the following table. The Test-Logic-Reset state sets the SUSPEND and ZBSINH Register values to a logic 0.

Table 72-22. ZBS use state characteristics with both TAP.7 and other ZBS use

ZBSINH	SUSPEND	EPU operating State	ZBS use by:	Until
0	0	RUNNING	EPU	Command allocates to STL

Table continues on the next page...

Table 72-22. ZBS use state characteristics with both TAP.7 and other ZBS use (continued)

ZBSINH	SUSPEND	EPU operating State	ZBS use by:	Until
0	1	SUSPENDED	STL	ZBS sequence allocates to EPU
1	0	STOPPED	STL	Test-Logic-Reset state allocates to EPU
1	1	Not possible		

72.7.5 System and EPU Paths

The System path is utilized when the external tool requires access to system (STL) resources. This path is used when either the SUSPEND Register is a logic 1 or the ZBS count is less than or equal to one. The EPU path is used otherwise.

The EPU scan path is constructed from five types of EPU scan paths:

- **Bypass** – A 1-bit scan path
- **Bit** – Supports set and test bit operations (a 1-bit shift register)
- **String** – Support 32-bit reads or 32-bit writes
- **Enumerate** – A 36-bit scan path that transports a TAPC address with T3 and above TAP.7s
- **Auxiliary** – An n-bit scan path that transports 1 – n bits using a conventional IEEE 1149.1 style DR-Scan path using Control Levels 4 and 5.

72.8 APU (Advanced Protocol Unit) Operation

72.8.1 Overview

The Advanced Protocol Unit (APU) is placed between the EPU and the RSU to create the T4 TAP.7 controller. The APU delivers advanced capabilities with a number of operating modes (new scan formats) that utilize the Standard Protocol and the Advanced Protocol in both the narrow and wide T4 TAP.7 versions.

The APU enables scan transfers with two signals by serializing the information related to a TAPC state machine state. It provides a number of serialization formats to balance scan flexibility and scan performance. It multiplexes the use of the TMSC signal for T4 TAP.7 controller functions. The serialization is bypassed to provide T3 TAP.7 capability.

With a wide TAP.7, the chip architect may choose to implement the TDIC and TDOC signal functions as fixed functionality (the T3 TDIC and TDOC functions) or as programmable between the T3 TDIC and TDOC signal functions and an alternate function using a TAP.7 controller register. In this case, the default signal function may be either of the programmable choices. Programmable TDIC and TDOC functionality provides a means to fully utilize these signals in any scan topology as the T3 TAP.7 functionality is fully supported.

The entire EPU infrastructure (i.e., ZBS detection, control-level management, and command generation) is utilized when either the Standard Protocol or the Advanced Protocol is used, as these TAP.7 controller attributes are controlled entirely from the TAPC state machine state progression. The EPU is unaware of the APU's existence. All T4 features are managed outside of the EPU.

The TAP.7 serialization schemes are specified with scan formats that complement the JScan 0-3 Scan Formats inherited from the T3 TAP.7. The scan formats are called advanced scan formats as they support two-signal operation.

Two groups of scan formats (MScan and OScan0-7) provide a number of options for the serialization of scan information for use in a Star-2 scan topology. The OScan Scan Format is broken into two groups with the same function, one group has better performance but may only be used with an external tool sourced TCKC. The external tool chooses a scan format that matches the constraints imposed by the application, chip components, and possibly the external tool itself.

The MScan and OScan formats address Test and Debug use cases. The mandatory MScan and OScan0-1 formats emphasize flexibility over performance. The remaining optional Oscan2-7 formats emphasize performance over flexibility by not transmitting unneeded information such as TDI and TDO in non-shift TAPC state machine states.

The optional capabilities added with T4 and above TAP.7s change the bit sequences seen at the TAP.7 signals. A TAP.7 controller comprehends only the bit sequences generated by the use of the features it supports. It is never exposed to bit sequences it does not comprehend. A check for supporting an enabled feature is made before the feature is used (alters the bit sequences). When a T4 TAP.7 controller detects the use of an unsupported scan format, it halts its operation and places itself in a state where its operation may be resumed. This state is henceforth called "offline". A TAP.7 controller that is not offline is henceforth called "online". While offline the TAP.7 controller awaits the detection of a

special signaling sequence called the Online Activation Protocol. This protocol sequence places an offline TAP.7 controller online and synchronizes the operation of all online TAP.7s.

The Advanced Protocol Unit supports the stall of a transfer by both the external tool and STL at any TAPC state.

The APU provides the following functions:

- Bypass (for operation with the Standard Protocol)
- Scan control (for SP use)
- Configuration Control (for CP use)

The Scan Control, Configuration Control, and Transport Control functions are idled when the Standard Protocol is used as the Bypass Function connects the TCKC and TMSC pins to the EPU.

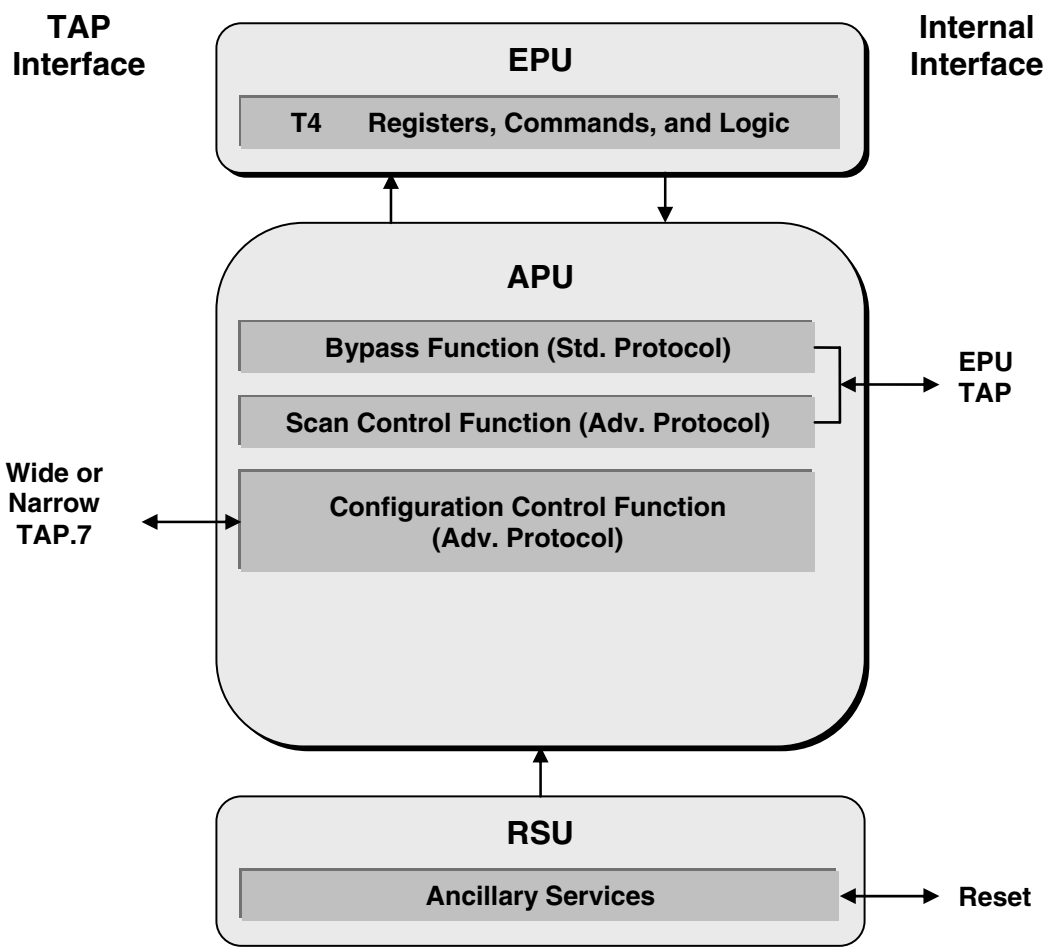

Figure 72-10. Conceptual block diagram of the APU functions

The APU's internal interface includes a connection to EPU registers, the EPU's TAP interface, connections to chip-level data channels (when they are implemented), and reset signaling with the EPU. The APU's TAP interface provides mutually exclusive use of the TMSC pin for:

- Bypass Function
- Scan Control Function
- Configuration Control Function

When the Standard Protocol is used, the APU's Bypass function connects the EPU directly to the TAP.7 pins. When the TDIC and TDOC pin functions are not available (narrow TAP.7 or TDIC and TDOC pin functions are an alternate function), the APU sources a logic 1 to the EPU inputs associated with these pins.

When the Advanced Protocol is used, the APU multiplexes the use of the TMSC pin between the other APU functions. Scan Control acts as a serial to parallel converter, translating the parallel information at the EPU's TAP interface into bidirectional serial transfers. Since the Scan Control is literally a protocol adaptor, the entire EPU infrastructure (ZBS detection, control-level management, and command generation) is utilized when either the Standard or Advanced Protocol is used, as these TAP.7 controller attributes are controlled entirely from the TAPC state progression.

72.8.2 Operation

The conceptual view of the APU operation is shown in the following figure.

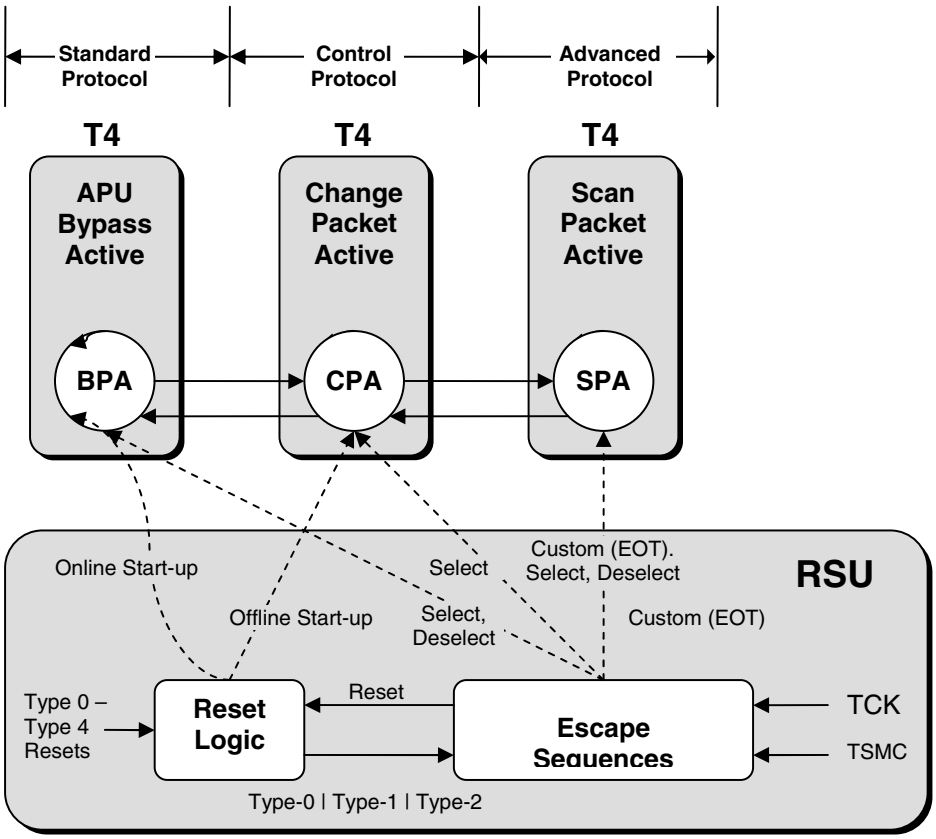

Figure 72-11. Conceptual view of APU operation

The APU operating states managing the use of the TAP pins and the ancillary (RSU) services use of the TMSC pin.

APU operating states:

- ***BPA*** – **B**y**P**ass **A**ctive
- ***CPA*** – **C**hange **P**acket **A**ctive
- ***SPA*** – **S**can **P**acket **A**ctive

72.8.2.1 BPA

The *BPA* state allocates the use of the TMSC pin to the Standard Protocol. This state is entered two ways:

- As a result of a TAP.7 controller reset when the TAP.7 controller starts up online.
- From the CPA state when a TAP.7 controller register write specifies the use of the Standard Protocol.

72.8.2.2 CPA

The *CPA* state allocates the use of the TMSC pin to a CP. This state is entered in one of three ways:

- As a result of a TAP.7 controller reset when the TAP.7 controller starts up offline.
- A value specifying the use of the Advanced Protocol is written to the SCNFMT Register when using the Standard Protocol.
- A TAP.7 controller register write occurs when using the Advanced Protocol.

72.8.2.3 SPA

The SPA state allocates the use of the TMSC pin to an SP. This state is entered when the SCNFMT Register specifies the use of the Advance Protocol when a CP ends.

72.8.3 Escape sequences

Escape-sequence detection provides services to the Reset Logic, Scan, Configuration Control, and Transport Control functions as outlined below:

- **Scan and Transport Control** – End of Transfer (EOT) escape sequence detected.
- **Configuration Control** – Synchronize Advanced Protocol (SAP) escape sequence.
- **Reset Logic** – Reset (RES) escape sequence detected.

An EOT escape sequence is used to increase the efficiency of OScan Scan formats.

An SAP escape sequence is used to place TAP.7 controllers online.

A RES escape sequence asynchronously causes generation of a Type-3 Reset. Following a RES escape sequence, the drive of the TMSC pin is inhibited so it is not driven when TCKC becomes a logic 0 immediately following the RES escape sequence.

72.8.4 Signal behaviors

The TCKC signal:

- The test clock

The TMSC signal:

- An input when the Standard Protocol is used
- Bi-directional when the Advanced Protocol is used

The TDI and TDO signals:

- Deleted with a narrow TAP.7
- One of two functions with a wide TAP.7
  - Fixed – as the TAP.7 TDIC and TDOC pin functions, or
  - Programmable – as the TAP.7 TDIC and TDOC signal functions or alternate functions with a TAP.7 controller reset establishing the default signal function.

72.8.5 APU Functions

72.8.5.1 Bypass Active (BPA) Function

When the Standard Protocol is used, the APU connects the EPU inputs and outputs directly to the TAP.7 pins. If the TDIC and TDOC pin functions are not present (e.g., a narrow TAP.7 or the TDIC and TDOC pins have an alternate function assigned to them), the APU provides a logic 1 to the EPU for unsupported pin functions and ignores the EPU's TDO output data.

72.8.5.2 Scan Packet Active (SPA) Function

The Scan Control function is encapsulated within the Scan Packet Active (SPA) state. With the Standard Protocol, the external tool and TAP.7 exchange the scan information associated with a single TAPC state machine state in one TCK period using the TMS(C), TDI(C), and TDO(C) pins. With the Advanced Protocol all or part of this information is exchanged serially within a Scan Packet (SP) as shown in . There is a one to one correspondence between SPs and TAPC state machine state changes, except when the SPA state precedes the CPA state. In this case the SP preceding a CP does not advance the TAPC state machine state.

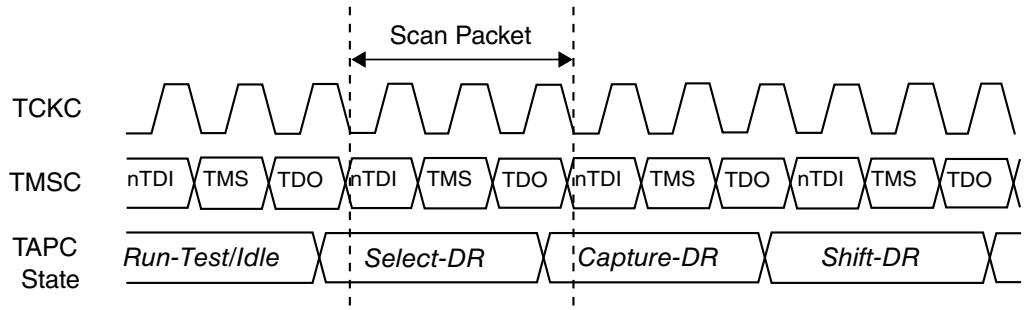

Figure 72-12. Scan Packet Sequence

A comparison of the parallel transfer of TAP information with the Standard Protocol and the serialization and de-serialization of the TAP information using the TCKC and TMSC pins with the Advanced Protocol is shown in FIGURE. The IEEE 1149.1 signals between the EPU and STL are prefixed with SYS_.

The APU manages the serialization and de-serialization of the scan information. The APU converts the TDI and TMS information within a Scan Packet (SP) into the TMS and TDI information presented to the EPU. It converts the combination of the EPU TDO and EPU TDO_OE signals into the TDO information in the same SP. If the EPU indicates that the TDO pin drive is not enabled, logic 1 TDO data is created, otherwise the TDO data is the supplied by either the EPU or STL.

Information within a Scan Packet is first passed from the external tool to the TAP.7 followed by information passed from the TAP.7 to the external tool. In this example the scan format specifies the exchange of the TMS, TDI, and TDO TAPC information. Each TAPC state machine state takes three TCKC periods. Other scan formats specify the exchange of different mixes of information. Control information is added with the most flexible scan formats. Some scan formats send less information and consequently take fewer TCKC periods.

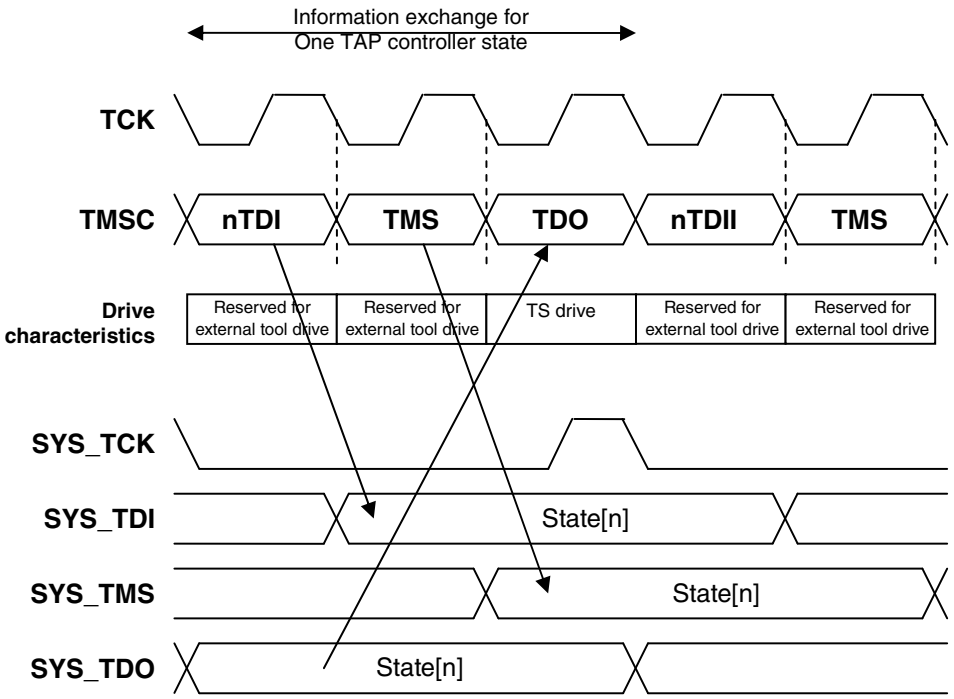

Figure 72-13. Serialization and De-serialization of Scan Packet Information

In order to produce comparable TAPC state machine state rates with a TAP.1 and TAP.7 controller:

- Full-cycle timing between the external tool and TAP.7 allows operation at higher TCKC frequencies.
- The number of bits transferred to advance a TAPC state machine is minimized. (reaching as few as one for some scan formats.)

The TAP.7 controller provides both full-cycle bit timing (falling TCKC edge to falling TCKC edge) and half-cycle bit timing (falling TCKC edge to rising TCKC edge), with a TAP.7 register used to define the type of timing used. Half-cycle timing is used as the default following a TAP.7 controller reset. The TCKC frequency is reduced to accommodate half-cycle timing.

With full-cycle timing, the TMSC input and output data are both output with and sampled with the falling edge of the TCKC. This means that the entire TCKC period may be spent transferring a bit from the external tool to the TAP.7 or vice-versa. The TCKC frequency can therefore be maximized when full-cycle timing is used. With half-cycle timing, the APU samples the TMSC input data with the rising edge of the TCKC and outputs TMSC data with the falling edge of TCKC.

Minimizing the number of bits transferred per TAPC state machine state is affected by a number of factors. The information that must be transferred per TAPC state machine state varies for different test and debug applications. Also, with some test and debug

applications, all TAPC state machine states do not require that the same amount of information be transferred. This is especially true with debug applications where specialized use of the TAP is more likely.

72.8.5.3 Control Process Active (CPA) Function

While using the Advanced Protocol, all TAP.7 configuration changes occur within the CPA state. All online and offline transitions also occur while in the CPA state. When entering the CPA state from the BPA or SPA state, the CPA state checks for the use of supported features affecting the Advanced Protocol. The CPA state is exited when the enabled features affecting the Advanced Protocol are supported.

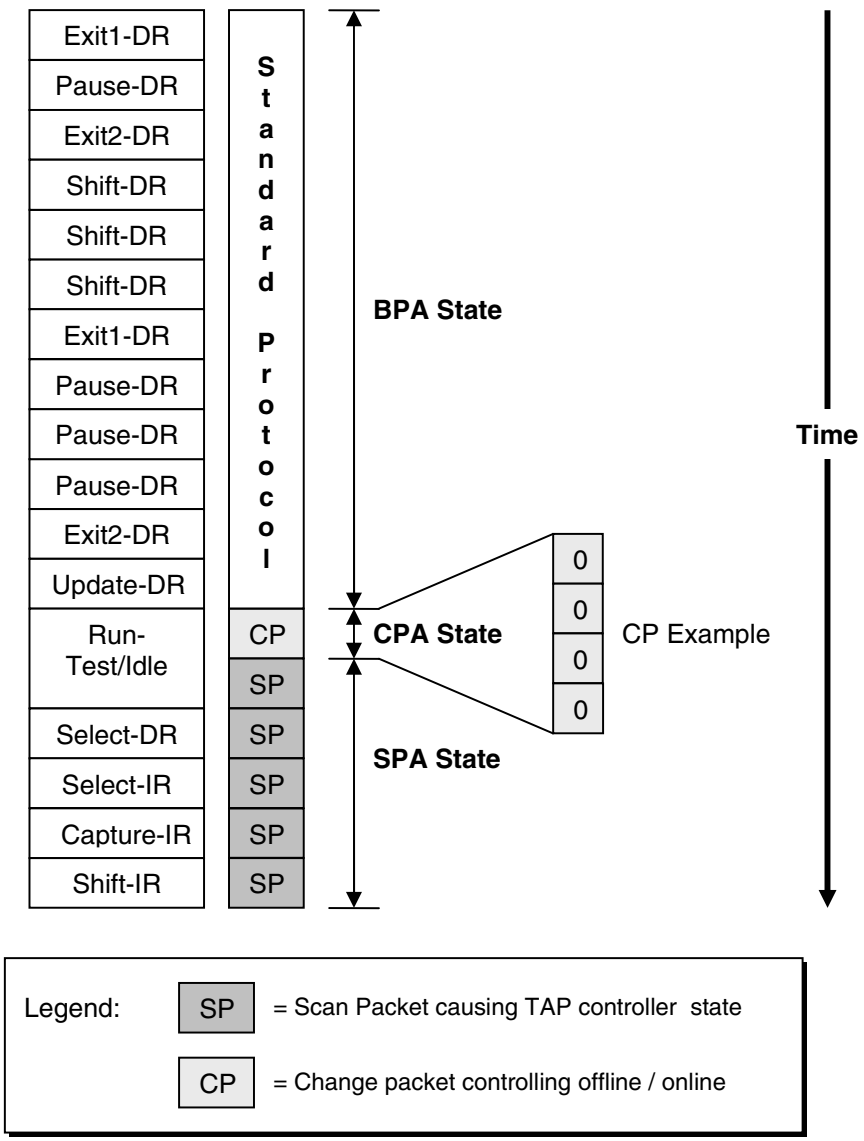

Figure 72-14. CPA State Entry from BPA State with Continued Online Operation

An SP preceding a CP does not advance the TAPC state machine state. This SP performs housekeeping functions that assure the contents of the SP preceding this SP have been fully utilized. This has significance when the SP contains control information that allows the STL to stall the completion of a SP.

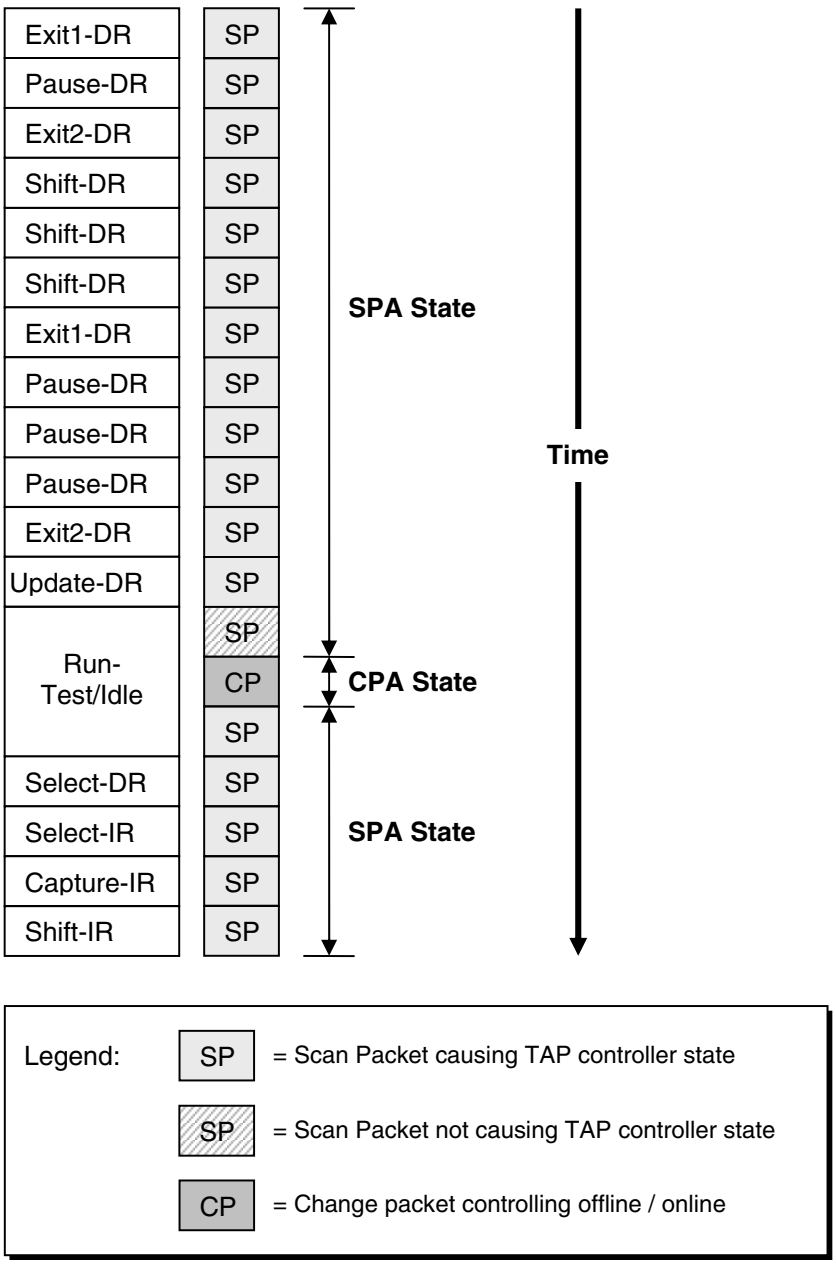

Figure 72-15. CPA State Entry from the SPA State with Continued Online Operation

When an unsupported feature is enabled, the TAP.7 controller is placed offline. This suspends the TAP.7 controller's operation at a point where its operation may later be synchronized to the remainder of the system. The APU stops advancing the EPU's and CLTAPC's TAPC state machine state while offline. It also suspends Data Channels activity while offline. The detection of the appropriate Online Activation Protocol while

the TAP.7 controller is offline places the TAP.7 controller online and causes an exit from the CPA state to the SPA state. An offline to online transition initiates the use of a predefined set of mandatory features in all online TAP.7 controllers to assure they operate synchronously.

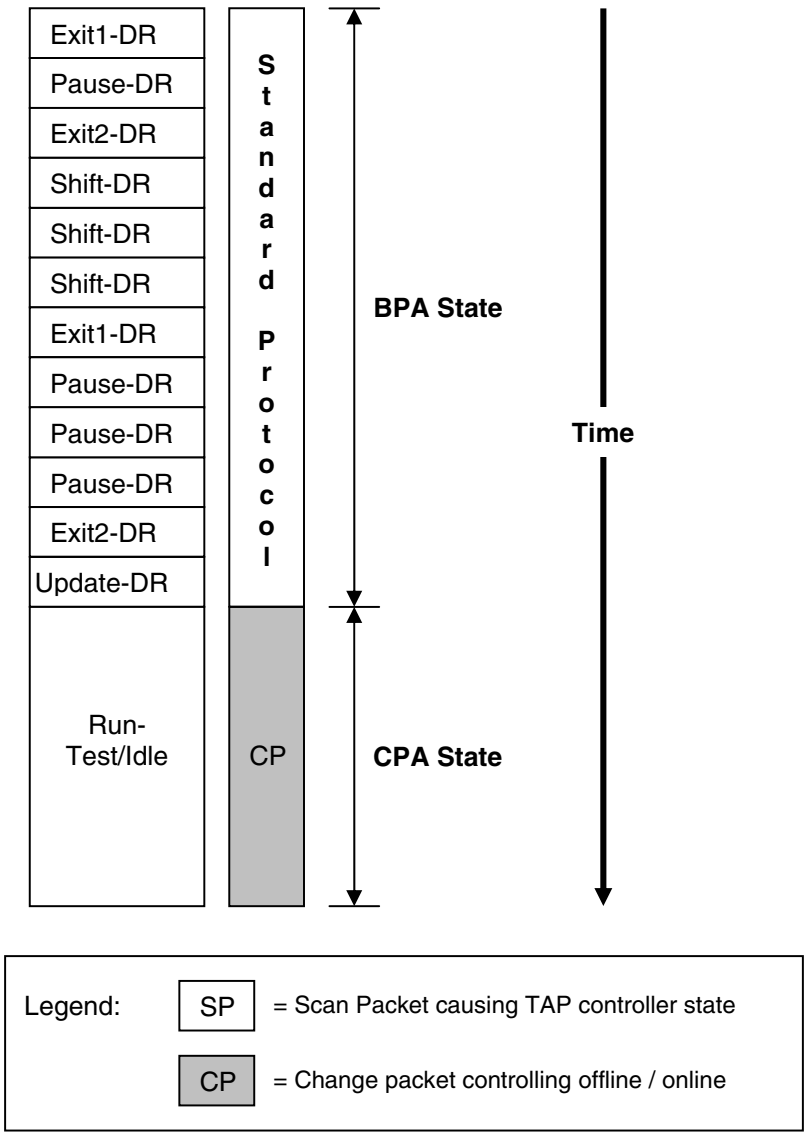

Figure 72-16. CPA State Entry from the BPA State with Offline Operation

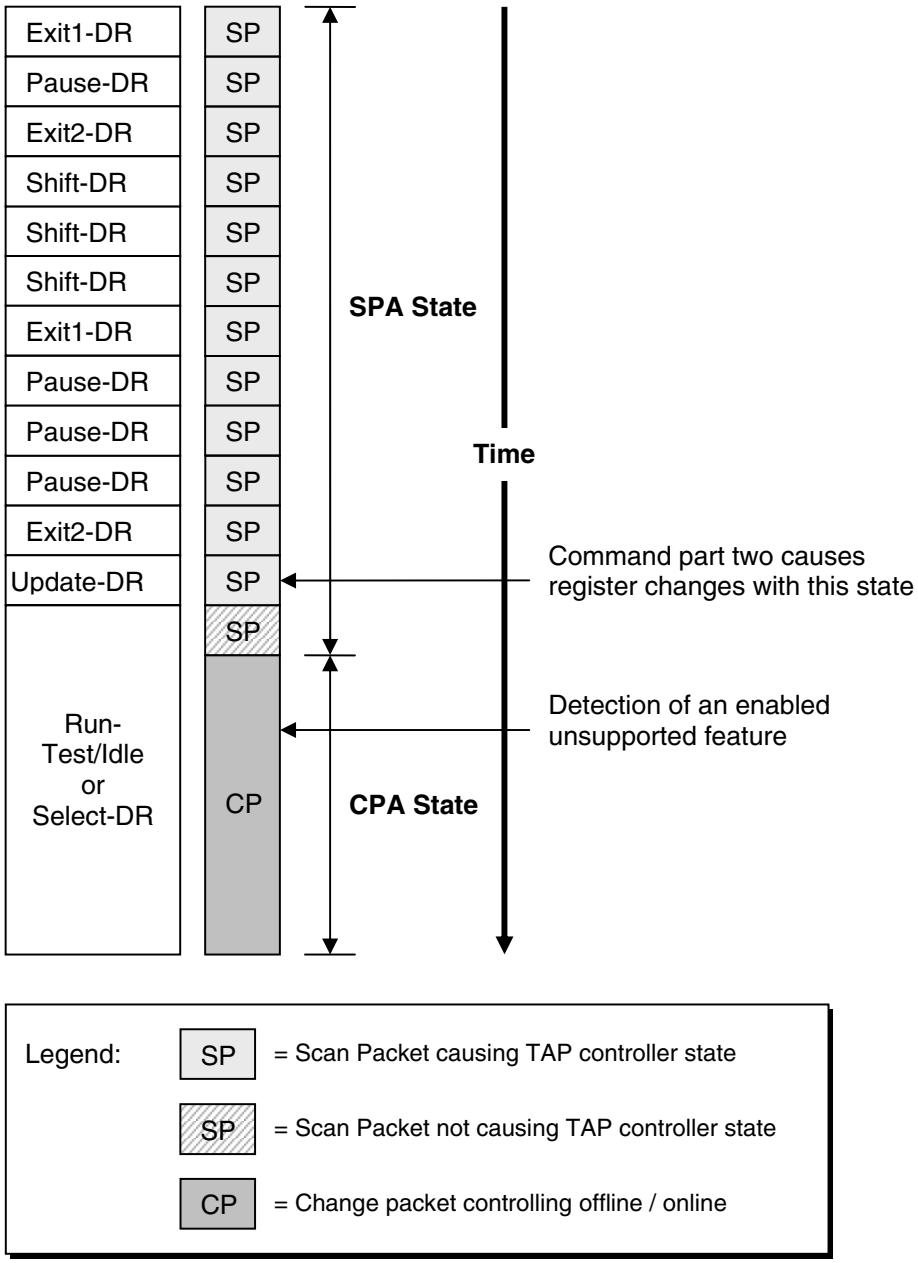

Figure 72-17. CPA State Entry from the SPA State with Offline Operation

A TAP.7 controller reset places the TAP.7 controller offline when the offline at start-up option is used. From this point the TAP.7 controller awaits being placed online.

72.8.6 Configuration Change Packets (CP)

A Change Packet (CP) is composed of three element types:

- **Preamble** – A 1-bit value that is a don't care. This bit facilitates a Standard to Advanced Protocol change with some external tool implementations.

- **Body** – Two or more bits representing one or more CP directives
  - **00** – CP_END
  - **01** – CP_NOP (extends the body by 1-bit)
  - **10** – CP_NOP (extends the body by 1-bit)
  - **11** – CP_RES (Generate a Type-3 TAP.7 controller reset coincident with the post amble bit.
- **Post amble** – A 1-bit value that is a don't care. This bit facilitates and Advanced to Standard Protocol change with some external tool implementations.

A minimum-length CP has a Preamble, a 2-bit Body, and a Post amble. This can be as simple as four logic zero values.

72.8.7 Scan Packet

A Scan Packet defines the period of TMSC pin activity where control information exchanged by the external tool and TAP.7 controller affects the TAPC state, except when the SP precedes a Change Packet. The external tool should view the Scan Packet as:

- Exchanging only the necessary TAPC information (TMS, TDI, and TDO or some subset thereof)
- Causing an advance of the TAP.7 TAPC state when it is not followed by a Change Packet.
- Causing an advance of the STL TAPC state when it is not followed by a Change Packet and when the STL is coupled.

With this perspective, the external tool views Scan Packets as running a virtual TAPC state machine at the TAP.7 pins. The effects of each Scan Packet take effect when the Scan Packet completes. The real TAP.7 and STL controller state machine states may change state before or after the virtual state machine.

72.8.8 SP Format

A SP serially exchanges the TDI, TMS, and TDO or a subset thereof, between the external tool and TAP.7 controller. Control information may be added to this exchange. A SP has three parts:

- **Payload** – Data + Control information (all scan formats), the payload content is varied to trade-off performance and flexibility. RDY bit(s) within the payload are included with some scan formats to provide the STL a means to stall progression of the TAPC state.
- **Delay** – Control information (optional) providing separation of adjacent payloads in time. Delay elements support simple external tool implementations where a delay element is used to stall progression of the TAPC state while it develops a new SP following the completion of the prior payload.

The header elements, delay elements, and control information within the payload element is consumed by the TAP.7 controller. This and other control information within the SP payload is not visible to the EPU and STL TAPCs.

72.8.8.1 Payload Element Content

72.8.8.1.1 Input and Output Bit Frames

An input bit frame is sourced by the external tool and an output bit frame is sourced by the TAP.7 controller. The payload may contain and input bit frame, an output bit frame, or both. When an input bet frame arrives at the TAP.7 controller, the TDI and TMS information within it is presented in parallel to the TAP.1 controllers within the EPU and STL. The output bit frame begins when the input frame is completed. The payload is completed when the EPU and STL are ready to utilize this information and the TDO data needed to complete the output bit frame is available. This process is repeated for each SP.

With input bit frames, MScan and OScan scan formats have no control bits input bit frames.

With output bit frames:

- TDO information passed to the external tool is a logic 1 when the EPU indicates the TDO pin would be high impedance.
- RDY bits provide TAP.7 stall opportunities with MScan and some OScan formats.
- PC0 and PC1 bits are added to MScan scan formats to allow Wire-ANDed output.

72.8.8.1.2 Varying the content of input and output bit frames

The various scan formats (MScan, OScan0-7) provide a number of options for the serialization of scan information for use in a Star-2 scan topology. These scan formats vary the content of SPs to balance flexibility and performance for different use cases. The amount of information transferred per TAPC state is based on the constraints imposed by these use cases. The MScan and OScan scan formats determine the factors affecting the payload content as shown in the following table.

Table 72-23. Factors determining the SP payload content

Scan format	Payload content determined by the:	
	TAPC state	Header
MScan	–	–
OScan	Yes	–

72.8.8.2 Delay Element Content

A delay element can be zero, one, two, or n bits in length. One and two bit delay elements are fixed length with neither the external tool or TAP.7 controller driving the TMSC pin. The TMSC pin is kept at the last value driven by either the external tool or TS. With an n-bit delay elements, the external tool drives the TMSC pin for the first n-1 bits and may drive the TMSC pin the nth bit. With an n-bit delay element the string of delay element bits is a series of directives virtually the same as those used by a CP (DLY_NOP, DLY_END, and DLY_RES).

72.8.8.3 Scan Formats

72.8.8.3.1 Overview

Scan formats utilizing the Advanced Protocol address different use cases. The amount of information transferred per TAPC state is based on the constraints imposed by these use cases. In one extreme two types of control information, the first allowing the stall of the completion of the Scan Packet, and the second supporting the Wire-AND of TAP.7 controller output are added to the TMS, TDI, and TDO information within the Scan Packet. In the other extreme, the external tool may minimize the information transferred for each TAPC state using its understanding of the application and transfer only the data of interest. In some cases the transfer of only one bit of information per TAPC is

required. There are a number of scan formats that operate between these two extremes. The external tool chooses a scan format that best matches the performance/functionality needs of the application.

The scan formats added to specify the use of the Advance Protocol are listed below:

- **MScan** – Maximum flexibility.
- **OScan0-7** – Optimized for test and debug applications.

These scan formats provide seven different functions. Five factors have influenced the definition of these scan formats:

- Supporting the capabilities of the IEEE1149.x and IEEE 1532 Standards.
- Providing the STL and external tool an opportunity to stall the TAPC state progression.
- Providing a minimum pin count and scalable functionality.
- Maximizing the efficiency of scan operations utilized for applications debug operations.
- Providing a rich set of capability for high end applications debug.

The performance and flexibility of MScan and OScan scan formats are shown in Table 72-24 and Table 72-26. The performance and flexibility of these scan formats are given subjective/approximate ratings in these tables. These ratings range from least to best. Use cases for these scan formats are also included in these tables.

72.8.8.3.2 MScan scan formats

The MScan scan format provides a universal scan function. It is the most flexible but lowest-performance scan format. The Scan Packets used by these scan formats are packed with data and control information and is the same for all TAPC states. This scan format accommodates the deployment of IEEE 1149.1 IP with non-compliant behavior within the STL. The STL is allowed to stall the TAPC state progression (to pace the arrival of Scan Packets with its ability to process them), and uses Wire-ANDed Output.

Table 72-24. MScan scan format use case summary

Scan format	Supporting	Performance	Flexibility	TCKC source
MScan	STL Stalls	Least	Best	External tool or TS
	Test			
	Non-compliant behavior STL IP

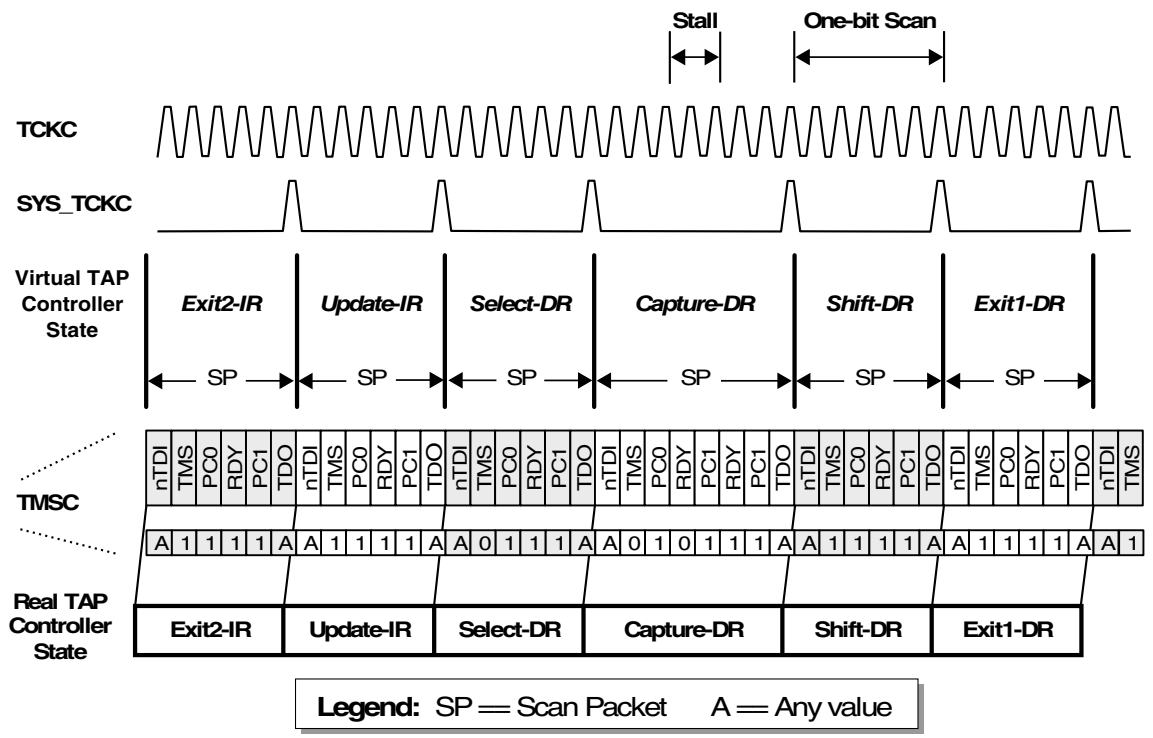

Figure 72-18. MScan Transaction

72.8.8.3.3 OScan Scan Formats

The OScan scan formats provide optimization choices where no knowledge of the data content of the scan exchange is needed. The Scan Packet content of these scan formats is modulated by a combination of the scan format and the TAPC state for some OScan scan formats. For instance, TDI data and TDO data is not exchanged for non-shift TAPC states and included in shift TAPC states in certain OScan formats. The modulation of Scan Packet content with TAPC state varies by scan format.

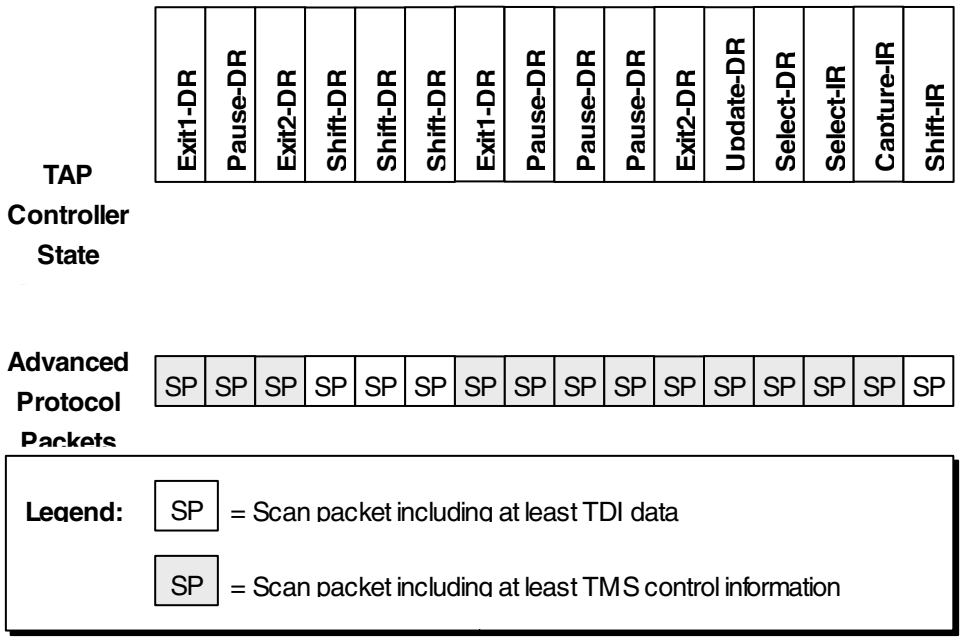

Figure 72-19. OScan Scan Packet content/TAPC state relationships

OScan scan formats replicate four functions in two forms:

- **OScan0 – OScan3:** Providing the best performance for a test clock source by the target system.
- **OScan 4 – OScan7:** Providing the best performance for a test clock sourced by the external tool.

The OScan4 – OScan7 scan formats are more efficient, as EOT escape sequences are used to identify an exit from the Shift-xR TAPC state. A Scan Packet associated with the Shift-xR TAPC state does not include a TMS bit. Instead, and EOT escape sequence overlaid on an nTDI bit causes an exit from shift TAPC state with no exit from this state occurring otherwise. A look at the 32-bit DR-Scan shows the impact of this optimization. A total of 96 bits are required when each Scan Packet associated with a Shift TAPC state when TMS is included in these Scan Packets while a total of 64 bits are required when TMS is not included in these Scan Packets. Assuming the EOT escape adds the equivalent of three bit periods, the number of TCK periods fo this transfer is 67/96 or roughly 70% of the total without this optimization.

These scan formats may only be used with an external tool sourced TCKC as EOTs are utilized to improve its performance. The OScan0 – OScan3 Scan Formats always have a TMS bit included in the Scan Packet. The OScan scan format use case summary is shown in the following table.

Table 72-26. OScan scan format use case summary

Scan Format	Supporting	Performance	Flexibility	TCKC Source
OScan0	Stalls	↓	Best	External tool
OScan1	Test		↑	
OScan2	Debug Performance			
OScan3	Debug Downloads (input only)	Best		
OScan4	Stalls	↓	Best	External tool or TS
OScan5	Test		↑	
OScan6	Debug Performance			
OScan7	Debug Downloads (input only)	Best		

Certain OScan optimizations are applied in a hierarchical manner.

- **Optimization I:** OScan1/OScan5 – RDY bit(s) and their trailing ONE bits are deleted from all Scan Packets.
- **Optimization II:** OScan2/OScan6 – Optimization I + nTDI and TDO bits are deleted from Scan Packets associated with non-shift TAPC states.
- **Optimization III:** OScan3/OScan7 – Optimization II + TDO bits are deleted from Scan Packets.
- **Optimization IV:** OScan4 – OScan7 – TMS bits are deleted from Scan Packets associated with shift TAPC states.

Table 72-27. OScan Scan Format "Payload"

72.9 Functional Description

This section combines the information given in the Ancillary Services, EPU Operation, and APU Operation sections into a single reference for performing common TAP.7 tasks.

72.9.1 Switching from Standard Protocol to Advanced Protocol

Upon exit of Type-0 to Type-4 reset, the CJTAG begins operation in Standard Protocol 4-pin mode. The following steps are required to move from Standard Protocol 4-pin mode to Advanced Protocol (either 4-pin or 2-pin) mode.

The first step required to move to the Advanced Protocol is to change the CJTAG control level to control level 2 via zero-bit scans (ZBS), as described in Control levels.

After the control level is set tocontrol level 2, TAP.7 commands can be executed as described in EPU Commands. Execution of the Store Scan Format (STFMT) to set the scan format to any OSCAN0-7 or MSCAN format begins the switch from the Standard Protocol to the Advanced Protocol.

Once the STFMT command is executed selecting an Advanced Protocol scan format, the CJTAG transitions to the intermediate Control Protocol mode. The Control Protocol uses TMS inputs to control Configuration Change Packets as described in Control Process Active (CPA) Function and Configuration Change Packets (CP). Loading a change packet body value of 00 (CP_END) results in the switch to the Advanced Protocol.

If Advanced Protocol 2-pin operation is desired, the APFC register should be written to a value of 10 or 11 prior to the execution of the STFMT command that selects an advanced scan format. The APFC register is written via the Store Conditional 2-bit (STC2) command described in Store Conditional 2-bit (STC2).

Chapter 73
JTAG Master (JTAGM)

73.1 Chip-specific JTAGM information

JCOMP pin needs to be kept LOW to use JTAGM module. If JCOMP pin is driven HIGH (by debugger or otherwise), JTAGM loses control over the debug port. Either external JTAG pins or JTAGM can be active at any given point of time. Once debugger is connected, the JTAGM can not be used without power-on-reset.

73.2 Introduction

The JTAG Master (JTAGM) is a module that is able to act as JTAG master inside the device. The module has a parallel interface that can exchange data with another serial communication module or via customer software.

The data transferred to this module is transformed to produce TCK, TMS, TDI and TRST outputs and to accept TDO inputs. The JTAGM is connected in the device to allow these five signals to connect to the JTAGC as if the JTAG data is coming from an outside tool. The JTAGM generates all required JTAG scan chains to allow software and high speed serial communication access to all JTAG mapped resources.

73.2.1 Overview

The JTAGM is the master to drive JTAG signals from within the device. It has options to receive parallel data from software through the IPS interface . It then sends this data on TDI, TMS and TCK to the JTAGC. The JTAGM also receives serial data through TDO from the JTAGC. The JTAGM has the following registers:

- Configuration register
- Status register

- Four data output registers
- RxCRC receive register
- Two data input registers

All these registers are memory mapped and can be accessed by software.

The clocks for the JTAGM are derived from the system clock. The JTAGM also samples the ready signal from the Nexus, to provide a more efficient handshake to the external tool to read and write any memory mapped address location within the device.

This figure shows the block diagram of the JTAGM.

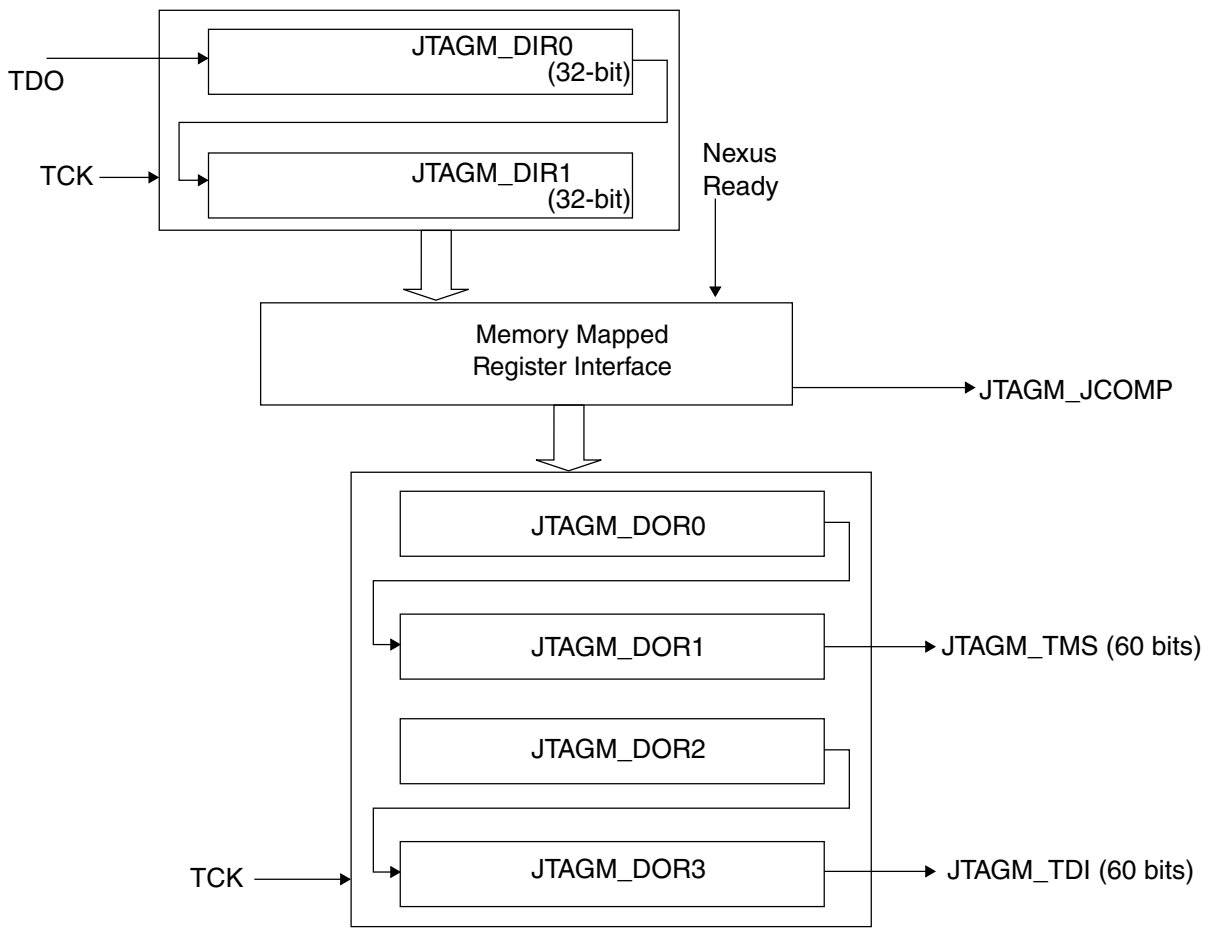

Figure 73-1. JTAGM block diagram

73.2.2 Feature description

The main features of the JTAGM are the following:

- Provides efficient handshake to the external tool to read any memory mapped address location within the device
- Provides software the option to write data for driving JTAG

73.3 Functional description

The JTAGM is simple in concept. TCK is generated from the device system clock. Data is pushed to the modules via a 32-bit wide parallel interface. The data is in the form of 60 bits of TMS data and 60 bits of TDI data. This data is the logical state to be driven onto the TMS and TDI output pins on each of the 60 TCK cycles. During these 60 TCK cycles, the TDO pin is sampled and the 60 bits of sampled data is transferred to the 32-bit wide module interface. This concept allows complete flexible generation on TMS and TDI data and capture of TDO data. The only limitation is that JTAG signals can only be generated in 60 TCK cycles packets. Extra cycles are wasted in idle cycles at the end of a scan chain.

73.3.1 JTAGM Ready signal

The Nexus Read/Write Access (RWA) module allows an external tool to read and write any memory mapped address location within the device via JTAG commands. Read accesses to memory take a finite amount of time and a JTAG read of the data register too soon results in erroneous data being read back. There is a bit in a JTAG register to show the read data is available.

73.3.1.1 Status register ready bit

A bit is provided in the JTAGM status register to indicate the status of the ready signal. To provide this ready signal functionality, the ready signal is monitored. If the ready signal has toggled between the start of the previous 60 TCK shift period and start of the current 60 TCK shift period, the ready bit in the JTAGM status register is set. Otherwise the ready bit in the status register is cleared.

The entire content of the 32-bit status register is appended to the 60 bits of JTAG TDO data captured along with 4 bits of 0-padding and sent as output on the parallel output port as a 96-bit payload on channel A. This provides back to the tool, an indication that the data read in the current transaction is valid.

73.3.1.2 Inter-JTAG frame gap timer

To operate in conjunction with the status register ready bit, a configurable timer is provided to force a programmable gap between the end of one 60-bit JTAG frame and the start of the next. This timer is configured via the JTAGM configuration register from 1 to 64 TCKs in 1 TCK intervals. Furthermore, if the ready signal asserts during this inter-frame gap period, the gap timer is aborted and the next JTAG frame starts immediately.

73.3.2 JTAGM to JTAGC serial interface

This figure shows the data transfer timings between JTAGM and JTAGC.

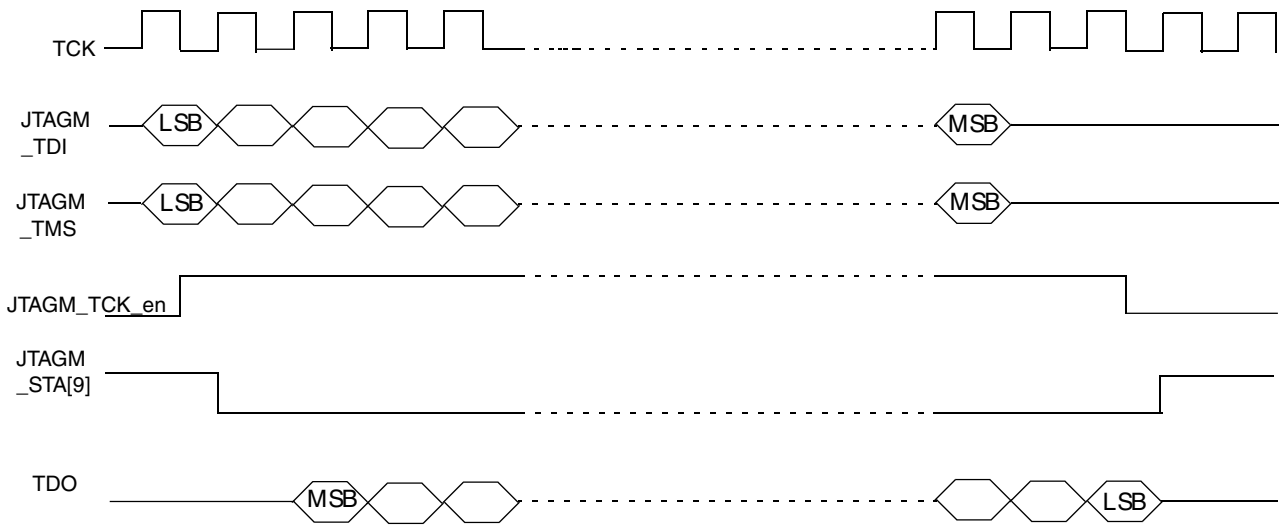

Figure 73-2. JTAGM to JTAGC serial interface diagram

73.3.3 Software interface

It is possible for software to write the 120 bits of JTAG data to be output and to read the 60 bits of data. The JTAGM module has an IPS interface.

73.4 Modes of operation

There are no special modes of operation. The JTAGM works normally in the debug mode.

73.5 Memory mapped registers

JTAGM supports only 32-bit write accesses to its registers. A byte write access will be converted into a 32-bit write; all other byte values in the register will become 0000_0000b.

JTAGM memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Module Configuration Register (JTAGM_MCR)	32	R/W	0300_0002h	73.5.1/3637
4	Status Register (JTAGM_SR)	32	R/W	0020_0200h	73.5.2/3640
8	Data Out Register 0 (JTAGM_DOR0)	32	R/W	0000_0000h	73.5.3/3641
C	Data Out Register 1 (JTAGM_DOR1)	32	R/W	0000_0000h	73.5.4/3642
10	Data Out Register 2 (JTAGM_DOR2)	32	R/W	0000_0000h	73.5.5/3642
14	Data Out Register 3 (JTAGM_DOR3)	32	R/W	0000_0000h	73.5.6/3643
1C	Data Input Register 0 (JTAGM_DIR0)	32	R	0000_0000h	73.5.7/3643
20	Data Input Register 1 (JTAGM_DIR1)	32	R	0000_0000h	73.5.8/3644

73.5.1 Module Configuration Register (JTAGM_MCR)

This register contains the status bits for the current transfer.

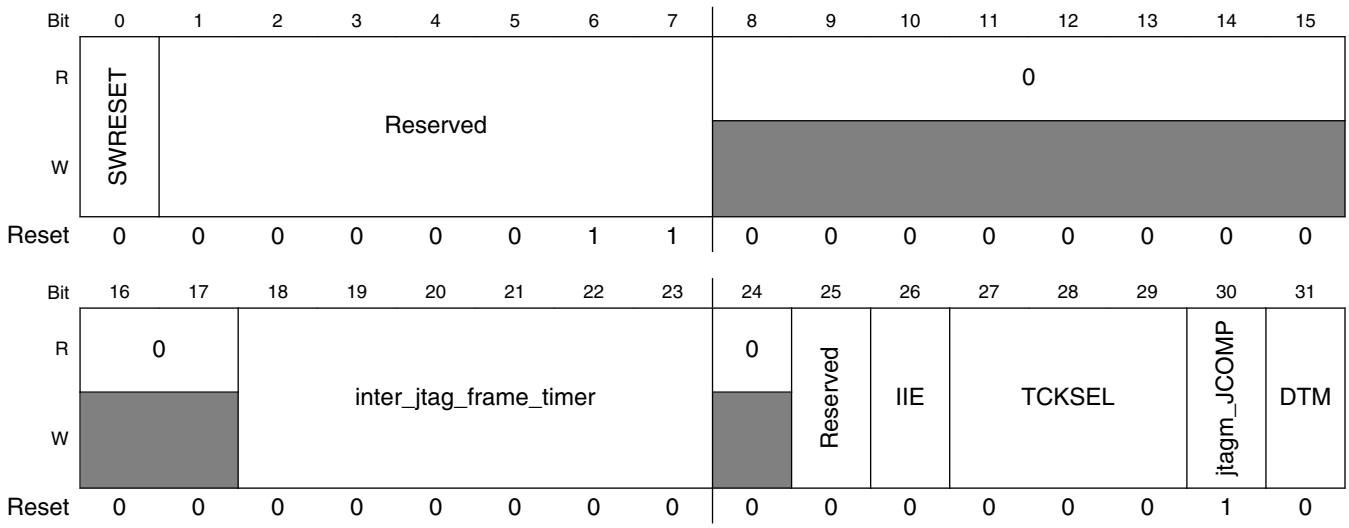
NOTE

An unexpected interrupt will occur if the Idle Interrupt is enabled after the end of frame transfer. The interrupt occurs after a JTAGM frame has completed when the JTAGM Idle Interrupt was not enabled (JTAGM_MCR[IIE] = 0b0), if the JTAGM module is then configured to enable interrupts (JTAGM_MCR[IIE] = 0b1). To clear any previous interrupts, set the Idle bit (JTAGM_SR[Idle]) before enabling a JTAGM idle interrupt (e.g. setting JTAGM_MCR[IIE] = 0b1).

NOTE

Bit-set operation on this register is prohibited as it can lead to device going to debug mode.

Address: 0h base + 0h offset = 0h



JTAGM_MCR field descriptions

Field	Description
0 SWRESET	Software Reset. Writing a 1 resets the state machine and counters inside JTAGM. It is a self clearing bit; after being written with a 1, this bit is auto-cleared within 3 TCK cycles. Writing a 0 has no effect.
1–7 Reserved	This field is reserved. The reserve bits value must not change during register write operation.
8–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–23 inter_jtag_frame_timer	TCK delay. 000000 0 TCK delay 000001 1 TCK delay ... ... 111111 63 TCK delay

13 Reserved	This field is reserved. Reserved to 0
14 Reserved	This field is reserved. Reserved to 0
15 TOOL	JTAGC status: JTAGC tool present, set when a debug tool is connected
16–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 Reserved	This field is reserved. The reserve bits value must not change during register write operation.
19 Reserved	This field is reserved.
20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 Nexus_err	Nexus error bit. It is set when there is an error, else it is 0.
22 Idle	Idle bit. Idle bit is cleared while a JTAG frame is in progress. This bit is set to 1 when a JTAG frame ends. Writing a 1 to the Idle bit clears the Idle_interrupt in SW Mode. A read always gives the JTAG frame status but does not give the write value.
23 NR	Status of Ready bit from Nexus RWA. This bit is automatically cleared when a new JTAG message is started. 0 RDY has not asserted indicating Nexus RWA is not ready 1 RDY has asserted indicating a Nexus RWA has completed bus access and is ready for the data register to be read
24–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

73.5.3 Data Out Register 0 (JTAGM_DOR0)

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Field	Description
0–27 TDO_HIGH	Higher word of data received on TDO, bits 32-59
28–31 Reserved	This field is reserved.

Chapter 74
Cyclic Redundancy Check (CRC) Unit

74.1 Introduction

The Cyclic Redundancy Check (CRC) computing unit is dedicated to the computation of CRC, off-loading the CPU. Each context has a separate CRC computation engine in order to allow the concurrent computation of the CRC of multiple data streams. The CRC computation is performed at speed without wait-state insertion. Bit-swap and bit-inversion operations can be applied on the final CRC signature. Each context can be configured with one of three hard-wired polynomials, normally used for most of the standard communication protocols. The data stream supports multiple data width (byte/halfword/word) formats.

74.2 Main features

- Three contexts for the concurrent CRC computation are supported
- Separate CRC engine for each context
- Zero-wait states during the CRC computation (pipeline scheme)
- Four hard-wired polynomials (two CRC-8, CRC-32 ITU-T V.42, and CRC-16-CCITT)
- Support for byte, halfword, or word width of the input data stream

74.2.1 Standard features

- Peripheral bus interface
- CRC-8 VDA CAN

- CRC-16-CCITT
- CRC-32 ITU-T V.42 (see note below)
- CRC-8-H2F Autosar polynomial

NOTE

Although the CRC-32 ITU-T V.42 polynomial is used for CRC generation, the generation algorithm differs (MISR) from the one used by the IEEE 802.3 standard.

74.3 Block diagram

The top level diagram of the CRC module is given in the following figure. Refer to Main features for number of contexts in this module.

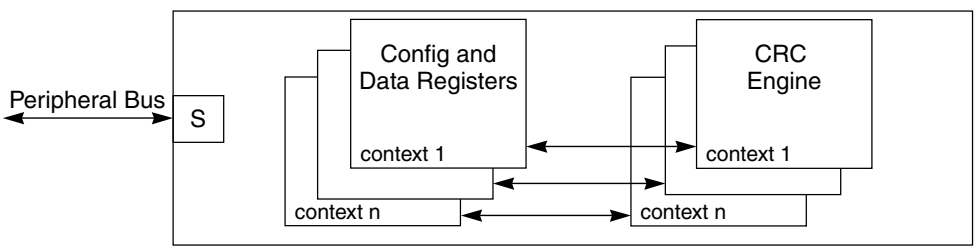

Figure 74-1. CRC top level diagram

74.4 External signal description

The CRC module does not generate any external signals.

74.4.1 Peripheral bus interface

The peripheral bus interface is a slave bus used for configuration and data streaming (CRC computation) purposes via CPU or DMA. The following bus operations (contiguous byte enables) are supported:

- Word (32 bits) data write/read operations to any registers
- Low and high halfword (16 bits, data[31:16] or data[15:0]) data write/read operations to any registers

- Byte (8 bits, data[31:24], data[23:16], data[15:8], or data[7:0]) data write/read operations to any registers
- Any other operation (free byte enables or other operations) must be avoided.

The CRC module generates a transfer error in the following cases:

- Any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral
- Any write/read operation different from byte/halfword/word (free byte enables or other operations) on each register

The registers of the CRC module are read/write accessible in each access mode:
- user
- supervisor

The following summarizes bus operation performance:

- Zero wait states (single bus cycle) for each write/read operation to the CRC_CFG and CRC_INP registers
- Zero wait states (single bus cycle) for each write operation to the CRC_ CSTAT register
- Double wait states (3 bus cycles) for each read operation to the CRC_ CSTAT or CRC_OUTP registers immediately following (next clock cycle) a write operation to the CRC_CSTAT, CRC_INP, or CRC_CFG registers belonging to the same context; in all the other cases, no wait states are inserted

74.5 CRC memory map and registers

CRC memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Configuration Register (CRC_CFG1)	32	R/W	See section	74.5.1/3648
4	Input Register (CRC_INP1)	32	R/W	0000_0000h	74.5.2/3649
8	Current Status Register (CRC_CSTAT1)	32	R/W	FFFF_FFFFh	74.5.3/3650
C	Output Register (CRC_OUTP1)	32	R	FFFF_FFFFh	74.5.4/3650
10	Configuration Register (CRC_CFG2)	32	R/W	See section	74.5.1/3648
14	Input Register (CRC_INP2)	32	R/W	0000_0000h	74.5.2/3649
18	Current Status Register (CRC_CSTAT2)	32	R/W	FFFF_FFFFh	74.5.3/3650

Table continues on the next page...

CRC memory map (continued)

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
1C	Output Register (CRC_OUTP2)	32	R	FFFF_FFFFh	74.5.4/3650
20	Configuration Register (CRC_CFG3)	32	R/W	See section	74.5.1/3648
24	Input Register (CRC_INP3)	32	R/W	0000_0000h	74.5.2/3649
28	Current Status Register (CRC_CSTAT3)	32	R/W	FFFF_FFFFh	74.5.3/3650
2C	Output Register (CRC_OUTP3)	32	R	FFFF_FFFFh	74.5.4/3650

74.5.1 Configuration Register (CRC_CFG*n*)

Access: User read/write.

Address: 0h base + 0h offset + (16d × i), where i=0d to 2d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0								0							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0										SWAP_ BYTEWISE	SWAP_BITWISE	POLYG		SWAP	INV
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	*	*	0	0

* Notes:

- POLYG field: Reset value is a function of n in CRC_CFGn. When n%2 = 0, reset value = 01b. When n%2 = 1,reset value = 00b. So CRC_CFG1 POLYG reset value = 00b (Since 1%2=1).

CRC_CFG*n* field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 SWAP_ BYTEWISE	Swap CRC_INP byte-wise

Table continues on the next page...

CRC_CFG*n* field descriptions (continued)

Field	Description
	NOTE: INV and SWAP bits are set to 1 for CRC-32 polynomial calculations. 0 Do not swap 1 Perform byte-wise swap on CRC_INP input data internally for CRC-32 polynomial calculations.
27 SWAP_BITWISE	Swap CRC_INP bit-wise 0 Do not swap 1 Perform bit-wise swap on CRC_INP input data internally for CRC-8 and CRC-16 polynomial calculations.
28–29 POLYG	Polynomial selection This bit can be written only during the configuration phase. 00 CRC-CCITT polynomial 01 CRC-32 polynomial 10 CRC-8 polynomial 11 CRC-8-H2F Autosar polynomial
30 SWAP	Swap selection This bit can be written only during the configuration phase. The swap operation is a bit-by-bit swapping of the content. 0 No swap selection applied on the CRC_OUTP content 1 Swap selection (MSB to LSB, LSB to MSB) applied on the CRC_OUTP content.
31 INV	Inversion selection This bit can be written only during the configuration phase. The inversion operation is a complement (or negation) of the content. 0 No inversion selection applied on the CRC_OUTP content 1 Inversion selection (bit x bit) applied on the CRC_OUTP content

74.5.2 Input Register (CRC_INP*n*)

Access: User read/write.

NOTE

High level code must be written in a way to realize byte- , halfword- and word-wide writes on assembler code level. Any endianness problem faced can be corrected by appropriate configuration of CRC_CFG[SWAP_BYTEWISE] and CRC_CFG[SWAP_BITWISE].

Address: 0h base + 4h offset + (16d × i), where i=0d to 2d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

CRC_CSTAT*n* field descriptions

Field	Description
0–31 CSTAT	CRC signature status This register includes the current status of the CRC signature. No bit swap and inversion are applied to this register. In the case of the CRC-CCITT polynomial, only the 16 least-significant bits are significant. The 16 most-significant bits are set to 0 during the computation. In the case of the CRC-8 polynomial, only the 8 least-significant bits are significant. The 24 most-significant bits are set to 0 during the computation. The CSTAT register can be written at byte, halfword, or word. This register can be written only during the configuration phase.

74.5.4 Output Register (CRC_OUTP*n*)

Access: User read-only.

Address: 0h base + Ch offset + (16d × i), where i=0d to 2d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

W																																
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

CRC_OUTP*n* field descriptions

Field	Description
0–31 OUTP	Final CRC signature This register includes the final signature corresponding to the CRC_CSTAT register value eventually swapped and inverted. In the case of the CRC-CCITT polynomial, only the 16 least-significant bits are significant. The 16 MSB bits are set to 0 during the computation. In the case of the CRC-8 polynomial, only the 8 least-significant bits are significant. The 24 most-significant bits are set to 0 during the computation.

74.6 Functional description

The CRC module supports the CRC computation for each context. Each context has its own complete set of registers, including the CRC engine. The data flow of each context can be interleaved. The data stream can be structured as a sequence of bytes, halfwords, or words. The input data sequence is provided, eventually mixing the data formats (byte, halfword, and word), writing to the input data register (CRC_INP).

The data stream is generally executed by *n* concurrent DMA data transfers (mem2mem) where *n* is less or equal to the number of contexts.

The standard generator polynomials are given in Equation 50 on page 3651, Equation 51 on page 3651, and Equation 52 on page 3651 for the CRC computation of each context. Two separate registers are available: CRC_INP for writing data and CRC_CSTAT for retrieving the (accumulated up to now) CRC.

$$x^8 + x^4 + x^3 + x^2 + 1$$

Equation 50. CRC8 VDA CAN

$$x^{16} + x^{12} + x^5 + 1$$

Equation 51. CRC-CCITT (x.25 protocol)

$$x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

Equation 52. CRC-32 (ITU-T V.42 protocol)

$$x^5 + x^3 + x^2 + x + 1$$

Equation 53. CRC-8-H2F (Autosar 4.0 protocol)

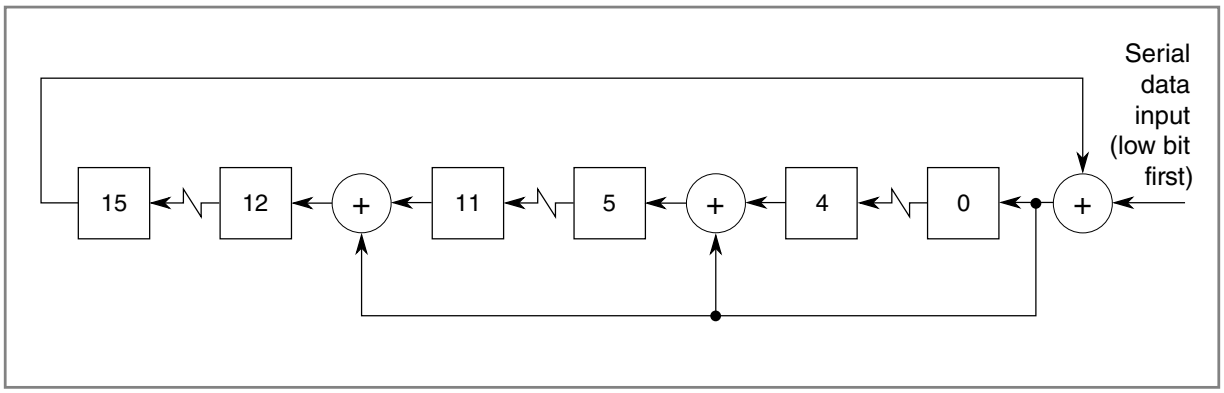

Figure 74-2. CRC-CCITT engine concept scheme

The initial seed value of the CRC can be programmed by initializing the CRC_CSTAT register. A diagram illustrating serial data loading of the CRC engine is shown in Figure 74-2 for the CRC-CCITT. Note that, conceptually, the least-significant, or "right-most," bit shown in Input Register (CRC_INP*n*), is fed first into the engine. The actual implementation executes the CRC computation in a single clock cycle (parallel data loading). A pipeline scheme has been adopted to decouple the IPS bus interface from the CRC engine in order to allow the computation of the CRC at speed (zero wait states).

If the CRC signature is used for encapsulation in the data frame of a communication protocol (for example, SPI, etc.), a bit swap (high bit for low bit or low bit for high bit) and/or bit inversion of the final CRC signature can be applied to CRC_OUTP before transmitting the CRC.

Use of the CRC module is summarized in the flow chart given in Figure 74-3.

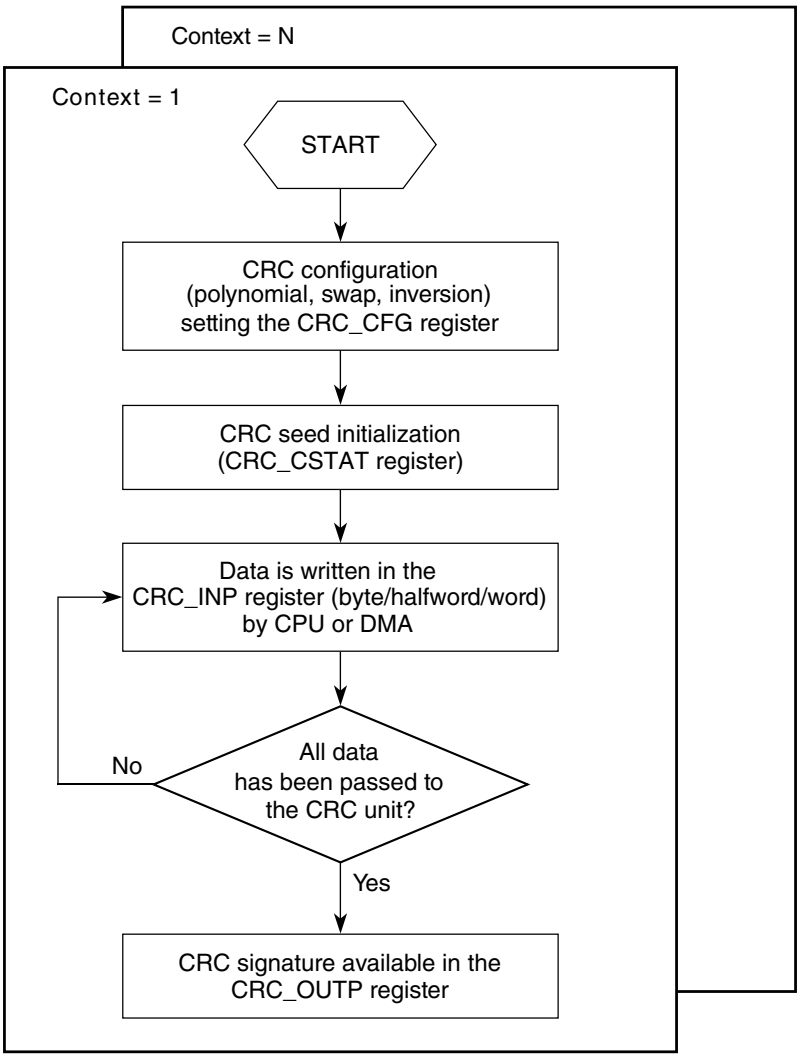

Figure 74-3. CRC computation flow

74.7 Use cases

74.7.1 Programming example

The number of contexts depends on the application. The overall number of contexts for the CRC peripheral depends on the number of peripherals that concurrently require intervention by the CRC module. Two main use cases are considered:

- Calculation of the CRC of the configuration registers during the process safety time
- Calculation of the CRC on the incoming/outcoming frames for the communication protocols (not protected with CRC by definition of the protocol itself) used as a safety-relevant peripheral

The signature of the configuration registers is computed correctly only if these registers do not contain any status bit.

Assuming that the DMA engine has *n* channels (greater than or equal to the number of contexts) configurable for the following types of data transfer—mem2mem, periph2mem, mem2periph—the following sequence, as shown in the following figure, is applied to manage the transmission data flow:

1. DMA/CRC module configuration (context x, channel x) by CPU
2. Payload transfer from the MEM to the CRC module (CRC_INP register) after MSB-to-LSB change (input mirroring) to calculate the CRC signature (phase1) by DMA (mem2mem data transfer, channel x)
3. CRC signature copy from the CRC module (CRC_OUTP register) to the MEM (phase 2) by CPU
4. Data block (payload + CRC) transfer from the MEM to the PERIPH module (for example, SPI Tx FIFO) (phase 3) by DMA (mem2periph data transfer, channel x)

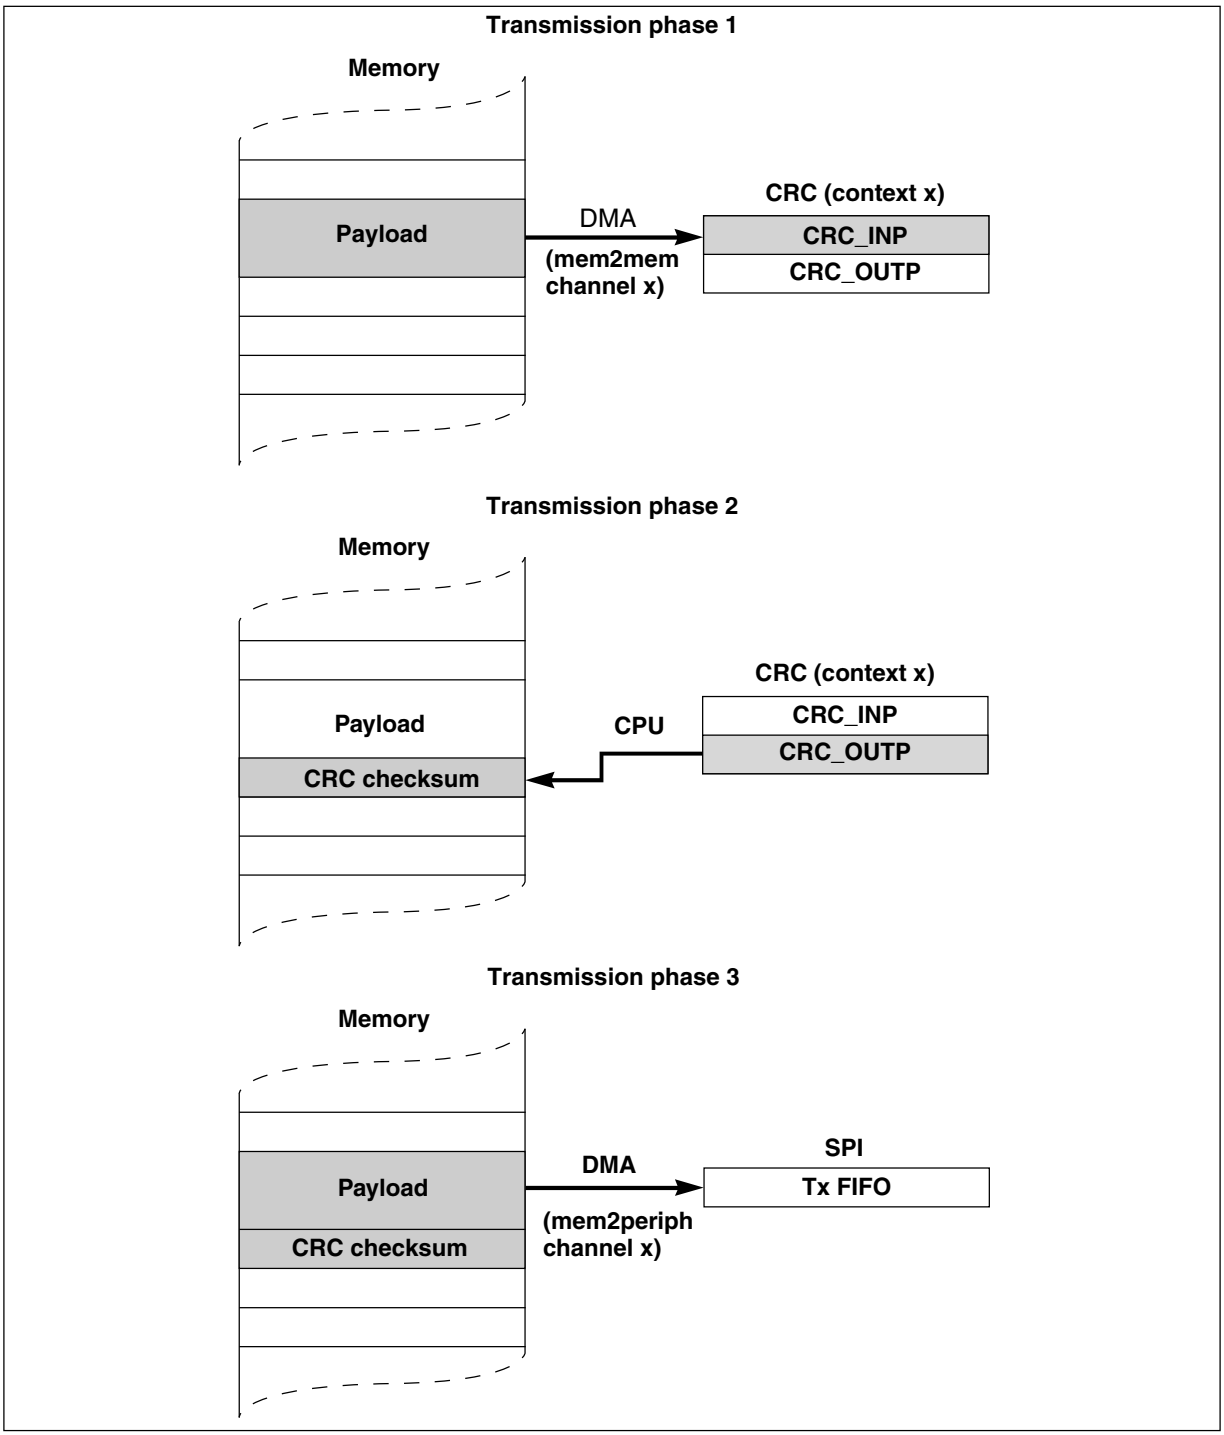

Figure 74-4. DMA-CRC transmission sequence

74.7.2 Register programming

- INV and/or SWAP (affecting the output only) can be applied to CRC-8, CRC-16, and CRC-32. Both can be applied together.

- SWAP_BITWISE (affecting the input only) can be applied for all polynomials if required by an application.
- SWAP_BYTEWISE (affecting the input only) can be applied for CRC-16 and CRC-32 polynomials only.
- SWAP_BITWISE has priority over SWAP_BYTEWISE when both are applied together.
- When generating CRC-32 for the ITU-T V.42 standard the user needs to set SWAP_BYTEWISE together with INV and SWAP.
- When generating CRC-16 the user needs to set SWAP_BITWISE bit.

Chapter 75
Memory Error Management Unit (MEMU)

75.1 Chip-specific MEMU information

75.1.1 MEMU system connections

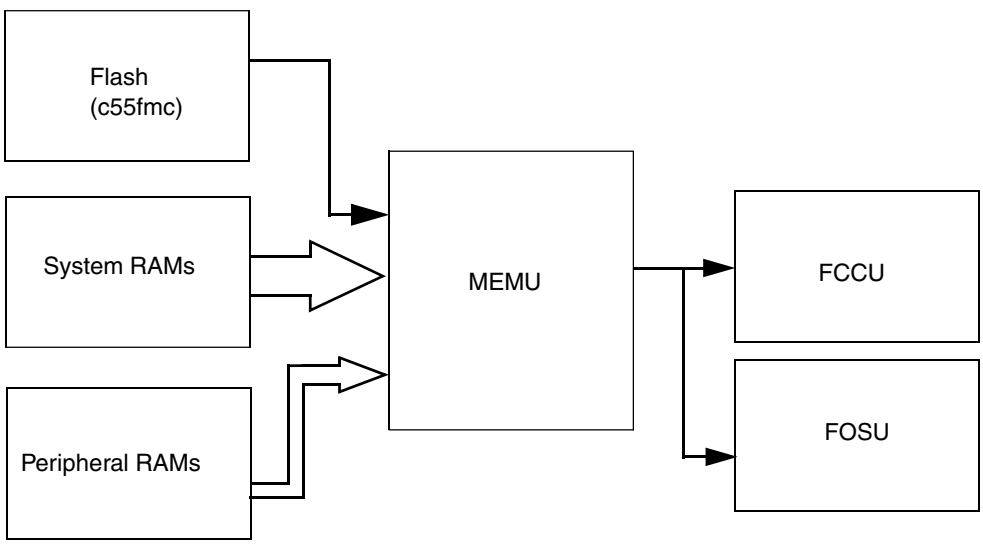

Figure 75-1. MEMU system connections

75.1.2 MEMU error sources

The following table shows the MEMU error sources for each instance configured on this chip.

Table 75-1. MEMU error sources

Instance	Value
Number of system RAM unique error sources	34

Table continues on the next page...

Table 75-1. MEMU error sources (continued)

Instance	Value
Number of peripheral RAM unique error sources	6
Number of flash memory unique error sources	3

75.1.3 Reporting tables implementation

There are 3 categories of error reporting for the MEMU:

- Flash error reporting
- System RAM error reporting—any RAM that is CPU accessible falls into this category.
- Peripheral RAM error reporting—any RAM that is not CPU accessible falls into this category.

Each category of error reporting has two tables associated with it, these are:

- Correctable Error Reporting Table
- Uncorrectable Error Reporting Table

Each entry in a reporting table corresponds to a unique error event. The number of entries supported by each table depends upon the error source.

The table below describes the number of entries in each reporting table for the different error sources.

Table 75-2. Number of entries in each reporting table

Error Source	Number of entries in correctable error reporting table	Number of entries in un-correctable error reporting table
Flash (c55fmc)	20	1
System RAM	10	1
Peripheral RAM	2	1

75.1.4 Concurrent overflow register (OFLW) implementation

Errors are reported to the MEMU from these categories:

- Flash memory
- System RAM
- Peripheral RAM

In an overflow condition, it is possible to identify the unique error source that caused the overflow. Corresponding error sources for the OFLW register details the corresponding error source to the respective field in the Concurrent Overflow registers.

Positions not explicitly listed in the tables below are reserved.

Table 75-3. Corresponding error sources for system RAM OFLW0 register

Bit number	Error source	Clock relationship with respect to MEMU
0	z4a Data TCM (DMEM)	Asynchronous
1	z4a Instruction Cache	Asynchronous
2[1]	z4a Data Cache	Asynchronous
3	z4a Instruction AHB	Asynchronous

8	PBRIDGE_1	Synchronous
9	DMA_e2eECC	Synchronous
10	SIPI	Synchronous
11	z7a Data TCM (DMEM)	Asynchronous
12[1]	z7a Instruction Cache	Asynchronous
13[1]	z7a Data Cache	Asynchronous
14	z7a Instruction AHB	Asynchronous
15	z7a Data AHB	Asynchronous
16	z7b Data TCM (DMEM)	Asynchronous
17[1]	z7b Instruction Cache	Asynchronous
18[1]	z7b Data Cache	Asynchronous
19	z7b Instruction AHB	Asynchronous
20	z7b Data AHB	Asynchronous
21	ENET	Synchronous
22	PRAM1 [2]	Synchronous
23	PRAM2 [2]	Synchronous
24	PRAM3 [2]	Synchronous
25	PRAM4 [2]	Synchronous
26	PRAM5 [2]	Synchronous
27	PRAM6 [2]	Synchronous
28	PRAM7 [2]	Synchronous
29	SPT_e2eECC	Synchronous
30	SPT_MOD_ORRAM_Access	Asynchronous
31	SPT_PDMA_OPRAM_Access	Asynchronous

1. Cache tag errors can be single-bit or double-bit. Cache data array errors are reported as single-bit errors only, regardless of the number of errors reported, since the logic does not exist in the cache to distinguish them.

2. RAM controller does not provide a multibit ECC error on a RAM read. It will only provide the error on a read-modify-write and an error detected. If there is an error on the read, it will pass the error along to the master accessing and leave it up to that master to handle it.

Table 75-4. Corresponding error sources for system RAM OFLW1 register

Bit number	Error source	Clock relationship with respect to MEMU
0	SPT_TRAM_Access	Asynchronous
1	CSE e2e ECC gasket error	Synchronous

Table 75-5. Corresponding error sources for flash memory OFLW register

Bit number	Error source	Clock relationship with respect to MEMU
0	Flash_Core0_SPT [1]	Synchronous
1	Flash_Core1 [1]	Synchronous
2	Flash_Core2_CSE [1]	Synchronous

1. In the event of a flash ECC error, the MEMU is alerted twice - once by the flash controller and once by the master e2e_ecc gasket.

Table 75-6. Corresponding error sources for peripheral RAM OFLW register

Bit number	Error source	Clock relationship with respect to MEMU
0	FlexRay Data RAM	Asynchronous
1	FlexRay LUT RAM	Synchronous
2[1]	FlexCAN Receiver Instance 0	Synchronous
3[1]	FlexCAN Receiver Instance 1	Synchronous
4[1]	FlexCAN Receiver Instance 2	Synchronous
5	DMA_TCD_ECC	Synchronous

1. Follow below steps to decode the logical address where the ECC error occurs from the address reported by MEMU: For example, MEMU reports ECC error on address 0xFFEC0180.
    1. Extract last three nibbles from the address and shift them to left left: ((0x180<<2)= 0x600).
    2. Refer the address calculated above in the column "injection address" of the table CAN_1 Error Injection Address Register (CAN_ERRIAR) - error injection addresses and Error Injection Address Register (CAN_ERRIAR),This table is different for FD and NON-FD CAN instances.
    3. Refer memory map address corresponding to step 2 Memory map (example; RXIMR0 at 0x880).
    4. To calculate exact address, append address from Step 2 or Step 3 to first 20 bits of base address (example; 0xFFEC0 to get logical address of 0XFFEC0880)

75.1.5 FlexRay lookup table (LUT) RAM alignment

Table 75-7. Flexray Lookup Table (LUT) RAM

75.2 Introduction

The MEMU is responsible for collection and reporting of error events associated with ECC (Error Correction Code) logic used on:

- System RAM
- Peripheral RAM
- Flash memory

When any of the following events occur the MEMU receives an error signal which causes an event to be recorded and corresponding error flags to be set and reported to FCCU (Fault Collection and Control Unit).

- Correctable Error: It comprises the following:
  - Single Bit error in the data part that is detected via ECC for:
    - System RAM
    - Peripheral RAM
    - Flash memory
- Uncorrectable Error: It comprises the following:
  - Multiple bit error that is detected via ECC for:
    - System RAM
    - Peripheral RAM
    - Flash memory
  - Addressing errors and unused data bit errors detected by ECC logic.

The MEMU system connections are chip-specific; see the chip-specific MEMU information.

When multiple errors are indicated from various sources at same instant, an Overflow can be indicated by the MEMU to the FCCU. Overflow can also be indicated if the reporting table entries are full and a new unique error is reported by the system.

MEMU processes the errors based on whether they are correctable or uncorrectable (from ECC logic), independent of the source generating these errors.

The MEMU has multiple instances of the basic reporting block; one each for:

- System RAM ECC
- Peripheral RAM ECC
- Flash memory ECC

Each instance has two reporting tables. Correctable errors are reported in one table, and the uncorrectable errors are reported in the other.

See Design overview for the reporting block details.

75.3 Features

The MEMU has the following features:

- Supports up to 128 error sources per the following reporting blocks (the number of error sources are chip-specific; see the chip-specific MEMU information):
  - System RAM ECC
  - Peripheral RAM ECC
  - Flash memory ECC
- Support for error reporting from the following category of error sources (for ECC):
  - System RAM
  - Peripheral RAM
  - Flash memory
- Unique reported errors are logged into the module's reporting table which is accessible to CPU via memory mapped CPU register programming interface.
- MEMU handles overflow during error assertion and reports status accordingly.
- Unique errors are stored in correctable and non correctable section of the reporting table and corresponding indication is generated to the FCCU.
- CPU can program the known errors into the reporting table to avoid their re-reporting by MEMU.
- CPU can clear the reporting table errors.
- The reporting table for uncorrectable errors supports only 1 entry.

75.4 Block diagram

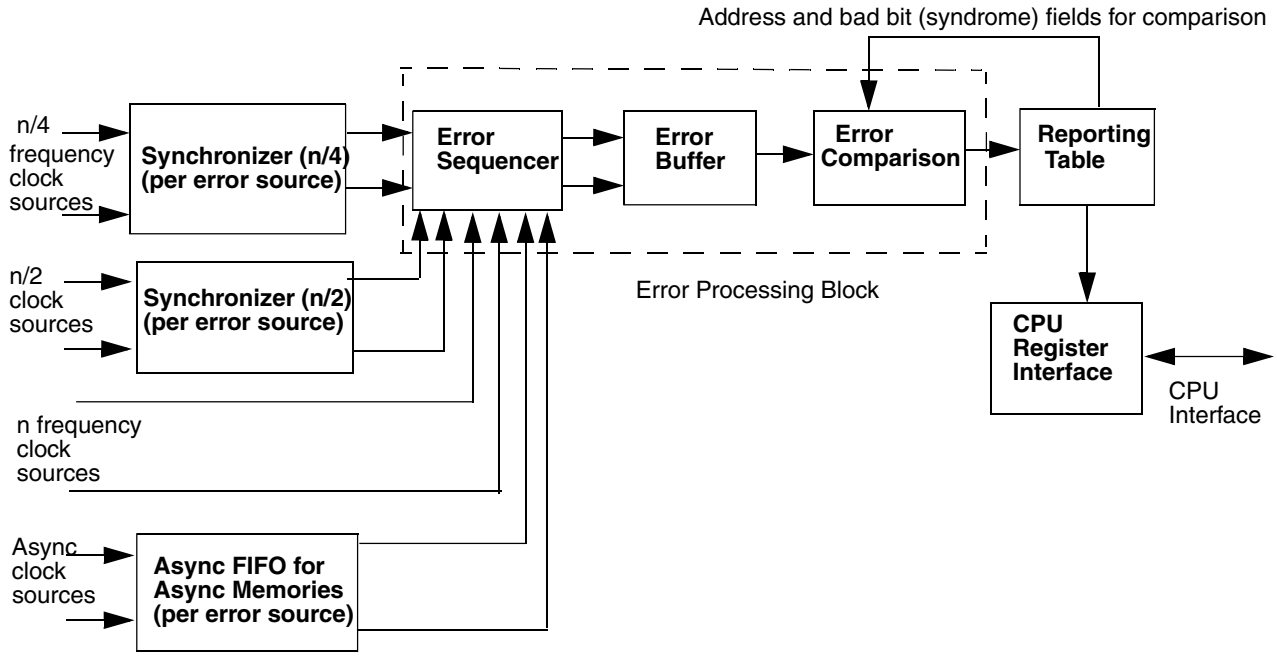

Figure 75-2. MEMU block diagram

75.5 Design overview

The MEMU should be enabled on power-on reset. The user software can write known error addresses into the reporting table to prevent reporting of those errors addresses to FCCU should they later be accessed in operation. All writes into the reporting table by the CPU that assert the Valid Bit (of the respective reporting table entry) will be indicated as a new error detected and will be reported to the FCCU. This feature can also be used as self-checking option of the MEMU and the MEMU-FCCU connection.

The MEMU design does not limit any particular sequence or errors. See Handling overflows (Multiple error reporting), for details on overflow behaviors.

The basic algorithm flow/architecture for error reporting in the MEMU is summarized below:

1. Synchronizer block

   For asynchronous inputs, a FIFO-based structure (per asynchronous channel) is implemented. All the error inputs (correctable error reported, uncorrectable error reported, error address and bad bits/syndrome) are concatenated and stored in the

FIFO. While storing the entry in the FIFO, a duplicity check is performed with the previously stored entry (the entry which was stored in the last cycle). If both the entries are duplicate the new entry is deleted and the pointers are rolled back to the old value, otherwise the new entry is stored. Whenever there is an overflow (FULL condition) in the Asynchronous FIFO, it is denoted by setting the Error Buffer Overflow or the EBO flag to the FCCU and the corresponding bit in the Concurrent Overflow Register is set.

For synchronous inputs, inputs are sampled whenever the corresponding clock synchronizing signal is asserted for a particular channel.

2. Error Processing block

This block is used to process the incoming errors coming from the device.

- Error Sequencer is used for sequencing the errors so that these are processed one per clock. In case of more than one errors detected by the sequencer logic, one is sent for the processing (error comparison block), the other is stored in the error buffer and the rest are marked as overflows in the Concurrent overflow register.
- All the sequences of incoming errors are supported. However, in case of multiple errors being asserted in back to back clock cycles, MEMU will process the errors being forwarded by the sequencer logic and register the rest of the errors as Concurrent Overflows in the Concurrent Overflow Register.

  For example, the MEMU processes a 0-2-2 sequence like this:

  1. The MEMU sends the first error directly to the processing.
  2. The MEMU stores the second error in the error buffer.
  3. The MEMU performs a uniqueness check, comparing the third error with the existing entry in the error buffer for uniqueness.

  If the errors are unique, the MEMU:

  - Classifies the fourth error as an overflow
  - Sets the corresponding EBO flag in Error flag register (MEMU_ERR_FLAG)

  If the errors are not unique, the MEMU:

  - Drops the third error
  - Stores the fourth error in the error buffer
  - Does not set any EBO flag in Error flag register (MEMU_ERR_FLAG)

- While storing the error in the error buffer, uniqueness is determined by comparing the error address, correctable or uncorrectable error type and the bad bit/syndrome (depending on ECC logic) of the incoming error with the one

stored in buffer. If the error buffer is full, and the incoming error to be stored in the error buffer is not yet in the error table, Error Buffer Overflow (EBO) is registered and the corresponding bit in the Concurrent Overflow Register is set., else the incoming error is dropped.

- While doing the error buffer uniqueness check, the type of error i.e Correctable Error (CE) or Uncorrectable Error UCE) is also compared, hence even if the Error Address and the Bad bit/syndrome fields (Depending on whether the incoming error is generated from ECC logic) of the incoming error matches with the error buffer, if the type of errors (CE and UCE) differ they are treated as unique
- Determine the type and uniqueness of errors in the error comparison block and store them in the correct reporting table (correctable or uncorrectable)
- Generate signals to assert the necessary flags. Be aware that it takes several MEMU clock cycles (<=5 unless the error gets temporarily stored in the error buffer due to a collision) for an error report to cause a signal to be sent to the FCCU.

3. Reporting table

   This is a pre-defined table in the MEMU to store the details for the device. For the reporting table if the entry is unique it is stored in the reporting table. If the entry is not unique it is not stored and discarded.

   The MEMU asserts proper flags when error is stored in the reporting table or an overflow is asserted. Flags are also asserted when the software writes the VLD bit to the reporting table.

   The CPU can clear the flags signaling errors or overflows to the FCCU directly by writing 1 at the corresponding valid bit of the status register (i.e. ..._CERR_STS or ..._UNCERR_STS). The clearing of flags is totally independent from the status of VLD bits in the reporting table.

   The reporting table sizes are chip-specific; see the chip-specific MEMU information.

4. Register block

   The CPU register programming interface provides the memory-mapped registers necessary for the CPU to access the reporting table and other control and status registers for the modules. Flags to FCCU will be asserted on write by CPU to the valid bit or by MEMU itself if a unique error is stored. However, in the situation when both MEMU and the CPU are accessing the same Register location, a wait cycle will be signaled to the CPU and the CPU command will be completed in the next clock cycle.

The software, in principle, is not supposed to write VLD to 1 if it is already 1.

The CPU register interface provides the decoding of the peripheral signals to allow access to the reporting table and other registers in module.

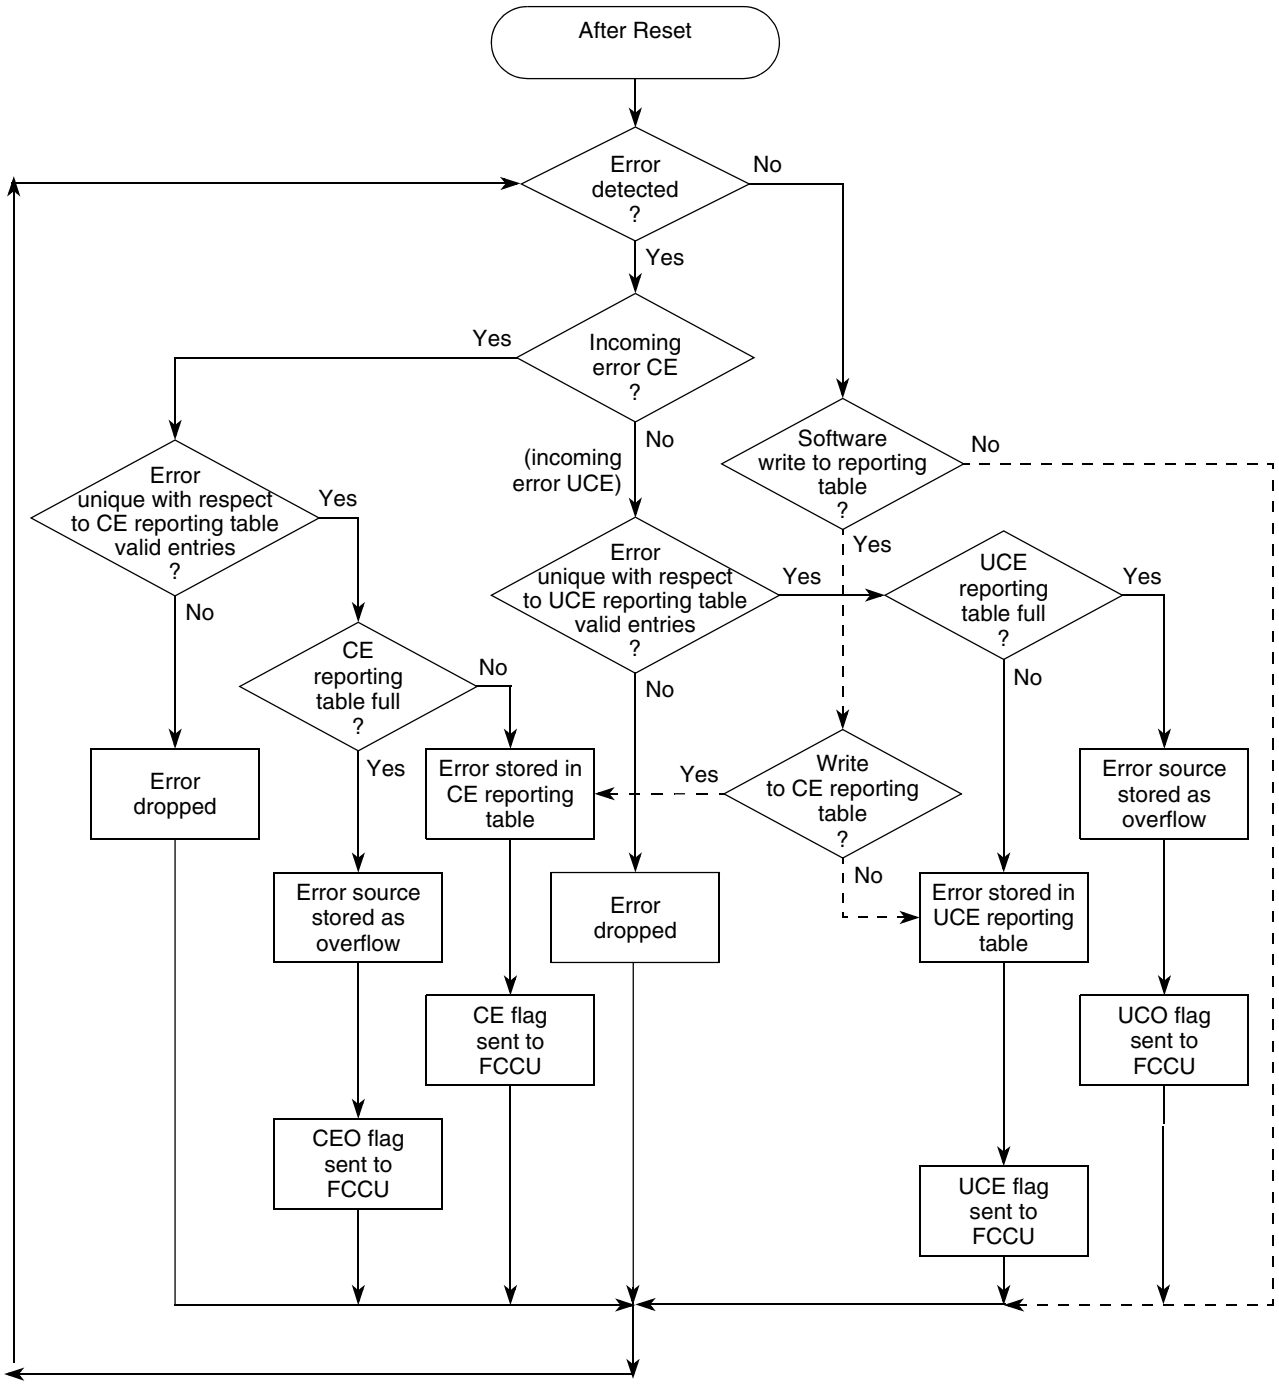

Figure 75-4. MEMU reporting table uniqueness check flow chart

75.6 External signal description

MEMU has no external signals.

75.7 Memory map and register definition

This section describes the registers on this module.

75.7.1 Overview

The memory map comprises 32-bit aligned registers that can be accessed via 8-bit,16-bit, or 32-bit accesses. Write access to reserved address locations will generate a transfer error. Read data from reserved locations will also generate a transfer error and the read data bus will return all 0's.

NOTE

The module does not check for correctness of the programmed values in registers. Software must ensure that the correct values are being written.

NOTE

The memory map in this section shows all the possible registers on this module and the associated offsets (which vary depending on the number of registers actually implemented). The actual availability, number and addresses of registers, and number of reported errors in the reporting table are chip-specific; see the Device Configuration chapter that describes how modules are configured and connected.

MEMU memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Control register (MEMU_CTRL)	32	R/W	0000_0000h	75.7.2/3674

MEMU_CTRL field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 SWR	Software Reset bit. Setting this will clear status flags and overflow register. However, the reporting table registers are not cleared. This bit will auto clear on next clock cycle. 0 No reset. 1 Reset asserted.
17–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

75.7.3 Error flag register (MEMU_ERR_FLAG)

Bits in the ERR_FLAG register indicate:

- A new entry in an error reporting table has been made (indicated by PR_CE, PR_UCE, F_CE, F_UCE, SR_CE, and SR_UCE)
- An overflow condition has been encountered when attempting to make a new entry in an error reporting table (indicated by SR_UCO, SR_CEO, F_UCO,F_CEO, PR_UCO, and PR_CEO)
- An overflow condition has been encountered in the internal error processing buffer of a MEMU reporting block.

Individual flags can be cleared by writing a '1'. This also resets the corresponding error indication to FCCU. Flags will not automatically reset if entries are removed from the reporting table. They have to be explicitly cleared by SW.

Bits SR_UCO, SR_CEO, F_UCO, F_CEO, PR_UCO, and PR_CEO are asserted when an overflow in the uncorrectable error reporting table is detected.

Access: User read/write

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

MEMU_ERR_FLAG field descriptions

Field	Description
0–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 PR_CE	Peripheral RAM ECC Correctable Error detect flag.

Table continues on the next page...

MEMU_ERR_FLAG field descriptions (continued)

Field	Description
	Indicates that a new and unique Peripheral RAM ECC correctable error is detected. Asserted when a new entry is inserted into the correctable error reporting table (either by CPU or module). 0 No new and unique error detected. 1 New entry in correctable error reporting table is made.
12 PR_UCE	Peripheral RAM ECC Uncorrectable Error Detect flag. Asserted when a new Peripheral RAM ECC uncorrectable error was detected or a new entry is inserted into the uncorrectable error reporting table (either by CPU or module). 0 No new and unique error detected. 1 New entry in uncorrectable error reporting table is made.
13 PR_CEO	Peripheral RAM ECC Correctable error Overflow flag. Asserted when the Peripheral RAM ECC correctable error reporting table is full and a new entry is attempted to be made to this table. 0 No Overflow. 1 Overflow in the correctable error reporting table detected.
14 PR_UCO	Peripheral RAM ECC Uncorrectable error Overflow flag. Asserted when the Peripheral RAM ECC uncorrectable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the uncorrectable error reporting table detected.
15 PR_EBO	Peripheral RAM ECC Error buffer Overflow flag. Asserted when the internal error processing buffer of Peripheral RAM ECC MEMU reporting block has overflowed. This can happen when too many errors are reported in a short interval of time for processing by MEMU. The channel(s) from which error reports were dropped due to the overflow are indicated in the XXXXX_OFLW registers. This field will also be set to 1 if the input ASYNC FIFOs overflow. 0 No Overflow. 1 Overflow in the internal error processing buffer detected.
16–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 F_CE	Flash ECC Correctable Error Detect flag. Indicates that a new and unique Flash ECC correctable error was detected. Asserted when a new entry to the correctable error reporting table is done (either by CPU or module). 0 No new and unique error detected. 1 New entry in correctable error reporting table is made.
20 F_UCE	Flash ECC Uncorrectable Error Detect flag. Asserted when: • a new Flash ECC uncorrectable error was detected. • a new entry to the uncorrectable error reporting table is done (either by CPU or module) 0 No new and unique error detected. 1 New entry in uncorrectable error reporting table is made.
21 F_CEO	Flash ECC Correctable Error Overflow flag. Asserted when the Flash ECC correctable error reporting table is full and a new entry is made to this table.

Table continues on the next page...

MEMU_ERR_FLAG field descriptions (continued)

Field	Description
	0 No Overflow. 1 Overflow in the correctable error reporting table detected.
22 F_UCO	Flash ECC Uncorrectable Error Overflow flag. Asserted when the Flash ECC uncorrectable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the uncorrectable error reporting table detected.
23 F_EBO	Flash ECC Error buffer Overflow. Flag Asserted when the internal error processing buffer of Flash ECC MEMU reporting block has overflowed. This can happen when too many errors are reported in a short interval of time for MEMU to process them all. The channel(s) from which error reports were dropped due to the overflow are indicated in the XXXXX_OFLW registers. This field will also be set to 1 if the input ASYNC FIFOs overflow. 0 No Overflow. 1 Overflow in the internal error processing buffer detected.
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 SR_CE	System RAM ECC Correctable Error detect flag. Indicates that a new and unique System RAM ECCcorrectable error is detected. Asserted when a new entry to the correctable error reporting table is done (either by CPU or module). 0 No new and unique error detected. 1 New entry in correctable error reporting table is made.
28 SR_UCE	System RAM ECC Uncorrectable Error Detect flag. Asserted when: • A new System RAM ECC uncorrectable error is detected • A new entry to the uncorrectable error reporting table is done (either by CPU or module) 0 No new and unique error detected. 1 New entry in uncorrectable error reporting table is made.
29 SR_CEO	System RAM ECC Correctable error Overflow flag. Asserted when the System RAM ECC correctable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the correctable error reporting table detected.
30 SR_UCO	System RAM ECC Uncorrectable error Overflow flag. Asserted when the System RAM ECC uncorrectable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the uncorrectable error reporting table detected.
31 SR_EBO	System RAM ECC Error buffer Overflow.

Table continues on the next page...

MEMU_ERR_FLAG field descriptions (continued)

Field	Description
	Flag asserted when the internal error processing buffer of System RAM ECC MEMU reporting block has overflowed. This can happen when too many errors are reported in a short interval of time for processing by MEMU. The channel(s) from which error reports were dropped due to the overflow are indicated in the XXXXX_OFLW registers. This field will also be set to 1 if the input ASYNC FIFOs overflow. 0 No Overflow. 1 Overflow in the internal error processing buffer detected.

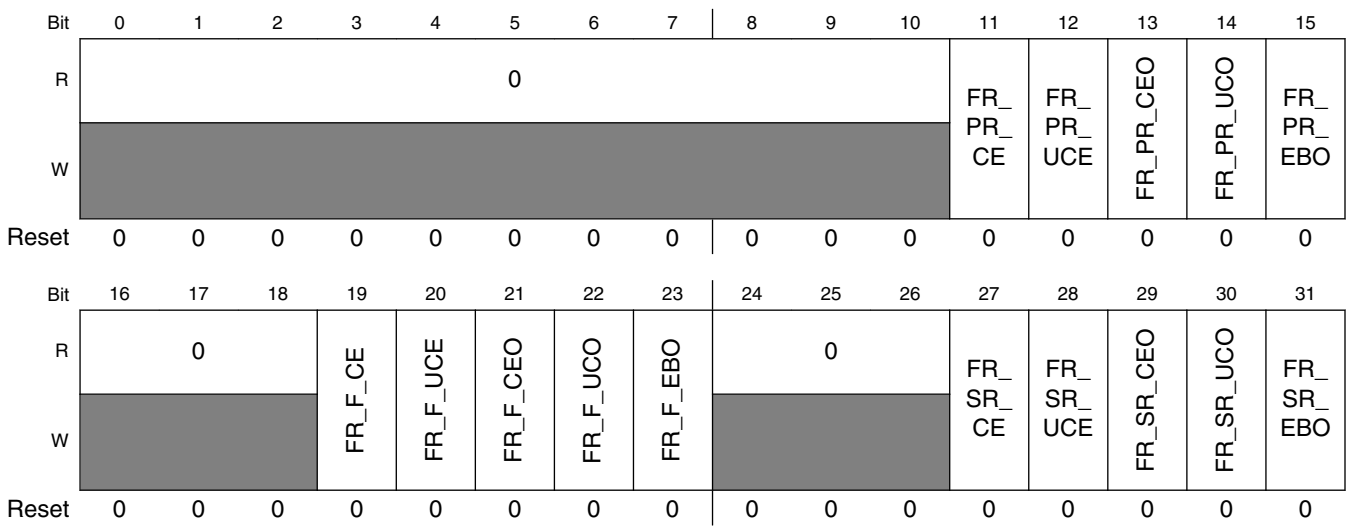
75.7.4 Debug register (MEMU_DEBUG)

This register is used to check the connections between MEMU & FCCU.

The error output of the MEMU towards FCCU shall stay set if forced until reset by SW via the MEMU in the normal way.

Access: User read/write

Address: 0h base + Ch offset = Ch



MEMU_DEBUG field descriptions

Field	Description
0–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 FR_PR_CE	Force Peripheral RAM Correctable Error detect flag. 0 Forcing is disabled. 1 Forces PR_CE flag going towards FCCU to 1.

Table continues on the next page...

MEMU_DEBUG field descriptions (continued)

Field	Description
12 FR_PR_UCE	Force Peripheral RAM Uncorrectable Error detect flag. 0 Forcing is disabled. 1 Forces PR_UCE flag going towards FCCU to 1.
13 FR_PR_CEO	Force Peripheral RAM Correctable Error overflow flag 0 Forcing is disabled. 1 Forces PR_CEO flag going towards FCCU to 1.
14 FR_PR_UCO	Forces Peripheral RAM Uncorrectable Error overflow flag. 0 Forcing is disabled. 1 Forces PR_UCO flag going towards FCCU to 1.
15 FR_PR_EBO	Forces Peripheral RAM Error Buffer Overflow Flag. 0 Forcing is disabled. 1 Forces PR_EBO flag going towards FCCU to 1.
16–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 FR_F_CE	Forces Flash Correctable Error detect flag 0 Forcing is disabled. 1 Forces F_CE flag going towards FCCU to 1.
20 FR_F_UCE	Forces Flash Uncorrectable Error detect flag 0 Forcing is disabled. 1 Forces F_UCE flag going towards FCCU to 1.
21 FR_F_CEO	Forces Flash Correctable Error overflow flag 0 Forcing is disabled. 1 Forces F_CEO flag going towards FCCU to 1.
22 FR_F_UCO	Forces Flash Uncorrectable Error overflow flag 0 Forcing is disabled. 1 Forces F_UCO flag going towards FCCU to 1.
23 FR_F_EBO	Forces Flash Error buffer Overflow flag 0 Forcing is disabled. 1 Forces F_EBO flag going towards FCCU to 1.
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 FR_SR_CE	Forces System RAM Correctable Error detect flag 0 Forcing is disabled. 1 Forces SR_CE flag going towards FCCU to 1.
28 FR_SR_UCE	Forces System RAM Uncorrectable Error detect flag 0 Forcing is disabled. 1 Forces SR_UCE flag going towards FCCU to 1.

Table continues on the next page...

MEMU_DEBUG field descriptions (continued)

Field	Description
29 FR_SR_CEO	Forces System RAM Correctable Error overflow flag 0 Forcing is disabled. 1 Forces SR_CEO flag going towards FCCU to 1.
30 FR_SR_UCO	Forces System RAM Uncorrectable Error overflow flag 0 Forcing is disabled. 1 Forces SR_UCO flag going towards FCCU to 1.
31 FR_SR_EBO	Forces System RAM Error buffer Overflow Flag 0 Forcing is disabled. 1 Forces SR_EBO flag going towards FCCU to 1.

75.7.5 System RAM correctable error reporting table status register (MEMU_SYS_RAM_CERR_STS*n*)

Access: User read/write

NOTE

The reporting table is not cleared on software reset.

Address: 0h base + 20h offset + (8d × i), where i=0d to 9d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	VLD	0														
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0								BAD_BIT							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

MEMU_SYS_RAM_CERR_STS*n* field descriptions

Field	Description
0 VLD	Valid bit. This indicates that the entry in reporting table is valid. Assertion of this bit causes the correctable error detect flag to be asserted. 0 Entry in table is invalid. 1 Entry in table is valid.
1–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 BAD_BIT	Bad bit field. Indicates the bit position in RAM where the error is detected. This is also known as the syndrome. For non-BIST type of errors, this field is not used and reads as 0xFF.

Table continues on the next page...

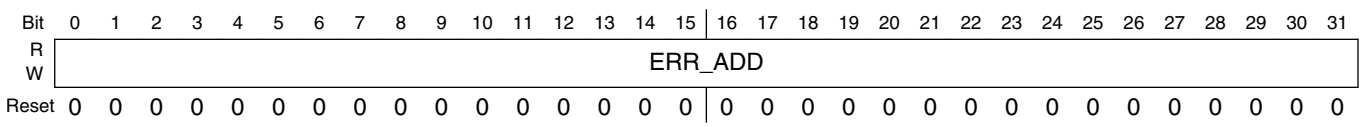
MEMU_SYS_RAM_CERR_STS*n* field descriptions (continued)

Field	Description
	Any value other than 0xFF - Position of the bit in RAM where error is found. 0xFF - Invalid Bad Bit. This field should not be used when processing errors.

75.7.6 System RAM correctable error reporting table address register (MEMU_SYS_RAM_CERR_ADDR*n*)

Access: User read/write

Address: 0h base + 24h offset + (8d × i), where i=0d to 9d



MEMU_SYS_RAM_CERR_ADDR*n* field descriptions

Field	Description
0–31 ERR_ADD	Error address field Indicates the address on which the error was detected.

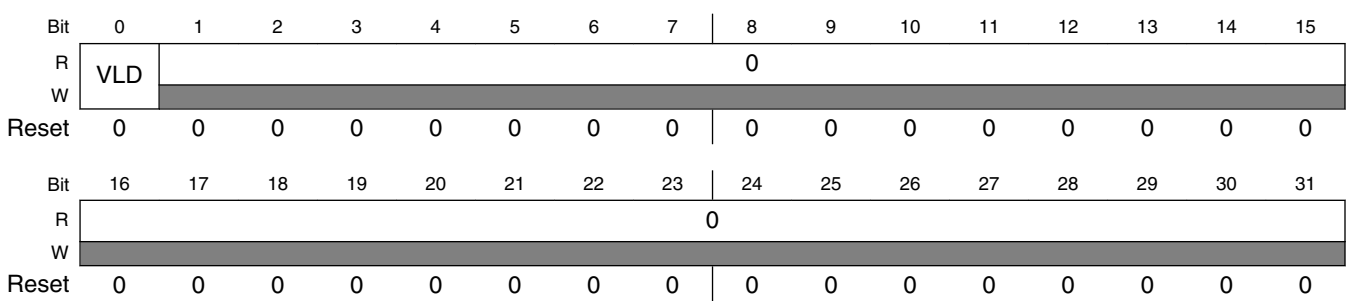
75.7.7 System RAM uncorrectable error reporting table status register (MEMU_SYS_RAM_UNCERR_STS)

Access: User read/write

NOTE

The reporting table is not cleared on software reset.

Address: 0h base + 70h offset = 70h



MEMU_SYS_RAM_UNCERR_STS field descriptions

Field	Description
0 VLD	Valid bit. This indicates that the entry in reporting table is valid. Assertion of this bit causes the uncorrectable error detect flag to be asserted. 0 Entry in table is invalid. 1 Entry in table is valid.
1–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

75.7.8 System RAM uncorrectable error reporting table address register (MEMU_SYS_RAM_UNCERR_ADDR)

Access: User read/write

NOTE

The reporting table is not cleared on software reset.

Address: 0h base + 74h offset = 74h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

MEMU_FLASH_OFLW*n* field descriptions

Field	Description
0–31 OFLW	Overflow Bit. Each bit corresponds to an error source and is asserted when any of the conditions mentioned in Handling overflows (Multiple error reporting) occurs.

75.8 Functional description

In this section, the term “bad bit” and “syndrome” are equivalent, and are used to indicate the position of the bit in error.

75.8.1 Initializing MEMU

MEMU is always enabled and can be configured by user software for known faults which the system/application has collected over a period of time. The MEMU logic will not update the reporting table corresponding to the programmed values which have the VLD bit SET.

The user software can write into the reporting table and must make VLD bit ='1' for the programmed entry to be valid. Any write by the CPU that asserts the VLD bit will cause a corresponding flag to FCCU.

The software can program the table with known error addresses by setting the valid bit and storing the corresponding error address. The sequence of programming to prevent a collision of reporting table entries written by the HW and the SW is as follows:

1. Check that the VLD bit is not set,
2. Write an invalid address/bad bit information,
3. Set VLD bit,
4. Check that the address still has an invalid value,
5. Write address/bad bit information to desired address.

If the FCCU is programmed to cause an IRQ on new MEMU table entries, steps 3 to 5 should be executed with interrupts disabled to prevent any fault handling SW to read the invalid address written in step 2). Note that in the case the software is in between the 3rd and the 5th step, and the MEMU writes a fault with the same address that Software wants to program, both the faults will be stored in the reporting table (i.e. duplicate entries).

75.8.2 Reading the reporting table

The software at any time can read the reporting table via the software programming interface. It should read the entries with the valid bit set and take necessary action. To invalidate any entry, the valid bit must be cleared. Reading an entry which does not have the VLD bit set will return invalid data.

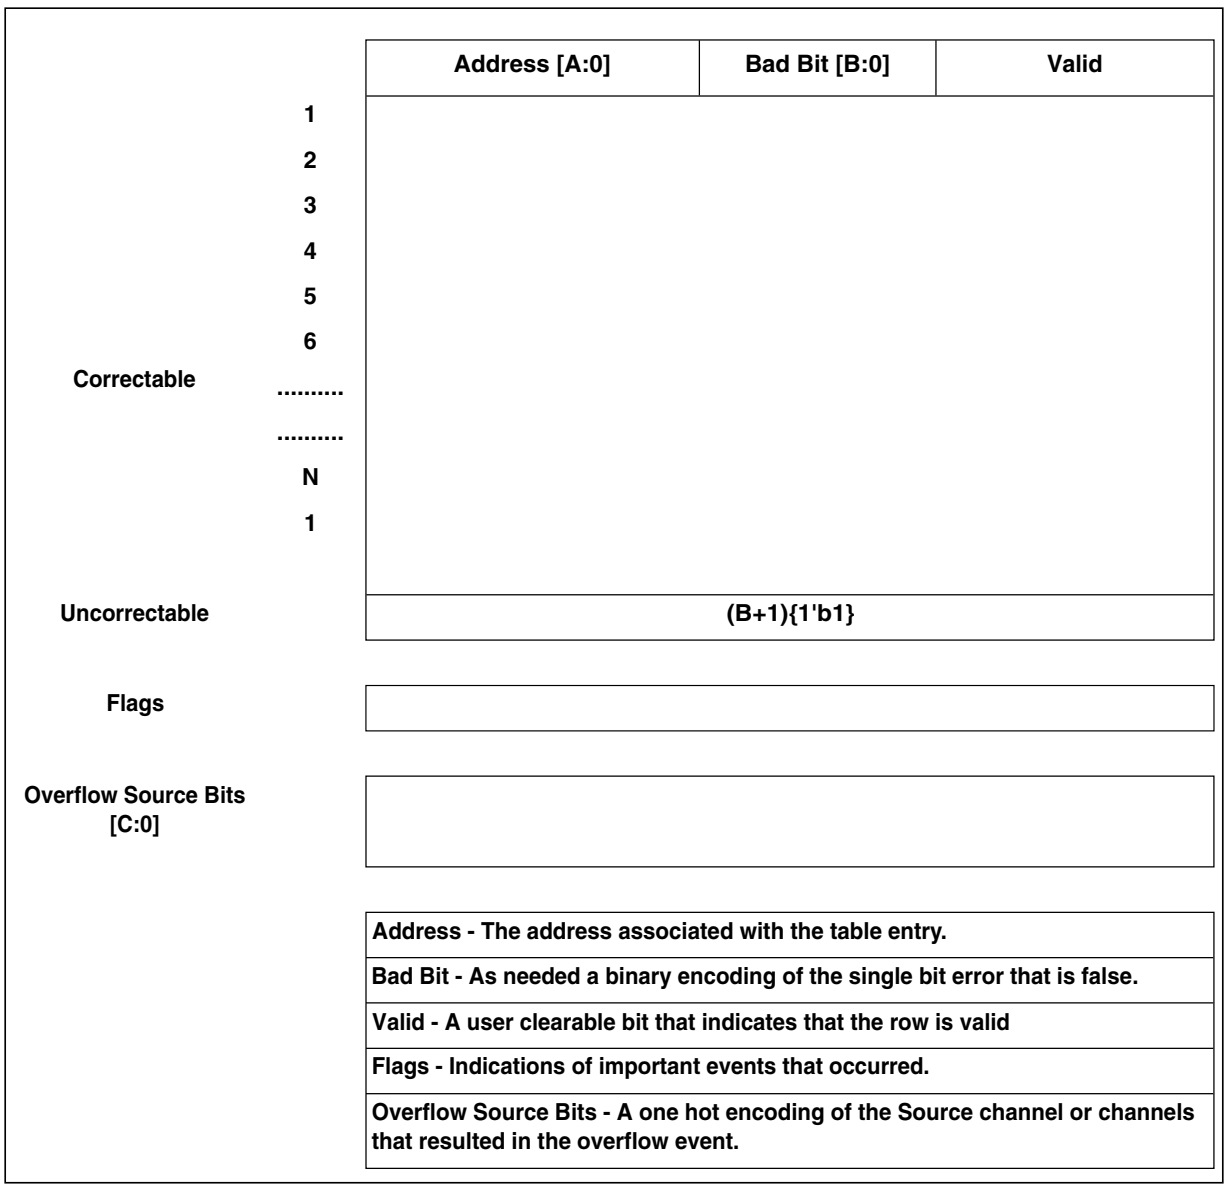

Figure 75-5. Generic representation of the reporting table of one MEMU reporting block

75.8.3 Handling overflows (Multiple error reporting)

When a bit in the overflow registers (either error buffer or reporting table though the overflow registers are same) is asserted it can indicate the occurrence of one of the following conditions:

1. Fault buffer overflow–More than two memories reporting a fault at the same instant or the input ASYNC FIFOs reach the FULL level (overflow)
    - More than 2 faults detected at same time. This would lead to overflow in the fault buffer. MEMU can process only one fault at a time while storing the other in the fault buffer. So this would be indicated as an overflow. The uniqueness check in the input buffer does not "guarantee" that an ECC-supervised memory with only one fault will not be marked as overflow source. If that one fault occurs together with two (or more) additional faults at the same cycle it can get flagged as an overflow.
2. Correctable/Uncorrectable Fault Overflow–Overflow in correctable and uncorrectable reporting table occurs only when a unique entry is to be stored but the tables are already full (all entries have valid bit set).
3. The Overflows will be stored in the bit-wise order i.e., if the fault bit 31 reports a fault, the bit 31 of the overflow register will be set to '1'.

Chapter 76
Fault Collection and Control Unit (FCCU)

76.1 Chip-specific FCCU information

76.1.1 Fault inputs

NCF is used to identify a non-critical fault input at the FCCU. The NCF sheet attached with this document shows the source of the fault signals and the type of fault inputs to which these signals are connected at the FCCU. See the device NCF sheet (Excel file) attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it.

NOTE

To enable any NCF via FCCU_NCF_En, the programming sequence as followed:

- Disable all the NCF channels by writing 0000_0000h in Noncritical Fault Enable (FCCU_NCF_En)[NCFEx].
- Enable the NCF channels and its corresponding reactions.

Before exiting the CONFIG state, ensure that the NCF's which are enabled by Noncritical Fault Enable (FCCU_NCF_En) [NCFEx] have the corresponding reactions programmed.

If the above sequence is not ensured then FOSU might give destructive reset.

To recovery of enabled non-critical faults, the programming sequence for defining the preset value of the timer as followed:

- Disable all the TOEn by writing 0000_0000h in Noncritical Fault Timeout Enable(FCCU_NCF_TOEn)[NCFTOEx].
- Enable the NCFs chanel corresponding Noncritical Fault Timeout Enable(FCCU_NCF_TOEn)[NCFTOEx].and IRQ Alarm Enable (FCCU_IRQ_ALARM_ENn)[IRQENx].

NOTE

DTCM corresponds to DMEM. For details, see Core chapters in this document.

76.1.1.1 Core lockstep and RCCU disablement in debug mode

In debug mode, the RCCUs are disabled, and the cores do not operate in Lockstep mode.

The actual enabled/disabled state of the RCCUs (including any automatic disablement by debug) can be read by software in the MCB_MISC2[RCCU_Z4_STATUS].

Table 76-1. MCB_MISC2 register details

Address	Register name	Width (in bits)	Access	Reset value
FFC0_C014h	MCB_MISC2	32	RW	0000_0000h

NOTE

When the Z4 Core enters into Debug Mode, DMA RCCU is also disabled along with the Z4 RCCU. The status of DMA RCCU can be read from MCB_MISC2[RCCU_DMA_STATUS].

76.1.2 Available FCCU output signals

The following table shows the available FCCU output signals implemented on this chip.

Table 76-2. FCCU output signals

FCCU output signal name	Chip-top signal name
EOUT[0][1]	FCCU_F[0]
EOUT[1]	FCCU_F[1]

1. During first configuration phase EOUT pads will be in high-Z state.

76.1.3 FCCU chip-specific register reset values

This table lists in alphabetical order by mnemonic the FCCU registers whose reset values are specific to this chip. (The reset values for all other FCCU registers are specified in Register descriptions.)

Register	Reset value
FCCU_CFG	See FCCU_CFG register bit value sources (N and C) by event.
FCCU_CFG_TO	0000_0006h
FCCU_NCF_CFG0	FFFF_FFFFh
FCCU_NCF_CFG1	FFFD_FFFFh
FCCU_NCF_CFG2	FFEF_FCCFh
FCCU_NCF_CFG3	FFFF_FFFFh
FCCU_NCF_E0	FFFF_FFFFh
FCCU_NCF_E1	0000_3FFFh
FCCU_NCF_E2	FF80_00C0h
FCCU_NCF_E3	FFFF_FFFFh
FCCU_NCF_TO	0000_1F00h
FCCU_NCF_TOE0	FFFF_FFFFh
FCCU_NCF_TOE1	FFFD_FFFFh
FCCU_NCF_TOE2	FFEF_FCCFh
FCCU_NCF_TOE3	FFFF_FFFFh
FCCU_NCFS_CFG0	0000_0000h
FCCU_NCFS_CFG1	0000_0000h
FCCU_NCFS_CFG2	0000_0000h
FCCU_NCFS_CFG3	0000_0000h
FCCU_NCFS_CFG4	0000_0000h
FCCU_NCFS_CFG5	0000_0000h
FCCU_NCFS_CFG6	0000_0000h
FCCU_NCFS_CFG7	0000_0000h
FCCU_MCS	0000_8083h (after reset the chip enters to the DRUN mode).

76.1.4 FCCU_CFG register event bit values by source (N and C)

For each bit in the Configuration (FCCU_CFG) register, this table specifies the values of *N* and *C* for this chip. For information on how to interpret and use these values, see FCCU_CFG register bit value sources (N and C) by event.

Bit	N (chip-specific or user-specified value provided by the bit's associated NVMCFG signal)	C (chip-specific value provided by the bit's associated constant inside the module)
0	0	0
1	0	0
2	0	0

Table continues on the next page...

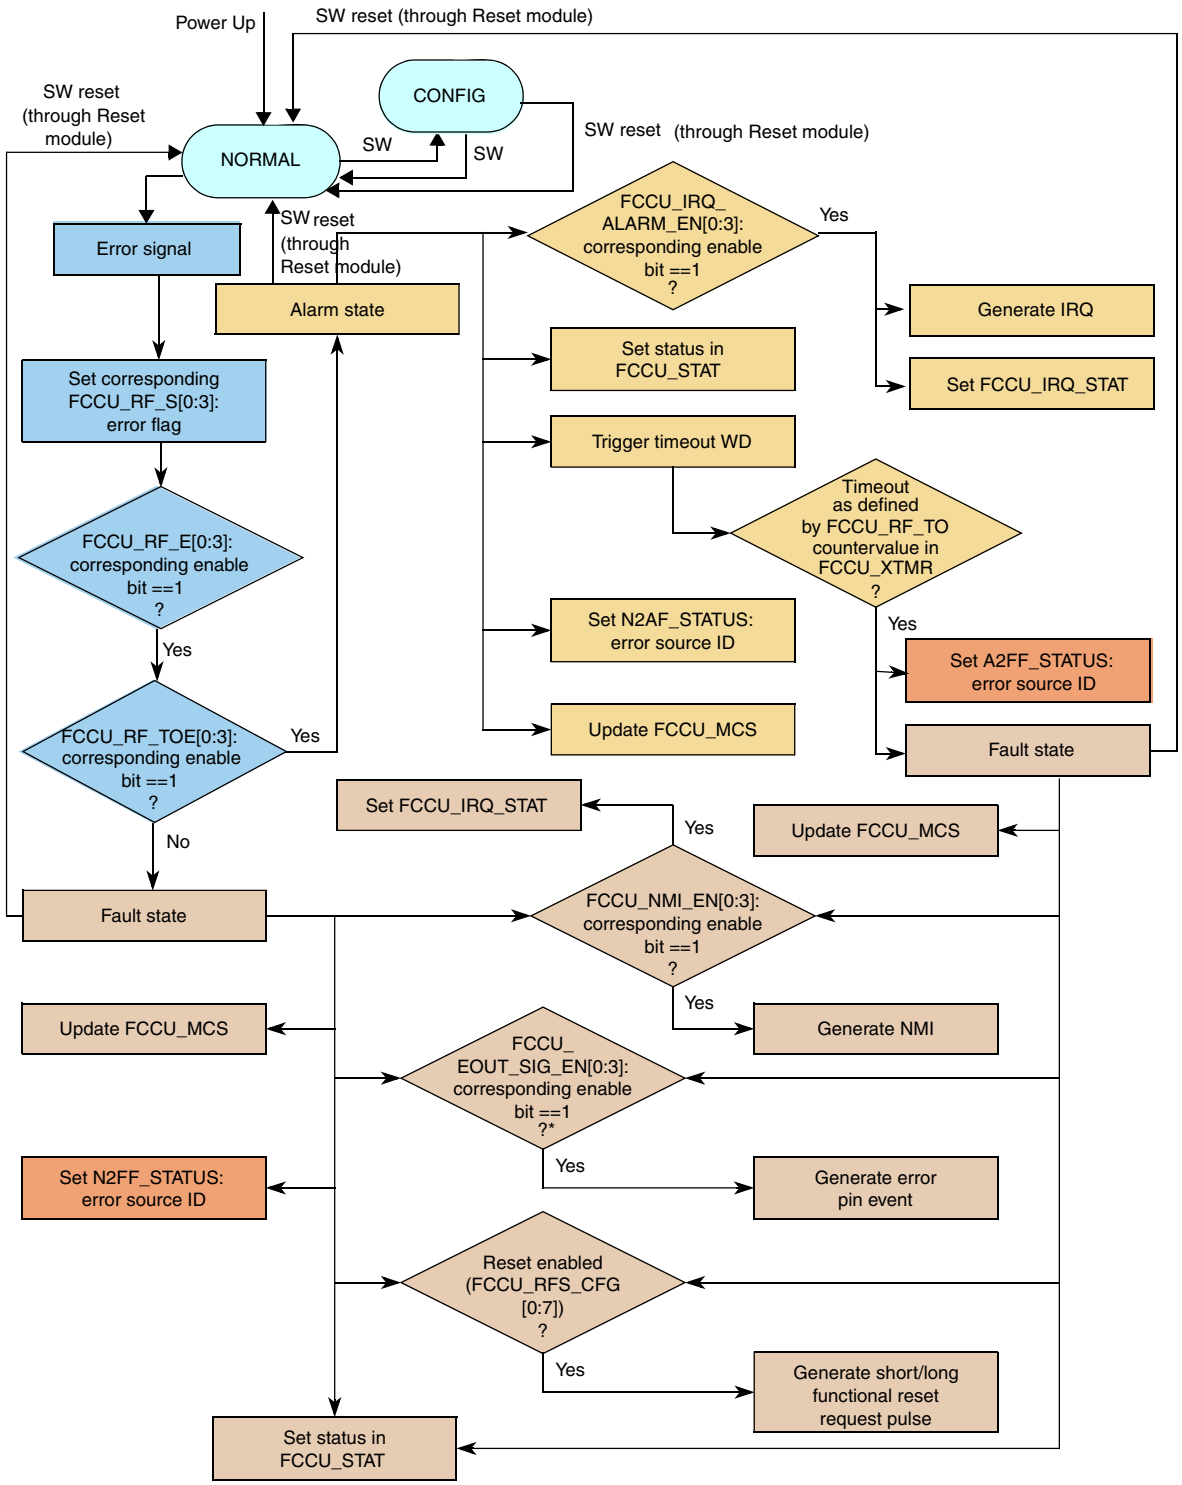
76.1.5 Fault signal flow diagram



* This condition must be satisfied only when FCCU is configured for Bistable fault-output mode (FCCU_CFG[FOM]).

Figure 76-1. Fault signal flow

76.1.6 FCCU FOSU Count Value

The fixed preprogrammed value for FOSU_Count is 0x1F40.

76.1.7 FCCU nvm_cfg-interface signal functions

Please refer to dcl_fccu in the attached DCF sheet for the description of the various the functions of the nvm_cfg signal interface of FCCU.

76.1.8 Clock sources

This table specifies the internal chip clock that is connected to each FCCU clock input.

Table 76-3. FCCU clock sources

FCCU clock input	Internal chip clock
CLKSYS	PBRIDGE_1_CLK
CLKSAFE0	IRC_CLK
CLKSAFE1	IRC_CLK

76.2 Introduction

The Fault Collection and Control Unit (FCCU) offers a hardware channel to collect faults and to place the device into a safe state when a failure in the device is detected. No CPU intervention is requested for collection and control operation.

The FCCU offers a systematic approach to fault collection and control. The distinctive features of the module are:

- Redundant collection of hardware checker (for example, RCCU) results
- Redundant collection of fault information from safety relevant modules on the device
- Collection of test results
- Configurable fault control
- Configurable internal reactions for each NCF:
  - No reaction

    - IRQ
    - Short functional reset
    - Long functional reset
    - NMI
- External reactions via configurable output pins
- Watchdog timer for the reconfiguration phase
- Lockable configuration
- Nonvolatile memory interface (NVMCFG signals) for configuration loading
- One of the fault-output (EOUT) signals is high to indicate operational (OK) state (in bi-stable operation mode). The above is not true in case the error out protocol is configured to be a toggling protocol, for example, dual rail and time switching.
- After power on, the EOUT signals have high impedance.[1] They show operational state only after configuration by software.
- In case of a failure event or on software request for Error pin indication, the pin(s) are set to faulty state for a minimum time T_min, even if SW tries to release it before (for the case of error pin configured in Bi-stable mode only).
- The overall fault detection, processing and indication time is less than 10 ms.
- The actual maximum time is 5 CLKSAFE cycles**.**

The FCCU circuitry is checked at the start-up by the self-checking procedure. The FCCU is operative with the default configuration immediately after the completion of the self-checking procedure. Internal (short or long functional reset request pulse, interrupt request) and external (EOUT signaling) reactions are statically defined or programmable. The default configuration can be modified only in the CONFIG state. FCCU is designed to function when CLKSYS is faster than the CLKSAFE clocks.

76.2.1 Acronyms and abbreviations

Term	Description
CF	Critical fault
CPU	Central processing unit
EOUT	Error out

Table continues on the next page...

1. Actual value depends on device specific setting at pad level.

Term	Description
FOSU	FCCU output supervision unit
FSM	Finite state machine
INTC	Interrupt controller
intf	Interface
IRQ	Interrupt request
MC_ME	Mode entry module
NCF	Noncritical fault
NMI	Nonmaskable interrupt
NVM	Nonvolatile memory
RCC	Redundancy control checkers
RCCU	Redundancy control checker unit
SoC	System-on-chip
STCU	Self-test control unit
SW	Software
WKPU	Wake-up unit

76.3 Main features

- Management of noncritical faults
- HW or SW fault recovery management
- Fault detection and collection
- Fault injection (fake faults)
- External reaction (fault state): EOUT signaling. Error indication via the pin(s) is controlled by the FCCU.
- Internal chip reactions (alarm state): interrupt request
- Internal chip reactions (fault state):
  - long functional reset request pulse
  - short functional reset request pulse
  - NMI
- Bi-Stable, Dual-Rail and Time Switching output protocols on EOUT
- Internal (to the FCCU) watchdog timer for the reconfiguration phase
- Configuration lock
- Nonvolatile memory interface (NVMCFG signals) for configuration loading

76.4 Block diagram

The following figure is a top-level diagram of the FCCU module.

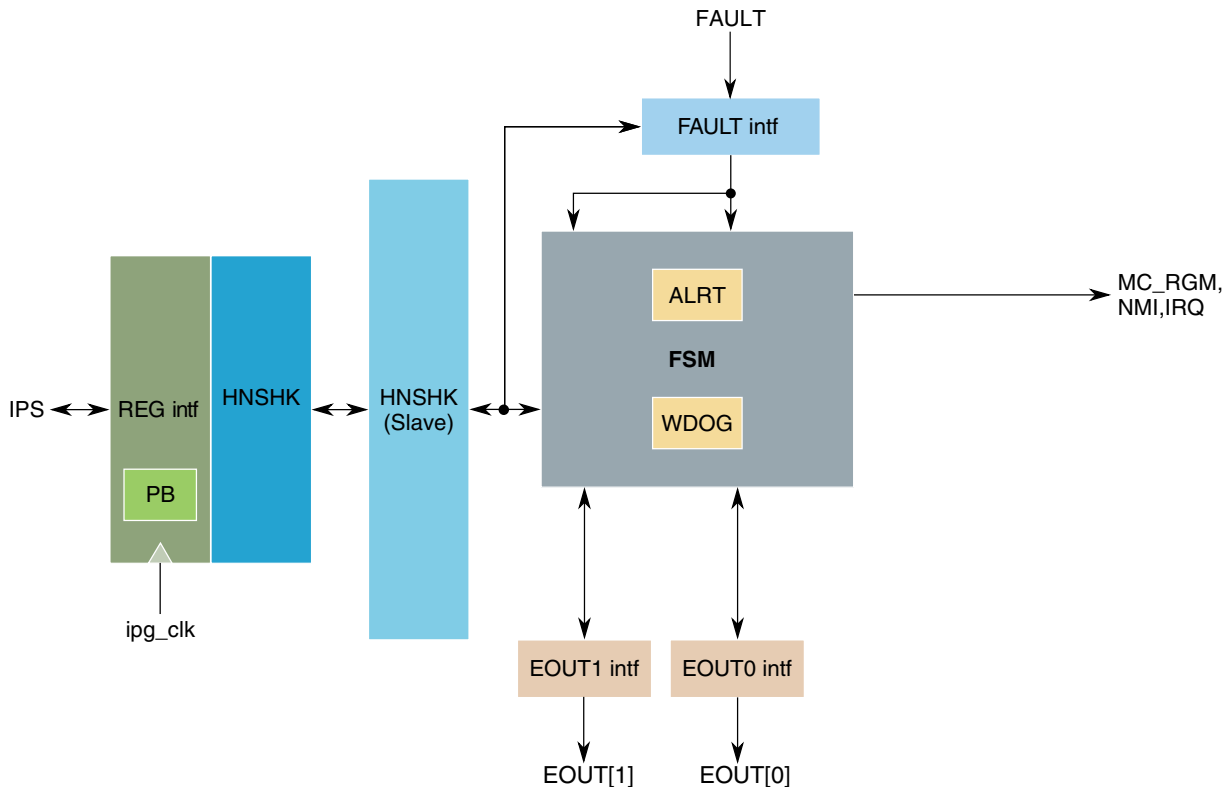


Figure 76-2. FCCU block diagram

This table describes the FCCU submodules.

Table 76-4. FCCU submodules

Submodule	Description
REG intf	Includes the register file, the IPS bus interface, the IRQ interface and the parity block (PB) for the configuration registers
HNSHK blocks (master and slave blocks)	Includes the FSM's ability to support the handshake between the REG interface and the FSM unit due to the usage of 2 asynchronous clocks (IPS system clock and RC oscillator clock)
FSM unit	Implements the main functions of the FCCU. The FSM also includes the: • Watchdog timer (WDG) • Alarm timer (ALRT)
FAULT intf	Implements the interface for the fault conditioning and management
EOUTx units	Implement the output stage to manage the EOUT interfaces

76.5 Signal description

76.5.1 Signals

This table describes the signals on the boundary of FCCU.

Signal	Direction	Function	Active level	Clock
Clock and reset				
CLKSYS	Input	System Clock—Supplies the primary clock.	Rising edge	—
CLKSAFE0	Input	Safe Clock 0—Supplies one of two 16 MHz clocks for use by various redundant submodules. This clock and CLKSAFE1 are often referred to as the same clock (CLKSAFE).	Rising edge	—
CLKSAFE1	Input	Safe Clock 1—Supplies one of two 16 MHz clocks for use by various redundant submodules. This clock and CLKSAFE0 are often referred to as the same clock (CLKSAFE).	Rising edge	—
EOUT interface				
EIN[1:0]	Input	Error Input—Provide the mechanism for FCCU to capture the states that off-chip logic drives on the associated EOUT[1:0] signals. (On the chip, the EOUT signals are connected to their corresponding EIN signals.) FCCU captures the states in the EIN1 and EIN0 fields.	—	Asynchronous
EOUT[1:0]	Output	Error Output—Indicate FCCU's condition (Faulty, Nonfaulty, or Configuration) to off-chip logic.	Programmable	CLKSAFE0, CLKSAFE1
FOSU interface				
FIF	Output	FCCU In Fault—Indicates to the FOSU module, if present, that FCCU is recognizing a fault. FCCU asserts and then deasserts this signal in two cases: *Case 1* When the EOUT signals are programmed to be always low (FCCU_SET_CLEAR), FCCU asserts this signal until the EOUT signals are programmed not to be always low. *Case 2*	High	CLKSAFE0, CLKSAFE1

Table continues on the next page...

Signal	Direction	Function	Active level	Clock
		When the EOUT signals are programmed not to be always low (FCCU_SET_CLEAR), FCCU asserts this signal when all of the following are true: • FCCU enters Fault state as the result of a fault. • If the fault is a noncritical fault, and the EOUT signals are in a fault-output mode (FOM) other than Bistable, the associated EOUTENx field is set to enabled. FCCU deasserts this signal when FCCU leaves Fault state.		
WKPU interface				
NMIWKPU	Input	WKPU Nonmaskable Interrupt Request—Receives nonmaskable interrupt requests from the WKPU module.	Low	CLKSYS
WAKEWKPU	Output	Wake WKPU—Wakes the WKPU module to bring the chip out of dormant state when FCCU enters Fault state as the result of a noncritical fault for which NMI is enabled as the reaction (FCCU_NMI_ENa[NMIENx]).	High	CLKSAFE0, CLKSAFE1
Interrupt interface				
NMIOUT	Output	Nonmaskable Interrupt Output—Sends a nonmaskable interrupt request to the processor core or cores when FCCU enters Fault state as the result of a noncritical fault for which NMI is enabled as the reaction (FCCU_NMI_ENa[NMIENx]).	Low	CLKSYS
NVM interface				
NVMCFG[21:0]	Input	Nonvolatile Memory Configuration—Provide the values of certain bits in the Configuration (FCCU_CFG) register when certain events occur. See Configuration (FCCU_CFG). Some or all of these signals may be driven by bits in a data record in nonvolatile (flash) memory or may be tied high (1) or low (0). See FCCU_CFG register bit value sources (N and C) by event.	Static value	—
SSCMDONE	Input	SSCM Done—After an FCCU reset, indicates that the SSCM module is now driving any NVMCFG signals	High	CLKSYS

Signal	Direction	Function	Active level	Clock
		that are associated with a data record stored in nonvolatile (flash) memory.		

76.6 Put FCCU in Configuration or Normal state

76.6.1 Introduction

You put FCCU in Configuration state to change its configuration. You put FCCU in Normal state to save changes to the configuration.

After you configure FCCU, you can lock its configuration to prevent accidental changes.

76.6.2 About changing states

When changing states, keep the following in mind:

- To put FCCU in Configuration state, FCCU must be in Normal state.
- After FCCU is reset, the configuration is temporarily locked. You must temporarily unlock the configuration before you can put FCCU in Configuration state.
- When FCCU is in Configuration state, FCCU doesn't actually save the changes you make to the configuration. To save changes to the configuration, you must manually put FCCU in Normal state. If FCCU automatically leaves Configuration state and enters Normal state because the configuration-timer interval (TO) expires (called a Configuration-state timeout), FCCU changes the value of the Configuration (FCCU_CFG) register to its Configuration-state-timeout value and the value of each of the other configuration registers to its reset value. For information on the Configuration-state timeout value, see FCCU_CFG register bit value sources (N and C) by event. For a list of configuration registers, see Configuration registers.

76.6.3 About locking the configuration

When locking the configuration, keep the following in mind:

- If you attempt to lock the configuration while FCCU is in Configuration state, FCCU doesn't actually lock the configuration until FCCU leaves Configuration state—that is, either you put FCCU in Normal state, or FCCU puts FCCU in Normal state because the configuration-timer interval (TO) expires.
- After you permanently lock the configuration, you must reset FCCU before you can put FCCU in Configuration state.

76.6.4 Put FCCU in Configuration state

1. From Supervisor mode, temporarily unlock the configuration (TRANSKEY).
2. To determine FCCU's state, run the OP3 operation (see Run an operation).
3. Check the operation status (OPS).
   - If the operation status is Successful, go to step 4.
   - If the operation status is Aborted, go to step 2.
4. Check the FCCU status (STATUS).
   - If the FCCU status is Configuration, FCCU is in Configuration state. Stop.
   - If the FCCU status is Normal, go to step 5.
   - If the FCCU status is Alarm or Fault, go to step 7.
5. To put FCCU in Configuration state, run the OP1 operation (see Run an operation).
6. Check the operation status (OPS).
   - If the operation status is Successful, FCCU is in Configuration state. Stop.
   - If the operation status is Aborted, the configuration is probably permanently locked. Go to step 9.
7. Recover all faults.
8. Go to step 2.
9. Reset FCCU.

76.6.5 Put FCCU in Normal state

1. To determine FCCU's state, run the OP3 operation (see Run an operation).
2. Check the operation status (OPS).
   - If the operation status is Successful, go to step 3.
   - If the operation status is Aborted, go to step 1.
3. Check the FCCU status (STATUS).
   - If the FCCU status is Normal, FCCU is in Normal state. Go to step 8.
   - If the FCCU status is Configuration, go to step 4.
   - If the FCCU status is Alarm or Fault, go to step 6.
4. To put FCCU in Normal state, run the OP2 operation (see Run an operation).
5. Check the operation status (OPS).

- If the operation status is Successful, FCCU is in Normal state. Go to step 8.
- If the operation status is Aborted, go to step 4.

6. Recover all faults.
7. Go to step 1.
8. If you want to prevent changes to the configuration, lock it:
   - To require a key to unlock the configuration, from Supervisor mode, temporarily lock the configuration (TRANSKEY).
   - To require a reset of FCCU to unlock the configuration, from Supervisor mode, permanently lock the configuration (PERMNTKEY).

     The configuration is permanently locked until FCCU is reset.

76.7 Run operations

76.7.1 Introduction

You run operations to perform actions such as putting FCCU in Configuration state or reading a timer. For a complete list of operations you can run, see OPR.

76.7.2 About running operations

When running operations, keep the following in mind:

- FCCU ignores any operations initiated while the operation status is In Progress.
- Certain operations must be unlocked before you can initiate them. After you initiate them, they are again locked.

76.7.3 Run an operation

1. Check the operation status (OPS).
2. If the operation status is In Progress, go to step 1.
3. If the operation must be unlocked before you can initiate it, unlock the operation (CTRLK) using a 32-bit write.

NOTE

The Control Key (FCCU_CTRLK) register used in this step and the Control (FCCU_CTRL) register used in the next

step must be written with consecutive instructions. Do not use read-modify-write instructions, such as bit-field instructions, to modify these registers.

4. Initiate the operation (OPR) using a 32-bit write.
5. Check the operation status (OPS).
6. If the operation status is In Progress, go to step 5.

The operation status is now Idle (OP15 only), Aborted, or Successful.

76.8 Functional description

76.8.1 Definitions

In general, the following definitions are applicable for the fault management:

- HW recoverable fault: the fault indication is an edge-triggered and level-sensitive signal that remains asserted until the fault cause is deasserted. That is, if logical 0 on the fault signal indicates fault, then the status flags are valid as long as the fault line stays at 0. The status is automatically cleared when the fault signal goes to 1. Typically the fault signal is latched external to the FCCU in the module where the fault occurred. The FCCU state transitions are consequently executed on the state changes of the input fault signal. No SW intervention in the FCCU is required to recover the fault condition.
- SW recoverable fault: the fault indication is a signal asserted without a defined time duration. The fault signal is latched in the FCCU. The fault recovery is executed following a SW recovery procedure (status/flag register clearing).

HW recoverable is an option to exclude the handling of error source/s by FCCU management SW, in case it is known that the fault is recoverable by itself when the fault condition gets corrected.

These type of chip resets reset the FCCU:
- Power-on
- Destructive
- Long functional, when initiated by the assertion of the chip reset pin (RESET_B)

These types of chip resets don’t reset the FCCU:
- Long functional, when initiated by anything other than the assertion of the chip reset pin (RESET_B)
- Short functional reset

For more information on each type of reset, see the MC_RGM and reset chapters.

76.8.2 FSM description

FCCU functionality is depicted by the finite state machine (FSM) state diagram.

Basically four states are identified with the following meaning:

- Configuration: Used only to modify the configuration of FCCU from its default. A subset of the FCCU registers, dedicated to define the FCCU configuration (global configuration, reactions to fault, timeout, noncritical fault masking) can be accessed in write mode only in Configuration state.

  Configuration state is accessible only in Normal state and if the configuration is not locked. The permanent configuration lock can be disabled by a reset which also resets the FCCU., The transient lock register is unlocked by writing BCh into it. FCCU gets transiently locked again if an invalid key is written into FCCU_TRANS_LOCK register (that is, other than BCh). Key to lock FCCU permanently is FFh, written in the FCCU_PERMNT_LOCK register.

  After the release of reset the state of the transient lock will be locked. The state of the permanent lock will be unlocked.

  The locking feature only restricts the FSM movement into Configuration state. Once the user enters Configuration state and then tries to lock the configuration, the locking of configuration will be effective after FCCU moves to Normal state, it will not be effective in the current Configuration state.

  The Configuration to Normal state transition can be executed by SW or automatically following a timeout condition of the watchdog. In case the timeout information and the SW request to mode change to Normal appears at the same time, watchdog timeout has the priority and hence the Configuration registers (those that are writable only in Configuration state) are reset to their default values. The movement to Normal is made.

  The incoming faults, occurring during the configuration phase (Configuration state) are latched in order to process them when FCCU is moved into Normal state, according to the new configuration.

  All pending faults that occur during Configuration state result in both of the following:

  - Highest-priority state transition
  - Interrupt generation (NMI or alarm IRQ)

If the state transition occurs, it gives the reset reaction corresponding to the worst case based on all the faults (pending or nonpending faults) that occurred during Configuration state.

- Normal: This is FCCU's operating state when no faults are occurring. It is also the default state on the reset exit. Following state transitions occur on one of the following events:
  - unmasked noncritical faults with the timeout disabled → FCCU moves to Fault state
  - unmasked noncritical faults with the timeout enabled → FCCU moves to Alarm state
  - masked noncritical faults → FCCU stays in Normal state
- Alarm: FCCU moves into Alarm state when an unmasked noncritical fault occurs and the timeout is enabled. The transition to Alarm state goes along with an interrupt alarm, if enabled. By definition, this fault may be recovered within a programmable timeout period, before it generates a transition to Fault state. The timeout is reinitialized if FCCU enters Normal state. The timeout restarts following the recovery from Fault state.
- Fault: FCCU moves into Fault state when one of the following condition occurs:
  - timeout related to a noncritical fault when FCCU is in Alarm state
  - unmasked noncritical faults with the timeout disabled

The transition from Normal/Alarm to Fault state goes along with the generation of:

- NMI interrupt (optional)
- EOUT signaling (optional)
- SW option: Soft reaction (Short functional reset request pulse if configured)
- SW option: Hard reaction (Long functional reset request pulse if configured)
- Non Maskable Interrupt (NMI) is routed to all cores.

After moving to Fault state, if there is either a previous pending fault or a new fault for which NMI is enabled, NMI generation takes place.

Multiple faults can occur at the same time. Consider the case where there is a fault for which Alarm state is enabled and IRQ is programmed along with a fault for which Alarm state is disabled. In that case, the FSM moves to Fault state, but with the generation of alarm IRQ for the fault which has IRQ enabled.

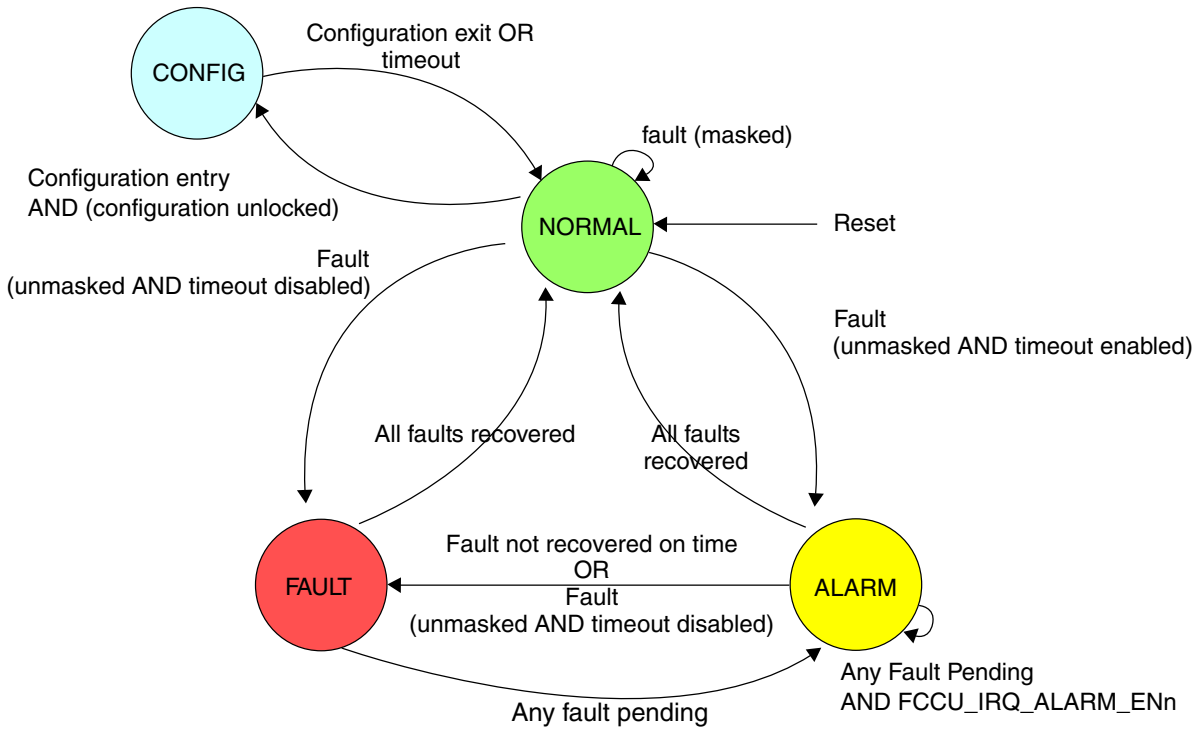

Figure 76-3. FCCU state diagram

76.8.3 Fault priority scheme and nesting

The FAULT state has a higher priority than the ALARM state in case of concurrent fault events (noncritical) that occur in the NORMAL state.

The ALARM to FAULT state transition occurs if a noncritical fault (unmasked and with time-out disabled) is asserted in the ALARM state.

The ALARM to NORMAL state transition occurs only if all the noncritical faults (including the faults that have been collected after the entry in the ALARM state) have been cleared (SW or HW recovery); otherwise the FCCU will remain in the ALARM state.

The FAULT to NORMAL state transition occurs only if all the noncritical faults (including the faults that have been collected after the entry in the FAULT/ALARM state) have been cleared (SW or HW recovery); otherwise the FCCU will move to the ALARM state (if any noncritical fault is still pending and the time-out is not elapsed).

In general, no fault nesting is supported except for the noncritical faults that cause an ALARM to FAULT state transition. In this case the NCF timer is stopped until the FAULT state is recovered. If FCCU is in ALARM state and another fault comes, which has its alarm timeout enabled, then the alarm timer shall not reload and shall not start again.

76.8.4 Fault recovery

The following timing diagrams describe the main use cases of the FCCU in terms of fault events and related recovery.

A typical sequence related to a noncritical FAULT management (ALARM state), see Figure 76-4 and Figure 76-5, is as follows:

- Noncritical fault assertion
- FCCU state transition (automatic): NORMAL → ALARM
  - alarm interrupt request (if enabled)
  - time-out running
- system state: RUN
- alarm interrupt management: FAULT recovery (by SW)
  - FCCU state transition ALARM → NORMAL

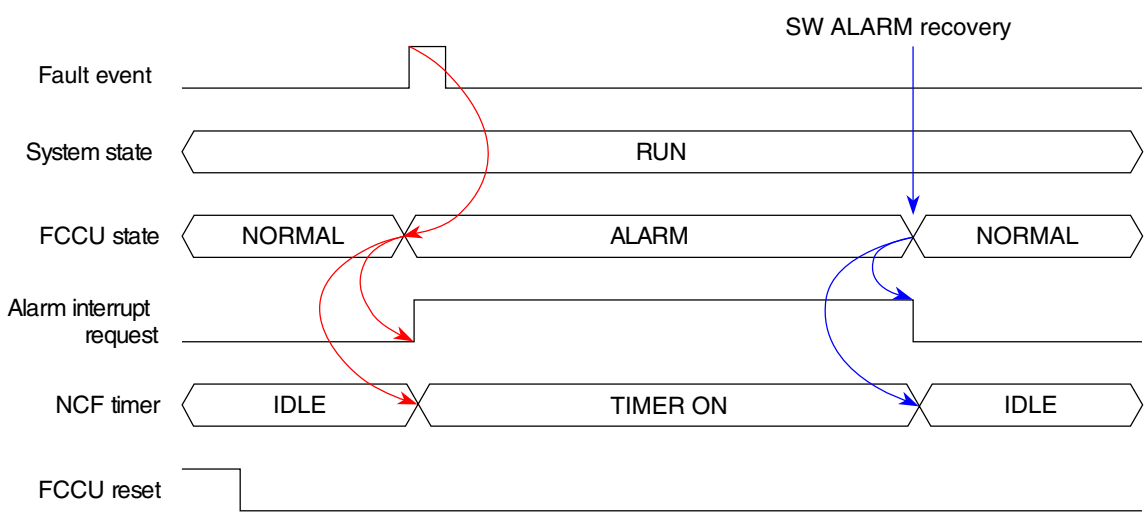

Figure 76-4. Noncritical FAULT (ALARM state) recovery (a)

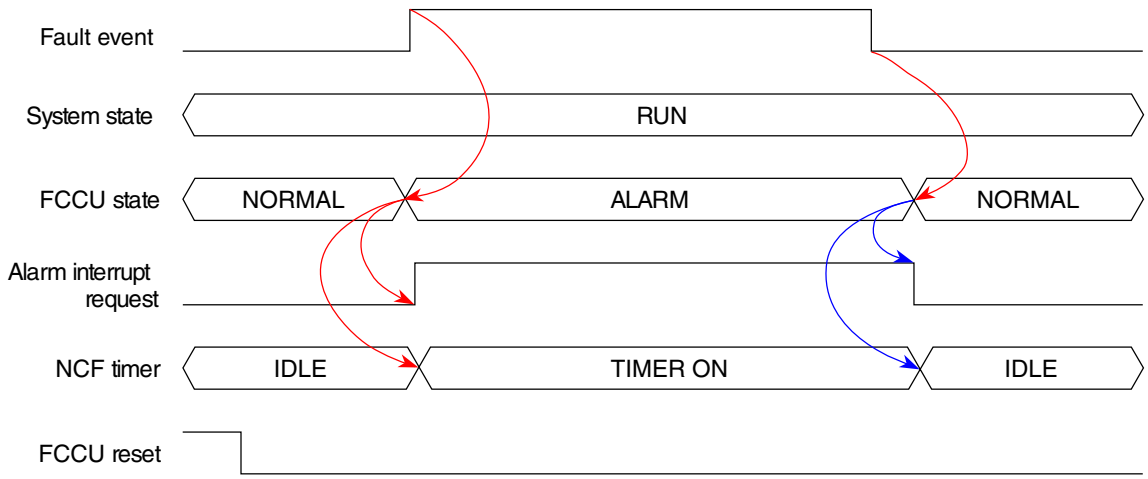

Figure 76-5. Noncritical FAULT (ALARM state) recovery (b)

A typical sequence related to a noncritical FAULT management (ALARM → FAULT state), see Figure 76-6, is as follows:

- Noncritical fault assertion
- FCCU state transition (automatic): NORMAL → ALARM
  - alarm interrupt request (if enabled)
  - time-out running
- FCCU state transition (following the time-out trigger): ALARM → FAULT
  - NMI assertion (if enabled)
- system state transition: RUN → SAFE
- NMI interrupt management (if enabled)
  - FAULT recovery (by SW): FCCU state transition FAULT → NORMAL
  - system state transition: SAFE → RUN

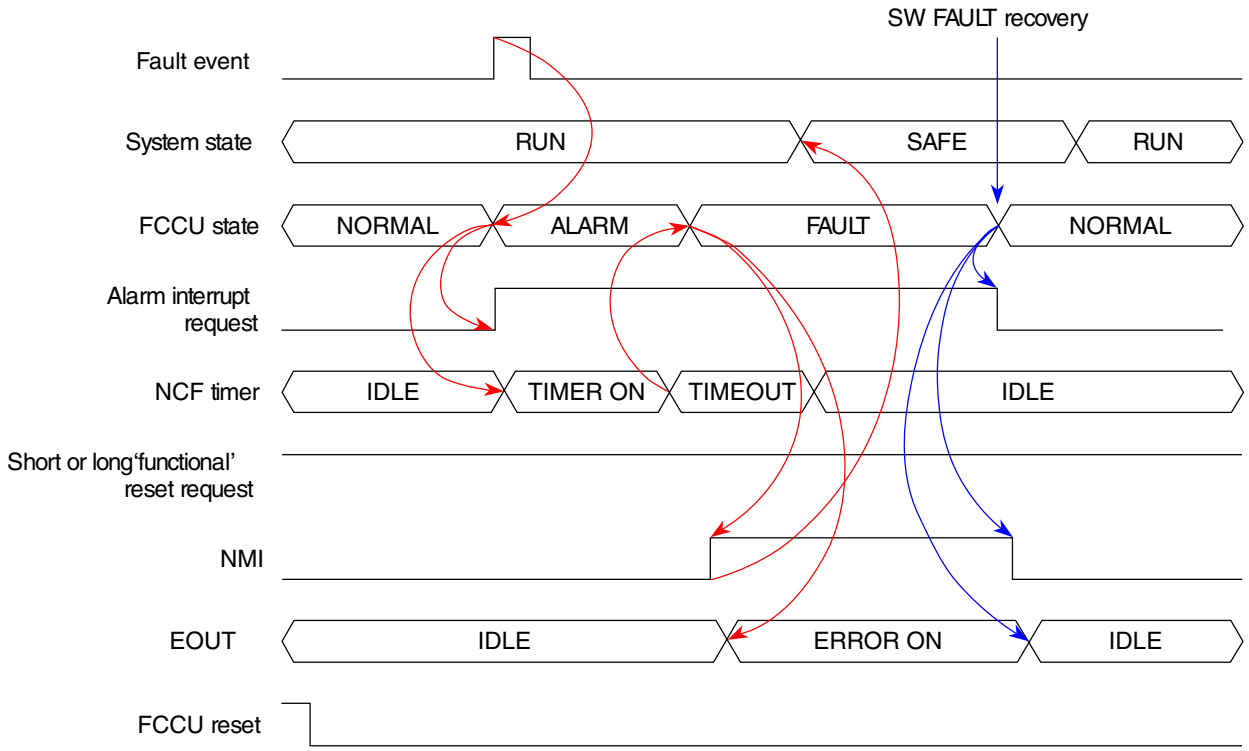

Figure 76-6. FAULT (ALARM → FAULT state) recovery

76.8.5 NMI/WKPU interface

NMIOUT is connected to all processor cores on the chip but is masked when any one of the following is true:

- An FCCU asynchronous reset is in progress.
- The chip is in RESET mode.
- The chip has automatically entered DRUN mode from RESET mode and software has not yet requested another mode change.

This figure shows the logical scheme.

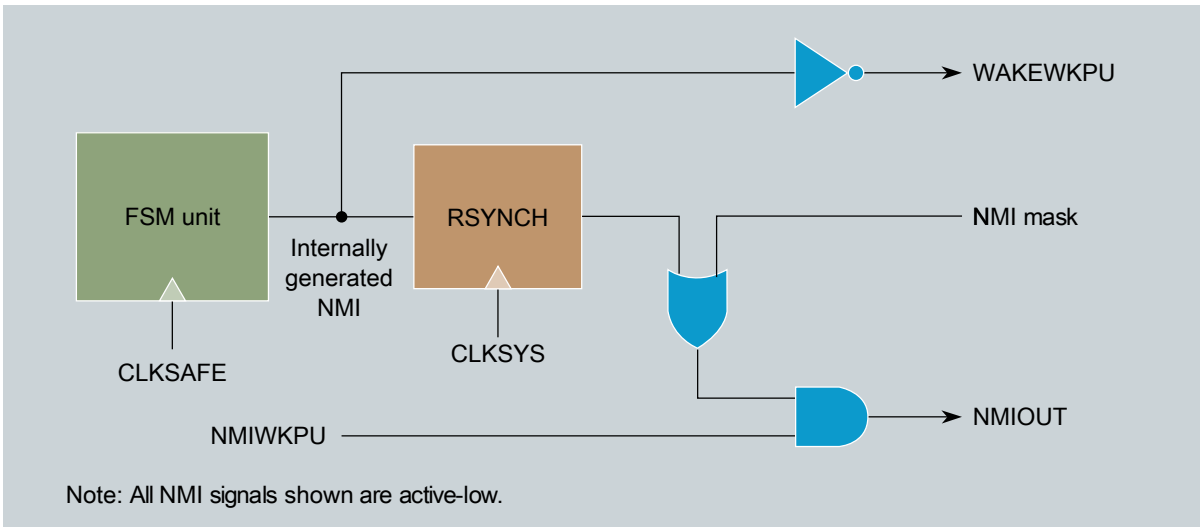

Figure 76-7. NMI/WKPU scheme

76.8.6 STCU interface

The STCU interface includes:

- A set of signals resulting from the self-checking procedure connected externally at the FCCU.

  The STCU fault signals are processed by the FCCU when the SoC is re-booted following the self-testing procedure. The STCU includes a status register that stores the self-testing results (flags).

- a mask that inhibits the EOUT dummy signaling until the STCU self-checking procedure has been completed.

During the self-testing procedure, depending on the STCU results, three cases are applicable:

1. STCU completes the self-testing procedure successfully. The SoC reboots and the FCCU is responsible for fault collection and indication.
2. STCU completes the self-testing procedure with low severity failures. The FCCU records the fault condition but does not, by default, trigger a reset cycle.
3. STCU completes the self-testing procedure with serious failures. The FCCU triggers a reset cycle in response to this fault input from the STCU. Because the fault condition survives reset, new reset cycles are subsequently triggered until the reset escalation feature takes control, freezing the chip in the reset state until a POR. This feature is optionally programmable using MC_RGM.

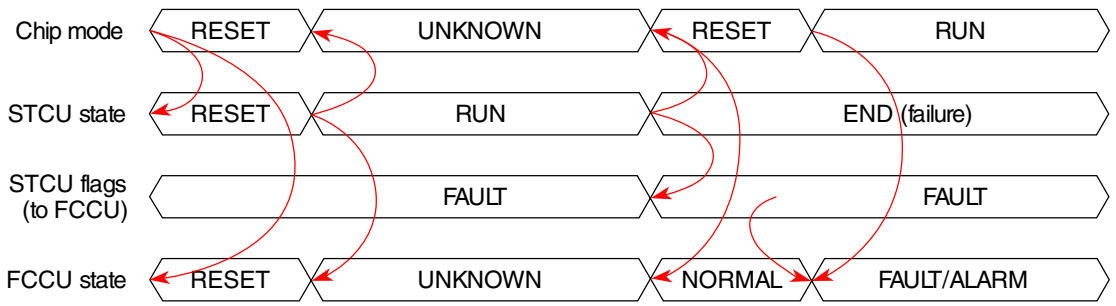

Figure 76-9. STCU-FCCU (case 2)

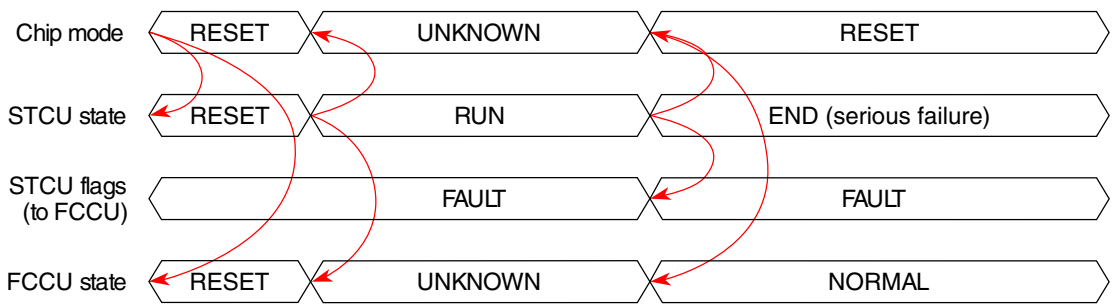

Figure 76-10. STCU-FCCU (case 3)

76.8.7 Nonvolatile memory interface

FCCU includes a nonvolatile memory interface (NVMCFG signals) that provides the values of certain bits in the Configuration (FCCU_CFG) register when certain events occur. See Configuration (FCCU_CFG). Whether any of these signals are actually connected to nonvolatile (flash) memory is chip-specific. Some or all of these signals may be driven by bits in a data record in nonvolatile (flash) memory or may be tied high (1) or low (0). See FCCU_CFG register bit value sources (N and C) by event.

The timing diagram related to the NVM interface is given in Figure 76-11.

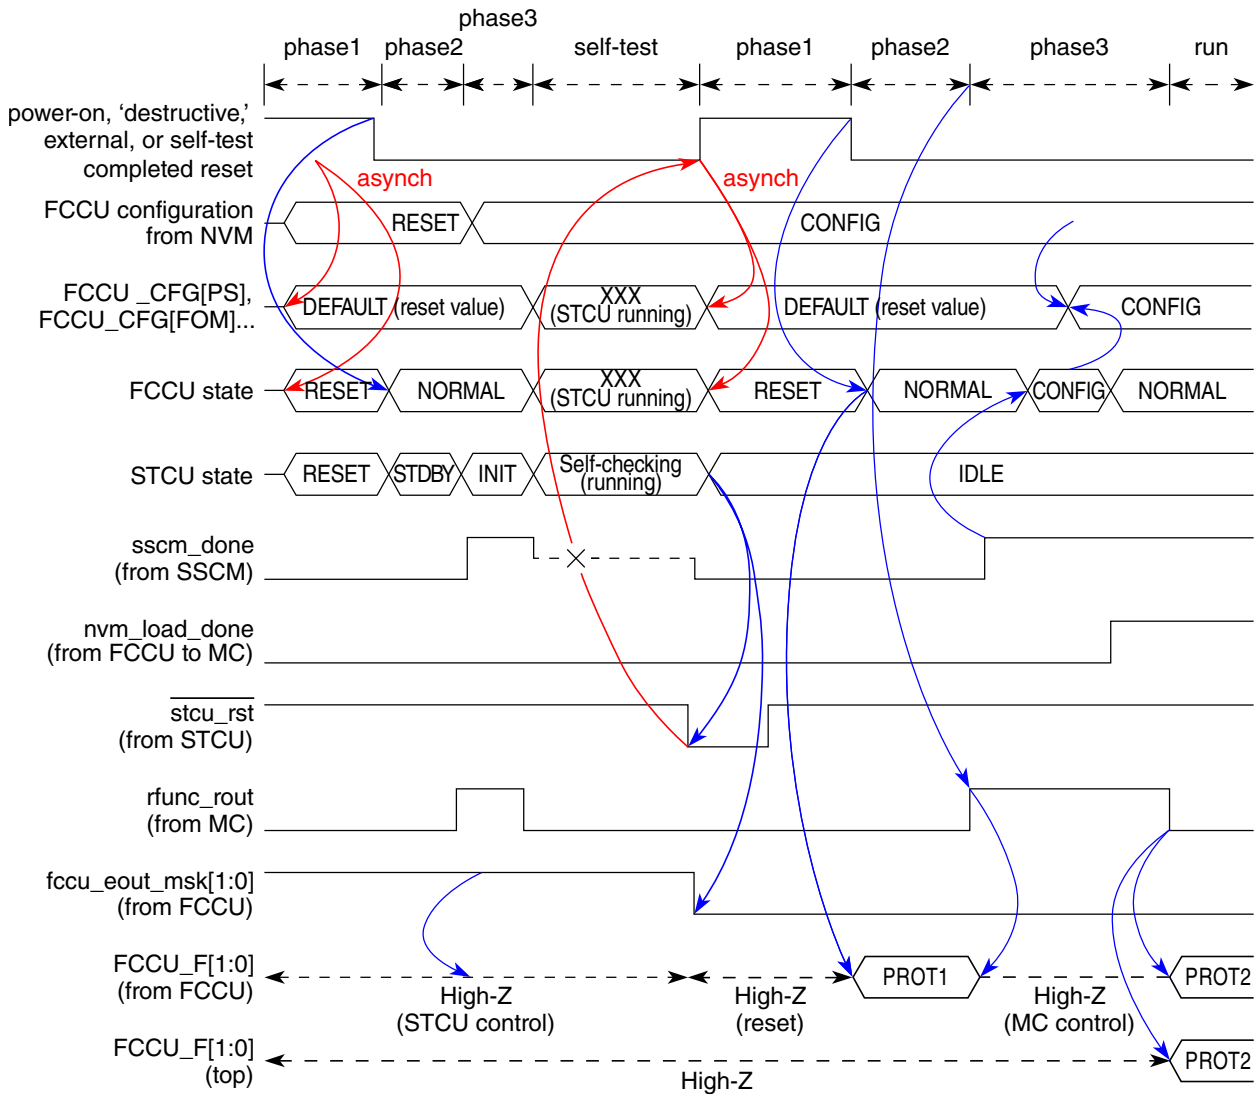

Figure 76-11. NVM interface

76.8.8 EOUT interface

76.8.8.1 Introduction

You use the EOUT[1:0] signals to indicate FCCU's condition to off-chip logic. For information on the availability and names of these FCCU signals on the boundary of this chip, see the chip-specific FCCU information.

76.8.8.2 The FCCU conditions

There are three FCCU conditions:

Condition	Description
Faulty	The fault-output (EOUT) timer is running (see How the fault-output (EOUT) timer works).
Nonfaulty	All of the following are true: • The fault-output (EOUT) timer is not running. • FCCU is in Alarm or Normal state.
Configuration	All of the following are true: • The fault-output (EOUT) timer is not running. • FCCU is in Configuration state.

76.8.8.3 How the fault-output (EOUT) timer works

FCCU starts the fault-output (EOUT) timer when all of the following are true:

- The fault-output (EOUT) signals are not programmed to be always low (FCCU_SET_CLEAR).
- The fault-output (EOUT) timer isn't already running.
- FCCU enters Fault state as the result of a fault.

When the fault-output (EOUT) timer is already running and a new fault occurs:

- When FCCU is in Configuration state: FCCU doesn't restart the fault-output (EOUT) timer.
- When FCCU is in Normal state or Alarm state:
  - And Alarm state is enabled for the fault (noncritical): FCCU enters (or remains in) Alarm state but doesn't restart the fault-output (EOUT) timer.
  - And Alarm state is disabled for the fault (noncritical): FCCU enters Fault state and restarts the fault-output (EOUT) timer.
- When FCCU is in Fault state: FCCU restarts the fault-output (EOUT) timer.

FCCU stops and reinitializes the fault-output (EOUT) timer when all of the following are true:

- If the EOUT signals are in Bistable fault-output mode (FOM), T_min has expired.
- All faults that caused FCCU to enter or remain in Fault state since FCCU started the fault-output (EOUT) timer have been cleared, causing FCCU to return to Normal state.

76.8.8.4 Prepare the EOUT signals to indicate FCCU's condition

Make sure all of the following are true:

- The EOUT signals are active (FCCU_SET_AFTER_RESET).
- The EOUT signals are controlled by FCCU's finite state machine (FCCU_SET_CLEAR).

76.8.8.5 More about the EOUT interface

Because SIUL2 does not control the pad-buffer enable for an Alternate function, FCCU provides a mechanism to drive the pads for EOUT[1:0] in Open-Drain (OD) mode (FCCU_CFG[OD]) so that a pad is in a high-impedance state when FCCU drives a logic 1 and is low when FCCU drives a logic 0.

Different fault-output modes (protocols) for the fault-output (EOUT) interface are supported (FCCU_CFG[FOM]):

- Dual-Rail
- Time-Switching
- Bistable
- Test

You can further configure the fault-output modes using the following attributes:

Attribute	Field	Setting used in the example diagrams and tables that follow
Switching mode	FCCU_CFG[SM]	Slow
Polarity selection	FCCU_CFG[PS]	For the faulty indication, EOUT1 is high, and EOUT0 is low.
Derived prescaler	FCCU_CFG[FOPE], FCCU_CFG[FOP]	0

The external monitor of the EOUT protocol should oversample the EOUT signals in order to synchronize periodically the external clock (used by the monitor) and CLKSAFE (which detects the edge transition of the EOUT protocol) in Dual-Rail or Time-Switching fault-output mode.

In case of a failure event or on software request for EOUT indication, the signal(s) are set to the faulty state for a minimum time T_min, even if software tries to release it before. If software configures the error pins to OK(1), and if a fault comes trying to drive the pin to NOK(0), then priority is given to the fault indication and the error signals indicate NOK,

such as an incoming fault is not masked when software has set the error signal to high. During the T_min by a non-software fault, the FCCU FSM moves independently of this signal state (low), and as soon as the timer expires, the pin behavior is dictated by the state in which the FSM finds itself in, and it is not possible to set the signals to OK by software moving FCCU to Configuration state, as long as this timer is running. No software intervention is needed to bring the signal from the low state.

Software can bring the pin back to OK state by clearing the faults and waiting for the T_min interval to expire, after which the FCCU automatically enters Normal state and the error signal indicates OK.

In case another failure event happens within T_min after a first one, the T_min counter is restarted.

NOTE

The transition from Fault to Configuration state is not possible but is shown to display the behavior in all four states—reset, normal, error, and configuration.

NOTE

FCCU remains in Normal state when a fault is disabled; therefore, *NA* (not applicable) appears in the following table.

NOTE

The following table is valid only when the EOUT signals are active (FCCU_SET_AFTER_RESET).

Table 76-5. FCCU error pin behavior on state transitions

Fault signaling state	Transition from Normal to Fault state			Normal+Configuration states			Transition from Normal to Alarm state		
	with Fault disabled | enabled						with Fault disabled | enabled		
	Internal error pin	Error pin enable	Error pad	Internal error pin	Error pin enable	Error pad	Internal error pin	Error pin enable	Error pad
Disabled	NA | OK	NA | 1	NA | OK	OK	1	OK	NA | OK	NA | 1	NA | OK
Enabled	NA | NOK	NA | 1	NA | NOK	OK	1	OK	NA | OK	NA | 1	NA | OK

NOTE

The first time FCCU is in Configuration state, the EOUT pads are in a high-impedance state; thereafter, their states reflect the programmed EOUT protocol.

76.8.8.6 Dual-rail protocol

Dual-rail encoding is an alternate method for encoding bits. In contrast with classical encoding, where each signal carries a single-bit value, dual-rail encoded circuits use two wires to carry each bit. The encoding scheme is given in Table 76-6 and the related timing diagram is given in Figure 76-12 and Figure 76-13.

Table 76-6. Dual-rail encoding

Logical state	Dual-rail encoding (output pins EOUT[1:0])	Note
non-faulty	10	toggling
non-faulty	01	
faulty	00	toggling
faulty	11	
reset	Hi impedence[1]	no toggling
configuration	same as NORMAL	toggling

1. Final value depends on the SoC setting at pad level.

In the RESET phase the output pins are set as "high impedance".

Note

Figure 76-12 and Figure 76-13 are formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

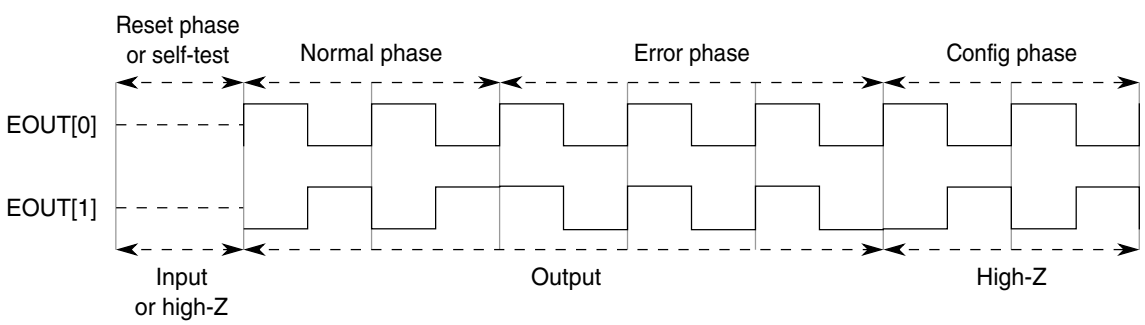

Figure 76-12. Dual-rail protocol (slow switching mode)

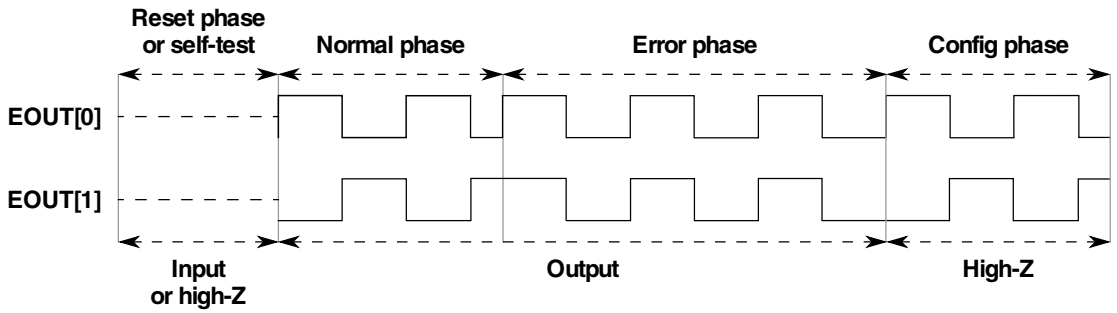

Figure 76-13. Dual-rail protocol (fast switching mode)

76.8.8.7 Time-switching protocol

The encoding scheme is given in Table 76-7 and the related timing diagram is given in Figure 76-14.

Table 76-7. Time-switching encoding

Logical state	Time-switching encoding (output pins EOUT[1:0])	Note
non-faulty	10	toggling
non-faulty	01	
faulty	10	no toggling
reset	high-Z[1]	no toggling
configuration	same as NORMAL	toggling

1. Final value depends on device specific settings at pad level.

As long as FCCU is in NORMAL or ALARM state, outputs will show "non-faulty" signal. Output pins #0, #1 will toggle between 01 and 10 with frequency specified by the CFG[FOP].

In the FAULT state, the output pin EOUT[0] is set as low.

In Time Switching mode the second output (EOUT[1]) is the inverted signal of first output (EOUT[0]).

In the RESET phase the output pins are set as "high impedance".[2]

Note

Figure 76-14 is formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

2. Actual value depends on device specific settings at pad level.

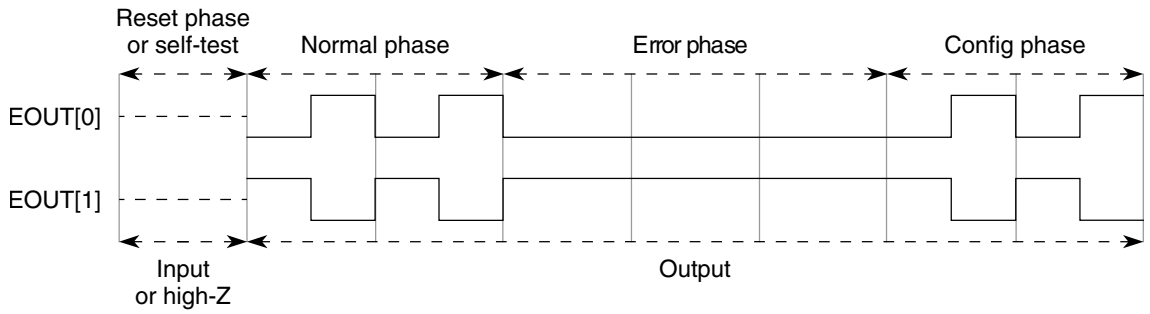

Figure 76-14. Time-switching protocol

76.8.8.8 Bi-stable protocol

The encoding scheme is given in Table 76-8 and the related timing diagram is given in Figure 76-15.

Table 76-8. Bi-stable encoding

Logical state	Bi-stable encoding (output pins EOUT[1:0])	Note
non-faulty	01	no toggling
faulty	10	no toggling
reset	high-Z[1]	no toggling
configuration	same as NORMAL	no toggling

1. Final value depends on device specific settings at pad level.

In the FAULT state, the faulty logical state is indicated. In NORMAL or ALARM state, "no-faulty" state is indicated. In Bi-stable mode the second output (EOUT[1]) is the inverted signal of first output (EOUT[0]).

In the RESET phase the output pins are set as "high impedance".[3]

Note

Figure 76-15 is formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

3. Actual value depends on device specific settings at pad level.

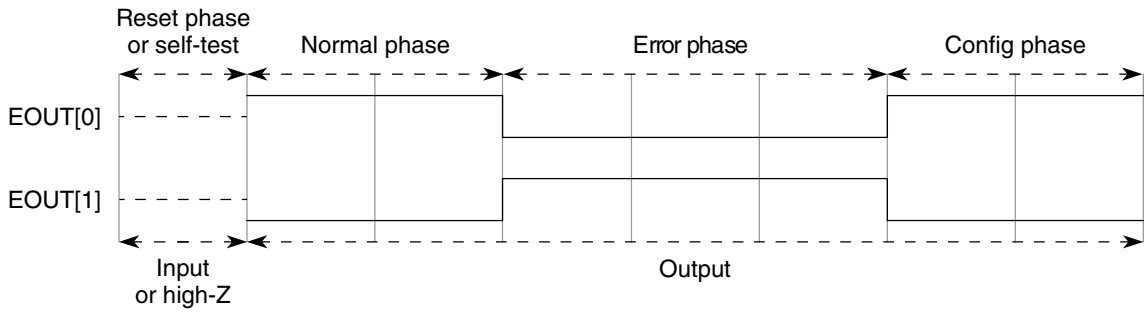

Figure 76-15. Bi-stable protocol

76.8.9 Fault signal flow

See the chip-specific FCCU information for the diagram of the signal flow.

76.9 Register descriptions

The FCCU registers are listed in the table below. Any address offset not explicitly mentioned in this table is reserved.

The FCCU supports word (32-bit), half-word (16-bit), and byte (8-bit) read and write accesses.

Follow these register-access guidelines:

- Don’t read from or write to any addresses that are not shown in the following table. Doing so may result in a transfer error.
- Don’t write to any of the configuration registers unless FCCU is in Configuration state. Doing so results in a transfer error.
- Don’t write to FCCU_TRANS_LOCK or FCCU_PERMNT_LOCK unless your code runs in Supervisor mode. Doing so results in a transfer error.

All the registers accessible in write mode only in CONFIG state are referred as configuration registers. These configuration registers return to the default value after configuration watchdog timer expires. These are the registers protected by FCCU_TRANS_LOCK and FCCU_PERMNT_LOCK registers. The configuration register setting has effect only when the FCCU state exits from the CONFIG state.

For each possible NCF failure source, a different reaction—including no reaction—is configurable through the use of NMI, IRQ, and long/short reset selection registers. It is not possible for a single event upset to switch off all reactions on failures as implementation is per fault source (but it will be possible to switch them all off by SW if intended). Failures themselves are not able to disable all reactions and indications.

The FCCU is not reset by short or long functional resets.

FCCU_CTRL field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 DEBUG	Debug Mode Enable Specifies whether Debug mode is enabled. If so, FCCU enters Debug mode when the Debug signal is asserted. When FCCU enters Debug mode, it halts operation and remains in the state it was in before it entered Debug mode. **NOTE:** FOSU doesn't halt when FCCU enters Debug mode. Therefore, FOSU can still cause a reset if a fault occurs while FCCU is in Debug mode. 0 Disabled 1 Enabled
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–25 OPS	Operation status. This bit can be read and cleared (via OP15 operation) by the software. 00 Idle 01 In progress 10 Aborted 11 Successful
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 OPR	Operation Run Initiates operations that perform actions such as putting FCCU in Configuration state or reading a timer. For information on how to run operations, see Run operations. FCCU ignores any write to this field while the operation status (OPS) is In Progress. After completion of an operation, FCCU sets this field to OP0. The following events result in an operation status (OPS) of Aborted: • Writing to a Noncritical Fault Status (FCCU_NCF_S*n*) register (which automatically initiates the OP12 operation) without first successfully unlocking the register (NCFK) • Initiating an OP1 operation when FCCU is not in Normal state or the configuration is locked • Initiating an OP1, OP2, or OP31 operation without first unlocking the operation (CTRLK) 00000 OP0—No operation 00001 OP1—Applies only when the configuration is unlocked, when FCCU is in Normal state, and immediately after you unlock the operation (CTRLK). Put FCCU in Configuration state. 00010 OP2—Applies only immediately after you unlock the operation (CTRLK). Put FCCU in Normal state. 00011 OP3—Capture FCCU's state and the states of the EOUT signals in the Status (FCCU_STAT) register. 00100 OP4—Read the FCCU frozen status flags (NA Freeze Status (FCCU_N2AF_STATUS)). 00101 OP5—Read the FCCU frozen status flags (AF Freeze Status (FCCU_A2FF_STATUS)). 00110 OP6—Read the FCCU frozen status flags (NF Freeze Status (FCCU_N2FF_STATUS)).

Table continues on the next page...

FCCU_CTRL field descriptions (continued)

Field	Description
	00111 OP7—Read the FCCU frozen status flags (FA Freeze Status (FCCU_F2A_STATUS)). 01000 Reserved 01001 Reserved 01010 OP10—Read the Noncritical Fault Status (FCCU_NCF_S*n*) register. 01011 Reserved 01100 OP12—Do not initiate this operation; it is automatically initiated by FCCU. A Noncritical Fault Status (FCCU_NCF_S*n*) register status clear operation is in progress. 01101 OP13—Clear the freeze status registers (see the freeze registers). 01110 OP14—Do not initiate this operation; it is automatically initiated by FCCU. A Configuration-state timeout is in progress. For more information, see Configuration registers. 01111 OP15—Set the operation status (OPS) to Idle. 10000 Reserved 10001 OP17—Read the Alarm-state timer (XTMR). 10010 Reserved 10011 OP19—Read the Configuration-state timer (XTMR). 10100 Reserved 10101–11110 Forbidden. Writing any of these values returns an operation status (OPS) of Aborted with no side effect. 11111 OP31—Applies only immediately after you unlock the operation (CTRLK). Load configuration data from the NVMCFG signals to certain fields in the Configuration (FCCU_CFG) register, but without resetting FCCU (for testing and debugging). See FCCU_CFG register bit value sources (N and C) by event. The operation status (OPS) for this operation is always Successful.

76.9.2 Control Key (FCCU_CTRLK)

Writable only with a 32-bit write. Unlocks locked operations so you can initiate them (OPR). For information on how to unlock locked operations before you initiate them, see Run an operation.

NOTE

Reading from this register always returns the value 0000_0000h.

Address: 0h base + 4h offset = 4h

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FCCU_CTRLK field descriptions

Field	Description
0–31 CTRLK	Locked-Operation Control Key Unlocks locked operations so you can initiate them (OPR). For information on how to unlock locked operations before you initiate them, see Run an operation. **NOTE:** You must initiate an operation in the instruction that immediately follows the instruction that unlocks it; otherwise, the operation is again locked. 9137_56AFh: Unlock OP1. 825A_132Bh: Unlock OP2. 29AF_8752h: Unlock OP31. Any other value: Do nothing.

76.9.3 Configuration (FCCU_CFG)

Writable only when FCCU is in Configuration state. Specifies the global configuration for FCCU.

The values of the bits in this register are affected by writes as well as any of the following events:

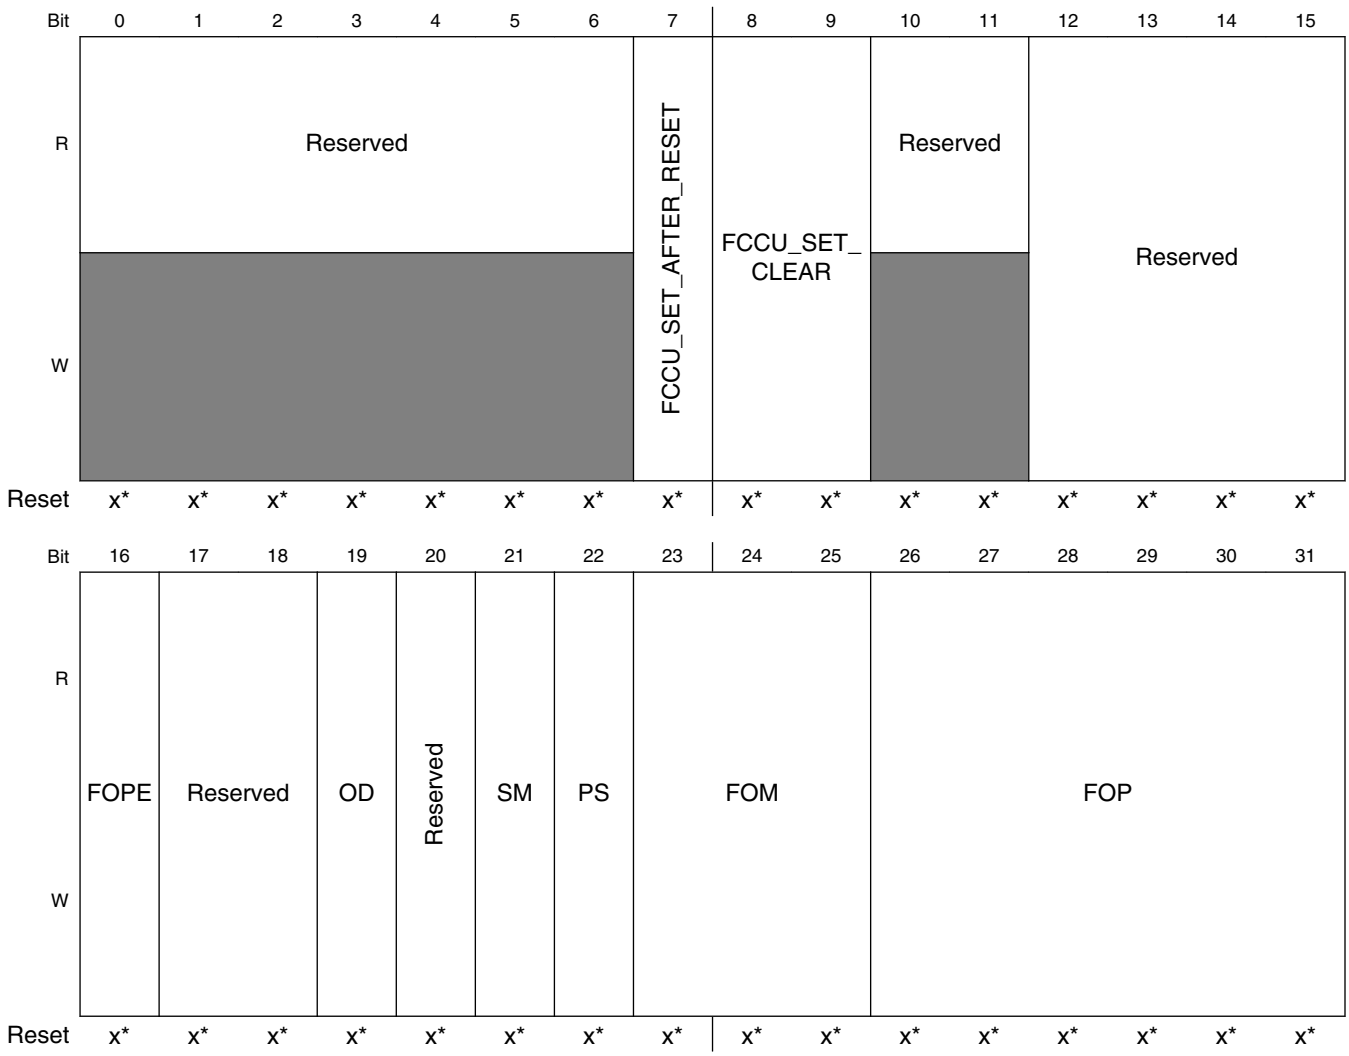
- The chip resets FCCU.
- FCCU automatically leaves Configuration state and enters Normal state because the configuration-timer interval (TO) expires. This is called a Configuration-state timeout.
- You run an OP31 operation.

For information on the sources of bit values for these events, see FCCU_CFG register bit value sources (N and C) by event.

NOTE

If you specify a new value for any of the fields in this register that affect the EOUT signals while the fault-output (EOUT) timer is running (FCCU is indicating a fault on the EOUT signals), FCCU doesn't use the new settings you specified until after the fault-output (EOUT) timer expires (FCCU stops indicating a fault on the EOUT signals).

Address: 0h base + 8h offset = 8h



* Notes:

- For information on this register's reset value, see FCCU_CFG register bit value sources (N and C) by event.x = Undefined at reset.

FCCU_CFG field descriptions

Field	Description
0–6 Reserved	This field is reserved.
7 FCCU_SET_AFTER_RESET	Fault-Output (EOUT) Activate For fault-output (EOUT) signaling, controls whether the EOUT signals are active. 0 Inactive (the EOUT signals are in a high-impedance state) 1 Active (the EOUT signals indicate FCCU's condition)
8–9 FCCU_SET_CLEAR	Fault-Output (EOUT) Control Applies only when the EOUT signals are active (FCCU_SET_AFTER_RESET). Controls whether the fault-output (EOUT) signals are controlled by FCCU's finite state machine (FSM).

Table continues on the next page...

FCCU_CFG field descriptions (continued)

Field	Description
	00 Controlled by the FSM 01 Always low 10 Controlled by the FSM 11 High until a fault occurs on a channel, regardless of whether that fault is disabled; thereafter, controlled by the FSM. Note: FCCU ignores an attempt to write this value if the fault-output (EOUT) timer is already running.
10–11 Reserved	This field is reserved.
12–15 Reserved	This field is reserved. Always write the reset value to this field.
16 FOPE	Fault-Output (EOUT) Prescaler Extension For fault-output (EOUT) signaling, specifies the most significant bit of the derived prescaler that controls the signaling frequency. For more information, see the description of the FOP field.
17–18 Reserved	This field is reserved. Always write the reset value to this field.
19 OD	Open-Drain Mechanism to select between Push-pull and Open drain(OD) mode for the error indicating pin(s) 0 Push-pull 1 Open-drain
20 Reserved	This field is reserved. Always write the reset value to this field.
21 SM	Fault-Output (EOUT) Switching Mode For fault-output (EOUT) signaling, controls how quickly the signals switch between faulty and nonfaulty indication. Applies only to Dual-Rail and Time-Switching fault-output modes. 0 Slow: No EOUT frequency violation during the FCCU state transition (Normal to Fault or vice versa, and Configuration to Normal). The indication transition occurs after a maximum delay equal to the duration of the semiperiod of the EOUT frequency. 1 Fast: The indication transition (Normal to Fault or vice versa, and Configuration to Normal) occurs immediately. A pulse with the minimum duration corresponding to the CLKSAFE period can occur in this mode. It implies a frequency violation of the EOUT protocol.
22 PS	Fault-Output (EOUT) Polarity Selection For fault-output (EOUT) signaling, controls the polarity of the signals for fault-output-mode indications that hold the signals low or high (versus toggling them or placing them in a high-impedance state). Applies only to Time-Switching fault-output mode (for faulty and configuration indications) and Bistable fault-output mode (for all indications). 0 For the faulty indication, EOUT1 is high, and EOUT0 is low. 1 For the faulty indication, EOUT1 is low, and EOUT0 is high.
23–25 FOM	Fault-Output (EOUT) Mode For fault-output (EOUT) signaling, controls the protocol of the signaling. **NOTE:** In the test modes, a simple double-stage resynchronization stage is used to resynchronize the EOUT input/outputs with CLKSAFE. 000 Dual-Rail (default state) [EOUT[1:0]= outputs] 001 Time-Switching [EOUT[1:0]= output to be used]

Table continues on the next page...

FCCU_CFG field descriptions (continued)

Field	Description
	010 Bistable 011 Reserved 100 Reserved 101 Test 0 (controlled by the FCCU_EINOUT register; EOUT1 is an output; EOUT0 is an input) 110 Test 1 (controlled by the FCCU_EINOUT register; EOUT1 and EOUT0 are both outputs) 111 Test 2 (controlled by the FCCU_EINOUT register; EOUT1 is an input; EOUT0 is an output)
26–31 FOP	Fault-Output (EOUT) Prescaler For fault-output (EOUT) signaling, specifies the least significant bits of the derived prescaler that controls the signaling frequency. The derived prescaler is the concatenation of FOPE and FOP and is represented by *{FOPE, FOP}*. The following equation defines the signaling frequency in terms of the CLKSAFE frequency ($CLKSAFE_{freq}$) and the derived prescaler: $EOUT_{freq} = CLKSAFE_{freq} / ((\{FOPE, FOP\} + 1) \times 2 \times 2048)$ The following example values and meanings are for the derived (7-bit) prescaler, not FOP alone. The meanings show the derived prescaler followed by the corresponding value by which the input clock frequency is then divided. 0000000: 0; divide by 2 × 2048 (4096) 0000001: 1; divide by 4 × 2048 (8192) 0000010: 2; divide by 6 × 2048 (12,288) … 0001000: 8; divide by 18 × 2048 (36,864) … 1111101: 125; divide by 252 × 2048 (516,096) 1111110: 126; divide by 254 × 2048 (520,192) 1111111: 127; divide by 256 × 2048 (524,288)

76.9.4 Noncritical Fault Configuration (FCCU_NCF_CFG*n*)

Contains the configuration of noncritical faults in terms of fault-recovery management. The configuration depends on the type of signaling of a fault event. Hardware-recoverable faults should be configured only if a previous latching stage captures and holds the physical fault; otherwise, the fault can be lost. All other faults should be configured as software faults.

NOTE

These registers are writable only when FCCU is in Configuration state.

Noncritical Fault Configuration (FCCU_NCF_CFG*n*) register (value of n)	Offset	NCFCx fields (value of x)	
		Most significant (leftmost) bit	Least significant (rightmost) bit

FCCU_NCF_CFG*n* field descriptions

Field	Description
0–31 NCFCx	Noncritical Fault Configuration. Defines the fault recovery mode. Hardware-recoverable faults are self-recovered (status flag clearing and related) if the root cause (input fault) has been removed. Software-recoverable faults are recovered (status flag clearing) by software clearing of the related status flag. For the mapping of the NCFCx fields among registers, see the earlier table in this register description. 0 Hardware-recoverable fault 1 Software-recoverable fault

76.9.5 Noncritical Fault State Configuration (FCCU_NCFS_CFG*n*)

The FCCU_NCFS_CFGx registers contain the configuration of each noncritical fault in terms of fault reaction (short or long functional reset request pulse) when it is the root cause for the FAULT state transition.

NOTE

These registers are writable only when the FCCU is in the CONFIG state.

Table 76-9 shows FCCU configuration register channels.

Table 76-9. FCCU NCFS configuration register channels

Field	Description
0–31 NCFSCx	Noncritical fault state configuration See Table 76-9 for register offset to channel number relationship. 00 No reset reaction 01 Short functional reset request pulse (FAULT state reaction) 10 Long functional reset request pulse (FAULT state reaction) 11 No reset reaction

76.9.6 Noncritical Fault Status (FCCU_NCF_S*n*)

The FCCU_NCF_Sx register contains the latched fault indication collected from the noncritical fault sources. Faults are latched also in the CONFIG state and independently from the enabling or reactions programmed for the NCF.

No reactions are executed until the FCCU moves in the NORMAL state.

FCCU reacts and moves from the NORMAL state into the ALARM state only if the respective enable bit for a fault is set in the FCCU_NCF_Ex register and the respective enable bit for the timeout is set in the FCCU_TOEx register.

FCCU reacts and moves from the NORMAL or ALARM state into the FAULT state if the respective enable bit for a fault is set in the FCCU_NCF_Ex register and the respective enable bit for the timeout is disabled in the FCCU_TOEx register.

FCCU reacts and moves from the ALARM state into the FAULT state if the timeout (FCCU_TO register) is elapsed before recovering from the fault.

The timeout is stopped only when the FCCU returns in the NORMAL state.

The FCCU_NCF_Sx register is encoded respectively into the N2FF_STATUS or A2FF_STATUS register to freeze the entry condition in the FAULT state. The status bits of the FCCU_NCF_Sx register, configured as SW recoverable faults, can be cleared by the following locked sequence:

1. Write the proper key into the FCCU_NCFK register.
2. Clear the status (flag) bit NCFSx => the opcode OP12 is automatically set into the FCCU_CTRL.OPR field.
3. Wait for the completion of the operation (FCCU_CTRL.OPS field).
4. Read the FCCU_NCF_Sx register in order to verify the effective deletion and in case of failure to repeat the sequence.

As result of the above sequence, in addition the FAULT interface provides support to clear the external fake FAULT root .

NOTE

There should not be any other operation in between the above steps.

The FCCU moves from the FAULT or ALARM state into the NORMAL state if all the source faults that caused the transition into the FAULT state have been removed (HW recoverable fault) or cleared via SW (SW recoverable fault). In case of nested faults that are not all recovered, the FCCU will remain in the FAULT or ALARM state.

The SW application executes the FCCU_NCF_Sx read operation by the following sequence:

1. Set the OP10 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the FCCU_NCF_Sx register.

In case of re-configuration of the FCCU (CONFIG state), before to return in NORMAL state the pending status bits into the FCCU_NCF_Sx must be cleared in order to avoid a false transition in ALARM/FAULT state.

The following faults are ignored:

- to write a wrong key into the FCCU_NCFK register
- to attempt to clear a HW recoverable fault

Noncritical Fault Status (FCCU_NCF_S*n*) register (value of n)	Offset	NCFSx fields (value of x)	
		Most significant (leftmost) bit	Least significant (rightmost) bit

FCCU_NCF_S*n* field descriptions

Field	Description
0–31 NCFSx	Noncritical fault status. The status bits related to the noncritical fault configured as HW recoverable faults are read-only and the flag is self cleared when the fault source is removed. For the mapping of the NCFSx fields among registers, see the earlier table in this register description. 0 No "noncritical" fault latched 1 "Noncritical" fault latched

76.9.7 Noncritical Fault Key (FCCU_NCFK)

The FCCU_NCFK register implements the key access to clear the status flags of the FCCU_NCF_Sx register.

The status bits of the FCCU_NCF_Sx register, configured as SW recoverable faults, can be cleared by the following locked sequence:

1. Write the key into the FCCU_NCFK register.
2. Clear the status (flag) bit NCFSx .

The key must be written for each FCCU_NCF_Sx clear operation.

The FCCU_NCFK register is not readable; a 0000_0000h value is always returned in case of read operation.

Address: 0h base + 90h offset = 90h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

FCCU_NCFK field descriptions

Field	Description
0–31 NCFK	Noncritical fault key = AB34_98FEh

76.9.8 Noncritical Fault Enable (FCCU_NCF_E*n*)

The FCCU_NCF_En registers enable the fault sources to allow a transition from the NORMAL into the FAULT or ALARM state. In case of fault masking, the respective status bit into the FCCU_NCF_Sn register is set (for debugging purposes), only the reaction is masked.

NOTE

These registers are writable only when the FCCU is in the CONFIG state.

NOTE

Any enabled fault should be programmed to result in a defined action. For example, set up an ALARM IRQ action by programming the IRQ Alarm Enable Register (FCCU_IRQ_ALARM_ENn).

Noncritical Fault Enable (FCCU_NCF_E*n*) register (value of n)	Offset	NCFEx fields (value of x)	
		Most significant (leftmost) bit	Least significant (rightmost) bit

FCCU_NCF_E*n* field descriptions

Field	Description
0–31 NCFEx	Noncritical fault enable For the mapping of the NCFEx fields among registers, see the earlier table in this register description. 0 No actions following the respective noncritical fault assertion 1 FCCU moves to ALARM or FAULT state

76.9.9 Noncritical Fault Timeout Enable (FCCU_NCF_TOE*n*)

The FCCU_NCF_TOEx registers enable a transition from the NORMAL state into the ALARM state if the respective noncritical fault is enabled (NCFEx and NCFTOEx are set). In case the respective timeout is disabled (NCFTOEx is cleared) and the noncritical fault is enabled (NCFEx is set) the FCCU moves into the FAULT state if the related noncritical fault is asserted. The timer (preset with the timeout value defined by FCCU_TO register) is started when the FCCU moves into the ALARM state. If the fault is not recovered within the timeout the FCCU moves from the ALARM state to the FAULT state.

NOTE

These registers are writable only when the FCCU is in the CONFIG state.

Noncritical Fault Timeout Enable (FCCU_NCF_TOE*n*) register (value of n)	Offset	NCFTOEx fields (value of x)	
		Most significant (leftmost) bit	Least significant (rightmost) bit

* Notes:
- The reset value is chip-specific. See the chip-specific FCCU information.x = Undefined at reset.

FCCU_NCF_TOE*n* field descriptions

Field	Description
0–31 NCFTOEx	Fault timeout enable For the mapping of the NCFTOEx fields among registers, see the earlier table in this register description. 0 FCCU moves into the FAULT state if the respective fault is enabled 1 FCCU moves into the ALARM state if the respective fault is enabled

76.9.10 Noncritical Fault Timeout (FCCU_NCF_TO)

Defines the preset value of the timer for the recovery of enabled noncritical faults. Once FCCU enters Alarm state, following the assertion of a noncritical fault that is enabled (NCFEa and NCFTOEa are set), the timer starts the countdown.

If the fault is not recovered within the timeout period, the FCCU moves from the Alarm state to the Fault state. The alarm timeout value should be programmed to be less than FOSU_COUNT, or destructive resets may be generated by FOSU timeouts.

NOTE

This register is writable only when FCCU is in Configuration state.

Address: 0h base + B4h offset = B4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

FCCU_NCF_TO field descriptions

Field	Description
0–31 TO	Noncritical Fault Timeout Timeout = (TO) × $T_{RC16MHz}$

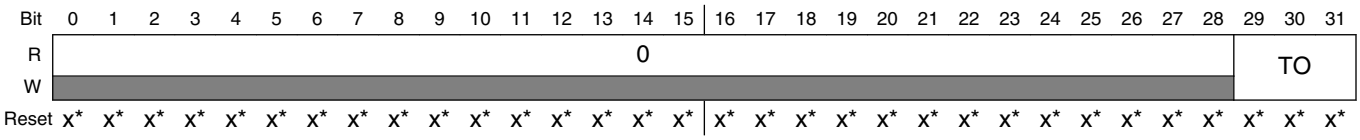
76.9.11 Configuration-State Timer Interval (FCCU_CFG_TO)

Writable only when FCCU is in Normal, Alarm, or Fault state (not in Configuration state). Not accessible while a Configuration-state timeout (OP14 operation) is in progress. Controls the maximum amount of time that FCCU can be in Configuration state.

NOTE

When a Configuration-state timeout occurs, FCCU changes the value of this register to its reset value.

Address: 0h base + B8h offset = B8h



* Notes:
- The reset value is chip-specific. See the chip-specific FCCU information.x = Undefined at reset.

FCCU_CFG_TO field descriptions

Field	Description
0–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 TO	Configuration-State Timer Interval Controls the maximum amount of time (T_max) that FCCU can be in Configuration state according to this equation: $T\_max = T_{16MHz} \times 2^{(TO + 10)}$ If you put FCCU in Configuration state and this timer interval expires (called a Configuration-state timeout), then FCCU: • Automatically leaves Configuration state and enters Normal state. • Changes the value of the Configuration (FCCU_CFG) register to its Configuration-state-timeout value and the value of each of the other configuration registers to its reset value. For information on the Configuration (FCCU_CFG) register's Configuration-state-timeout value, see FCCU_CFG register bit value sources (N and C) by event. For a list of configuration registers, see Configuration registers. **NOTE:** Make sure the Configuration-state timer interval is less than the FOSU module's timer interval; otherwise, a fault that occurs while FCCU is in Configuration state can cause FOSU to generate a chip reset. The FOSU timer interval (FOSU_COUNT) is chip-specific. See the chip-specific FCCU information. 000: 64 µs ... 111: 8192 µs

76.9.12 IO Control (FCCU_EINOUT)

The FCCU_EINOUT register allows the following operations typically in NORMAL state:

- to control the EOUT[1] output level when the FCCU is configured in "Test1" or "Test0" fault output mode (FCCU_CFG.FOM)

- to control the EOUT[0] output level when the FCCU is configured in "Test1" or "Test2" fault output mode (FCCU_CFG.FOM)
- to observe the EOUT[1:0] signals in input mode

Table 76-10 shows Bi-stable encoding.

Table 76-10. Bi-stable encoding

Mode = FCCU_CFG.FOM	EOUT[0]	EOUT[1]
Test1	output	output
Test2	output	input
Test0	input	output

NOTE

Due to the resynchronization stage of the EOUT interface, there is a latency of a few CLKSAFE cycles following a write/read operation of the FCCU_EINOUT register.

FCCU_EINOUT field descriptions

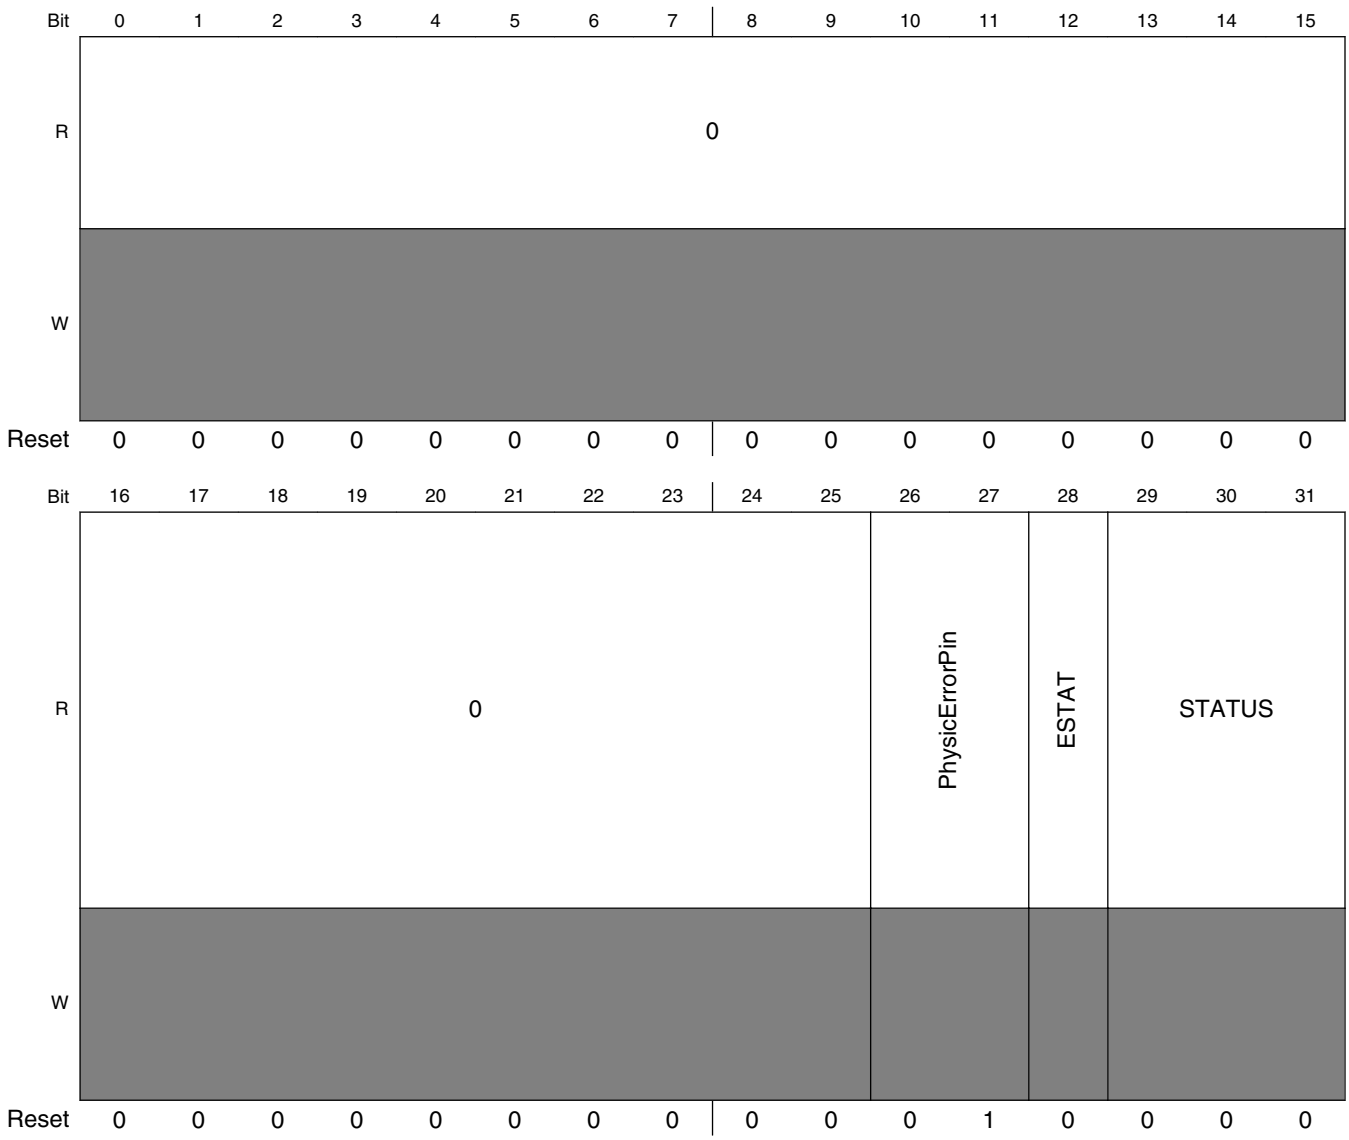
Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 EIN1	Error Input 1 Applies only when the EOUT signals are active (FCCU_SET_AFTER_RESET). Indicates the state of the EIN1 signal. 0 Low 1 High
27 EIN0	Error Input 0 Applies only when the EOUT signals are active (FCCU_SET_AFTER_RESET). Indicates the state of the EIN0 signal. 0 Low 1 High
28–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 EOUT1	Error out 1 (significant only if the FCCU_CFG.FOM = Test1 or Test0 => EOUT[1] configured in output mode). The EOUT1 set/clear the respective EOUT[1] output signal if FCCU_CFG.FOM = 110 or 101, otherwise it is a "don't-care" value. **NOTE:** When the configuration watchdog timer expires, FCCU changes the value of this field to its reset value. 0 force EOUT[1] = 0 1 force EOUT[1] = 1
31 EOUT0	Error out 0 (significative only if the FCCU_CFG.FOM = Test1 or Test2 => EOUT[0] configured in output mode). The EOUT0 set/clear the respective EOUT[0] output signal if FCCU_CFG.FOM = 110 or 111, otherwise it is a "don't care" value. **NOTE:** When the configuration watchdog timer expires, FCCU changes the value of this field to its reset value. 0 force EOUT[0] = 0 1 force EOUT[0] = 1

76.9.13 Status (FCCU_STAT)

The FCCU_STAT register includes the FCCU status for debugging/test purposes. The FCCU finite state machine operates by the RC oscillator clock asynchronous with the system clock. The FCCU status read operation requires a safe mechanism operated by a HW/SW synchronization sequence. The SW application executes a FCCU status read operation by the following sequence:

1. Set the OP3 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the FCCU status (FCCU_STAT register).

Address: 0h base + C0h offset = C0h



FCCU_STAT field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–27 PhysicErrorPin	Fault Output (EOUT) States Applies only after successfully running an OP3 operation (OPR) and only when the EOUT signals are active (FCCU_SET_AFTER_RESET). Indicates the states that FCCU is driving on the EOUT signals. 00 EOUT1 is low; EOUT0 is low. 01 EOUT1 is low; EOUT0 is high. 10 EOUT1 is high; EOUT0 is low. 11 EOUT1 is high; EOUT0 is high.
28 ESTAT	Fault State

Table continues on the next page...

FCCU_STAT field descriptions (continued)

Field	Description
	Applies only after successfully running an OP3 operation (OPR). Indicates whether FCCU is in Fault state. 0 Not in Fault state (in Normal, Alarm, or Configuration state) 1 In Fault state
29–31 STATUS	FCCU State Applies only after successfully running an OP3 operation (OPR). Indicates FCCU's state. 000 Normal 001 Configuration 010 Alarm 011 Fault 100 Reserved 101 Reserved 110 Reserved 111 Reserved

76.9.14 NA Freeze Status (FCCU_N2AF_STATUS)

The N2AF_STATUS register contains a unique code to identify the "noncritical fault" source (fccu_ncf[x]) that caused the state transition from the NORMAL state to the ALARM state. In case of multiple fault conditions the fault source cannot be identified. This register is for test/debug purposes.

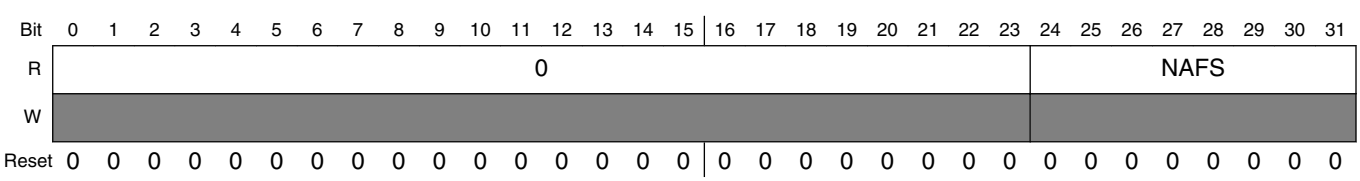
The SW application executes the N2AF_STATUS read operation by the following sequence:

1. Set the OP4 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the N2AF_STATUS register.

The SW application executes the N2AF_STATUS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field). (All the freeze registers are cleared by this operation.)

Address: 0h base + C4h offset = C4h



FCCU_N2AF_STATUS field descriptions

Field	Description
0–23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–31 NAFS	Normal to Alarm Frozen Status 00000000 No transition from NORMAL to ALARM state 00000001 NORMAL to ALARM state transition cause => fccu_ncf[0] fault 00000010 NORMAL to ALARM state transition cause => fccu_ncf[1] fault 00000011 NORMAL to ALARM state transition cause => fccu_ncf[2] fault ... 10000000 NORMAL to ALARM state transition cause => fccu_ncf[127]/ fault 11111111 NORMAL to ALARM state transition cause => multiple fccu_ncf[]/ faults

76.9.15 AF Freeze Status (FCCU_A2FF_STATUS)

The A2FF_STATUS register contains a unique code to identify the timeout trigger (noncritical fault) that caused the state transition from the ALARM state to the FAULT state. In case of multiple fault conditions the fault source cannot be identified. This register is for test/debug purposes.

The SW application executes the A2FF_STATUS read operation by the following sequence:

1. Set the OP5 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the A2FF_STATUS register.

The SW application executes the FCCU_AFFS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).

All the freeze registers are cleared by this operation.

Address: 0h base + C8h offset = C8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

FCCU_A2FF_STATUS field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–23 AF_SRC	Fault source 00 No fault 01 Reserved 10 "Noncritical" fault 11 Multiple and/or "noncritical" faults
24–31 AFFS	Alarm to Fault Frozen Status 00h: No transition from ALARM to FAULT state 01h: ALARM to FAULT state transition cause => fccu_ncf[0]/ fault timeout fault 02h: ALARM to FAULT state transition cause => fccu_ncf[1]/ fault timeout fault 03h: ALARM to FAULT state transition cause => fccu_ncf[2]/ fault timeout fault ... 80h: ALARM to FAULT state transition cause => fccu_ncf[127]/ fault timeout fault FFh: ALARM to FAULT state transition cause => multiple fccu_ncf[]/ faults timeout faults

76.9.16 NF Freeze Status (FCCU_N2FF_STATUS)

The N2FF_STATUS register contains a unique code to identify the source of the noncritical fault that caused the state transition from the NORMAL state to the FAULT state. In case of multiple fault conditions the fault source cannot be identified. This register is for test/debug purposes. The SW application executes the N2FF_STATUS read operation by the following sequence:

1. Set the OP6 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the N2FF_STATUS register.

The SW application executes the N2FF_STATUS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field). (All the freeze registers are cleared by this operation.)

Address: 0h base + CCh offset = CCh

FCCU_N2FF_STATUS field descriptions

Field	Description
0–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–23 NF_SRC	NF_SRC: Fault source 00 No fault 01 Reserved 10 "Noncritical" fault 11 Multiple "noncritical" faults
24–31 NFFS	Normal to Fault Frozen Status 00h: No transition from NORMAL to FAULT state 01h: NORMAL to FAULT state transition cause => fccu_ncf[0] fault 02h: NORMAL to FAULT state transition cause => fccu_ncf[1] fault 03h: NORMAL to FAULT state transition cause => fccu_ncf[2] fault ... 80h: NORMAL to FAULT state transition cause => fccu_ncf[127] fault FFh: NORMAL to FAULT state transition cause => multiple fccu_ncf[] faults

76.9.17 FA Freeze Status (FCCU_F2A_STATUS)

The F2AF_STATUS register contains a unique code to identify the source of the noncritical fault (fccu_ncf[x]) that caused the state transition from the FAULT state to the ALARM state. In case of multiple fault conditions the fault source cannot be identified. This register is for test/debug purposes.

The SW application executes the F2AF_STATUS read operation by the following sequence:

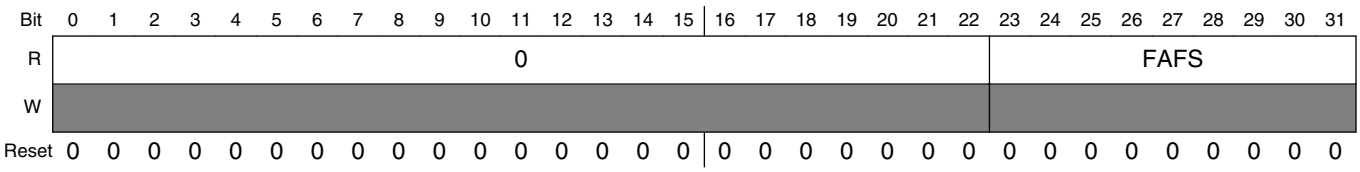
1. Set the OP7 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the F2AF_STATUS register.

The SW application executes the F2AF_STATUS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field.

2. Wait for the completion of the operation (FCCU_CTRL.OPS field). (All the freeze registers are cleared by this operation.)

Address: 0h base + D0h offset = D0h



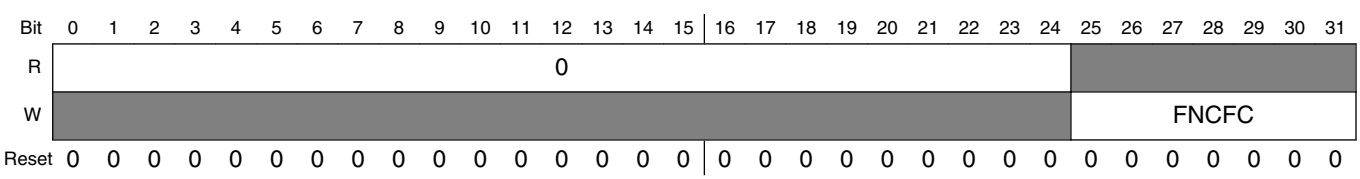
FCCU_F2A_STATUS field descriptions

Field	Description
0–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–31 FAFS	Fault to Normal Frozen Status 00h: No transition from FAULT to ALARM state 01h: FAULT to ALARM state transition cause => fccu_ncf[0]/ fault 02h: FAULT to ALARM state transition cause => fccu_ncf[1]/ fault 03h: FAULT to ALARM state transition cause => fccu_ncf[2]/ fault ... 80h: FAULT to ALARM state transition cause => fccu_ncf[127]/ fault FFh: FAULT to ALARM state transition cause => multiple fccu_ncf[] faults

76.9.18 Noncritical Fault Fake (FCCU_NCFF)

The FCCU_NCFF register contains a unique code to set a noncritical fault in mutually exclusive mode by the external FAULT interface (signal setting). It allows the SW emulation of the noncritical faults, by the injection of the fault directly in the FAULT root, in order to verify the entire path and reaction. The reaction following a fake noncritical fault cannot be masked. The FCCU_NCFF is a write-only register with a set of codes corresponding to each noncritical fault injection.

Address: 0h base + DCh offset = DCh



FCCU_NCFF field descriptions

Field	Description
0–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–31 FNCFC	FNCFC/ : Fake noncritical fault code **NOTE:** Only writing to this register, fake fault injection occurs, writing 00 and default value being zero give different results. 00h: Fake noncriticalfault injection at noncriticalfault source 0 01h: Fake noncriticalfault injection at noncriticalfault source 1 02h: Fake noncriticalfault injection at noncriticalfault source 2 ... 7Fh: Fake noncriticalfault injection at noncriticalfault source 127

76.9.19 IRQ Status (FCCU_IRQ_STAT)

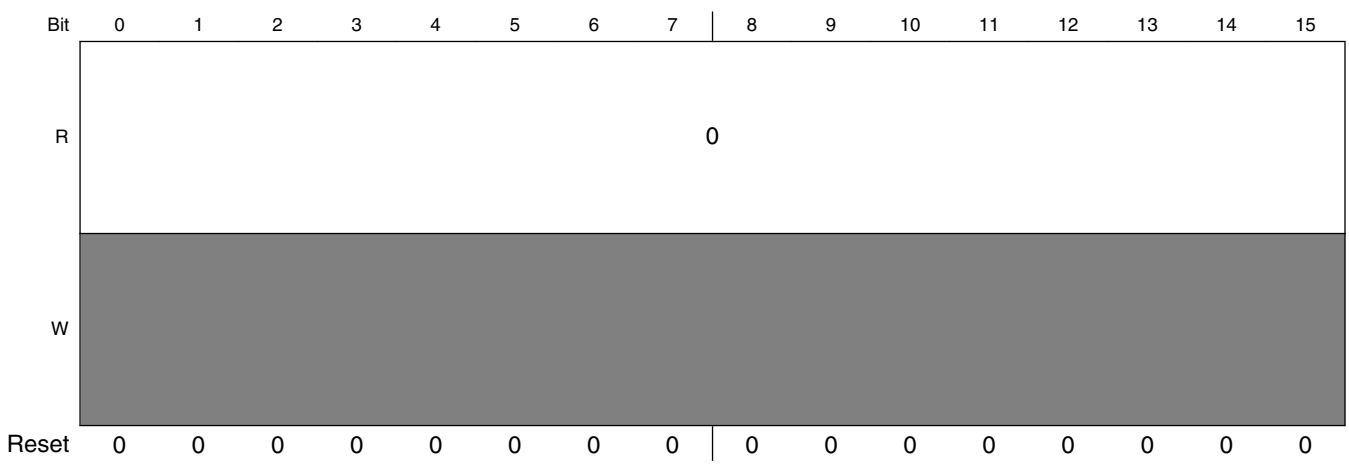
The FCCU_IRQ_STAT register provides the FCCU interrupt status related to the following events:

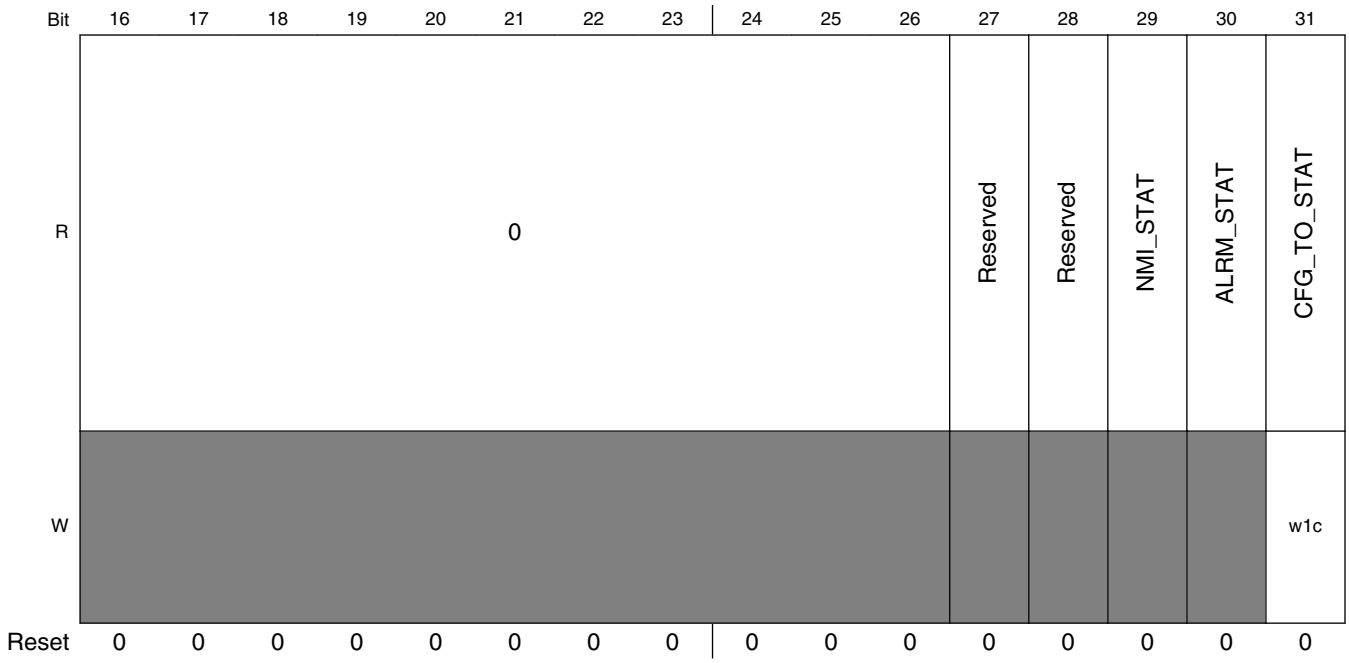
- Configuration timeout error
- Alarm interrupt
- NMI interrupt

The configuration timeout interrupt is asserted if the CFG_TO_STAT bit of the FCCU_IRQ_STAT register is set and the CFG_TO_IEN bit of the FCCU_IRQ_EN register is also set. It is cleared when a 1 is written to the CFG_TO_STAT bit.

The NMI and ALARM interrupts are asserted and cleared according to the FCCU state. The status bits of the FCCU_IRQ_STAT trace the status of the related interrupt lines.

Address: 0h base + E0h offset = E0h





FCCU_IRQ_STAT field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 Reserved	This field is reserved.
28 Reserved	This field is reserved.
29 NMI_STAT	NMI Interrupt Status 0 NMI interrupt is OFF 1 NMI interrupt is ON
30 ALRM_STAT	Alarm Interrupt Status 0 Alarm interrupt is OFF 1 Alarm interrupt is ON
31 CFG_TO_STAT	Configuration Timeout Status 0 No configuration timeout error 1 Configuration timeout error

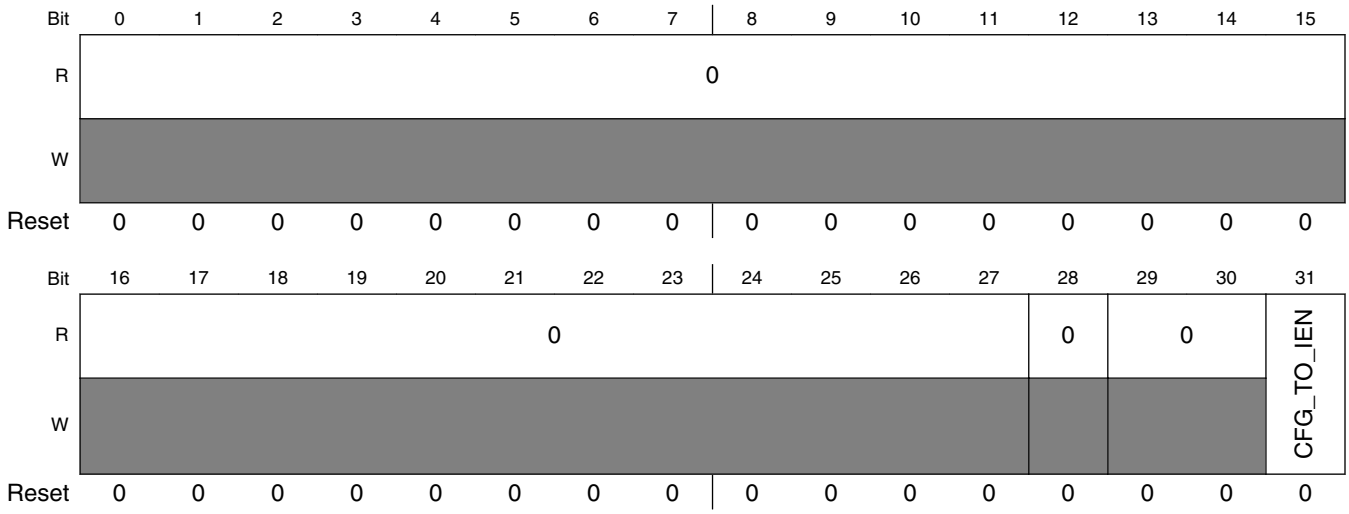
76.9.20 IRQ Enable (FCCU_IRQ_EN)

The FCCU_IRQ_EN register defines the FCCU interrupt enable register related to the following event:

- Configuration timeout error

The configuration timeout interrupt is asserted if the CFG_TO_STAT bit of the FCCU_IRQ_STAT register is set and the CFG_TO_IEN bit of the FCCU_IRQ_EN register is also set.

Address: 0h base + E4h offset = E4h



FCCU_IRQ_EN field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 CFG_TO_IEN	Configuration Timeout Interrupt Enable 0 Configuration timeout interrupt disabled 1 Configuration timeout interrupt enabled

76.9.21 XTMR (FCCU_XTMR)

The FCCU_XTMR register contains the read values of the Alarm or Watchdog Timer. These timers are clocked by CLKSAFE.

The SW application executes the timer read operation by the following sequence:

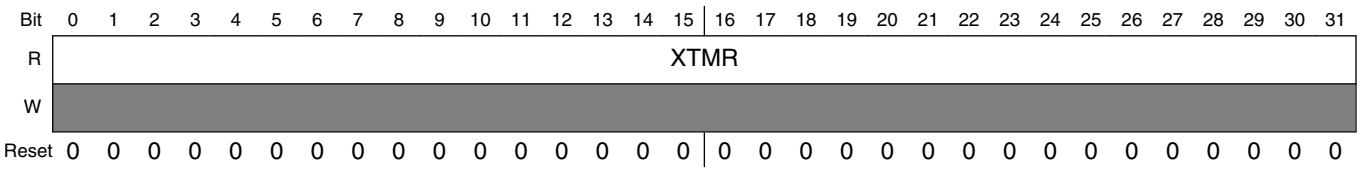
1. Set any of the following operations into the FCCU_CTRL.OPR field:
   - OP17
   - OP19
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the FCCU_XTMR register.

Table 76-11 shows Timer state/value.

Table 76-11. Timer state/value

TIMER	CONFIG state	NORMAL state	ALARM state	FAULT state
ALARM	00000000h	Initial value	Running	Idle/End of count
CFG	Running	0001FFFFh	0001FFFFh	0001FFFFh

Address: 0h base + E8h offset = E8h



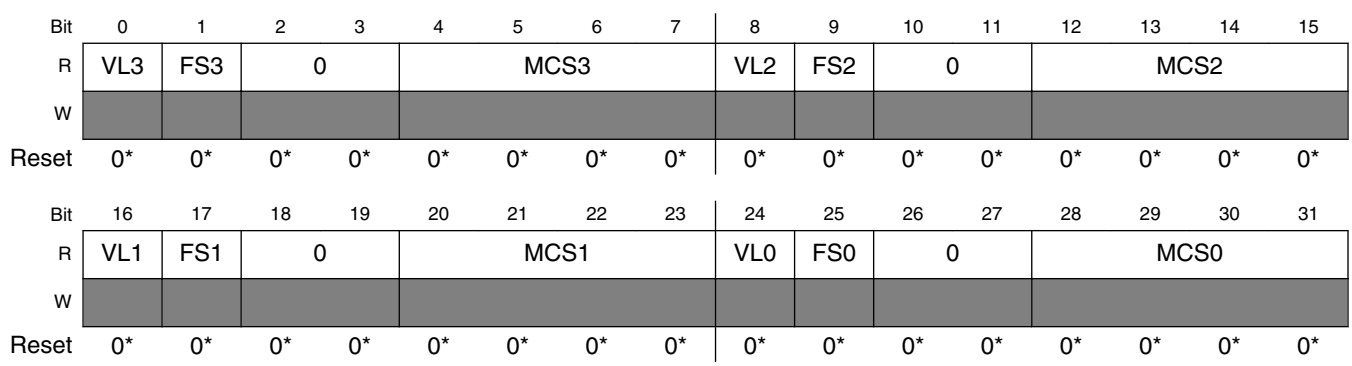
FCCU_XTMR field descriptions

Field	Description
0–31 XTMR	Alarm/Watchdog The current timer value is measured in CLKSAFE cycles. These bits can be read by the software.

76.9.22 Mode Controller Status (FCCU_MCS)

Indicates the last four chip modes—as defined by the MC_ME module—and whether FCCU was in Fault state and NMIOUT was asserted (as the result of a noncritical fault) when FCCU captured each mode.

Address: 0h base + ECh offset = ECh



* Notes:

- The reset value is chip-specific. See the chip-specific FCCU information. (The MC_ME module changes the value of the register immediately after the chip leaves RESET mode.)

FCCU_MCS field descriptions

Field	Description
0 VL3	Valid 3—Indicates whether MCS3 and FS3 are valid. 0 Invalid 1 Valid
1 FS3	Fault Status 3 Indicates whether FCCU was in Fault state and NMIOUT was asserted (as the result of a noncritical fault) when FCCU captured MCS3. **NOTE:** This field might occasionally be inaccurate because the MC_ME module provides the chip modes to FCCU in synchronization with CLKSYS, but FCCU captures the chip modes in synchronization with CLKSAFE. 0 Not in Fault state or NMIOUT not asserted 1 In Fault state and NMIOUT asserted
2–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–7 MCS3	Mode Controller State 3—Indicates the fourth most recent chip mode.
8 VL2	Valid 2—Indicates whether MCS2 and FS2 are valid. 0 Invalid 1 Valid
9 FS2	Fault Status 2 Indicates whether FCCU was in Fault state and NMIOUT was asserted (as the result of a noncritical fault) when FCCU captured MCS2. **NOTE:** This field might occasionally be inaccurate because the MC_ME module provides the chip modes to FCCU in synchronization with CLKSYS, but FCCU captures the chip modes in synchronization with CLKSAFE. 0 Not in Fault state or NMIOUT not asserted 1 In Fault state and NMIOUT asserted
10–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–15 MCS2	Mode Controller State 2—Indicates the third most recent chip mode.
16 VL1	Valid 1—Indicates whether MCS1 and FS1 are valid. 0 Invalid 1 Valid
17 FS1	Fault Status 1 Indicates whether FCCU was in Fault state and NMIOUT was asserted (as the result of a noncritical fault) when FCCU captured MCS1. **NOTE:** This field might occasionally be inaccurate because the MC_ME module provides the chip modes to FCCU in synchronization with CLKSYS, but FCCU captures the chip modes in synchronization with CLKSAFE. 0 Not in Fault state or NMIOUT not asserted 1 In Fault state and NMIOUT asserted

Table continues on the next page...

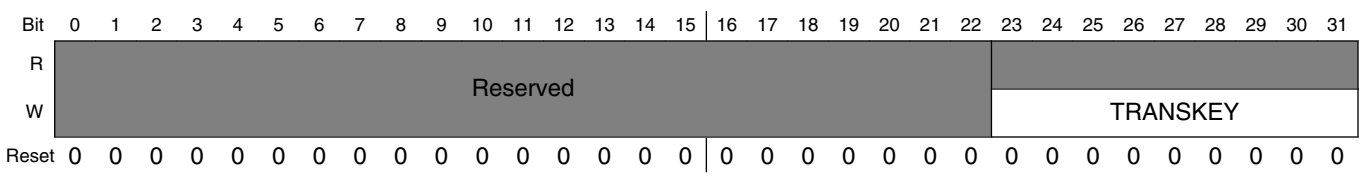
FCCU_MCS field descriptions (continued)

Field	Description
18–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–23 MCS1	Mode Controller State 1—Indicates the second most recent chip mode.
24 VL0	Valid 0—Indicates whether MCS0 and FS0 are valid. 0 Invalid 1 Valid
25 FS0	Fault Status 0 Indicates whether FCCU was in Fault state and NMIOUT was asserted (as the result of a noncritical fault) when FCCU captured MCS0. **NOTE:** This field might occasionally be inaccurate because the MC_ME module provides the chip modes to FCCU in synchronization with CLKSYS, but FCCU captures the chip modes in synchronization with CLKSAFE. 0 Not in Fault state or NMIOUT not asserted 1 In Fault state and NMIOUT asserted
26–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 MCS0	Mode Controller State 0—Indicates the most recent (current) chip mode.

76.9.23 Transient Configuration Lock (FCCU_TRANS_LOCK)

Writable only by code running in Supervisor mode. Temporarily locks and unlocks the configuration. Locking the configuration prevents FCCU from entering Configuration state.

Address: 0h base + F0h offset = F0h



FCCU_TRANS_LOCK field descriptions

Field	Description
0–22 Reserved	This field is reserved.
23–31 TRANSKEY	Transient Configuration Lock Writable only by code running in Supervisor mode. Temporarily locks and unlocks the configuration. Locking the configuration prevents FCCU from entering Configuration state. BCh: Unlock.

Table continues on the next page...

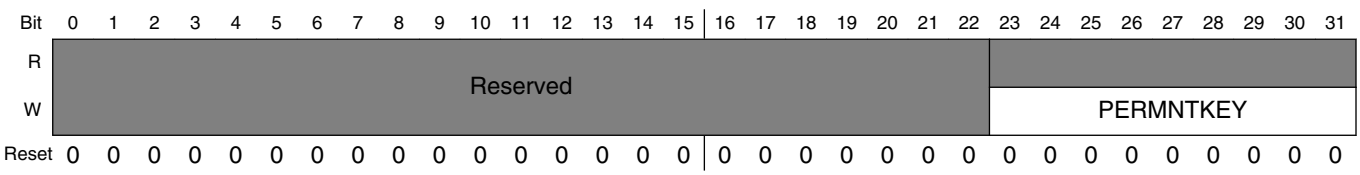
FCCU_TRANS_LOCK field descriptions (continued)

Field	Description
	Any other value: Lock.

76.9.24 Permanent Configuration Lock (FCCU_PERMNT_LOCK)

Writable only by code running in Supervisor mode. Permanently locks the configuration, which prevents FCCU from entering Configuration state until FCCU is reset.

Address: 0h base + F4h offset = F4h



FCCU_PERMNT_LOCK field descriptions

Field	Description
0–22 Reserved	This field is reserved.
23–31 PERMNTKEY	Permanent Configuration Lock Writable only by code running in Supervisor mode. Permanently locks the configuration, which prevents FCCU from entering Configuration state until FCCU is reset. FFh: Lock. Any other value: Do nothing.

76.9.25 Delta T (FCCU_DELTA_T)

The FCCU_DELTA_T register is used for programming the value of delta_T constant, in microseconds.

NOTE

This register can be written only when the FCCU is in CONFIG state.

NOTE

Reserved bits should always be written as all 0's.

Address: 0h base + F8h offset = F8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	Reserved		Reserved													
W

FCCU_DELTA_T field descriptions

Field	Description
0–1 Reserved	This field is reserved.
2–15 Reserved	This field is reserved.
16–17 Reserved	This field is reserved.
18–31 DELTA_T	Bistable Minimum Fault-Output (EOUT) Faulty Interval Applies only to Bistable fault-output mode (FOM). Controls the minimum amount of time (T_min) that the fault-output (EOUT) timer runs according to this equation: T_min = 250 µs + DELTA_T The following values and meanings are for DELTA_T: 00_0000_0000_0000: 0 µs 00_0000_0000_0001: 1 µs … 11_1111_1111_1110: 16,382 µs 11_1111_1111_1111: 16,383 µs **NOTE:** The durations shown for the DELTA_T values are for CLKSAFE clock signals running at exactly 16 MHz. However, the CLKSAFE signals are sourced from an internal chip clock signal (for example, IRC)—or an integer division of it (see the chip-specific FCCU information)—that has a trimmed frequency variation. Therefore, the DELTA_T durations may vary. See your chip's data sheet for the trimmed frequency variation (for example, δF_{var}).

76.9.26 IRQ Alarm Enable (FCCU_IRQ_ALARM_EN*n*)

These registers enable the corresponding IRQ alarm.

IRQ Alarm Enable (FCCU_IRQ_ALARM_EN*n*) register (value of n)	Offset	IRQENx fields (value of x)	
		Most significant (leftmost) bit	Least significant (rightmost) bit
0	0FCh	31	0
1	100h	63	32
2	104h	95	64
3	108h	127	96

NOTE

These registers can be written only when the FCCU is in CONFIG state.

Address: 0h base + FCh offset + (4d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

FCCU_NMI_EN*n* field descriptions

Field	Description
0–31 NMIENx	NMI enable See Table 76-12 for register offset to channel number relationship. 0 NMI is disabled for error (NCF) source x. 1 NMI is enabled for error (NCF) source x.

76.9.28 Bistable Fault-Output (EOUT) Mode Signaling Enable (FCCU_EOUT_SIG_EN*n*)

Writable only when FCCU is in Configuration state. Applies only when the EOUT signals are active (FCCU_SET_AFTER_RESET). When FCCU is configured for Bistable fault-output mode (FOM), controls whether fault-output (EOUT) signaling is enabled for the associated noncritical fault channel (x). (For other fault-output modes, fault-output signaling is always enabled, regardless of the value of this field.)

When FCCU is configured for a fault-output mode other than Bistable, controls whether FCCU asserts the FIF signal when a fault occurs on the associated noncritical fault channel (x). (When FCCU is configured for Bistable fault-output mode, FCCU always asserts the FIF signal when a fault occurs on the channel, regardless of the value of this field.)

Bistable Fault-Output (EOUT) Mode Signaling Enable (FCCU_EOUT_SIG_EN*n*) register (value of n)	Offset	EOUTENx fields (value of x)	
		Most significant (leftmost) bit	Least significant (rightmost) bit
0	11Ch	31	0
1	120h	63	32
2	124h	95	64
3	128h	127	96

Address: 0h base + 11Ch offset + (4d × i), where i=0d to 3d

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FCCU_EOUT_SIG_EN*n* field descriptions

Field	Description
0–31 EOUTENx	Bistable Fault-Output (EOUT) Mode Signaling Enable x Writable only when FCCU is in Configuration state. Applies only when the EOUT signals are active (FCCU_SET_AFTER_RESET). When FCCU is configured for Bistable fault-output mode (FOM), controls whether fault-output (EOUT) signaling is enabled for the associated noncritical fault channel (x). (For other fault-output modes, fault-output signaling is always enabled, regardless of the value of this field.) When FCCU is configured for a fault-output mode other than Bistable, controls whether FCCU asserts the FIF signal when a fault occurs on the associated noncritical fault channel (x). (When FCCU is configured for Bistable fault-output mode, FCCU always asserts the FIF signal when a fault occurs on the channel, regardless of the value of this field.) **NOTE:** When FCCU is configured for a fault-output mode other than Bistable, you must set this field to enabled to ensure that FCCU asserts the FIF signal when a fault occurs on the associated noncritical fault channel (x) so the FOSU module doesn't mistakenly generate a destructive chip reset. For the mapping of the EOUTENx fields among registers, see the earlier table in this register description. 0 Disabled 1 Enabled

76.9.29 Configuration registers

76.9.29.1 Definition

Configuration registers are registers that:

- Let you configure FCCU's Alarm-state timer interval, fault channels, and fault-output (EOUT) signals.
- You can write to only when the configuration is not locked (see Lock and unlock the configuration) and FCCU is in Configuration state (see Put FCCU in Configuration or Normal state).
- Save the values you write to them while FCCU is in Configuration state only after you manually put FCCU in Normal state. If FCCU automatically leaves Configuration state and enters Normal state because the configuration-timer interval (TO) expires (called a Configuration-state timeout), FCCU changes the value of the FCCU_CFG register to its Configuration-state-timeout value and the value of each of the other configuration registers to its reset value. For information on the Configuration-state timeout value, see FCCU_CFG register bit value sources (N and C) by event.

76.9.29.2 The configuration registers

The following registers are the configuration registers, listed in offset order from lowest to highest:

- Configuration (FCCU_CFG)
- Noncritical Fault Configuration (FCCU_NCF_CFG*n*)
- Noncritical Fault State Configuration (FCCU_NCFS_CFG*n*)
- Noncritical Fault Enable (FCCU_NCF_E*n*)
- Noncritical Fault Timeout Enable (FCCU_NCF_TOE*n*)
- Noncritical Fault Timeout (FCCU_NCF_TO)
- Delta T (FCCU_DELTA_T)
- IRQ Alarm Enable (FCCU_IRQ_ALARM_EN*n*)
- NMI Enable (FCCU_NMI_EN*n*)
- Bistable Fault-Output (EOUT) Mode Signaling Enable (FCCU_EOUT_SIG_EN*n*)

76.9.30 FCCU_CFG register bit value sources (N and C) by event

Certain events affect the bit values of the Configuration (FCCU_CFG) register; when one of these events occurs, the bit value is either unaffected, or FCCU changes it to one of the following:

- N: a chip-specific (or, for some chips, user-specified) value provided by the bit's associated NVMCFG signal
- C: a chip-specific value provided by the bit's associated constant inside the module

For each bit in the Configuration (FCCU_CFG) register, this table shows the associated NVMCFG signal, if any, and indicates the source of the bit value for the events that affect it. For specific values of *N* and *C* for each bit, see the chip-specific FCCU information.

Bit	NVMCFG signal	FCCU reset	Configuration-state timeout	OP31 operation
0	21	N	C	N
1	20	N	C	N
2	19	N	C	N
3	18	N	C	N
4	17	N	C	N
5	16	N	C	N
6	15	N	C	N
7	—	C	C	(Unaffected)

31	0	N	C	N

76.10 FCCU Output Supervision Unit

The FOSU provides a supervision of the primary fault notification path by analyzing FCCU behavior for correctness. It waits for any reaction of the FCCU in a fixed time window after a fault is signaled.

The intention of the FOSU is to provide a secondary fault reaction path in most cases when the FCCU fails but not to needlessly propagate a fault which is already handled by the FCCU in a full chip reset. Only a failed primary fault reaction (that is, FCCU's failure) is a reason for the secondary reaction to take over (and generate a destructive reset request).

There is a 'do nothing' input coming from the FCCU that indicates that the FCCU is programmed for no reaction for ALL FAULTS. It is a "static" input in the sense that it does not change after FCCU configuration. The FOSU masks the incoming faults with

the 'do nothing' control from the FCCU, meaning that a fault is not captured by the FOSU if the 'do nothing' signal is asserted, (i.e., a disabled fault). There is no minimum pulse width requirement on the fault indication other than what is required by the technology, which is the same as that of the FCCU. FOSU does not monitor FCCU for the case of faults occurring during CONFIG state.

The FOSU contains a timer with a duration of FOSU_COUNT, driven by CLKSAFE. The timer is initialized and started on any captured, enabled fault. While the timer is running, any subsequent captured fault will neither restart nor reinitialize the timer. The timer is stopped when the FCCU shows any of the following reactions (the FOSU does not check whether the reaction is the configured one for the faults which occurred):

- Reset: Long or short functional reset
- IRQ: NMI or Alarm
- Error out triggered (by FCCU or by SW)

When the timer is stopped, the fault capture logic is cleared in order to ensure that the timer is not restarted due to faults still 'stuck' in the capture logic. The timer will then be restarted by the next new failure indication. When the timer expires, the FOSU's failure indicator output is asserted after it ensures that the fault is enabled and the static "fccu program to do nothing" signal is deasserted. This is because FCCU uses settings after it exits CONFIG state, even if fault captured before the exit.

The FOSU's failure indicator output is connected to one of the MC_RGM's 'destructive' reset inputs, so its assertion will cause a reset sequence to be initiated starting at PHASE0. The FOSU module is reset with the same reset as is used by the FCCU, which is asserted on power-on, 'destructive', and external resets. When this reset is asserted, the FOSU's capture logic is cleared, its timer is kept stopped and in a non-expired state, and its failure indicator output is deasserted.

NOTE

FOSU is triggered on assertion of enabled fault. In case the triggering fault is disabled, FOSU times-out without reaction.

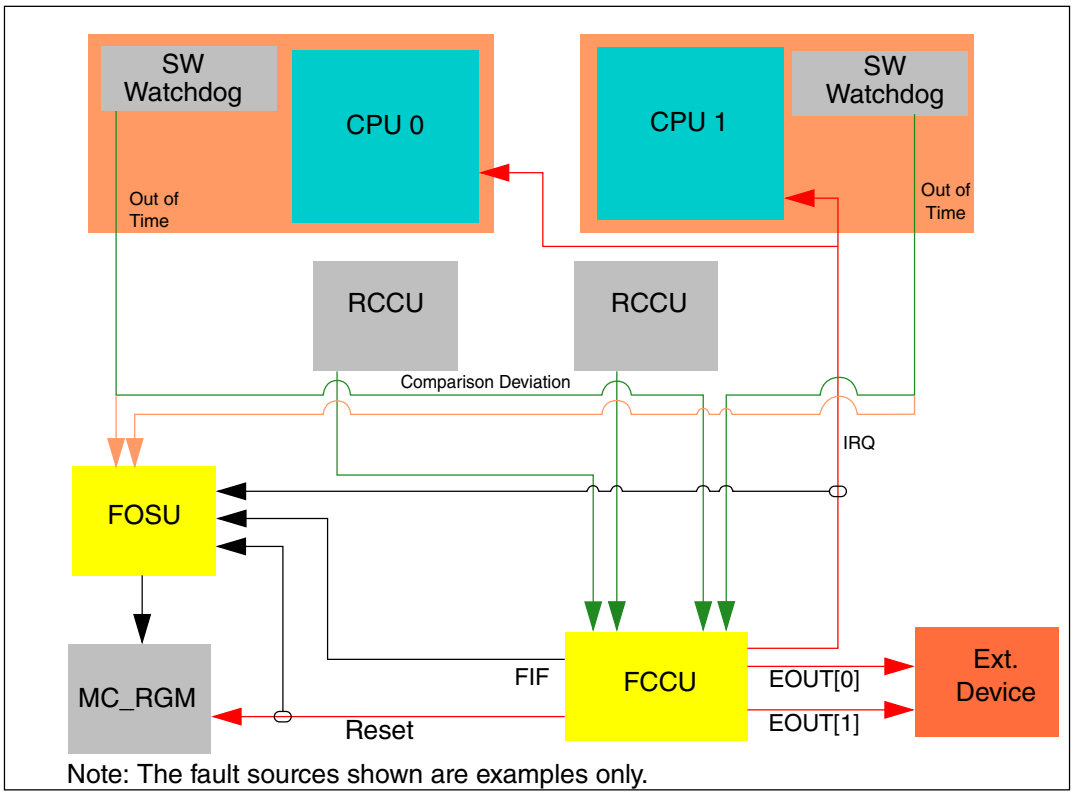

Figure 76-16. FOSU connections to the FCCU and MC_RGM

It is important to remember that there will be no FCCU reaction to a fault while the FCCU is in the CONFIG state. For this reason, the FCCU should not be kept in CONFIG for longer than the FOSU_COUNT duration. Otherwise, there is a risk that an incoming error report causing the FOSU to mistakenly see the FCCU as having failed, and then resets the MCU.

NOTE

FCCU and FOSU timeout counter settings: The FCCU counter value should always be programmed less than the FOSU counter value, FOSU_COUNT, or destructive resets may be generated by an FOSU time-out. This ensures that the FOSU reacts only when the FCCU fails to react to any particular fault.

76.11 Use cases and limitations

76.11.1 Configuration guidelines

Follow these guidelines to configure FCCU:

- If you want FCCU to react to a fault on a noncritical fault channel:
  - Enable the channel (NCFEx).
  - Enable at least one type of Fault-state reaction for the channel: chip reset (NCFSCx), fault-output (EOUT) signaling (EOUTENx), or nonmaskable interrupt (NMIENx).
  - If you enable chip reset as the type of Fault-state reaction for the channel (NCFSCx), enable either Alarm state (NCFTOEx) or at least one other type of Fault-state reaction for the channel: fault-output (EOUT) signaling (EOUTENx) or nonmaskable interrupt (NMIENx).
  - If you enable Alarm state for the channel (NCFTOEx), enable the Alarm-state reaction (IRQENx).
  - If you enable Alarm state for the channel (NCFTOEx), make sure the Alarm-state timer interval (TO) is less than the FOSU module's timer interval; otherwise, FOSU generates a chip reset every time a fault occurs on the channel. The FOSU timer interval (FOSU_COUNT) is chip-specific. See the chip-specific FCCU information.

NOTE

If you enable a noncritical fault channel but disable all reactions for that channel, FCCU changes state if necessary but doesn't perform any reaction because reactions are disabled. If you enable reactions for a noncritical fault channel but disable that channel, and FCCU is in Normal state when a fault occurs on the channel, FCCU doesn't enter Alarm or Fault state and therefore doesn't perform any reaction.

76.11.2 Recommendations to configure FCCU

1. After a power on, 'destructive', or long external reset, where both system and FCCU are reset, the following steps could be followed to configure FCCU:
   a. Check and clear any pending fault status
   b. Verify FCCU is in NORMAL state, else repeat step(a) above
   c. Configure FCCU
2. After a short external or any 'functional' reset of the system, arising out of a reset request from FCCU or other sources, the following steps could be followed to reconfigure FCCU:
   a. If active, wait for the Error out T_min to expire
   b. Check and clear fault status
   c. Error pin moves to "non faulty" state, once fault status is cleared and T_min expires

d. Verify FCCU is in NORMAL state, else repeat step(a) above
e. Read and verify value in FCCU_NCF_Ex
f. Reconfigure FCCU, if necessary

Chapter 77
Self-Test Control Unit (STCU2)

77.1 Chip-specific STCU2 information

77.1.1 STCU2 configuration

The STCU includes eight LBIST partitions and 92 MBIST CUTs.

The Self-Test can be initiated as follows:

- Offline Self-Test can be initiated whenever a Destructive/Long external reset/POR reset occurs
- Online Self-Test can be initiated whenever the Software Programs

Before starting self-test, make sure that:

- All previous applications are terminated
- PLL1 should be configured for 240 MHz PHI clock
- PLL1 should be selected as the system clock
- PLL1 should be selected as source for all auxiliary clocks

NOTE

If an erase (or program) operation is going on in the Flash, then any request for LBIST, or any customer accessible self test mechanism that utilizes the flash scan interface should be disabled. Ensure Flash is in IDLE state before starting LBIST.

For running online self-test, choose maximum STCU2_CFG[LB_DELAY] and the maximum shift frequency is 45 MHz for 4:4:2:1 clock mode and 60 MHz for 4:2:2:1 clock mode or 2:2:2:1 clock mode. Shut-down self-test is a self-test configured and initiated by software (online self-test). Since the self-test is destructive, it is supposed to be run at shut-down if desired at all.

NOTE

Pattern Count and MISR values are dependent on test coverage requirements for the system.

NOTE

An HVD event on VDD_LV_CORE or VDD_HV_ADC will not prevent the offline STCU self-test from executing if it is enabled and the HVD is masked through DCF configuration. If the HVD remains engaged when the STCU completes the self-test, a destructive reset will occur causing the offline STCU self-test to repeat continually until the HVD condition is removed.

The following table describes the mapping between the MBIST number, as the STCU2 captures it, and the appropriate memory.

NOTE

DTCM in the table below is referred to as "DMEM" in the Core Complex Overview and the Core description chapters.

MBIST partitions are referred as "NMCUTs" in the STCU chapter.

Table 77-1. MBIST mapping

Partition number	Address Range (If applicable)	Memory
0	0xFFFFC000 - 0xFFFFFFFF	BAM_ROM
1	Memory Mapping mentioned in Section Error Injection Address Register (CAN_ERRIAR)	CAN_0
2	Memory Mapping mentioned in Section CAN_1 Error Injection Address Register (CAN_ERRIAR) - error injection addresses	CAN_1
3	IP-Internal / Not System Memory Mapped	FLEXRAY DATA
4	Following Registers are mapped to LUT RAM: "Message Buffer Cycle Counter Filter Register (FR_MBCCFRn), Message Buffer Frame ID Register (FR_MBFIDRn), Message Buffer Index Register (FR_MBIDXRn), Message Buffer Data Field Offset Register (FR_MBDORn), LRAM ECC Error Test Register (FR_LEETRn)"	FLEXRAY LUT
5	IP-Internal / Not System Memory Mapped	ETHERNET TX
6	IP-Internal / Not System Memory Mapped	ETHERNET RX
7	IP-Internal / Not System Memory Mapped	CORE0 DCACHE

77.1.1.1 Supported BIST sequences

NXP has validated and therefore supports only particular STCU2 built-in self-test (BIST) sequences for this chip. For descriptions of the supported BIST sequences for this chip, see the engineering bulletin EB00853 (for online self-test) and EB834 (for offline self-test). Contact your NXP sales representative for details.

77.1.1.2 STCU2 register reset values

The following table shows chip-specific reset values for several STCU2 registers. All other register reset values are shown in Register description.

NOTE

These are the reset values when startup self-test is not configured by DCFs. Otherwise, these values change per the DCF configurations of startup self-test.

Table 77-3. STCU2 register reset values

Register	Reset value
STCU2 Configuration Register (STCU2_CFG)	7F00_0000h
STCU2 PLL Configuration Register (STCU2_PLL_CFG)	0000_0000h
STCU2 Watchdog Register Granularity (STCU2_WDG)	0000_FFFFh
STCU2 CRC Expected Status Register (STCU2_CRCE)	FFFF_FFFFh
STCU2 CRC Read Status Register (STCU2_CRCR)	0000_0000h[1]
STCU2 Error FM Register (STCU2_ERR_FM)	0000_0000h
STCU2 On-Line LBIST Reset Management (STCU2_LBRMSW)	0000_0000h
STCU2 LBIST Unrecoverable FM Register (STCU2_LBUFM)	0000_0000h
STCU2 MBIST Unrecoverable FM Low Register (STCU2_MBUFML)	0000_0000h
STCU2 MBIST Unrecoverable FM Medium Register (STCU2_MBUFMM)	0000_0000h
STCU2 MBIST Unrecoverable FM High Register (STCU2_MBUFMH)	0000_0000h
STCU2 LBIST Control Register (STCU2_LB_CTRLn)	0000_0000h
STCU2 LBIST PC Stop Register (STCU2_LB_PCSn)	0000_0000h
STCU2 Off-Line LBIST MISR Expected Low Register (STCU2_LB_MISRELn)	FFFF_FFFFh
STCU2 Off-Line LBIST MISR Expected High Register (STCU2_LB_MISREHn)	FFFF_FFFFh
STCU2 Off-Line LBIST MISR Read Low Register (STCU2_LB_MISRRLn)	0000_0000h[1]
STCU2 Off-Line LBIST MISR Read High Register (STCU2_LB_MISRRHn)	0000_0000h[1]
STCU2 On-Line LBIST MISR Expected Low Register (STCU2_LB_MISRELSWn)	FFFF_FFFFh
STCU2 On-Line LBIST MISR Expected High Register (STCU2_LB_MISREHSWn)	FFFF_FFFFh
STCU2 On-Line LBIST MISR Read Low Register (STCU2_LB_MISRRLSWn)	0000_0000h[1]
STCU2 On-Line LBIST MISR Read High Register (STCU2_LB_MISRRHSWn)	0000_0000h[1]
STCU2 MBIST Control Register (STCU2_MB_CTRLn)	0000_0000h

1. The value of this register gets updated if offline self-test or online self-test is run.

77.1.1.3 AUTOLOCK_VALUE for register write access and DCF_COMPLETION value for DCF write completion

Register write-access watchdog timer refers to two clock-cycle values related to the STCU2's write-access watchdog. The following table provides these values on this chip.

Clock-cycle value	Number of STCU2 clock cycles
AUTOLOCK_VALUE	4096
DCF_COMPLETION	8

77.1.1.4 STCU hardware Abort behavior

If STCU2_ERR_STAT[ABORTHW] bit is set, it is recommended to clear all faults of FCCU.

77.1.1.5 Wait time for writing to the online registers

When writing to the online registers, the user must wait for the expiration of the offline key. The time the user should wait is (IPS_CLK)*4096 clock periods. If the IPS_CLK is 60 MHz then the user must wait (1/60)*4096 = 68.26 μs.

77.1.1.6 On-Line reset generation (only MBIST)

The On-Line execution of the MBIST does not generate any reset from STCU2 at the end of the execution. This is because the software application has to manage all the possible consequences related to the write operations performed by the MBIST execution other than preventing any read/write operation during the Self-Test execution. If necessary, the software must also restore the memory content (only for RAMs) at the end of the Self-Test execution.

77.1.1.7 On-Line reset generation (LBIST enabled)

The LBRMSW register should be configured to generate a global functional reset after LBIST online self-test. It is not recommended to use a dedicated reset due to random data injected by the LBIST Controller.

NOTE

If an ABORT condition is detected by STCU2 during the On-Line Self-Test execution, independently of the value of the LBRMSW register, only the related reset line is pulsed to prevent any potential dangerous system level operations.

77.1.1.8 PLL Loss of Lock during selftest

If PLL-LOL happens when MBIST run is in progress or when LBIST run is in progress, then the selftest run will be aborted with appropriate flags set in STCU2_ERR_STAT register

If the PLL-LOL happens during the small window between the MBIST and LBIST runs, then system moves to safe clock, i.e IRC. There are two possibilities after this:

1. If the LOL event happens before the STCU state machine hits the “CHECK_PLL” state, then STCU waits for the PLL to get locked again.
   - If PLL re-lock happens before timeout window, then the STCU state-machine proceeds as normal. LBIST will be run in the remaining time window till STCU WDOG expires. Depending on the time required to complete LBIST, the LBIST will either complete or time-out.
   - If the PLL re-lock does not happen and the timeout window expires, then STCU exits self-test with time-out reset.
2. If the LOL event happens after the “CHECK_PLL” state, then the LBIST run continues on IRC clock and completes.

77.2 Introduction

The *STCU2 self-test control unit* is a hardware module that:

- Manages the execution of built-in self-tests (BISTs)
- Indicates whether each BIST passed

77.3 Main features

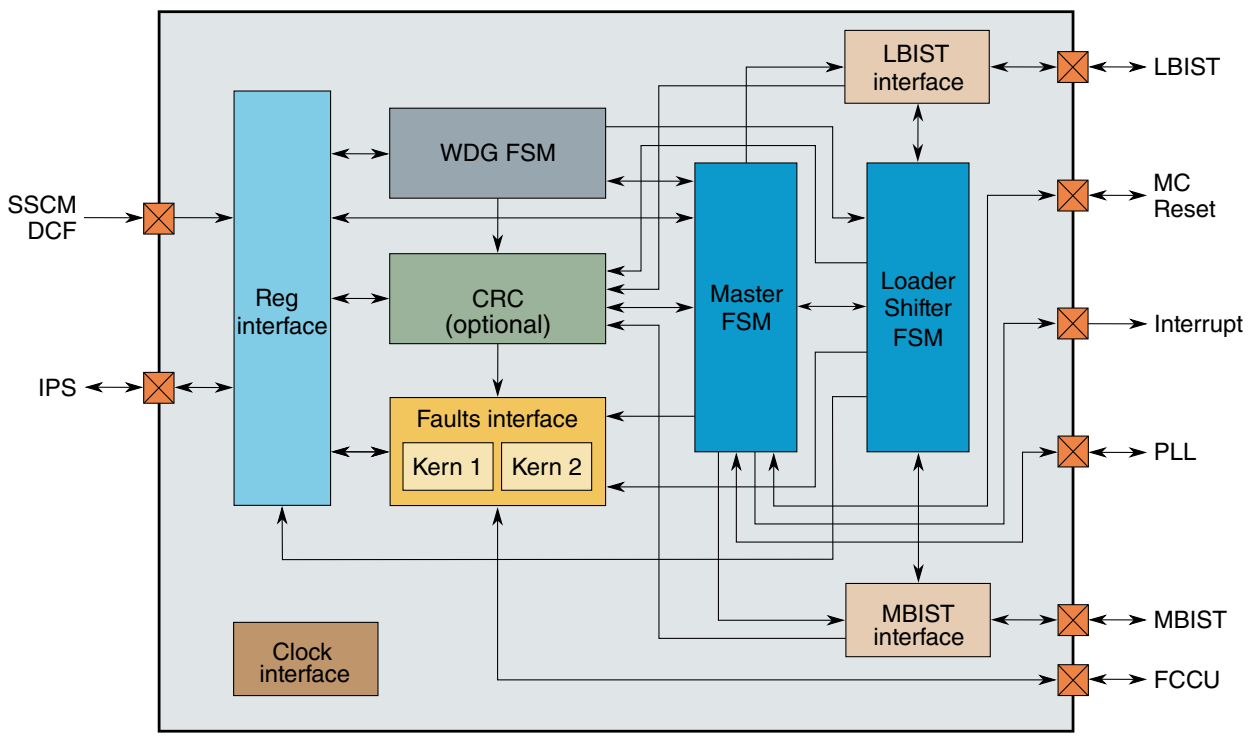
- Internal Peripheral System (IPS) interface for reading from and writing to the STCU2 registers during runtime (online) via the CPU
- SSCM Device Configuration Format (DCF) interface for writing to the STCU2 registers from nonvolatile memory during reset (offline) via the SSCM module (has priority over the IPS interface)
- Programmable scheduler for BIST execution
- LBIST concurrent/sequential execution
- MBIST concurrent/sequential execution
- Programmable LBIST delayed concurrent start
- 32-bit CRC for STCU2 self-checking capability (enabled by CRCEN)
- Programmable internal clock prescaler to reduce internal and BIST TCK clocks
- Programmable PLL direct control during offline BIST sequence
- PLL Lock signal monitoring during BIST sequences

- Programmable BIST-sequence-execution watchdog timer that specifies the maximum time allowed for the execution of a BIST sequence
- Fixed offline-initialization watchdog timer that specifies the maximum time allowed for offline initialization before indicating an initialization fault
- Fixed register-write-access watchdog timer that specifies the maximum amount of time that STCU2 allows you to write to its registers after you unlock them
- Fields that indicate the execution status of each:
  - Online MBIST
  - Offline MBIST
  - Online LBIST
  - Offline LBIST
- Fields that indicate the status of each type of online STCU2 internal error condition
- Fields that indicate the status of each type of offline STCU2 internal error condition
- A field that indicates the status of an online hardware abort
- Programmable fault mapping for each BIST for controlling the type of fault that STCU2 reports (recoverable or unrecoverable) when the BIST fails to execute
- Programmable fault mapping for each STCU2 internal error condition for controlling the type of fault that STCU2 reports (recoverable or unrecoverable) when the condition occurs
- Signals for reporting recoverable and unrecoverable faults to the FCCU module
- Redundant recoverable and unrecoverable fault-generation logic to improve reliability
- FCCU recoverable and unrecoverable fault-injection mechanism
- CRCE register access to perform redundant check by software
- LBIST MISRE register access to perform redundant check by software
- Offline BIST-sequence bypass capability
- Global register write-protection mechanism that requires two security key codes
- Global automatic power saving when a BIST sequence is completed, Bypass mode is selected, or a watchdog timer time-out is detected

- ITF/watchdog automatic clock wake-up mechanism when software unlocks the STCU2 registers for write access
- ITF/watchdog automatic power saving when the fixed register-write-access watchdog timer times out

77.4 Block diagram

This diagram shows the parts of STCU2:



This table describes the parts of STCU2:

Part	Function
Reg interface	Provides access to: • Registers • The security key logic • The Internal Peripheral System (IPS) interface • The SSCM Device Configuration Format (DCF) interface
CRC	Performs STCU2 self-checking by sampling a set of selected internal signals when STCU2 is running.
Fault interface	Does the following: • Collects the fault conditions caused by STCU2 internal error conditions and each BIST executed in a sequence.

Table continues on the next page...

Part	Function
	• Depending on the fault mapping for a given BIST, sets the global recoverable or unrecoverable status flag. • Manages the recoverable and unrecoverable fault lines to and from the FCCU module • Manages the set/clear injection mechanism provided by the FCCU module. To improve the intrinsic reliability of this critical logic, the generation logic is duplicated.
Clock interface	Manages the internal and the BIST TCK clock prescaler, the internal clock-gating power saving, and the wake-up clock feature.
WDG FSM (watchdog finite state machine)	Provides the following: • A programmable BIST-sequence-execution watchdog timer that specifies the maximum time allowed for the execution of a BIST sequence • A fixed offline-initialization watchdog timer that specifies the maximum time allowed for offline initialization before indicating an initialization fault • A fixed register-write-access watchdog timer that specifies the maximum amount of time that STCU2 allows you to write to its registers after you unlock them
Master FSM (finite state machine)	Coordinates and schedules all of the operations performed during a BIST sequence.
Loader Shifter FSM (finite state machine)	Programs the BIST registers and reads back the data to be checked at the end of each test operation.
LBIST interface	Provides the interface between the chip's LBIST engines and the STCU2 controllers.
MBIST interface	Provides the interface between the MBIST controller and the STCU2 controllers.

77.5 IPS bus interface

The IPS bus interface is a slave bus used for configuration purposes via CPU. The following bus read operations (contiguous byte enables) are supported:

- Word (32 bits) data read operations to any registers
- Low and high half-words (16 bits, data[31:16] or data[15:0]) data read operations to any registers
- Byte(8 bits, data[31:24] or data[23:16] or data[15:8] or data[7:0]) data read operations to any registers
- Any other operation (free byte enables or other operations) has to be avoided.

The same operations are also supported in write mode only in the following scenario:

- The Self-Test sequence parameters are loaded before Off-Line Self-test is executed

- The IPS access on a specific register is allowed by software only when the bit STCU2_CFG.WRP is cleared
- In all the other conditions the write operations are not supported and all the STCU2 registers can be only read. Only exceptions are the following read/write bits: STCU2_CFG.WRP, STCU2_ERR_STAT.UFSF and STCU2_ERR_STAT.RFSF. See related register description for additional details

The STCU2 module generates a transfer error in the following cases:

- Any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral
- Any write/read operation different from byte/halfword/word (free byte enables or other operations) on each register
- Any write operation on Double Security Key register applying a wrong sequence of keys (the two write operations cannot be interleaved with other access to STCU2 registers)
- Any write operation performed on a register when the Double Security keys have not been applied
- Any write operation performed on registers when the STCU2_CFG.WRP bit is set and the access is performed through software (IPS interface)
- Any write operation performed through software (IPS interface) on Read/On-Line_Write/Off-Line registers
- Any write operation performed off-line on registers in which writing operation is allowed only in the On-Line Self-Test phase when STCU2_CFG[WRP] = 1
- Any write operation performed on Read Only registers

The registers of the STCU2 module are accessible (read/write) in each access mode: user, supervisor or test.

In case there are write operations on bits marked as reserved, the transfer error is not generated.

NOTE

See the chip-specific STCU2 information for the wait time necessary to write to the online registers.

77.6 BISTs and BIST partitions

77.6.1 Definition: BIST

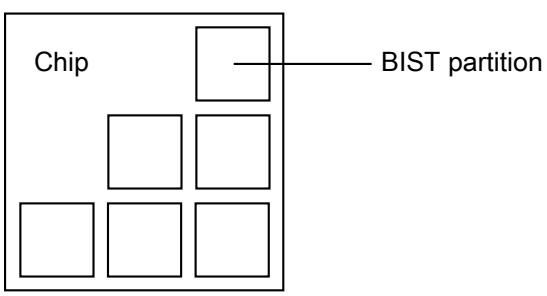
A *built-in self-test (BIST)* is a test that the chip can execute to verify the functional integrity of a part of itself. The chip uses STCU2 and other on-chip hardware to execute a BIST.

77.6.2 Definition: BIST partition

A *built-in self-test (BIST) partition* is a part of a chip for which a BIST has been defined. The hardware that is included in a given BIST partition is chip-specific. For a list of the hardware included in each of the BIST partitions on this chip, see the chip-specific STCU2 information.

77.6.3 Example: BIST partitions on a chip

This is an example of a chip with six built-in self-test (BIST) partitions:



77.6.4 Types of BIST partitions

The STCU2 module on this chip supports the following type or types of built-in self-test (BIST) partitions:

BIST partition type	Description
Memory BIST (MBIST) partition	An SRAM or ROM block
Logic BIST (LBIST) partition	One or more digital modules

77.7 BIST sequences

77.7.1 Definition: BIST sequence

A *built-in self-test (BIST) sequence* is a programmable series of one or more phases, each of which executes one or more individual BISTs.

77.7.2 STCU2 executes MBISTs before LBISTs

If a built-in self-test (BIST) sequence includes both MBISTs and LBISTs, STCU2 executes the MBISTs first.

77.7.3 Example: Single-phase BIST sequence

This is an example of a single-phase BIST sequence in which STCU2 executes only one BIST:

Phase	BIST executed
0	MBIST 16

77.7.4 Example: Multiphase BIST sequence

This is an example of a multiphase BIST sequence in which STCU2 executes more than one BIST in parallel in some phases:

Phase	BISTs executed
0	MBISTs 7, 38
1	MBIST 23
2	MBISTs 6, 16, 29, 23
3	LBIST 12
4	LBISTs 13, 8, 11
5	LBISTs 19, 6

77.7.5 Types of BIST sequences

The STCU2 module on this chip supports these types of built-in self-test (BIST) sequences:

BIST sequence type	Description
Online BIST sequence	A BIST sequence that STCU2 executes during runtime at the request of software. Application software configures and initiates execution of the BIST sequence by loading values into STCU2 registers. Use this type of BIST sequence when you want to test the chip hardware but need to minimize the system startup time. Also use it for failure diagnostics and quality control within a manufacturing environment. You can choose the most appropriate point during runtime at which to execute this type of BIST sequence.
Offline BIST sequence	A BIST sequence that STCU2 automatically executes during reset, either when power is first applied to the chip or when the chip resets STCU2. The chip's SSCM module configures and initiates execution of the BIST sequence by loading values into STCU2 registers from Device Configuration Format (DCF) records that are stored in the chip's UTEST flash memory. Use this type of BIST sequence when you want to test the chip hardware before runtime. The location of the DCF record area is chip-specific. The size of the DCF record area is sequence-specific. For the location of the DCF record area, see the chip-specific STCU2 information.

77.7.6 Supported BIST sequences

NXP has validated and therefore supports only specific built-in self-test (BIST) sequences for this chip. For a list of the supported BIST sequences, see the chip-specific STCU2 information.

77.7.7 Definition: Default offline BIST sequence

The *default offline built-in self-test (BIST) sequence* is the offline BIST sequence whose configuration NXP has programmed into the chip's Device Configuration Format (DCF) records that are stored in the chip's UTEST flash memory.

If you choose to use the default offline BIST sequence, or if it's the only one supported by NXP, there is no need to create additional DCF records for the offline BIST sequence.

77.8 Functional description

77.8.1 FSM description

The module has three state machines that work together: Master State Machine, Loader/ Shifter State Machine, and the Watchdog State Machine. Basically the Master State Machine is the core unit of the STCU2 module. It coordinates all the Self Test operations and the other State Machines. The Loader/Shifter State Machine is used to program the MBIST and the LBIST parameters and to retrieve the related results depending on the parameters stored into the STCU2 registers and under the control of the Master State Machine. The Watchdog State Machine evaluates all the schedule time for MBIST and LBIST and the time-out in case of wrong STCU2 programming.

77.8.2 Reset management

Assertion of the STCU2 reset input signal initializes the STCU2 module status, forcing the Off-Line Self-Test condition and cleaning up all the registers and state machine of the module.

The reset signals generated by the STCU2 module at the end of the Self-Test execution phase depends on the Self-Test conditions and on the content of the LBRMSW register.

77.8.2.1 Off-Line reset generation

At the end of the Off-Line Self-Test execution the STCU2 raises the global functional reset.

77.8.2.2 On-Line reset generation

See the chip-specific STCU2 information for details about On-Line reset generation.

77.8.3 Built-in self-test scheduling

The STCU2 module has been designed to be very flexible allowing to program the parallel/serial execution of the MBIST or LBIST depending on the power/timing/ coverage constraints. The limitation in the programming flexibility is described in Design implementation information.

The mechanism used to provide this flexibility is a linked list where the starting pointer is the bitfield STCU2_CFG.PTR. The first LBIST is mapped on 00h, the second on 01h, and so on. The first MBIST is mapped to the address 10h, the second to 11h and so on. The additional pointers are in the bitfield STCU2_LB_CTRL[X].PTR for LBIST[X] (where X is the selected LBIST) and STCU2_MB_CTRL[Y].PTR for MBIST (where Y is the selected MBIST) and have to be filled depending on the selected sequence of run. The additional bitfield STCU2_LB_CTRL.CSM and STCU2_MB_CTRL.CSM provide the flexibility to run concurrently or sequentially the chosen set of the LBIST or MBIST or to close the linked list setting the NIL pointer. For more details, see STCU2 LBIST Control (STCU2_LB_CTRL*n*) and STCU2 MBIST Control Register (STCU2_MB_CTRL*n*) .

NOTE

Program operation should ensure that no flash write/erase operations are ongoing when online LBIST is triggered. Otherwise, a flash segment may be corrupted.

77.8.4 ABORT management

The STCU2 module provides On-Line Self-Test execution abort. When the abort is detected, the On-Line Self-Test operation stops running and the status of the currently running MBIST or LBIST is saved into the related registers to provide intermediate results that might be useful in case of debug or in case of concurrent run. In case of LBIST run, see Reset management, for more details about reset specific management when abort is detected.The following sections describe the differences between these two modalities.

77.8.4.1 Hardware ABORT management

The STCU2 enters the hardware abort condition as a consequence of a Functional reset which causes Self-Test execution to abort .

When hardware abort is detected the bit ABORTHW of the STCU2_ERR_STAT register is set. This flag allows the software to diagnose what has happened during the On-Line Self-Test execution run.

77.8.5 PLL interface

The STCU2 module is able to directly control the PLL during the Off-Line Self-Test operations depending on the status of the STCU2_RUN[MBPLLEN] and STCU2_RUN[LBPLLEN].

When STCU2_RUN[RUN] is set to start the Off-Line Self-test operations, the STCU2 takes control of the PLL and changes the PLL clock configurations parameters according to the values programmed into the STCU2_PLL_CFG register.

When the STCU2_RUN[MBPLLEN] is active and the MBIST is currently selected, the STCU2 waits for the PLL lock signal. As soon as the lock happens, the STCU2 forces the clock to switch to the PLL output clock. This allows the MBIST to proceed at the PLL output frequency. At the end of the MBIST run the clock source is reverted to the original one.

Same behavior will be applied when STCU2_RUN[LBPLLEN] is active and LBIST is currently selected.

77.8.6 FCCU interface

The FCCU interface is the hardware flag mechanism towards the system, to indicate the occurrence of an Unrecoverable fault and/or a Recoverable fault failure during the Self Test sequence.

To diagnose physical defects on the two fault signals, a fault injection mechanism is also provided. In this case, the FCCU interface allows the user application to check the integrity of the UF and RF connection lines between the STCU2 and the FCCU. Refer to the description of FCCU fault injection mechanism to understand how the UF/RF set/clear mechanism works.

77.8.7 Watchdogs

The STCU2 implements three different watchdogs to ensure that operations are finished in time.

77.8.7.1 Initialization watchdog timer

The STCU2 has two initialization operating modes: program the self-test sequence and run it (Safety mode) or bypass completely the self-test sequence setting the bit STCU2_CFG.BYP. In case there are faults during the initialization phase preventing the selection of one of these two operating modes, a hard-coded watchdog time-out flags the wrong behavior.

77.8.7.2 Built-in self-test watchdog timer

The LBIST and MBIST execution time has to be configured as described in STCU2 Watchdog Granularity (STCU2_WDG), to account for the overall execution time of the Self-Test sequence. In case the selected LBISTs or MBISTs are not yet completed during the Off-line Self-Test assigned time, the current LBISTs or MBISTs execution is interrupted and a failure is flagged into STCU2_ERR_STAT.WDTO and STCU2_MBEL/M/H or STCU2_LBE registers while in case of On-Line Self-Test into STCU2_ERR_STAT.WDTOSW and STCU2_MBELSW/MSW/HSW or STCU2_LBESW.

In case of multiple sequential run in the same On-Line/Off-Line session and the time-out happens in the middle of a sequential run, the next sequential run will be skipped and the execution ends with the current updated status of the registers reported above.

In all the cases, the STCU2 reset generation is managed in one of the modes described in Reset management.

77.8.7.3 Register write-access watchdog timer

As explained in the STCU2_SKC register description:

- A key mechanism protects STCU2 registers during the self-test configuration phase (both online/offline) by preventing any unwanted access.
- A hardware watchdog timer locks register-write access after a number of STCU2 clock cycles. To refresh the hardware watchdog timer before it times out, write only security key 2 to STCU2_SKC.

AUTOLOCK_VALUE is the number of STCU2 clock cycles after which the hardware watchdog timer locks register-write access. See the chip-specific STCU2 information for the value of AUTOLOCK_VALUE.

NOTE

For write completion, each DCF record requires a number of STCU2 clock cycles equal to DCF_COMPLETION. The maximum number of DCF records that can be executed before the watchdog timer must be refreshed is AUTOLOCK_VALUE divided by DCF_COMPLETION. See the chip-specific STCU2 information for the value of DCF_COMPLETION.

The hardware watchdog timer is particularly useful in case STCU2_CFG[WRP] is 0 during the software self-test configuration. In this case, the software application might enable write access to the STCU2 registers.

77.8.8 CRC

The CRC block is used to increase the intrinsic coverage of the STCU2 module and implements a 32-bit ethernet protocol polynomial to evaluate the signature of the most important and critical internal signals. This feature is by default switched off but it can be turned on setting the bit STCU2_CFG.CRCEN. Once this bit is set the expected signature has to be programmed into the STCU2_CRCE register; at the end of the Self-Test execution the STCU2 updates the content of the STCU2_CRCR register with the evaluated signature and compares this value with the expected one previously programmed into STCU2_CRCE. In case of mismatches a UF/RF condition is flagged depending on the fault mapping selected into the STCU2_ERR_FM register.

NOTE

The CRC calculation depends on the internal state of the STCU2 when the online/offline self test is started. The STCU2's internal state is dependent on DCF values and their programming sequence for offline selftest. The calculated CRC value can be determined by running an LBIST test under known conditions. The CRC unit produces a stable and predictable result but is dependent on several stimuli (including programming order and the initial internal state of the STCU2 design) during online self test. To calculate a CRC value, run an LBIST test on known good silicon with a predefined software programming sequence. Record the CRC result value. Then provide the STCU2 programming sequence and the initial register vlaues for further runs if the CRC feature is to be used. Once a known good CRC value is determined, the CRC value will not change from one run to another so long as the user does not change the STCU2 programming sequence or any of the

values used to program STCU2 registers. To obtain a consistant CRC calculated value, the STCU must start from the same state compared to the state when the CRC was originally evaluated.

77.8.9 SSCM interface

The SSCM interface is used to program the STCU2's configuration parameters without the CPU intervention after a reset trigger event initializes the STCU2. This bus interface has the priority over the IPS.

77.9 Register description

During Offline SELFTEST, once the STCU2 registers are configured they cannot be overridden.

During Online SELFTEST, once the STCU2 registers are configured they cannot be overridden via IPS till the selftest is complete.

The STCU2 registers are listed in this section.

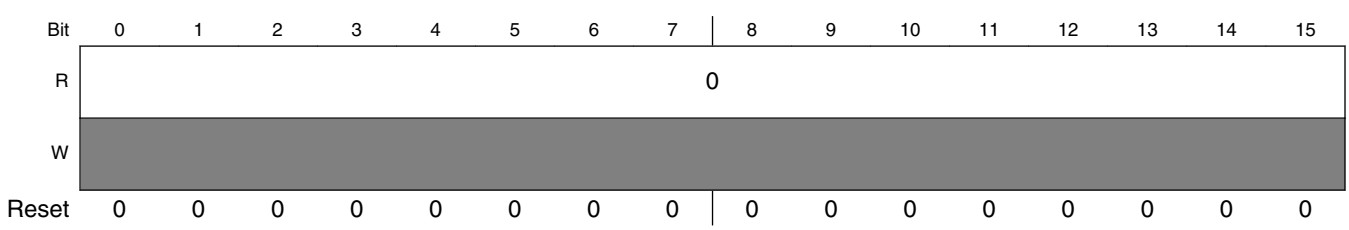
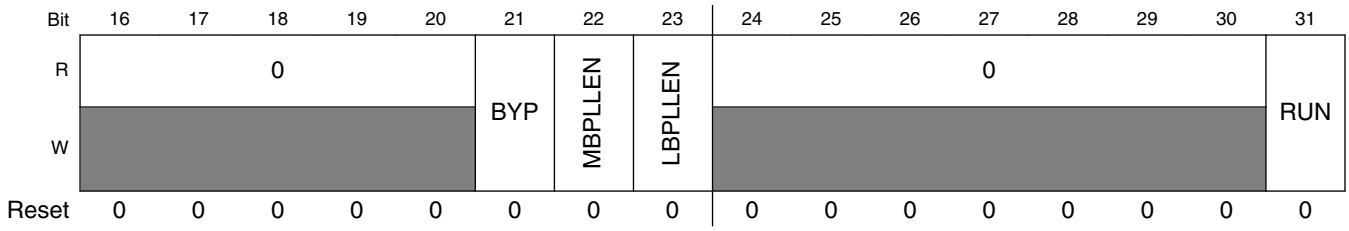
77.9.1 STCU2 Run Register (STCU2_RUN)

The STCU2_RUN register defines the RUN bit to start the off-line self testing procedure.

The R/W fields in this register are readable at any time. However, you can write to these fields only when Off-line Self-Test phase is still active.

Address: 0h base + 0h offset = 0h





STCU2_RUN field descriptions

Field	Description
0–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 BYP	Bypass mode 0 Off-Line Self-Test is active. In case the RUN bit into the STCU2_RUN register is not set before the Hard-Coded WDG Time-out, the WDTO error is generated into the STCU2_ERR_STAT register. 1 Off-Line Self-Test is completely bypassed and the access to STCU2 is locked until the STCU2_SKC register is written according to the request access mode.
22 MBPLLEN	Off-Line MBIST with PLL Enabled 0 Off-Line MBIST is executed without using the on-chip PLL. 1 Off-Line MBIST is executed enabling the on-chip PLL control interface selecting the parameters defined into STCU2_PLL_CFG register.
23 LBPLLEN	Off-Line LBIST with PLL Enabled 0 Off-Line LBIST is executed without using the on-chip PLL. 1 Off-Line LBIST is executed enabling the on-chip PLL control interface selecting the parameters defined into STCU2_PLL_CFG register.
24–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 RUN	RUN: RUN The RUN bit is automatically cleared by the STCU2 when the off-line self testing procedure has been completed. 0 Idle 1 Off-Line Self testing procedure is running

77.9.2 STCU2 Run Software Register (STCU2_RUNSW)

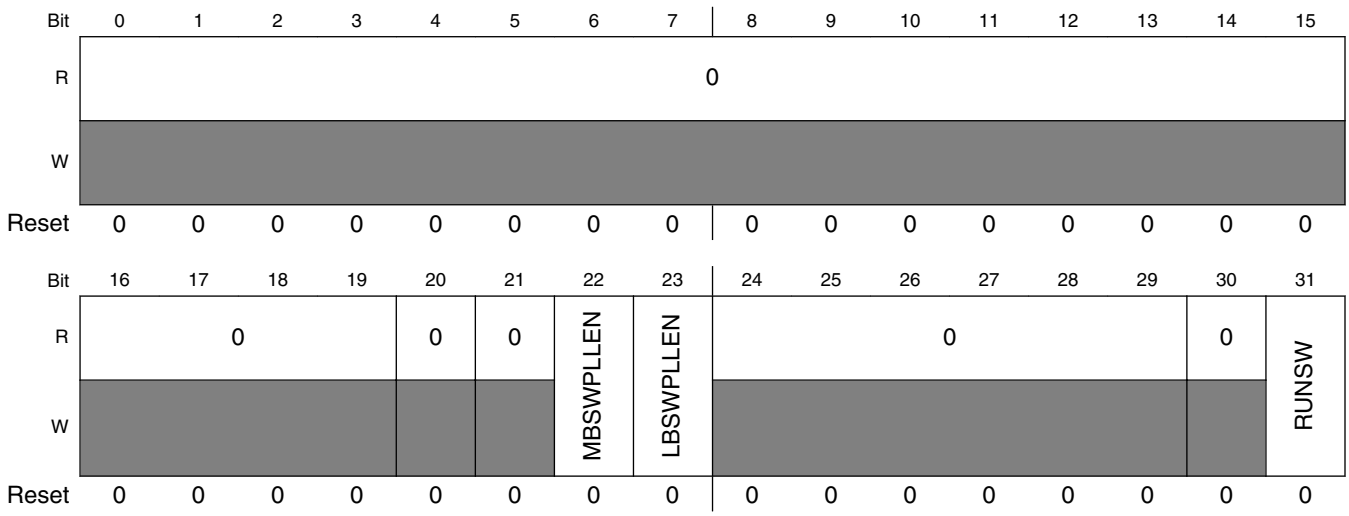
The STCU2_RUNSW register defines the RUN bit to start the on-line self testing procedure.

The R/W fields in this register are readable at any time. However, you can write to these fields only when both of the following conditions are true:

- STCU2_CFG[WRP] = 0
- On-line Self-Test phase is active. The On-Line condition starts when the Off-Line is over. In this condition, system is alive and the SW can program the STCU2

Register description

Address: 0h base + 4h offset = 4h



STCU2_RUNSW field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 MBSWPLLEN	On-Line MBIST with PLL Enabled 0 On-Line MBIST is executed without using the on-chip PLL. 1 On-Line MBIST is executed using the PLL configuration provided by software. STCU2 does not take the PLL control but monitors the PLL lock signal to check if PLL is working correctly.
23 LBSWPLLEN	On-Line LBIST with PLL Enabled 0 On-Line LBIST is executed without using the on-chip PLL. 1 On-Line LBIST is executed using the PLL configuration provided by software. STCU2 does not take the PLL control but monitors the PLL lock signal to check if PLL is working correctly.
24–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 RUNSW	RUNSW The RUNSW bit is automatically cleared by the STCU2 when the on-line self testing procedure has been completed. 0 Idle 1 On-line self testing procedure is running

77.9.3 STCU2 SK Code Register (STCU2_SKC)

The STCU2_SKC register implements the security key code mechanism needed to access in write mode to the other STCU2 registers. In order to unlock the STCU2 access after:

- The STCU2 asynchronous reset
- The end of the STCU2 run

the software (IPS bus)or the SSCM interfaces have to apply the following sequence:

- write the key1 into the STCU2_SKC register
- write the key2 into the STCU2_SKC register

Depending on the off/on-line test step, the two keys will be different. Byte write operation is not allowed since the full key has to be recognized as one unit.

It should be noted that after the Self-Test sequence has been completed or the Bypass feature has been enabled (setting the bit BYP into the STCU2_CFG), the SSCM interface is no longer available.

In case of invalid access or sequence (Key1/2 have to be applied consecutively), a transfer error on the IPS or SSCM busis asserted depending on the selected source. The STCU2 write access is locked and to unlock the access the sequence has to be applied again.

In case the STCU2 register access lasts more cycles than the one defined into the Hard-coded WDG time-out, the STCU2 write access is locked and the WDG and Register ITF clocks are switched off. Also in this case, in order to enable again the write access to the STCU2 and the WDG and Register ITF clocks, it is required to apply again the sequence.

In case it is required to extend the STCU2 register access cycles before the Hard-coded WDG time-out expires, only the Key2 has to be applied. The effect of this write operation is to re-initialize the WDG time-out counter. In such a condition, Key1 has not to be applied otherwise a transfer error on the IPS bus is asserted depending on the selected source. The STCU2 write access is locked and to unlock the access the sequence has to be applied again.

The STCU2_SKC register is not readable. The value 00000000h is always returned in case of read operation.

Address: 0h base + 8h offset = 8h

STCU2_SKC field descriptions

Field	Description
0–31 SKC	STCU2 security key code for off-line Test = D3FEA98Bh: Key1 to unlock the write access the STCU2 = 2C015674h: Key2 to unlock the write access the STCU2 STCU2 security key code for on-line Test = 753F924Eh: Key1 to unlock the write access the STCU2 = 8AC06DB1h: Key2 to unlock the write access the STCU2

77.9.4 STCU2 Configuration Register (STCU2_CFG)

NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_CFG register includes the global configuration of the STCU2 and can be updated both in the Off/On-Line Test steps.

The access to this register is described in the following figure. It further depends on the state of the WRP bit as follows:

- When WRP = 0: The register can be written during the on-line Self-Test case without restrictions
- When WRP = 1:
  - The only bit that can be written without any restriction is WRP.
  - In case there are software operations that write all the register's bits, a transfer error is raised only if the value of the selected byte written differs from the current status of the register. This functionality has been implemented to prevent potential compilation behavior that might invalidate this single bit clean capability.

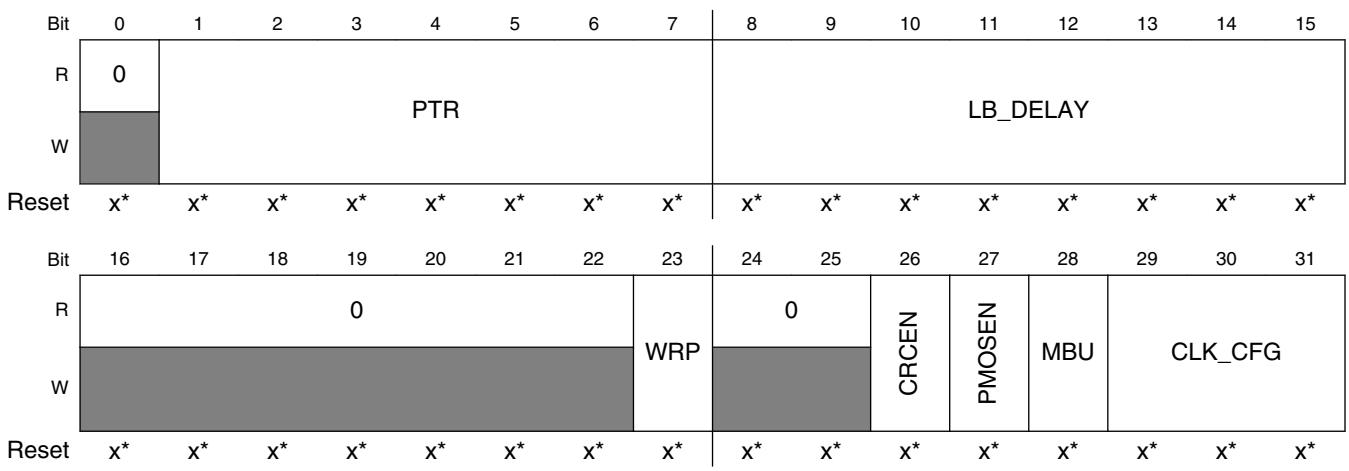
MBIST can be run in three different test types according to how the STCU2_CFG register bits 27 and 28 are set.

The following table describes the test algorithm and coverage of the different test types.

Table 77-4. MBIST algorithm and coverage according to test type

MBIST Type	STCU2_CFG[PMOSEN]	STCU2_CFG[MBU]	MBIST Algorithm	Internal Nodes/ Circuits Additionally Covered by Test	Use Case	Test Cycle
Full Test	1	0	Test memory using all built in algorithms. Open PMOS algorithm included	Address Decoder and Bitcell as well as resistive defects in the address decoder	Used by MCU production test. Recommended to use in the field for MBIST online self-test.	About 3 to 4x more than Auto Test
Reduced Test	0	0	Test memory using all built in algorithms except the open PMOS algorithm.	Address Decoder and Bitcell	Recommended to use in the field for MBIST online self-test if the Full Test takes too long.	About 10% less than Full Test
Auto Test	x	1	A smaller set of algorithms which target latent defect mechanisms.	Latent defects such as NBTI of the PMOS transistors in the bitcells	Recommended to use for MBIST offline self-test as an optimum balance of test time vs. fault coverage.	About 3 to 4x faster than Full Test

Address: 0h base + Ch offset = Ch



* Notes:
- The reset value is chip-specific; see the chapter that describes how modules are configured and connected.x = Undefined at reset.

STCU2_CFG field descriptions

Field	Description
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–7 PTR	LBIST or MBIST pointer PTR defines the logical pointer to the first LBIST or MBIST to be scheduled when the self testing procedure is enabled. PTR is the entry pointer to a linked list of BIST descriptors. If PTR = 0 then the LBIST0 is initially scheduled.

Table continues on the next page...

STCU2_CFG field descriptions (continued)

Field	Description
	You can always read this field. In the off-line Self-Test phase, you can always write to this field. In the on-line Self-Test phase, you can write to this field only when WRP = 0. 0h to (LBIST -1): pointer to LBIST 10h to (10h + MBIST -1): pointer to MBIST 7Fh: pointer to NIL. No BIST execution.
8–15 LB_DELAY	Delay LBIST run LB_DELAY defines the delay between the LBIST starts when more than a single LBIST is selected to be executed concurrently with the purpose of smoothing the power consumption transient. The allowed delay time are the following: 00h: No delay 01h: 1 x16 STCU2 Core clock cycles 02h: 2 x 16 STCU2 Core clock cycles 03h: 3 x 16 STCU2 Core clock cycles ... FDh: 253 x 16 STCU2 Core clock cycles FEh: 254 x 16 STCU2 Core clock cycles FFh: 255 x 16 STCU2 Core clock cycles Note that in case the Frequency of the STCU2 core clock is 16 MHz, the delay parameters is expressed in µs. **NOTE:** This field should be written with 0xFF for self test run. You can always read this field. In the off-line Self-Test phase, you can always write to this field. In the on-line Self-Test phase, you can write to this field only when WRP = 0.
16–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 WRP	Write Protection 0: Specific STCU2 registers can be written through IPS bus interface after Off-Line Self-Test sequence has been completed 1: Specific STCU2 registers cannot be written though IPS also after Off-Line Self-Test sequence has been completed preventing in such a way any user application write operation
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 CRCEN	CRCEN: CRC Enable comparison You can always read this field. In the off-line Self-Test phase, you can always write to this field. In the on-line Self-Test phase, you can write to this field only when WRP = 0. 0 The CRC comparison is not performed and the STCU2_ERR_STAT.CRCS[SW] and STCU2_ERR_STAT.UF/RF global flags are not updated in case of mismatches between STCU2.CRCE and STCU2.CRCR values 1 The CRC comparison is performed and the status is updated into the related flags of the STCU2_ERR_STAT register
27 PMOSEN	MBIST PMOS Test Enable When MBU is 1 then "Auto test" MBIST test type will be selected regardless of the setting of this field.

Table continues on the next page...

STCU2_CFG field descriptions (continued)

Field	Description
	0 When MBU is 0 then selects the "Reduced test" MBIST test type. 1 When MBU is 0 then selects the "Full test" MBIST test type.
28 MBU	MBIST MBU Test Enabled 0 Either "Full test" or "Reduced test" MBIST test type will be selected according to the PMOSEN value. 1 Selects "Auto test" MBIST test type regardless of the PMOSEN value.
29–31 CLK_CFG	Logic, Memory BIST and STCU2 core CLK Clock configuration CLK_CFG defines the ratio between the sys_clk and the TCK used to program both the LBIST and the MBIST and the STCU2 core clock. The punch-out mechanism is used to generate the derived clocks. The allowed configurations are the following: 000: sys_clk 001: sys_clk/2 010: sys_clk/3 ... 101: sys_clk/6 110: sys_clk/7 111: sys_clk/8 You can always read this field. In the off-line Self-Test phase, you can always write to this field. In the on-line Self-Test phase, you can write to this field only when WRP = 0.

77.9.5 STCU2 PLL Configuration Register (STCU2_PLL_CFG)

NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_PLL_CFG register defines the parameters used to program the PLL only when the Off-line L/MBIST are performed and STCU2_RUN[MBPLLEN] = 1 or STCU2_RUN[LBPLLEN] = 1.

In the On-line condition, these bits are not effective. It is also possible to set the PLL during active On-line mode to prevent any potential functionality issue.

The R/W fields in this register are readable at any time. However, you can write to these fields only when Off-line Self-Test phase is still active.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

- The reset value is chip-specific; see the chapter that describes how modules are configured and connected.x = Undefined at reset.

STCU2_PLL_CFG field descriptions

Field	Description
0–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–7 PLLODF	PLL Output Division Factor The value of this field drives the Output Division factor of the PLL embedded into the device. Refer to the PLL specifications to define the exact mapping between the PLLODF value and the related PLL's Output Division factor.
8–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–15 PLLIDF	PLL Input Division Factor The value of this field drives the Input Division factor of the PLL embedded into the device. Refer to the PLL specifications to define the exact mapping between the PLLIDF value and the related PLL's Input Division factor.
16–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25–31 PLLLDF	PLL Loop Division Factor The value of this field drives the Loop Division factor of the PLL embedded into the device. Refer to the PLL specifications to define the exact mapping between the PLLLDF value and the related PLL's Loop Division factor.

77.9.6 STCU2 Watchdog Granularity (STCU2_WDG)

NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_WDG register defines the time limit for LBIST and MBIST execution, providing a protection mechanism in case of deadlock or endless conditions during the self test procedure.

When the offline self test sequence is not run and the STCU2_CFG[BYP] field is not set, bits 15..0 define the time-out before the STCU2_ERR[WDTO] field is set and the STCU2 core clock is switched off.

In case offline/online self test sequence is run, the STCU2_WDG value defines the time-out of the execution run.

The register fields are always readable. You can write to these fields when either of the following conditions is true:

- Offline self test phase is active
- Online self test phase is active and CFG[WRP] = 0

Address: 0h base + 14h offset = 14h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

* Notes:
- The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

STCU2_WDG field descriptions

Field	Description
0–31 WDGEOC	Watchdog End of Count Timer This value defines the time limit for offline and online self test execution to ensure correct operation within the allowed time. **NOTE:** If this register is programmed while STCU2_RUN[RUN]=1, the new STCU2_WDG value, programmed after STCU2_RUN, does not take effect. The allowed values are: 0000 0000h: 1 × 16 STCU2 Core clock cycles 0000 0001h: 2 × 16 STCU2 Core clock cycles 0000 0002h: 3 × 16 STCU2 Core clock cycles ... FFFF FFFDh: 4294967294 × 16 STCU2 Core clock cycles FFFF FFFEh: 4294967295 × 16 STCU2 Core clock cycles FFFF FFFFh: 4294967296 × 16 STCU2 Core clock cycles

77.9.7 STCU2 CRC Expected Status Register (STCU2_CRCE)

NOTE

See the chip specific information for the default reset value of this field.

The STCU2_CRCE register includes the expected signature of the CRC-32 (ethernet protocol). The CRC-32 bit engine is initialized at STCU2_CRCE_RES and computes the CRC signature of the STCU2's critical signals and when STCU2_CFG[CRCEN] = 1, it is able to provide the Self-Check capability of the STCU2 managing the CRCS[SW] bits of the STCU2_ERR_STAT register. The polynomial CRC used to evaluate the status of this register is the following:

$$X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^{8} + X^{7} + X^{5} + X^{4} + X^{2} + X + 1$$

CRC-32 [ethernet protocol]

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2_CFG[WRP] = 0

Address: 0h base + 1Ch offset = 1Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

* Notes:
- x = Undefined at reset.

STCU2_CRCE field descriptions

Field	Description
0–31 CRCE	CRC expected signature

77.9.8 STCU2 CRC Read Status Register (STCU2_CRCR)

NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_CRCR register reports the value obtained at the end of the Off/On-line Self-Test sequence. It might be used for diagnoses and also as additional check with respect to the CRCS[SW] bit of the STCU2_ERR_STAT register.

The content of this register is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1.

Address: 0h base + 20h offset = 20h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

* Notes:
- The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

STCU2_CRCR field descriptions

Field	Description
0–31 CRCR	Read CRC signature

77.9.9 STCU2 Error Register (STCU2_ERR_STAT)

The STCU2_ERR_STAT register includes the status flags related to the STCU2 internal fault conditions occurred during the configuration or the On/Off-Line self testing execution.

The UFSF and RFSF can be set/cleared using the FCCU dedicated channels.

The access to this register is described in the following figure and as follows:

- If you select the byte write capability to write only the UFSF and RFSF, then there is no restriction in writing these bits.
- If your software performs the write operations on other bits besides UFSF/RFSF, then a transfer error is generated only if the value you are writing to the other bits differs from their value currently stored in the register. This functionality has been implemented to prevent potential compilation behavior that might invalidate the UFSF/RFSF single bit set/clean capability.

Address: 0h base + 24h offset = 24h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

STCU2_ERR_STAT field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 ABORTHW	On-line hardware abort flag You can always read this field. The content of this field is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1. 0 No hardware abort was requested during the On-Life Self-Test sequence 1 A hardware abort was detected during the On-Life Self-Test sequence
7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 LOCKESW	On-Line LOCK Error You can always read this field. The content of this field is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1. 0 In case PLL is enabled, it is correctly locked during the Self-Test sequence 1 When the PLL is enabled, this flag highlight that there has been an unexpected PLL unlock event during the On-Line Self-Test sequence execution. The On-Line Self-test run is stopped and the status of the current running LBISTs or MBISTs is saved into the related registers. The LOCK signal is monitored during the LBIST run when STCU2_RUNSW.LBSWPLLEN is set and/or during the MBIST run when STCU2_RUNSW[MBSWPLLEN] = 1.
12 WDTOSW	On-Line Watchdog time-out You can always read this field. The content of this field is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1. 0 LBIST and MBIST time slot have been completed within the assigned watchdog time. 1 LBIST and MBIST time slot haven't been completed within the assigned watchdog time or there are internal mismatches among End of Execution signals. The conditions that flag the failures are the following: • MBIST BEND status flags that at least one of the selected MBIST run is not finished • lbist_done of the selected LBIST flags the LBIST run is/are not finished

Table continues on the next page...

STCU2_ERR_STAT field descriptions (continued)

Field	Description
13 CRCSSW	On-Line CRC Status This flag is activated ONLY when On-Line Self Test is performed and STCU2_CFG.CRCEN is set to 1 otherwise it is always forced to 0 preventing in such a way the generation of the related STCU2_ERR_STAT.UFSF/RFSF bits. In both the cases, the content of the STCU2_CRCR register report the current evaluated CRC. You can always read this field. The content of this field is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1. 0 Successful CRC comparison or comparison has been masked (STCU2_CFG.CRCEN set to 0) 1 Failed CRC comparison
14 ENGESW	On-Line Engine Error You can always read this field. The content of this field is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1. 0 Valid Engine execution 1 Invalid Engine execution. The following conditions set this bit: • STCU2 state machines (Watchdog, Master and Loader/Shifter) selects an unused code • Serial pass/fail status of the selected MBIST and the global BBAD flag are not aligned • Serial bend status of the selected MBIST and the global BEND flag are not aligned
15 INVPSW	On-Line Invalid Pointer You can always read this field. The content of this field is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1. 0 Valid linked pointer list 1 Invalid linked pointer list. The following conditions set this bit: • Initial LBIST or MBIST pointer is out of range • LBIST is selected when MBIST is concurrently running or vice versa • Error in the LBIST/MBIST linking (execution generates an infinite loop)
16–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 UFSF	Unrecoverable Faults Status Flag This flag reports the global status of the UF. This field can be set or cleared using the FCCU dedicated channel, and can also be set or cleared by software. 0 No errors that trigger the Unrecoverable Faults condition 1 There are errors that trigger the Unrecoverable Faults condition
23 RFSF	Recoverable Faults Status Flag This flag reports the global status of the RF. This field can be set or cleared using the FCCU dedicated channel, and can also be set or cleared by software. 0 No errors that trigger the Recoverable Faults condition 1 There are errors that trigger the Recoverable Faults condition
24–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 LOCKE	Off-Line LOCK Error 0 The PLL is correctly locked during the Self-Test sequence 1 When the PLL is enabled, this flag highlights that there has been an unexpected PLL unlock event during the Off-Line Self-Test sequence execution. The Off-Line Self-test run is stopped and the status

Table continues on the next page...

STCU2_ERR_STAT field descriptions (continued)

Field	Description
	of the current running LBISTs or MBISTs is saved into the related registers. The LOCK signal is monitored during the LBIST run when STCU2_RUN[LBPLLEN] = 1 and/or during the MBIST run when STCU2_RUN[MBPLLEN] = 1.
28 WDTO	Off-Line Watchdog time-out 0 LBIST and MBIST time slot have been completed within the assigned watchdog time. 1 LBIST and MBIST time slot haven't been completed within the assigned watchdog time or there are internal mismatches among End of Execution signals. The conditions that flag the failures are the following: • The STCU2_RUN[RUN] bit or the STCU2_RUN[BYP] bit is not set before the Watchdog reaches the End of Count • MBIST BEND status flags that at least one of the selected MBIST run is not finished • lbist_done of the selected LBIST flags the LBIST run is/are not finished
29 CRCS	Off-Line CRC status This flag is activated ONLY when Off-Line Self Test is performed STCU2_CFG[CRCEN] is set to 1 otherwise it is always forced to 0 preventing in such a way the generation of the related STCU2_ERR_STAT.UFSF/RFSF bits. In both the cases, the content of the STCU2_CRCR register report the current evaluated CRC. 0 Successful CRC comparison or comparison has been masked (STCU2_CFG[CRCEN] programmed to 0) 1 Failed CRC comparison
30 ENGE	Off-Line Engine Error 0 Valid Engine execution 1 Invalid Engine execution. The following conditions set this bit: • STCU2 state machines (Watchdog, Master and Loader/Shifter) selects an unused code • Serial pass/fail status of the selected MBIST and the global BBAD flag are not aligned • Serial bend status of the selected MBIST and the global BEND flag are not aligned
31 INVP	Off-Line Invalid pointer 0 Valid linked pointer list 1 Invalid linked pointer list. The following conditions set this bit: • Initial LBIST or MBIST pointer is out of range • LBIST is selected when MBIST is concurrently running or vice versa • Error in the LBIST/MBIST linking (execution generates an infinite loop)

77.9.10 STCU2 Error FM Register (STCU2_ERR_FM)

NOTE

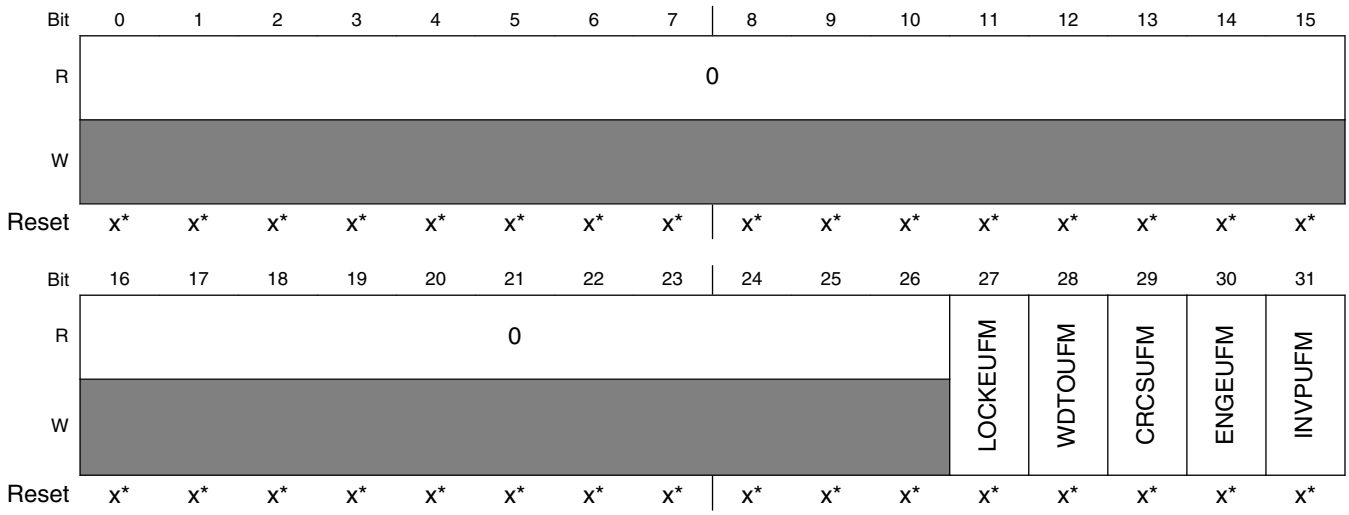
The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_ERR_FM register defines the fault mapping of the STCU2 faults described into the register STCU2_ERR_STAT in terms of Unrecoverable or Recoverable Fault. All sources of internal faults can be routed to UF and RF.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2_CFG[WRP] = 0

Address: 0h base + 28h offset = 28h



* Notes:
- The reset value is chip-specific; see the chapter that describes how modules are configured and connected.x = Undefined at reset.

STCU2_ERR_FM field descriptions

77.9.16 STCU2 LBIST Unrecoverable FM Register (STCU2_LBUFM)

NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_LBUFM register defines the fault mapping of each LBIST in terms of Unrecoverable or Recoverable Fault.

The size of the register depends on the number of LBIST .

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2_CFG[WRP] = 0

Address: 0h base + 40h offset = 40h

77.9.23 STCU2 On-Line MBIST Status Low Register (STCU2_MBSLSW)

The STCU2_MBSLSW register includes the results corresponding to the execution of the selected On-Line MBIST in the range NMCUT = 0-31.

The size of the register depends on the number of BISTed RAMs/ROMs.

The content of this register is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1.

77.9.24 STCU2 On-Line MBIST Status Medium Register (STCU2_MBSMSW)

The STCU2_MBSMSW register includes the results corresponding to the execution of the selected On-Line MBIST in the range NMCUT = 32..63.

The size of the register depends on the number of BISTed RAMs/ROMs.

The content of this register is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1.

77.9.28 STCU2 On-Line MBIST End Flag High Register (STCU2_MBEHSW)

The STCU2_MBEHSW register includes the End Flag related to the execution of the selected On-Line MBIST in the range NMCUT = 64-95.

The size of the register depends on the number of BISTed RAMs/ROMs.

The content of this register is initialized to its reset value as soon as STCU2_RUNSW[RUNSW] = 1.

Address: 0h base + 70h offset = 70h

77.9.29 STCU2 MBIST Unrecoverable FM Low Register (STCU2_MBUFML)

NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_MBUFML register defines the fault mapping, in terms of Unrecoverable or Recoverable fault, of the MBIST in the range NMCUT = 0-31.

The size of the register depends on the number of BISTed RAMs/ROMs.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2_CFG[WRP] = 0

Address: 0h base + 74h offset = 74h

77.9.32 STCU2 LBIST Control (STCU2_LB_CTRL*n*)

NOTE

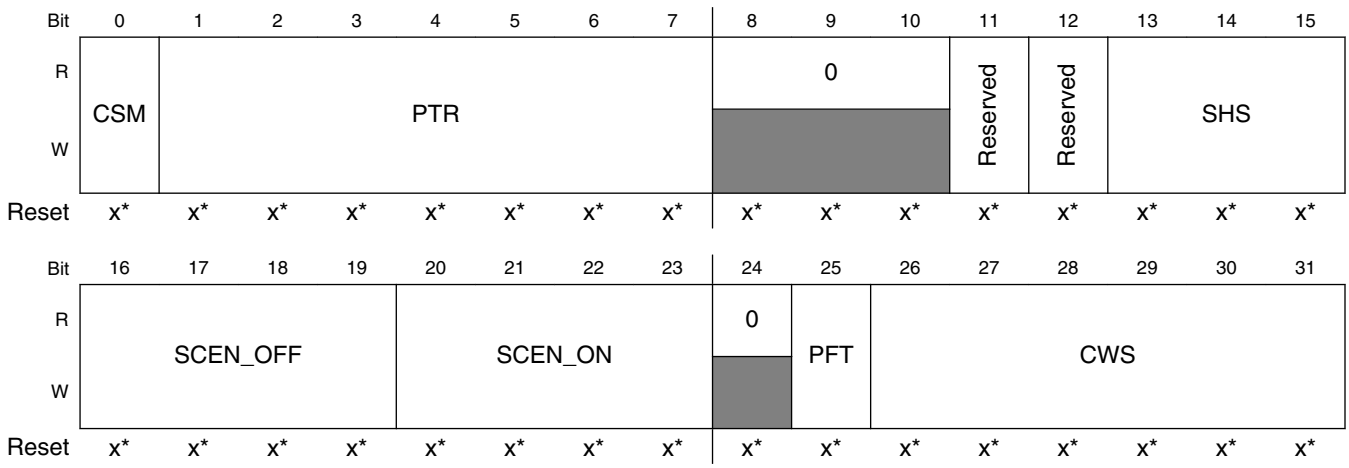
The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_LB_CTRL register defines the control setting of each LBIST controller.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Offline self test phase is active
- Online self test phase is active and STCU2_CFG[WRP] = 0

Address: 0h base + 100h offset + (64d × i), where i=0d to 7d



* Notes:
- The reset value is chip-specific; see the chapter that describes how modules are configured and connected.x = Undefined at reset.

STCU2_LB_CTRL*n* field descriptions

Field	Description
0 CSM	Concurrent/sequential mode The next LBIST is scheduled concurrently to the current one if the CSM bit is set to 1; otherwise, it is scheduled sequentially to the completion of the current LBIST execution. 0 Sequential mode 1 Concurrent mode
1–7 PTR	Next LBIST pointer PTR defines the logical pointer to the next LBIST. In case of NIL pointer the CSM bit has to be set Sequential (0) to define this is the end of the list. The self testing procedure is stopped when the current LBIST has been completed. LBIST POINTERS 0000b - pointer to LBIST partition 0 0001b - pointer to LBIST partition 1 0010b - pointer to LBIST partition 2 0011b - pointer to LBIST partition 3 0100b - pointer to LBIST partition 4 0101b - pointer to LBIST partition 5 0110b - pointer to LBIST partition 6 0111b - pointer to LBIST partition 7

Table continues on the next page...

STCU2_LB_CTRL*n* field descriptions (continued)

Field	Description
	... 0x7F - pointer to NIL, end of LBIST execution Values not defined in this list will result in an error being set in the STCU2_ERR register.
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 Reserved	This field is reserved. **NOTE:** This reserved field is writeable but do not write any value to it other than its reset value
12 Reserved	This field is reserved. **NOTE:** This reserved field is writeable but do not write any value to it other than its reset value
13–15 SHS	Shift speed SHS defines the shift speed 000 Shift at full rate of STCU2 core clock 001 Shift at 1/2 rate of STCU2 core clock 010 Shift at 1/3 rate of STCU2 core clock 011 Shift at 1/4 rate of STCU2 core clock 100 Shift at 1/5 rate of STCU2 core clock 101 Shift at 1/6 rate of STCU2 core clock 110 Shift at 1/7 rate of STCU2 core clock 111 Shift at 1/8 rate of STCU2 core clock
16–19 SCEN_OFF	Scan enable OFF SCEN_OFF defines the number of clock cycles OFF following the falling transition on the SCEN **NOTE:** Scen_off must be programmed to a value >=1 0000 0 delay cycles 0001 1 delay cycle 0010 2 delay cycles 0011 3 delay cycles 0100 4 delay cycles 0101 5 delay cycles 0110 6 delay cycles 0111 7 delay cycles 1000 8 delay cycles 1001 9 delay cycles 1010 10 delay cycles 1011 11 delay cycles 1100 12 delay cycles 1101 13 delay cycles 1110 14 delay cycles 1111 15 delay cycles
20–23 SCEN_ON	Scan enable ON SCEN_ON defines the number of clock cycles OFF following the rising transition on the SCEN **NOTE:** Scen_on delay register value must be programmed to a value >=1>

Table continues on the next page...

STCU2_LB_CTRL*n* field descriptions (continued)

Field	Description
	0000 0 delay cycles 0001 1 delay cycle 0010 2 delay cycles 0011 3 delay cycles 0100 4 delay cycles 0101 5 delay cycles 0110 6 delay cycles 0111 7 delay cycles 1000 8 delay cycles 1001 9 delay cycles 1010 10 delay cycles 1011 11 delay cycles 1100 12 delay cycles 1101 13 delay cycles 1110 14 delay cycles 1111 15 delay cycles
24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 PFT	Past Flush Test The LBIST controller, by default, applies 32 Flush Test patterns. This bit allows to skip/apply the Flush test pattern sequence.
26–31 CWS	Capture window size CWS defines the capture window size. 000000: Illegal 000001: Controller waits 1 shift cycle for capture to finish. 000010: Controller waits 2 shift cycles for capture to finish. 000011: Controller waits 3 shift cycles for capture to finish. ... 111110: Controller waits 62 shift cycles for capture to finish. 111111: Controller waits 63 shift cycles for capture to finish.

77.9.33 STCU2 LBIST PC Stop Register (STCU2_LB_PCS*n*)

NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_LB_PCS register defines the pattern counter stop of each LBIST controller.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2_CFG[WRP] = 0

Address: 0h base + 104h offset + (64d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

STCU2_LB_PCS*n* field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–31 PCS	Pattern counter stop PCS defines the pattern counter stop value.

77.9.34 STCU2 Off-Line LBIST MISR Expected Low Register (STCU2_LB_MISREL*n*)

NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2_LB_MISREL register defines the LSB part (31-0) of the Expected MISR of the Off-Line LBIST controller.

The size of the register depends on the number of MISR bits of the related LBIST.

The R/W fields in this register are readable at any time. However, you can write to these fields only when Off-line Self-Test phase is still active.

Address: 0h base + 110h offset + (64d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

STCU2_MB_CTRL*n* field descriptions

Field	Description
0 CSM	Concurrent/sequential mode 0 Sequential mode 1 Concurrent mode
1–7 PTR	Next LBIST or MBIST pointer

Table continues on the next page...

STCU2_MB_CTRL*n* field descriptions (continued)

Field	Description
	PTR defines the logical pointer to the next LBIST or MBIST to be scheduled. The next LBIST orMBIST is scheduled concurrently to the current one if the CSM bit is set to 1; otherwise it is scheduled sequentially to the completion of the current MBIST execution. In case of NIL pointer the CSM bit must be set Sequential (0) to define this is the end of the list. The self-testing procedure is stopped when the current MBIST has been completed. 0h to (LBIST -1): pointer to LBIST 10h to (10h + MBIST -1b): pointer to MBIST 7Fh: pointer to NIL. No BIST execution. others: invalid pointer => an error is set into the STCU2_ERR register.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

77.10 Use cases and limitations

The STCU2 module is designed to give high flexibility during the on/off-line test. In the following are reported the programming operations that have to be performed to correctly use the functionality of this module considering the three typical usage cases:

- the Off-line Self Test Sequence after a reset trigger event
- the bypass mode of the Self Test Sequence after a reset trigger event
- the On-line Self-test Sequence

77.10.1 Offline self-test sequence

This is the typical mode of using the STCU2 module after reset trigger event is applied to STCU2. The SSCM DCF bus is used to retrieve the STCU2 schedule and L/MBIST execution parameters stored into the NVM memory.The target is to cover the amount of physical defects in the digital logic and in the System RAMs/ROMs according to the System specifications. The sequence is the following:

- Unlock the Off-Line STCU2 access writing the Key1/Key2 sequence into the STCU2_SKC register
- Program the LBIST fault reaction conditions (UF/RF) setting the STCU2_LBUFM register
- Program the MBIST fault reaction conditions (UF/RF) setting, depending on the number of memories, the STCU2_MBUFML/M/H registers
- Program the STCU2 internal fault reaction conditions (UF/RF) setting the STCU2_ERR_FM register
- Program the STCU2_LB_CTRL, STCU2_LB_PCS, STCU2_MISREL/H registers of each LBIST to be executed.
- Program the STCU2_MB_CTRL registers of each NMCUT to be executed

- Program the STCU2_WDG register to define the time budget assigned for the L/MBIST execution
- Program the STCU2_CFG register to define: the core and LBIST/MBIST TCK clock prescaling factor setting the CLK_CFG bits, the LB_DELAY field to delay the LBIST start when many LBIST are run concurrently to mitigate the potential transient power issue during the start-up phase, the PMOSEN or MBU in order to define the algorithm to be used during MBIST run, the CRCREN bit to enable the self-checking feature and finally set the pointer to the first LBIST/NMCUT to be executed
- In case the internal CRC comparison has been enabled, program the CRCE value expected at the end of the off-line Self Test sequence into the STCU2_CRCE register
- In case the PLL usage has been enabled, program the STCU2_PLL_CFG value in order to set the required system frequency
- Program the RUN bit into the STCU2_RUN register to enable the Off-Line Self-Test execution and the L/MBPLLEN bits to enable the PLL during L/MBIST execution according to STCU2_PLL_CFG register content
- Start the Off-Line Self-Test and, depending on PLL management and L/MBIST execution order, when PLL LOCK is high.
- Wait the WDGEOC run time execution specified into the STCU2_WDG register.
- The STCU2 switches off the core clock at the end of the Self-Test run and releases the PLL control in case this feature has been enabled.
- The STCU2 resets the STCU2_RUN[RUN] bit and the device exits from boot sequence. In case there are failures, the STCU2 flags these failures toward the FCCU.
- The software application reads the STCU2_LBS flag register to check the failed LBIST when UF or RF conditions is/are detected.
- The software application reads the STCU2_LBE flag register to check the LBIST still on-going when UF or RF is/are detected.
- The software application reads the STCU2_MBSL/M/H flag registers, depending on the number of memories, to check the failed RAMs/ROMs Memory BIST when UF or RF is/are detected.
- The software application reads the STCU2_MBEL/M/H flag registers, depending on the number of memories, to check if the RAMs/ROMs Memory BIST is still on-going when UF or RF is/are detected.
- The software application reads the bits INV, ENGE, CRCS, WDTO, LOCKE of the STCU2_ERR_STAT register to check whether there has been an internal STCU2 engine/parameters failure when UF or RF is/are detected.

- In case the CRCEN bit has been enabled, the software application read the CRCE and CRCR registers to check the coherence with the bit CRCS of the STCU2_ERR register.
- The software application reads for each device's LBIST, the STCU2_LBMISREL/H and STCU2_LBIST_MISRRL/H registers to check the coherence with the STCU2_LBS bits.

NOTE

The software application reads operations on the STCU2 CRC and LBIST MISR registers after off-line self test execution has been successfully performed are just an additional reliability layer added to improve the already implemented Auto Self-Test feature included into STCU2.

77.10.2 Online self test sequence

The online self test sequence is the most commonly used STCU2 application mode. The IPS interface is used to program the STCU2 registers and to schedule LBIST and MBIST execution. Since online LBIST and MBIST operations clean-up the content of Digital Logic (LBIST) or RAM (MBIST) tested, activation of this mode must be approached with caution. The suggested sequence is the following:

1. Ensure the RUN_CFG field value in all implemented MC_ME_PCTL*n* registers forces the associated peripheral to a frozen, clock gated state.
2. Write the Key1/Key2 sequence to the SKC register to unlock online STCU2 access.
3. Ensure CFG[WRP]=0 to enable IPS bus access to the online self test registers.
4. If required, program the following registers to select the LBIST, MBIST and STCU2 internal fault reaction: LBUFM, MBUFML/M/H and ERR_FM.

NOTE

The LBIST, MBIST and STCU2 internal fault reaction should have been already programmed during the offline self test sequence and so there should be no need to program again. However, in case they have not been programmed or there is the need of changing them for any reason, they can be overwritten.

5. Select the reset management options for online LBIST execution by programming the LBRMSW register.
6. The LB_CTRL and LB_PCS registers should have been already programmed during offline self test sequence and so they should not need to be programmed again.

However, if they have not been programmed or there is the need of changing them for any reason, they can be overwritten. The registers LB_MISRELSW/HSW have to be programmed according to the expected signature.

7. Overwrite/Program the MB_CTRL registers of each NMCUT to be executed.
8. Overwrite/Program the WDG register to define the time budget assigned for the L/MBIST execution
9. Overwrite/Program the CFG register to define: the core and L/MBIST TCK clock prescaling factor setting the CLK_CFG bits, the LB_DELAY field to delay the LBIST start when many LBIST are run concurrently to mitigate the potential transient power issue during the start-up phase, the CRCREN bit to enable the self-checking feature and finally set the pointer to the first LBIST/NMCUT to be executed.
10. In case the internal CRC comparison has been enabled, overwrite/program the CRCE value expected at the end of the online self test sequence into the CRCE register
11. Program the RUNSW[RUNSW] field to enable online self test execution; the L/MBSWPLLEN bits to enable the PLL lock signal monitor during L/MBIST execution
12. Start the online self test and depending on PLL management and L/MBIST execution order, also when PLL LOCK is high.
13. Wait the WDGEOC run time execution specified into the WDG register
14. The STCU2 switch-off the core clock at the end of the self test run
15. The functional reset activated is managed by the LBRMSW register (See step 5).
16. In case, at least one of the selected LBIST enables the Global functional reset, the STCU2 requests a functional reset which restarts the system while, when all the selected LBIST enables its own dedicated functional reset, only these local reset lines are applied and only the related LBIST partitions are cleaned-up.
17. The STCU2 resets the RUNSW[RUNSW] field. In both the reset cases and in case of fault/s, the STCU2 flags the failure toward the FCCU.
18. The software application reads the LBSSW flag register to check the failed LBIST when UF or RF conditions is/are detected.
19. The software application reads the LBESW flag register to check if the LBIST is still on-going when UF or RF is/are detected.
20. The software application reads the MBSLSW/MSW/HSW flag registers, depending on the number of memories, to check the failed RAMs/ROMs Memory BIST when UF or RF is/are detected.
21. The software application reads the MBELSW/MSW/HSW flag registers, depending on the number of memories, to check if the RAMs/ROMs Memory BIST is still on-going when UF or RF is/are detected.
22. The software application reads the bit INVPSW, ENGESW, CRCSSW, WDTOSW, LOCKESW of the ERR_STAT register to check whether there has been an internal STCU2 engine/parameters failure when UF or RF is/are detected.

23. In case the CRCEN bit has been enabled, the software application reads the CRCE and CRCR registers to check the coherence with the bit CRCSSW of the STCU2_ERR register.
24. The software application reads for each device's LBIST, the LBMISRELSW/HSW and LBIST_MISRRLSW/HSW registers to check the coherence with the LBS bits

NOTE

1. A reset is necessary after running any kind of online self test.
2. The software application read operations on the STCU2 CRC and LBIST MISR registers after successful online self test execution are an additional reliability layer to improve the auto-self-test feature included in the STCU2.
3. Flash memory must be in the idle state when BIST execution is started. Program and erase functionality must not be enabled when entering BIST execution.

77.10.3 Bypass USER Mode

In this case, the USER application parameters stored in FLASH and read by SSCM are written in order to skip the Self-Test procedure after a reset trigger event is applied. It might be useful in case the device is not configured for applications requiring improved reliability. The sequence is the following:

1. Unlock the STCU2 access writing the Off-Line Key1/Key2 sequence into the STCU2_SKC register
2. Set the BYP bit in the STCU2_RUN register

After BYP bit is set, the core clock is switched off, the Self-Test sequence is not applied and the system can wake up and start the user application.

77.10.4 Design implementation information

The following list reports the limitations related to the current implementation:

- Every NMCUT BIST can be run once during the online or offline self-test procedure.
- It is not possible to run LBIST and MBIST concurrently.
- Because software has full control of the system while applications are running during the online self-test, STCU2 is not allowed to take control of the PLL but can just monitor the lock signal to flag wrong unlock events.

Chapter 78
Error Injection Module (EIM)

78.1 Chip-specific EIM information

The EIM has only one channel (channel 0). It is used to inject errors on the DMA TCD RAM (64-bit data, 8-bit ECC) interface.

78.2 Introduction

The Error Injection module is mainly used for diagnostic purposes. It provides a method for diagnostic coverage of the peripheral memories. See the chip-specific EIM information to determine which peripheral memories are supported by this method.

78.2.1 Overview

The Error Injection Module (EIM) provides support for inducing single-bit and multi-bit inversions on read data when accessing peripheral RAMs. Injecting faults on memory accesses can be used to exercise the SEC-DED ECC function of the related system.

NOTE

The following diagram shows an example EIM implementation with a 64-bit read data bus and an 8-bit checkbit bus.

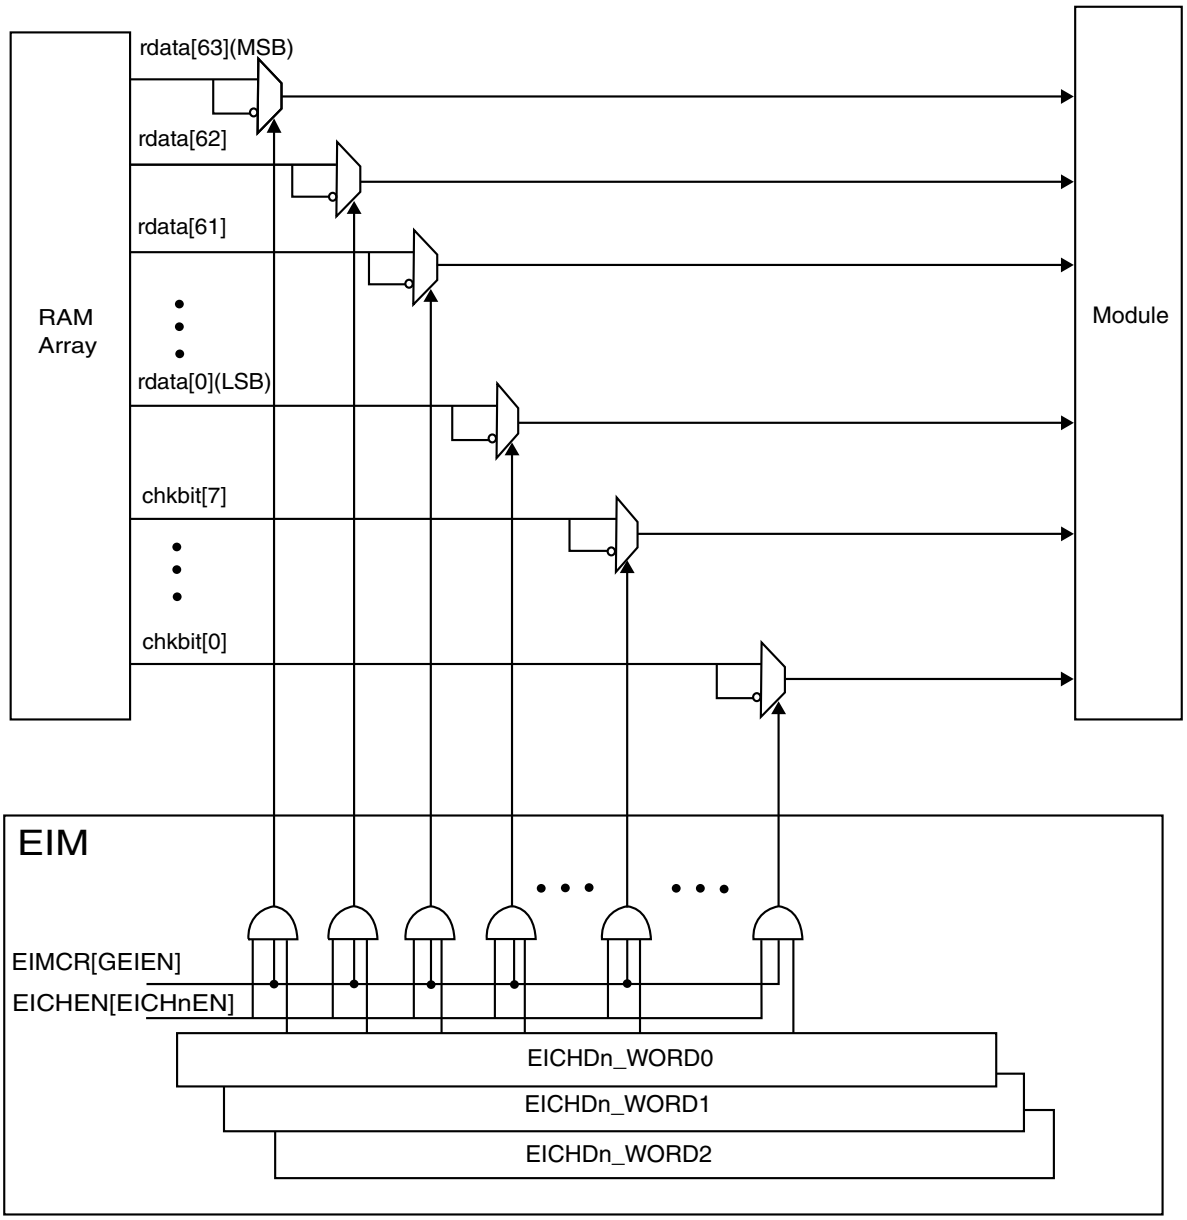

Figure 78-1. EIM functional block diagram (64-bit read data bus and 8-bit checkbit bus)

78.2.2 Features

The EIM includes these features:

- Supports 1 error injection channel
- Protection against accidental enable and reconfiguration error injection function via two-stage enable mechanism

78.3 Memory map and register definition

The EIM provides an IPS programming model mapped to an on-platform peripheral slot.

Programming model access

All system bus masters can access the programming model:

- Only in supervisor mode
- Using only 32-bit (word) accesses

Any of the following attempted references to the programming model generates an IPS error termination:

- In user mode
- Using non-32-bit access sizes
- To undefined (reserved) addresses

Attempted updates to the programming model while the EIM is in the midst of an operation will result in non-deterministic behavior.

Error injection channel descriptor: function and structure

Each error injection channel descriptor:

- Specifies a mask that defines which bits of the read data and checkbit bus from target RAM are inverted on a read access.
- Consists of a 128-bit (16-byte) structure, composed of four 32-bit words, in the EIM programming model.
  - Each descriptor consists of Error Injection Channel Descriptor Word0-1 (EICHD*n*_WORD0-1) and, depending on the implementation, Word2 (EICHD*n*_WORD2).
  - When Word2 is unused, the corresponding word in the 16-byte structure is unused.
  - The fourth word in the 16-byte structure is always unused.

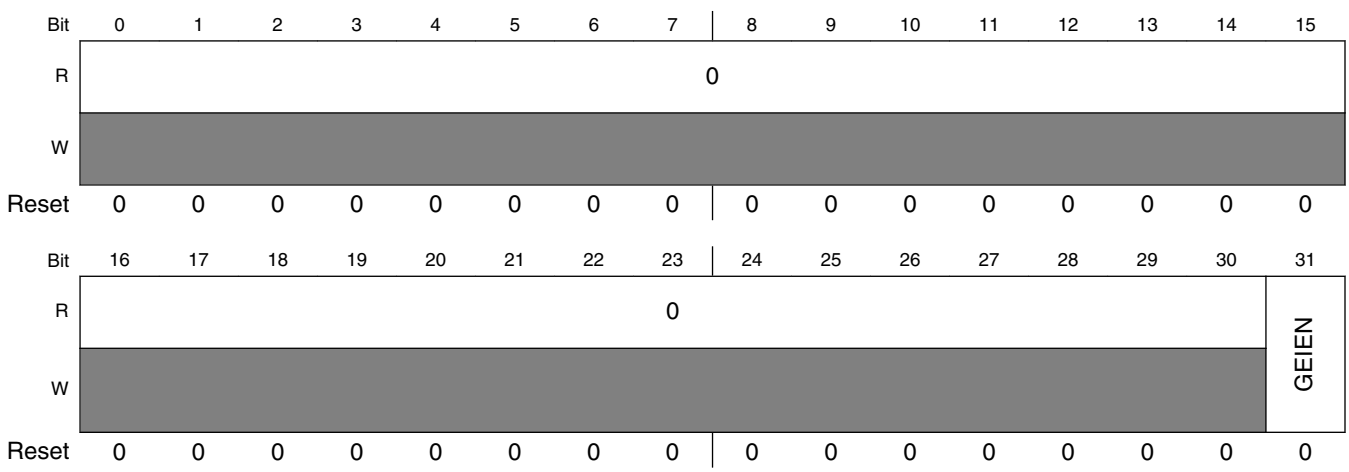
EIM memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Error Injection Module Configuration Register (EIM_EIMCR)	32	R/W	0000_0000h	78.3.1/3898
4	Error Injection Channel Enable register (EIM_EICHEN)	32	R/W	0000_0000h	78.3.2/3899
100	Error Injection Channel Descriptor, Word0 (EIM_EICHD0_WORD0)	32	R/W	0000_0000h	78.3.3/3900
104	Error Injection Channel Descriptor, Word1 (EIM_EICHD0_WORD1)	32	R/W	0000_0000h	78.3.4/3901
108	Error Injection Channel Descriptor, Word2 (EIM_EICHD0_WORD2)	32	R/W	0000_0000h	78.3.5/3901

78.3.1 Error Injection Module Configuration Register (EIM_EIMCR)

The EIM Configuration Register is used to globally enable/disable the error injection function.

Address: 0h base + 0h offset = 0h



EIM_EIMCR field descriptions

Field	Description
0–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
31 GEIEN	Global Error Injection Enable This bit globally enables or disables the error injection function of the EIM. This field is initialized by hardware reset. 0 Disabled 1 Enabled

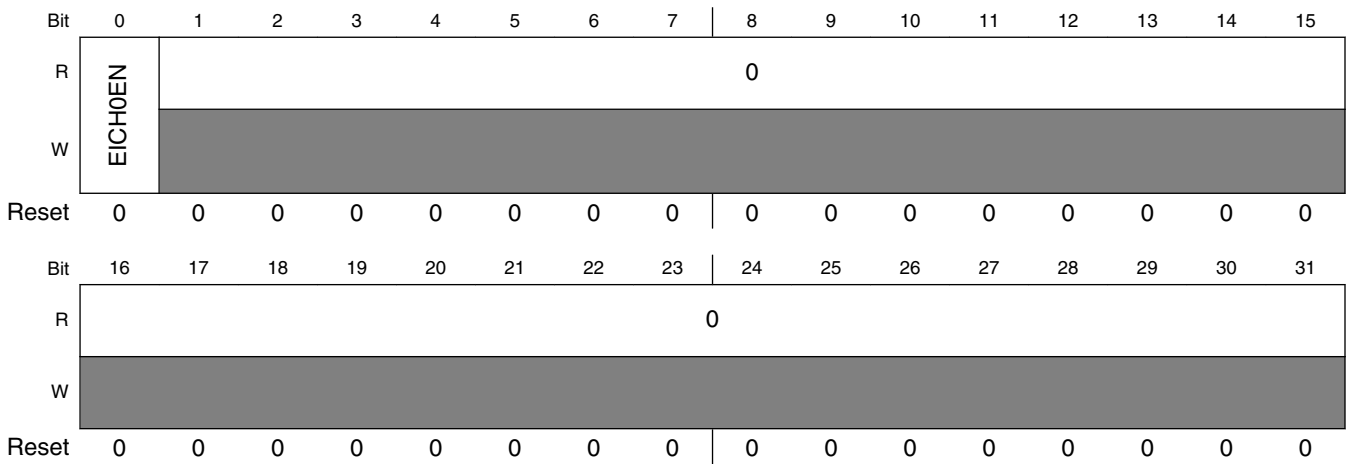
78.3.2 Error Injection Channel Enable register (EIM_EICHEN)

Each field of the Error Injection Channel Enable register (EICHEN) is used to enable or disable the corresponding error injection channel.

NOTE

To enable an error injection channel, the Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted.

Address: 0h base + 4h offset = 4h



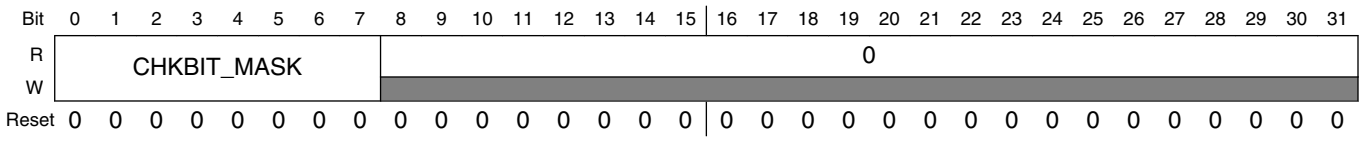
EIM_EICHEN field descriptions

Field	Description
0 EICH0EN	Error Injection Channel 0 Enable This field enables the corresponding error injection channel. The Global Error Injection Enable (EIMCR[GEIEN]) field must also be asserted to enable error injection. After error injection is enabled, all subsequent read accesses incur one or more bit inversions as defined in the corresponding EICHD*n*_WORD registers. Error injection remains in effect until the error injection channel is manually disabled via software. Any write to the corresponding EICHD*n*_WORD registers clears the corresponding EICHEN[EICH*n*EN] field, disabling the error injection channel. 0 Error injection is disabled on Error Injection Channel 0 1 Error injection is enabled on Error Injection Channel 0
1–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

78.3.3 Error Injection Channel Descriptor, Word0 (EIM_EICHD*n*_WORD0)

The first word of the Error Injection Channel Descriptor defines a left-justified mask field (CHKBIT_MASK) whose width is up to 8 bits. Each bit of CHKBIT_MASK specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified on read accesses. Successful writes to this field clear the corresponding error injection channel valid bit, EICHEN[EICH*n*EN].

Address: 0h base + 100h offset + (256d × i), where i=0d to 0d



EIM_EICHD*n*_WORD0 field descriptions

Field	Description
0–7 CHKBIT_MASK	Checkbit Mask This field defines a bit-mapped mask that specifies whether the corresponding bit of the checkbit bus from the target RAM should be inverted or remain unmodified. The width of the field for the channel is defined in the chip-specific EIM information. 0 The corresponding bit of the checkbit bus remains unmodified. 1 The corresponding bit of the checkbit bus is inverted.
8–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

78.3.4 Error Injection Channel Descriptor, Word1 (EIM_EICHD*n*_WORD1)

The second word of the Error Injection Channel Descriptor defines the bits in the mask corresponding to bytes 0–3 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. Successful writes to this field clear the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Address: 0h base + 104h offset + (256d × i), where i=0d to 0d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

EIM_EICHD*n*_WORD1 field descriptions

Field	Description
0–31 B0_3DATA_ MASK	Data Mask Bytes 0-3 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. For details about which bits in this field are implemented for the applicable channel and how the bits map to bytes 0-3 of the read data bus, see the chip-specific EIM information. 0 The corresponding bit of bytes 0-3 on the read data bus remains unmodified 1 The corresponding bit of bytes 0-3 on the read data bus is inverted.

78.3.5 Error Injection Channel Descriptor, Word2 (EIM_EICHD*n*_WORD2)

The third word of the Error Injection Channel Descriptor, when present, defines the bits in the mask corresponding to bytes 4–7 of the read data bus. Each bit specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified on read accesses. Successful writes to this field clear the corresponding error injection channel valid field, EICHEN[EICH*n*EN].

Address: 0h base + 108h offset + (256d × i), where i=0d to 0d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R W	B4_7DATA_MASK																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

EIM_EICHD*n*_WORD2 field descriptions

Field	Description
0–31 B4_7DATA_ MASK	Data Mask Bytes 4-7 This field defines a bit-mapped mask that specifies whether the corresponding bit of the read data bus from the target RAM should be inverted or remain unmodified. For details about which bits in this field are implemented for the applicable channel and how the bits map to bytes 4-7 of the read data bus, see the chip-specific EIM information. 0 The corresponding bit of bytes 4-7 on the read data bus remains unmodified. 1 The corresponding bit of bytes 4-7 on the read data bus is inverted.

78.4 Functional description

The EIM provides protection against accidental enabling and reconfiguration of the error injection function by enforcing a two-stage enablement mechanism. To properly enable the error injection mechanism for a channel:

- Write 1 to the EICHEN[EICH*n*EN] field, where *n* denotes the channel number.
- Write 1 to EIMCR[GEIEN].

NOTE

When the use case for a channel requires writing any EICHD*n*_WORD register, write the EICHD*n*_WORD register before executing the two-stage enablement mechanism. A successful write to any EICHD*n*_WORD register clears the corresponding EICHEN[EICH*n*EN] field.

The EIM supports 1 error injection channel. Each channel:

- is assigned to a single memory array interface.
- intercepts the assigned memory read data bus and checkbit bus and injects errors by inverting the value transmitted for selected bits on each bus line.

On a memory read access, the applicable EICHD*n*_WORD registers define which bits of the read data and/or checkbit bus to invert.

Figure 78-1 depicts the interception and override of a 64-bit read data bus and an 8-bit checkbit data bus for an example memory array.

78.4.1 Error injection scenarios

The EIM supports these cases of error injection:

- To generate a single-bit error, invert only 1 bit of the CHKBIT_MASK or DATA_MASK in the EICHD*n*_WORD registers.
- To generate a multi-bit error, invert only 2 bits of the CHKBIT_MASK or DATA_MASK in the EICHD*n*_WORD registers.

NOTE

An attempt to invert more than 2 bits in one operation might result in undefined behavior.

Chapter 79
Register Protection (REG_PROT)

79.1 Chip-specific REG PROT information

79.1.1 Register protection (REG_PROT) configuration

The following table lists the all of the protected registers.

Table 79-1. Protected registers

Module	Register	Reg offset	Protect size[1]	Description

1. 3 = 32 bit, 2 = 16 bit, and 1 = 8 bit

NOTE

Register protection is implemented considering 8bytes payload size for CAN_0 and CAN_2.

79.2 Overview

The Register Protection (REG_PROT) module offers a mechanism to protect defined memory-mapped address locations in a module under protection from being written. The address locations that can be protected are module-specific.

The protection module is located between the module under protection and the peripheral bridge (PBRIDGE/AIPS-Lite). This is shown in the following figure.

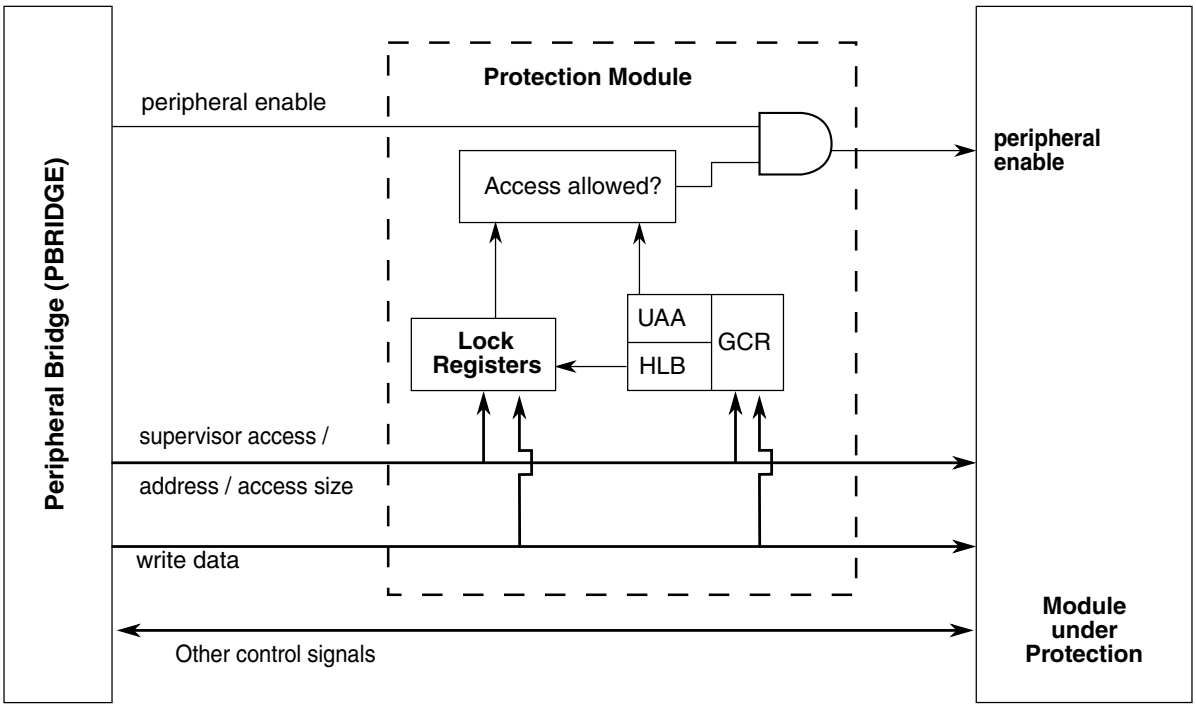

Figure 79-1. REG_PROT Block Diagram

79.3 Features

Register Protection includes these distinctive features:

- Restrict write accesses for the module under protection to supervisor mode only
- Lock registers for first 6 KB of memory-mapped address space
- Write to address mirror automatically sets corresponding lock bit
- Once configured lock bits can be protected from changes

79.4 Modes of operation

The Register Protection module is operable when the module under protection is operable.

79.5 External signal description

There are no external signals.

79.6 Memory map and register definition

This section provides a detailed description of the memory map of a module with register protection. The original 16 KB module memory space is divided into five areas as shown in the following figure.

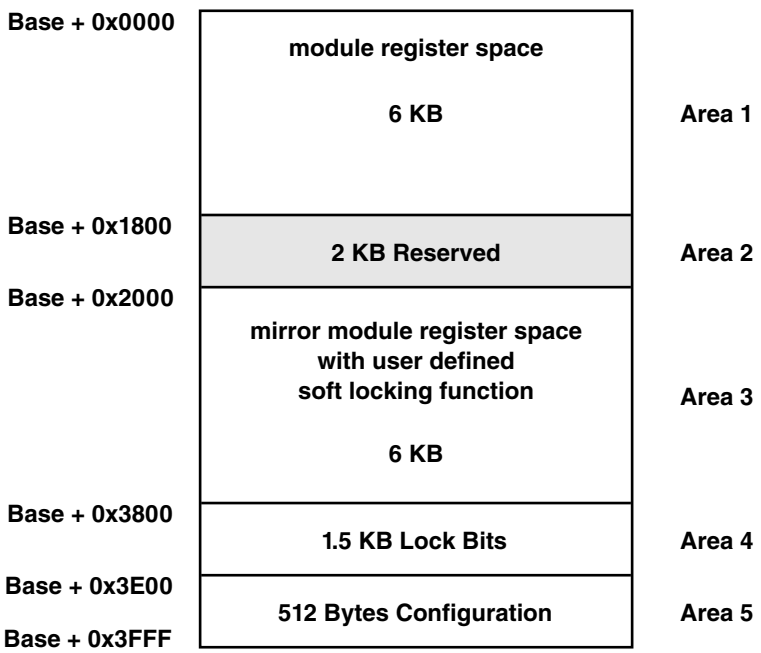

Figure 79-2. REG_PROT Memory Diagram

- Area 1 is 6 KB and holds the normal functional module registers and is transparent for all read/write operations.
- Area 2 is 2 KB starting at offset 0x1800 is a reserved area, which shall not be accessed.
- Area 3 is 6 KB, starting at offset 0x2000 and is a mirror of area 1. A read/write access to an offset 0x2000+X will read/write the register at offset X. However a write access to offset 0x2000+X will additionally set the optional Soft Lock Bits for this offset X in the same cycle as the register at offset X is written. This provides for an automatic write and lock operation. Not all registers in area 1 need to have protection defined by associated Soft Lock Bits. For unprotected registers at offset Y, accesses to offset 0x2000+Y will be identical to accesses at offset Y.

- Area 4 is 1.5 KB and holds the Soft Lock Bits, one bit per byte in area 1. The four Soft Lock Bits associated with one module register word are arranged at byte boundaries in the memory map. The Soft Lock Bit registers can be directly written using a bit mask.
- Area 5 is 512 bytes large and holds the configuration bits of the protection mode. There is one configuration hard lock bit per module that prevents all further modifications to the Soft Lock Bits and can only be cleared by a system reset once set. The other bits, if set, will allow user access to the protected module.

If any locked byte is accessed with a write transaction, a transfer error will be issued to the system and the write transaction will not be executed. This is true even if not all accessed bytes are locked.

Accessing unimplemented 32-bit registers in Areas 4 and 5 will result in a transfer error.

79.6.1 Memory map

Following is the memory map for a module which is protected via a REG_PROT module.

Table 79-2. Generic Protected Module Memory Map

Offset	Use
0x0000	Module Register 0 (MR0)
0x0001	Module Register 1 (MR1)
0x0002	Module Register 2 (MR2)
0x0003 - 0x17FF	Module Register 3 (MR3) - Module Register 6143(MR6143)
0x1800 - 0x1FFF	Reserved
0x2000	Module Register 0 (MR0) + Set Soft Lock Bit 0 (LMR0)
0x2001	Module Register 1 (MR1) + Set Soft Lock Bit 1 (LMR1)
0x2002 - 0x37FF	Module Register 2 (MR2) + Set Soft Lock Bit 2 (LMR2) - Module Register 6143 (MR6143) + Set Soft Lock Bit 6143 (LMR6143)
0x3800	Soft Lock Bit Register 0 (SLBR0): Soft Lock Bits 0-3
0x3801	Soft Lock Bit Register 1 (SLBR1): Soft Lock Bits 4-7
0x3802 - 0x3DFF	Soft Lock Bit Register 2 (SLBR2): Soft Lock Bits 8-11 -Soft Lock Bit Register 1535 (SLBR1535): Soft Lock Bits 6140-6143
0x3E00 - 0x3FFB	Reserved
0x3FFC	Global Configuration Register (GCR)

Note

Reserved registers in area #1 will be handled as specified in the protected module's documentation.

79.6.2 Register descriptions

This section describes in address order all the REG_PROT registers. Each description includes a standard register diagram with an associated figure number. Details of register bit and field function follow the register diagrams, in bit order.

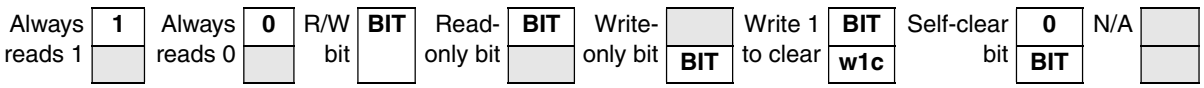

Figure 79-3. Register description

79.6.2.1 Module Registers (MR0-6143)

This is the lower 6 KB module memory space which holds all the functional registers of the module that is protected by the REG_PROT module.

79.6.2.2 Module register and set soft lock bit (LMR0-6143)

This is memory area #3 that provides mirrored access to the MR0-6143 registers with the side effect of setting Soft Lock Bits in case of a write access to a MR that is defined as protectable by the locking mechanism. Each MR is protectable by one associated bit in a SLBRn.SLBm, according to the mapping described in the Soft Lock Bit Register section.

79.7 Memory map and registers

REG_PROT memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
3800	Soft Lock Bit Register n (REG_PROT_SLBRn)	8	R/W	00h	79.7.1/3970
3FFC	Global Configuration Register (REG_PROT_GCR)	32	R/W	0000_0000h	79.7.2/3972

79.7.1 Soft Lock Bit Register *n* (REG_PROT_SLBRn)

The Soft Lock Bit Registers hold the Soft Lock Bits for the protected registers in memory area #1, which is the normal register address space of the protected module. Each SLB register has a four Soft Lock Bits (SLB0-SLB3), each of which controls write access to a byte in memory area #1. Each Soft Lock Bit also has a corresponding Write Enable bit in the same register that controls whether the Soft Lock Bit can be written. The following table shows the mapping between the Soft Lock Bits to the bytes in memory area #1.

Table 79-3. Soft Lock Bits vs. Protected Address

Soft Lock Bit	Protected address
SLBR0.SLB0	MR0
SLBR0.SLB1	MR1
SLBR0.SLB2	MR2
SLBR0.SLB3	MR3
SLBR1.SLB0	MR4
SLBR1.SLB1	MR5
SLBR1.SLB2	MR6
SLBR1.SLB3	MR7
SLBR2.SLB0	MR8
...	...

NOTE

- As many as 1536 Soft Lock Bit Registers (SLBRn) may be implemented, depending on the number of protected module register bytes.
- Access in User Mode is read-only; in Supervisor Mode access is read/write.

Address: 0h base + 3800h offset = 3800h

Bit	0	1	2	3	4	5	6	7
Read	0	0	0	0	SLB0	SLB1	SLB2	SLB3
Write	WE0	WE1	WE2	WE3				
Reset	0	0	0	0	0	0	0	0

REG_PROT_SLBRn field descriptions

Field	Description
0 WE0	Write Enable Bits for Soft Lock Bits (SLB) WE0 enables writing to SLB0

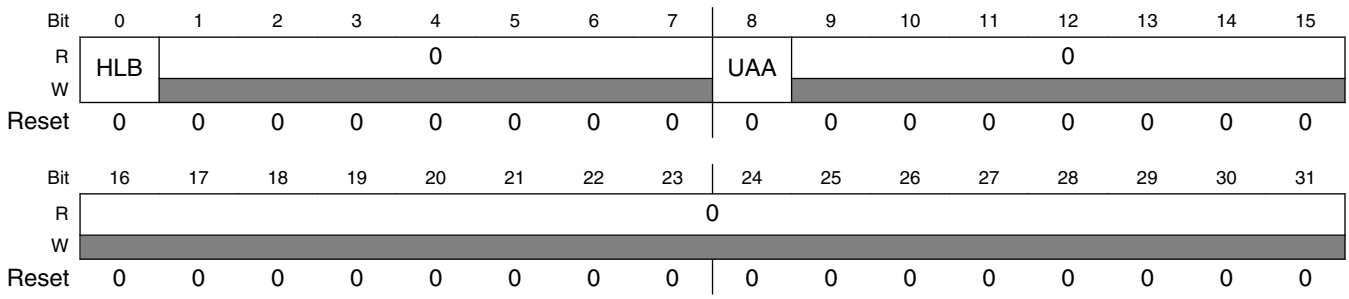
Table continues on the next page...

REG_PROT_SLBRn field descriptions (continued)

Field	Description
	1 Value is written to SLB 0 SLB is not modified
1 WE1	Write Enable Bits for Soft Lock Bits (SLB) WE1 enables writing to SLB1 1 Value is written to SLB 0 SLB is not modified
2 WE2	Write Enable Bits for Soft Lock Bits (SLB) WE2 enables writing to SLB2 1 Value is written to SLB 0 SLB is not modified
3 WE3	Write Enable Bits for Soft Lock Bits (SLB) WE3 enables writing to SLB3 1 Value is written to SLB 0 SLB is not modified
4 SLB0	Soft Lock Bits for one MRn register SLB0 can block accesses to MR[n *4 + 0] 1 Associated MRn byte is locked against write accesses 0 Associated MRn byte is unprotected and writable
5 SLB1	Soft Lock Bits for one MRn register SLB1 can block accesses to MR[n *4 + 1] 1 Associated MRn byte is locked against write accesses 0 Associated MRn byte is unprotected and writable
6 SLB2	Soft Lock Bits for one MRn register SLB2 can block accesses to MR[n *4 + 2] 1 Associated MRn byte is locked against write accesses 0 Associated MRn byte is unprotected and writable
7 SLB3	Soft Lock Bits for one MRn register SLB3 can block accesses to MR[n *4 + 3] 1 Associated MRn byte is locked against write accesses 0 Associated MRn byte is unprotected and writable

79.7.2 Global Configuration Register (REG_PROT_GCR)

Address: 0h base + 3FFCh offset = 3FFCh



REG_PROT_GCR field descriptions

Field	Description
0 HLB	Hard Lock Bit This register cannot be cleared once it is set by software. It can only be cleared by a system reset. **NOTE:** Access in User Mode is read/write if UAA is set to 1 otherwise it is read-only; in Supervisor Mode access is read/write. 1 All SLB bits are write protected and can not be modified. 0 All SLB bits are accessible and can be modified.
1–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 UAA	User Access Allowed. Controls the User and Supervisor mode access to registers of the module under protection, as well as the REG_PROT_GCR and REG_PROT_SLBR*n*. 1 The registers in the module under protection can be accessed in the mode defined for the module registers without any additional restrictions. 0 The registers in the module under protection can be written in supervisor mode only. All write accesses in non-supervisor mode are not executed and a transfer error is issued. This access restriction is in addition to any access restrictions imposed by the protected IP module.
9–31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

79.8 Functional description

The following sections describe the functional characteristics of the Register Protection module.

79.8.1 General

This module provides a generic register (address) write-protection mechanism. The protection size can be:

- 32-bit (address == multiples of 4)
- 16-bit (address == multiples of 2)
- 8-bit (address == multiples of 1)

Which addresses are protected and the protection size depends on the SoC and/or module.

For all addresses (peripheral registers) that are protected there are SLBRn.SLBm bits that specify whether the address is locked. When an address is locked it can only be read but not written in any mode (supervisor/normal). If an address is unprotected the corresponding SLBRn.SLBm bit is always 0b0 no matter what software is writing to.

79.8.2 Change lock settings

To change the setting whether an address is locked or unlocked the corresponding SLBRn.SLBm bit needs to be changed. This can be done using the following methods:

- Modify the SLBRn.SLBm directly by writing to area #4
- Set the SLBRn.SLBm bit(s) by writing to the mirror module space (area #3)

Both methods are explained in the following sections.

79.8.2.1 Change lock settings directly via Area #4

In memory area #4 the lock bits are located. They can be modified by writing to them. Each SLBRn.SLBm bit has a mask bit SLBRn.WEm which protects it from being modified. This masking makes clear-modify-write operations unnecessary.

The following figure shows two modification examples. In the left example there is a write access to the SLBRn register specifying a mask value which allows modification of all SLBRn.SLBm bits. The example on the right specifies a mask which only allows modification of the bits SLBRn.SLB[3:1].

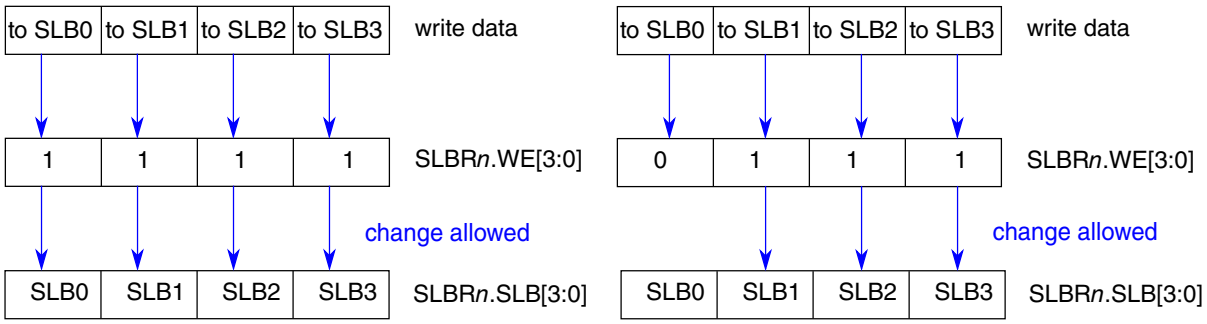


Figure 79-4. Change lock settings directly via Area #4

The previous figure shows four registers that can be protected 8-bit wise. The following figures show registers with 16- and 32-bit protection respectively:

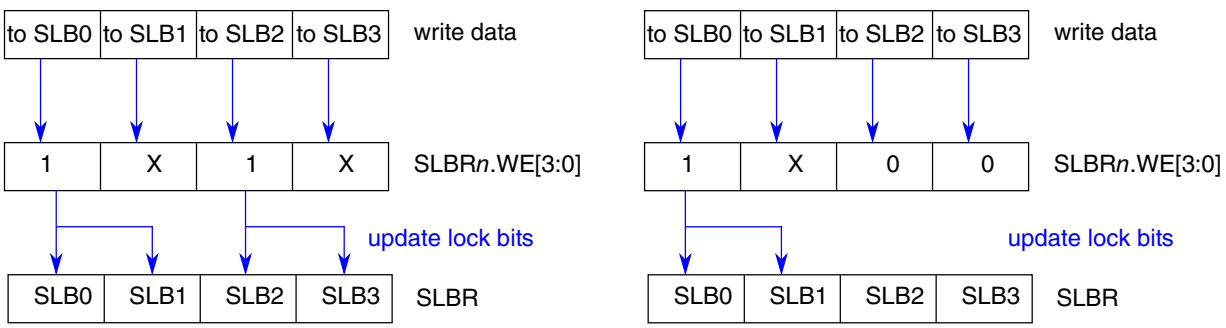

Figure 79-5. Change lock settings for 16-bit protected addresses

On the right side of the previous figure it is shown that the data written to SLBRn.SLB[0] is automatically written to SLBRn.SLB[1] also. This is done as the address reflected by SLBRn.SLB[0] is protected 16-bit wise. Note that in this case the write enable SLBRn.WE[0] must be set while SLBRn.WE[1] does not matter. As the enable bits SLBRn.WE[3:2] are cleared the lock bits SLBRn.SLB[3:2] remain unchanged.

In the example on the left side of the previous figure the data written to SLBRn.SLB[0] is mirrored to SLBRn.SLB[1] and the data written to SLBRn.SLB[2] is mirrored to SLBRn.SLB[3] as for both registers the write enables are set.

The next figure shows a 32-bit wise protected register. When SLBRn.WE[0] is set the data written to SLBRn.SLB[0] is automatically written to SLBRn.SLB[3:1] also. Otherwise SLBRn.SLB[3:0] remains unchanged.

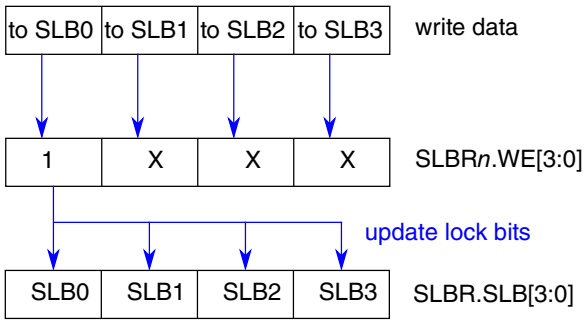

Figure 79-6. Change lock settings for 32-bit protected addresses

The following figure shows a mixed protection size configuration:

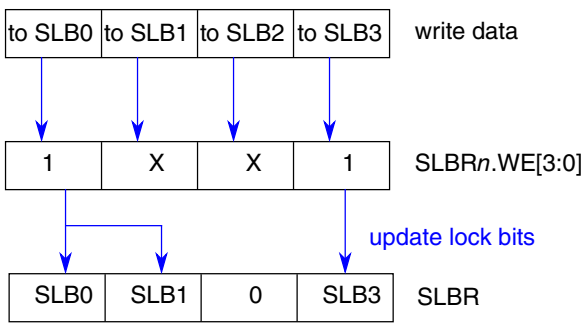

Figure 79-7. Change lock settings for mixed protection

The data written to SLBRn.SLB[0] is mirrored to SLBRn.SLB[1] as the corresponding register is 16-bit protected. The data written to SLBRn.SLB[2] is blocked as the corresponding register is unprotected. The data written to SLBRn.SLB[3] is written to SLBRn.SLB[3].

79.8.2.2 Enable locking via mirror module space (Area #3)

It is possible to enable locking for a register after writing to it. To do so the mirrored module address space must be used. For example:

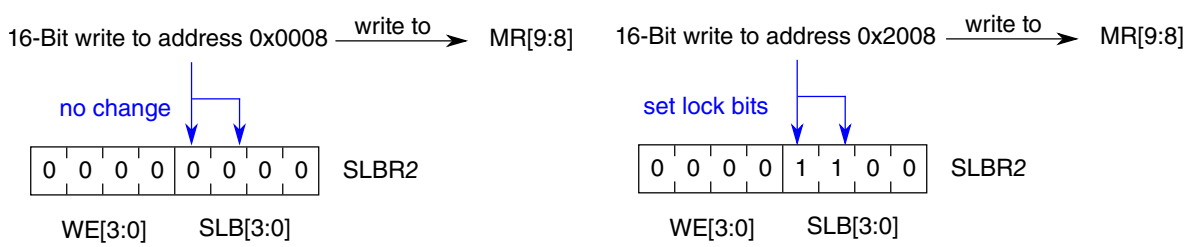

Figure 79-8. Enable Locking Via Mirror Module Space (Area #3)

When writing to address 0x0008 the registers MR9 and MR8 in the protected module are updated. The corresponding lock bits remain unchanged (see the left part of Figure 79-5).

When writing to address 0x2008 the registers MR9 and MR8 in the protected module are updated. The corresponding lock bits SLBR2.SLB[1:0] are set while the lock bits SLBR2.SLB[3:2] remain unchanged (right part of Figure 79-5).

The following figure shows an example where some addresses are protected and some are not:

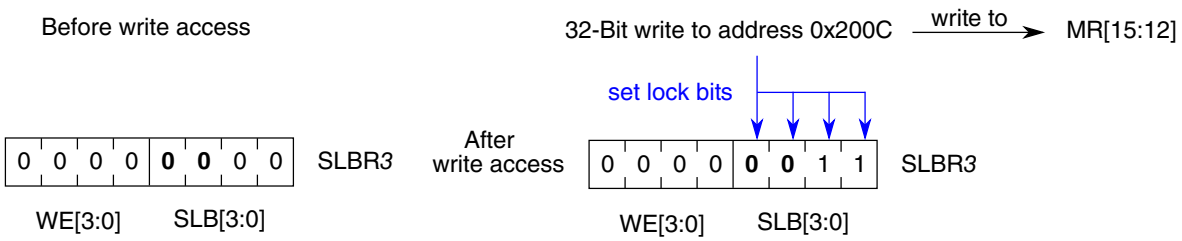

Figure 79-9. Enable locking for protected and unprotected addresses

In the previous figure addresses 0x0C and 0x0D are unprotected. Therefore their corresponding lock bits SLBR3.SLB[1:0] are always 0b0 (shown in bold). When doing a 32-bit write access to address 0x200C only lock bits SLBR3.SLB[3:2] are set while bits SLBR3.SLB[1:0] stay 0b0.

Note

Lock bits can only be set via writes to the mirror module space. Reads from the mirror module space will not change the lock bits.

79.8.2.3 Write protection for locking bits

Changing the locking bits through any of the procedures mentioned in Change lock settings directly via Area #4 and Enable locking via mirror module space (Area #3) is only possible as long as the bit GCR.HLB is cleared. Once this bit is set the locking bits can no longer be modified until there is a system reset.

79.8.3 Access errors

The protection module generates transfer errors under several circumstances. For the area definition refer to Figure 79-2

1. If accessing area #1 or area #3, the protection module will pass on any access error from the underlying Module under Protection.
2. If user mode is not allowed, user writes to all areas will assert a transfer error and the writes will be blocked.

3. If accessing the reserved area #2, a transfer error will be asserted.
4. If accessing unimplemented 32-bit registers in area #4 and area #5 a transfer error will be asserted.
5. If writing to a register in area #1 and area #3 with Soft Lock Bit set for any of the affected bytes a transfer error is asserted and the write will be blocked. Also the complete write operation to non-protected bytes in this word is ignored.
6. If writing to a Soft Lock Register in area #4 with the Hard Lock Bit being set a transfer error is asserted.
7. Any write operation in any access mode to area #3 while Hard Lock Bit GCR.HLB is set

Chapter 80
Password and Device Security Module (PASS)

80.1 Chip-specific PASS information

80.1.1 Chip-specific Password and Device Security Module (PASS) information

The PASS module is used to implement password-based read and write protection for flash blocks. Up to four levels of password protection can be implemented for each flash block.

NOTE

The registers discussed in this section are initialized via DCF records, so the reset values depend on user settings.

See DCF tables for detailed information about DCF clients for the PASS (Excel file) attached to this document.

Each password group defined in the DCF records has a set of four LOCK*n* registers association with it—PASS_LOCK*n*_PG*n*. The bits of these registers are associated with specific flash blocks. The mapping is shown in the Flash Block Assignment tables of the device.

See the Flash block assignment table (Excel file) attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the Excel file to open it and select the PASS LOCK Reg tab.

NOTE

Users should ensure that no program or erase operations are occurring on any memory partitions shared with the UTEST block before initiating a password challenge. This can be monitored through C55FMC_MCR[PGM] and C55FMC_MCR[ERS] fields in C55FMC memory map.

80.1.2 Flash Test Mode protection

In Failure Analysis Lifecycle, Flash Test Mode entry is protected by combination of below two inputs.

1. DCF_FTMP (Refer to attached DCF Sheet)
2. TEST MODE ENABLE_DCF_CLIENT

Table 80-1. Flash Test Mode protection

DCF_FTMP	TEST MODE ENABLE DCF CLIENT	Flash TEST MODE ACCESS
0	Don't care	YES (NO Test mode enable PASSWORD REQUIRED)
1	0	Test Mode not enabled.
1	1	YES (Test mode enable PASSWORD REQUIRED)

80.2 Introduction

80.2.1 Overview

The Password and device security (PASS) module shown in the following figure, receives password challenges and determines their validity. It also maintains the device security and access states.

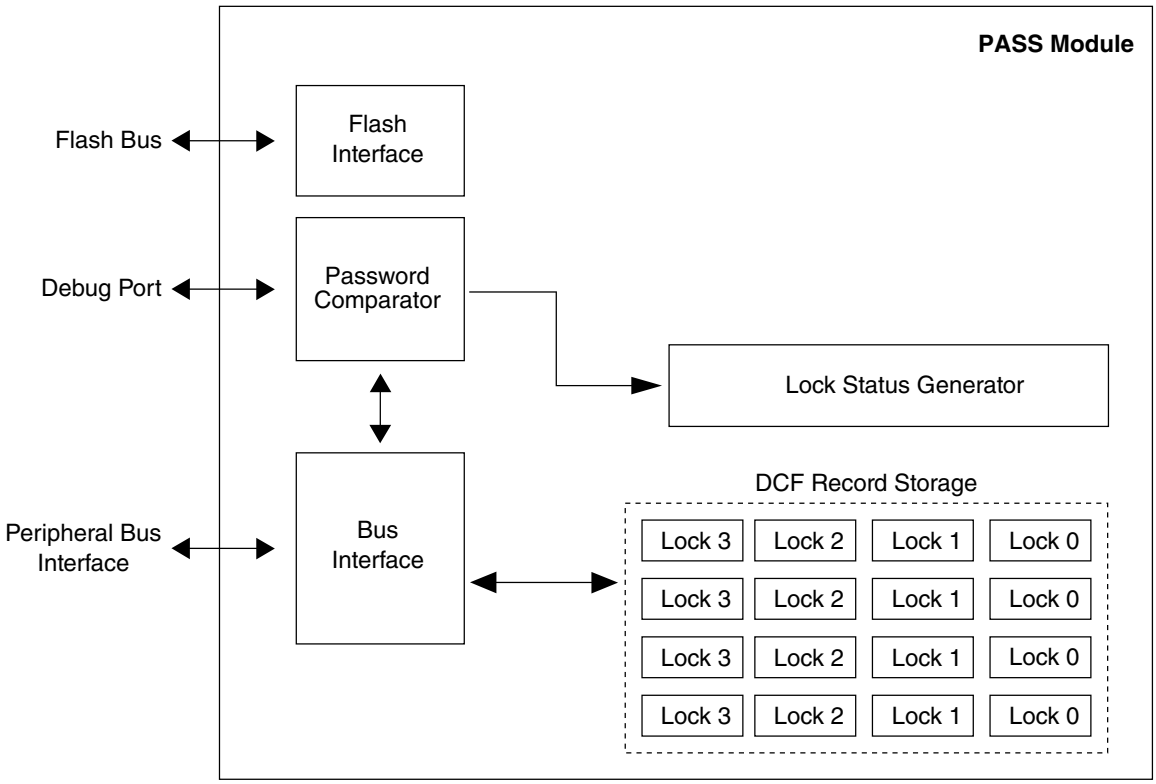

Figure 80-1. PASS module block diagram

80.2.2 Features

The PASS includes these distinctive features:

- Life Cycle status
- Password comparison
- JTAG password comparison
- Test mode enable Configuration and Password Comparison
- Flash read, write, and erase control

80.2.3 Modes of operation

The PASS operates identically in all system modes.

80.3 Memory map and register definition

This section provides a detailed description of all memory-mapped registers and DCF clients in the PASS.

Where a DCF client is listed, the reset value of that register may automatically be pre-loaded during reset based on the data stored in DCF Records in flash UTEST region.

The following table shows the memory map for the PASS. Note that all addresses are offsets; the absolute address for registers may be calculated by adding the specified offset to the base address of the PASS. The address of the DCF client is local to the PASS module and must be qualified with the appropriate Client Select (CS[14:0]) for the PASS module, as defined in the DCF Record Section of the Reference Manual.

NOTE

Non-implemented registers generate bus aborts if enabled.

The following registers are available in the PASS. The shaded bits are reserved for future use. For future compatibility, only write '0' to these bits; they always read '0'.

PASS memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Life Cycle Status Register (PASS_LCSTAT)	32	R	See section	80.3.1/3983

80.3.1 Life Cycle Status Register (PASS_LCSTAT)

The Life Cycle Status Register reflects the production status and DCF Censorship client status of the device. It is possible to mature the device (move the device life cycle forward), but never to revert the life cycle to an earlier state.

The reset value of the LCSTAT register LIFE field derives from an external life cycle management module (like SSCM). It is a 3-bit life cycle. This register simply displays the life cycle input from external blocks.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	CNS	JUN	TME	0												
W																
Reset	*	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0													LIFE		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	*	*	*

* Notes:
- LIFE field: Reset value is the Life Cycle of the device, and is unaffected by reset.
- CNS field: Reset value depends on the Censorship DCF client

PASS_LCSTAT field descriptions

Field	Description
0 CNS	This field indicates whether the DCF Censorship client has been written with a DCF record to 0x55AA or if the DCF Censorship client contains any other value than 0x55AA. The bit can be set (or cleared) via DCF Record in UTest Flash. **NOTE:** If no DCF record has been written to affect the value of the CNS bit, its reset value will be 1. 1 DCF Censorship Client value is anything other than 0x55AA. 0 DCF Censorship client value is 0x55AA.
1 JUN	This field indicates whether the device has been temporarily uncensored. Successful transmission of the JTAG password sets this bit to '1', otherwise it will be 0. (In life cycle FA, the JUN bit will always be 0.) Unsuccessful transmission clears this bit.
2 TME	Test Mode enable. This field indicates whether the test mode DCF Client is set to enable test mode in FA. 0 Test mode cannot be enabled 1 Test mode can be enabled with test mode password
3–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–31 LIFE	The life cycle setting is manipulated externally (SSCM). Pass displays a 3-bit input life cycle 000 Failure Analysis 001 Reserved 010 OEM Production 011 Customer Delivery 100 Reserved 101 Reserved 110 MCU Production 111 In Field

80.3.2 Challenge Selector Register (PASS_CHSEL)

This register determines which password group is challenged via the Challenge Input Register.

When the Master Only (MO) bit of the PASS_LOCK3_PGn register is set, only the master that unlocked access to the passgroup settings will be able to access these registers. The CMST field of the Challenge Status Register will reflect the locking master. When the Master Only (MO) bit of the PASS_LOCK3_PGn register is not set, the passgroup settings can be accessed by any master.

When a master writes this register, its ID sets the CMST field of the Challenge Status register.

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

PASS_CHSEL field descriptions

Field	Description
0–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30–31 GRP	Password Group to unlock 00 Password Group 0 01 Password Group 1 10 Password Group 2 11 Password Group 3

80.3.3 Challenge Status Register (PASS_CSTAT)

This register provides status information for the password challenge.

Only the master shown in this register can access the CINn registers - access by other masters result in a comparison fail regardless of the values written.

Address: 0h base + 10h offset = 10h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

PASS_CSTAT field descriptions

Field	Description
0–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–31 CMST	ID of the master which has last written the CHSEL register

80.3.4 Challenge Input Register (PASS_CIN*n*)

This register is used to provide the Challenge word *n* for a password group as selected by the Challenge Selector Register.

After programming the Challenge Selector Register, the password challenge needs to be written with eight 32-bit writes from CIN0 to CIN7 in that order. The most significant 32 bits of the password challenge must be written to CIN0. Once CIN7 is written, the password is compared. The write access only completes after the comparison has been executed. In case of a successful password comparison, the PASS module stores the ID of the master which has written CIN0 to CIN7 in the PASS_LOCK3_PGn register of the selected password group, as well as clears the PGL bit of that register.

All accesses to these registers need to be made by the bus master that wrote the CHSEL register previously. If another master writes any of the CIN registers before the original master has written CIN7, the comparison fails.

Address: 0h base + 20h offset + (4d × i), where i=0d to 7d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

PASS_CIN*n* field descriptions

Field	Description
0–31 PW32	32 bits of the 256-bit password challenge. Only 32-bit writes may be used.

80.3.5 Password Group *n* - Lock 0 Status Register (PASS_LOCK0_PG*n*)

Each Password Group has one Lock 0 Status register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked the register becomes writable. For additional details of the LOCK bits, refer to the Flash memory description.

The LOCK bits do not come into effect before the life cycle has matured to *OEM Production* or older.

LOCK0_PG*n* register functions are as shown in this section.

NOTE

Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during functional reset. The default value before any DCF record is written is '1', indicating that a block is locked.

During the Customer Delivery life cycle, the user must program a valid password or a DCF record that writes to this register to unprotect the UTEST for each password group in order to prevent permanent and irreversible locking of Flash blocks.

Warning

Failure to program valid passwords or DCF records for all password groups before the life cycle matures to OEM Production renders the part unusable.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible. However, unless the life cycle is OEM Production or older, the Flash blocks are always unlocked, regardless of the values in the password groups.

Address: 0h base + 100h offset + (16d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*

* Notes:

- MIDLOCK field: For each implemented bit of this field, if no DCF records have been written to change the lock state, the bit will reset to ‘1’.

- LOWLOCK field: For each implemented bit of this field, if no DCF records have been written to change the lock state, the bit will reset to ‘1’.
- TSLOCK field: If no DCF records have been written to change the TS bit state, the bit will reset to ‘1’.

PASS_LOCK0_PG*n* field descriptions

Field	Description
0 TSLOCK	UTest NVM Lock. This bit is used to lock the UTest NVM block from programs (erase protection not needed since UTest NVM is OTP and not erasable).
1 Reserved	This field is reserved.
2–15 LOWLOCK	Low Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.
16–31 MIDLOCK	Mid Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

80.3.6 Password Group *n* - Lock 1 Status Register (PASS_LOCK1_PG*n*)

Each Password Group has one Lock 1 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked, the register becomes writable . For additional details of the LOCK bits, refer to the Flash description.

The LOCK bits do not come into effect before the life cycle matures to OEM Production or older.

LOCK1_PG*n* register functions are as shown in this section.

NOTE

Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during functional reset . The default value before any DCF record is written is '1', which indicates a block is locked. If no DCF records have been written to change the lock state, the bits will reset to '1'.

During the Customer Delivery life cycle, the user must program a valid password or a DCF record that writes this register to unprotect the UTEST for each password group to prevent permanent and irreversible locking of Flash blocks.

CAUTION

Failure to program valid passwords or DCF records for all password groups before the life cycle matures to OEM Production renders the part unusable. However, additional DCF Records can be written to UTEST to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible. However, unless the life cycle is OEM Production or older, the Flash blocks are always unlocked, regardless of the values in the password groups.

Address: 0h base + 104h offset + (16d × i), where i=0d to 3d

* Notes:
- HIGHLOCK field: For each implemented bit of this field, if no DCF records have been written to change the lock state, the bit will reset to ‘1’.

PASS_LOCK1_PG*n* field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–31 HIGHLOCK	High Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

80.3.7 Password Group *n* - Lock 2 Status Register (PASS_LOCK2_PG*n*)

Each Password Group has one Lock 2 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked, the register becomes writable . For additional details of the LOCK bits, refer to the Flash description.

The LOCK bits do not come into effect before the life cycle is matured to OEM Production or older.

NOTE

Lock registers can only be accessed with 32-bit operations.

LOCK2_PG*n* register functions are as shown in this section.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during functional reset . The default value before any DCF record is written is ‘1’, which indicates a block is locked.

During the Customer Delivery life cycle, the user must program a valid password or a DCF record that writes this register to unprotect the UTEST for each password group in order to prevent permanent and irreversible locking of Flash blocks.

Warning

Failure to program valid passwords or DCF records for all password groups before the life cycle matures to OEM Production renders the part unusable. However, additional DCF Records can be written to UTEST to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible. However, unless the life cycle is OEM Production or older, the Flash blocks are always unlocked, regardless of the values in the password groups.

Address: 0h base + 108h offset + (16d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

* Notes:

- L_256LCK field: For each implemented bit of this field, if no DCF records have been written to change the lock state, the bit resets to ‘1’.

PASS_LOCK2_PG*n* field descriptions

Field	Description
0–31 L_256LCK	Lower 256KByte Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

80.3.8 Password Group *n* - Lock 3 Status Register (PASS_LOCK3_PG*n*)

Each Password Group has one Lock 3 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked, the register becomes writable.

The LOCK bits do not come into effect before the life cycle matures to OEM Production or older.

LOCK3_PGn register functions are as shown in this section.

NOTE

Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during functional reset . The default value before any DCF record is written is '1', which indicates a block is locked.

During the Customer Delivery life cycle, the user must program a valid password or a DCF record that writes this register to unprotect the UTEST for each password group in order to prevent permanent and irreversible locking of Flash blocks.

Warning

Failure to program valid passwords or DCF records for all password groups before the life cycle matures to OEM Production renders the part unusable. However, additional DCF Records can be written to UTEST to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible. However, unless the life cycle is OEM Production or older, the Flash blocks are always unlocked, regardless of the values in the password groups.

Once a censored device enters the Failure Analysis life cycle, read protection is active regardless whether the system is in debug mode or not. It is still possible to unlock Flash regions with the correct passwords, however. Flash Utest region controlled by LOCK3[0] is read unlocked in Failure Analysis life cycle.

NOTE

Do not toggle DBL and RLx bits with the same write command. Use one instruction to program the DBL bit and a separate instruction to toggle the RLx bits.

Address: 0h base + 10Ch offset + (16d × i), where i=0d to 3d

* Notes:

- U_256LCK field: For each implemented bit of this field, if no DCF records have been written to change the lock state, the bit will reset to '1'.
- RL0 field: If no DCF records have been written to change the RL0 bit lock state, the bit will reset to a logic 1. This Flash block region is always readable if the life cycle is Customer Delivery or earlier. To determine if this region is readable for Life Cycle states later than Customer Delivery, consult the Flash Memory Read Protection Truth Table.
- RL1 field: If no DCF records have been written to change the RL1 bit lock state, the bit will reset to a logic 1. This Flash block region is always readable if the life cycle is Customer Delivery or earlier. To determine if this region is readable for Life Cycle states later than Customer Delivery, consult the Flash Memory Read Protection Truth Table.
- RL2 field: If no DCF records have been written to change the RL2 bit lock state, the bit will reset to a logic 1. This Flash block region is always readable if the life cycle is Customer Delivery or earlier. To determine if this region is readable for Life Cycle states later than Customer Delivery, consult the Flash Memory Read Protection Truth Table.
- RL3 field: If no DCF records have been written to change the RL3 bit lock state, the bit will reset to a logic 1. This Flash block region is always readable if the life cycle is Customer Delivery or earlier. To determine if this region is readable for Life Cycle states later than Customer Delivery, consult the Flash Memory Read Protection Truth Table.
- RL4 field: If no DCF records have been written to change the RL4 bit lock state, the bit will reset to a logic 1. This Flash block region is always readable if the life cycle is Customer Delivery or earlier. To determine if this region is readable for Life Cycle states later than Customer Delivery, consult the Flash Memory Read Protection Truth Table.
- MO field: If no DCF records have been written to change the MO bit lock state, the bit will reset to ‘1’.
- DBL field: If no DCF records have been written to change the DBL bit lock state, the bit will reset to ‘1’.
- PGL field: Reset value depends on life cycle. If life cycle is Customer Delivery or earlier, the value will be 0, otherwise 1.

PASS_LOCK3_PG*n* field descriptions

Field	Description
0 PGL	Password Group Lock. This bit may be set in software to lock the password group, when the device is older than Customer Delivery. Before that the value of the bit is always 0. This bit is only updatable from SW path. It cannot be updated from DCF load from Flash. This bit would be automatically locked once Flash Scanning is finished after functional reset. This bit can be cleared by writing a valid password to the Password Challenge Input Registers. 0 Password group registers are unlocked. All four registers in the Password group may be read and written without restriction. 1 Password group registers are locked. Writes to the password group registers have no effect. Read accesses work normally. (If life cycle is Customer Delivery or earlier, this bit has no effect and the registers are always unlocked.)
1 DBL	Debug Interface Lock. The default value of this bit would be '1' if not updated from flash. At power on, this bit would be updated from DCF records in flash. This bit cannot be updated from FLASH after first functional reset. After first functional reset, it can only be updated by writing to it once the passgroup has been unlocked via the PASS Password challenge mechanism.

Table continues on the next page...

PASS_LOCK3_PG*n* field descriptions (continued)

Field	Description
	0 Debug interface is unlocked. Accessed to all JTAG clients is allowed 1 Debug interface is locked. Only access to JTAG password challenge register is possible. Access to all other JTAG clients is blocked
2 MO	Master Only. 0 All masters can modify the passgroup settings if PGL is cleared 1 Only the Master which unlocked the passgroup can change the passgroup settings
3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–7 MSTR	Master Access. Only the Master with this matching master ID can change the passgroup settings. This field is loaded with the ID of the master which unlocked the passgroup once the correct password is provided.
8–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 RL4	Read Lock Regison 4 lock bit. The default value of this bit would be '1' if not updated from flash. At power on, this bit would be updated from records loaded in flash. This bit cannot be updated from FLASH after first functional reset. After first functional reset, It can only be updated by Test Access Port or Through PASS Password challange mechanism. 0 Region 4 is not protected. 1 Region 4 is protected.
12 RL3	Region 3 is protected. The default value of this bit would be '1' if not updated from flash. At power on, this bit would be updated from records loaded in flash. This bit cannot be updated from FLASH after first functional reset. After first functional reset, It can only be updated by Test Access Port or Through PASS Password challange mechanism. 0 Region 3 is not protected. 1 Region 3 is protected.
13 RL2	Region 2 is protected. The default value of this bit would be '1' if not updated from flash. At power on, this bit would be updated from records loaded in flash. This bit cannot be updated from FLASH after first functional reset. After first functional reset, It can only be updated by Test Access Port or Through PASS Password challange mechanism. 0 Region 2 is not protected. 1 Region 2 is protected.
14 RL1	Region 1 is protected. The default value of this bit would be '1' if not updated from flash. At power on, this bit would be updated from records loaded in flash. This bit cannot be updated from FLASH after first functional reset. After first functional reset, It can only be updated by Test Access Port or Through PASS Password challange mechanism. 0 Region 1 is not protected. 1 Region 1 is protected.
15 RL0	Region 0 is protected.

Table continues on the next page...

PASS_LOCK3_PG*n* field descriptions (continued)

Field	Description
	The default value of this bit would be '1' if not updated from flash. At power on, this bit would be updated from records loaded in flash. This bit cannot be updated from FLASH after first functional reset. After first functional reset, It can only be updated by Test Access Port or Through PASS Password challange mechanism. 0 Region 0 is not protected. 1 Region 0 is protected.
16–31 U_256LCK	Upper 256 KB Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

80.4 DCF clients

The following table shows the DCF clients for the PASS.

Where a DCF client is listed, the reset value of that register may automatically be pre-loaded during reset based on the data stored in DCF Records in Flash UTEST region.

The address of the DCF client is local to the PASS module and must be qualified with the appropriate Client Select (CS[14:0]) for the PASS module, as defined in the DCF Record Section of the Reference Manual or in DCF sheet attached to this document.

Table 80-2. PASS DCF clients

Offset	Register	Access	Reset Value	DCF Client Address (ADDR[14:0])	Section
Censorship					
None	Censorship	None	0x0000_0000	0x00B0	Censorship
Test mode enable					
None	Test mode enable	None	0x0000_0001	0x00E0	Test mode enable DCF Client

80.4.1 Censorship

Censorship is a DCF client that is *not* accessible by software. It is automatically pre-loaded during reset with data stored in DCF Record format in the Flash UTEST region.

80.4.2 Test mode enable DCF Client

This DCF client is used to configure the password protected Test mode enable feature. See Test mode enable for details.

The Test mode DCF Client is not directly readable in software, but the state of the Test mode bit can be read in the LCSTAT register (Life Cycle Status Register (PASS_LCSTAT)).

80.5 Functional description

The primary purpose of the PASS is to provide fine-grained access control to the Flash and debugger interface. It utilizes the DCF mechanism, as described in the SSCM section.

80.5.1 Censorship

Censorship is the overall control that enables and disables two independent security features: Debug Interface access and flash memory read protection.

The Debug Interface access is controlled by the CNS and LIFE bits of the LCSTAT register (Life Cycle Status Register (PASS_LCSTAT)) according to the Debug Interface Access truth table. The flash memory read protection is also controlled by the CNS and LIFE bits of the LCSTAT register according to the Flash memory read protection truth table.

The CNS bit is set or cleared by executing a DCF record that writes to the Censorship DCF client (See Censorship). The LIFE bits of the LCSTAT register are controlled by the SSCM using user programmed values from specific locations in the UTEST flash.

80.5.2 Debug Interface Access

The debug interface is fully enabled in Customer Delivery life cycle. But from OEM Production life cycle, it can be blocked using censorship and unlocked by either entering a 256 bits password via JTAG or by software clearing the DBL bit the PASS_LOCK3 registers (See Password Group *n* - Lock 3 Status Register (PASS_LOCK3_PG*n*)). Both these debug enabling options are further conditioned by life cycle.

The table below describes all options for enabling/blocking Debug Interface access

Table 80-4. Debug Interface Enable Truth Table

Input Conditions				Outcome
Lifecycle[1]	**Censorship**	**Debug Enable (LOCK3[DBL] bit)**	**JTAG Password**	**Debug Interface Enable**
Customer Delivery	Don't Care	Don't Care	Don't Care	Enabled
OEM Production	Not censored	Don't Care	Don't Care	Enabled
	Censored	Unlocked (DBL=0)	Don't Care	Enabled
		Locked (DBL=1)	Matched	Enabled
			Not Matched	Blocked
In Field	Not censored	Don't Care	Don't Care	Enabled
	Censored	Unlocked (DBL=0)	Don't Care	Enabled
		Locked (DBL=1)	Matched	Enabled
			Not Matched	Blocked
Failure Analysis	Don't Care	Don't Care	Don't Care	Enabled

1. Life cycle is governed by life cycle management module (for, example SSCM)

80.5.2.1 JTAG Password Challenge

To enable the Debug Interface Access, the JTAG password challenge register in the JTAGC, can be written by an external tool. If that password matches the JTAG password stored in UTEST flash, Debug Interface Access is enabled. The password matching is done only after the chip has come out of reset PHASE3. The Debug Interface Access stays enabled until the next destructive reset.

80.5.3 Flash Memory Read Protection

Flash Memory Read Protection is a security feature that can selectively make regions of the flash memory unreadable. Any attempt to read a region of flash that is read protected results in the read access terminating with a transfer error. This is consistent for all bus masters including debug bus masters.

The assertion of flash memory region read protection is controlled by Life Cycle, Censorship and whether the Debug Interface access is enabled or blocked. The Flash memory read protection truth table describes the combination of conditions that drive Flash Memory Read Protection.

The intention of the feature is to protect the contents of the flash from being read. The flash memory is readable in normal operation, allowing the application to run, but becomes read protected when a Debug tool is attached and enabled (JTAG password or LOCK3[DBL] bit).

The flash memory is also read protected when the life cycle status is Failure Analysis. This life cycle is used for a module field failure, where the device is returned for failure analysis. This protection prevents the contents of the flash memory from being read.

The flash memory is divided into a number of Regions (3 to 5 depending on the device). The assignment of the regions is defined in the device reference manual.

Table 80-5. Flash Memory Read Protection Truth Table

INPUTS			OUTPUTS	
Lifecycle	**Censorship**	**Lock3[RLx]**	**Read Protected RL[0] (UTEST)**	**Read Protected RL[4:1] (Other Regions)**
Customer Delivery	Don't Care	Don't Care	Readable	Readable
OEM Production / IN Field	Uncensored	Don't Care	Readable	Readable
	Censored	Locked (1)	Read Blocked	Read Blocked
		Unlocked (0)	Readable	Readable
Failure Analysis	Uncensored	Don't Care	Readable	Readable
	Censored	Locked (1)	Readable	Read Blocked
		Locked (0)	Readable	Readable

80.5.4 Flash Memory Write and Erase Protection

This section describes write and erase permissions for flash memory. From Power ON to SSCM Done, all regions of flash memory are in locked state. After Power ON, SSCM scans flash memory for valid DCF records. These DCF records carry program and erase protection settings for flash memory regions. SSCM module finds the settings and load

them into PASS configuration via the DCF path. Once SSCM Done is asserted, the new configuration loaded by SSCM into PASS come into force and unlocks different regions of flash for program and erase.

To enable write and erase access of a particular region of flash memory, add corresponding DCF records in the flash memory once chip comes out of reset (i.e. SSCM Done). User can also change the settings by providing valid password to the PASS module, and by modifying the settings of following registers bits fields:

- PASS_LOCK0_PGn[MIDLOCK]
- PASS_LOCK0_PGn[LOWLOCK]
- PASS_LOCK1_PGn[HIGHLOCK]
- PASS_LOCK2_PGn[L_256LCK]
- PASS_LOCK3_PGn[U_256LCK]

See chip-specific PASS information for mapping of the above mentioned bits fields.

In the PASS module there is no individual access protection for Write or Erase access types, but Write and Erase accesses summated.

80.5.5 Test mode enable

Test mode can be used for testing different features of Flash and internal blocks. These features can be used in Failure analysis life cycle. Following are the guidelines for customers:

- During customer assembly, customer programmes DCF Record in UTEST to write test mode DCF client with 1.
- During customer assembly, the customer programmes the test mode enable Password into Flash
- The customer maintains a system for retrieving these passwords for the life of the module
- If the part is returned to JDP for FA, the customer must provide the test mode enable password that was originally programmed into the device.
- If the password is lost or irretrievable, the customer must accept that FA cannot be done.

NOTE

Usage of this case causes restrictions on failure analysis.

80.5.6 Test mode enable password

The Test mode enable password is a password entered by the manufacturer via JTAG interface, during device FA, to gain access to Flash Test Mode. Flash Test Mode is required to perform Vt Distribution analysis and other tests on an MCU. This password is only functional during FA life cycle. During other life cycles, Flash Test Mode is either available; completely blocked; or requires the Retest Password. Flash blocks that are assigned as sealed during production are locked against any form of Flash test, including reading, erasing and Vt Distribution analysis.

80.5.6.1 Test mode enable password generation

The Test mode enable password is created by the customer during their module assembly process. It must be programmed into UTEST Flash while in Customer Delivery life cycle.

When an MCU is returned to manufacturer for FA, it must be in FA life cycle and the password must also be provided to the manufacturer to allow access to Flash Test Mode. Therefore the customer should develop a process for managing Test mode enable passwords for the life of the module.

80.5.6.2 Test mode enable password storage

The test mode enable password is 224 bits (28 bytes) wide and is to be stored in UTEST Flash at a fixed location. See the device reference manual for the address of the test mode password.

The password region of UTEST Flash is readable only when in Customer Delivery life cycle. In any life cycle after this (including FA life cycle), this region is read protected.

80.5.6.3 Test mode enable password Challenge entry

The Test mode enable password challenge in entered by an external tool to the password register in JTAGC

As the Test mode enable password is 224 bits; and the JTAGC password register is 256, only the least significant 224 bits of the register are used.

80.5.6.4 Test mode enable password compare

The Test mode password challenged, is compared against the password stored in UTEST Flash. Only the least significant 224 bits are compared as the most significant 32 bits of the Flash page contain different data not related to Test mode enable.

If the password matches, Flash Test Mode access is allowed until the next POR reset.

There are no passwords that the hardware will detect as illegal. All 0 and all 1 are valid passwords.

80.6 Initialization/application information

80.6.1 Reset

The reset state of each individual bit is shown within the Register Description section. However, many bits receive their values based on DCF records stored in the UTEST Flash memory block.

80.6.2 Setting lock bits in a password group

There is no restriction on setting and clearing lock registers in the UTEST Flash, apart from the available space for DCF records. It is possible to set and clear them multiple times.

Table 80-6. CS/ADDR Values for Lock Registers

Chapter 81
Tamper Detection Module (TDM)

81.1 Chip-specific TDM information

81.1.1 Chip-specific TDM information

Flash block assignment tables contains the TDM configuration registers implementation in this device.

See the device Flash block assignment (Excel file) attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the Excel file to open it and select the TDR and OTP LOCK Reg tab.

81.2 Overview

The Tamper Detection Module provides a type of flash memory erase protection mechanism that requires software to write a record associated with one or more blocks in a Tamper Detection Region (TDR) before the block(s) can be erased. The mechanism does not *prohibit* an erase operation on any block within a TDR—it requires a record to be written before the operation can execute. Collectively, the records are referred to as a "diary". At minimum, the diary serves as an erase counter. Because the diary record content is customer-defined, the diary can also serve as a history.

Up to 4 TDRs can be defined via DCF records.

The following figure shows the block diagram of the TDM and its interface to other system components.

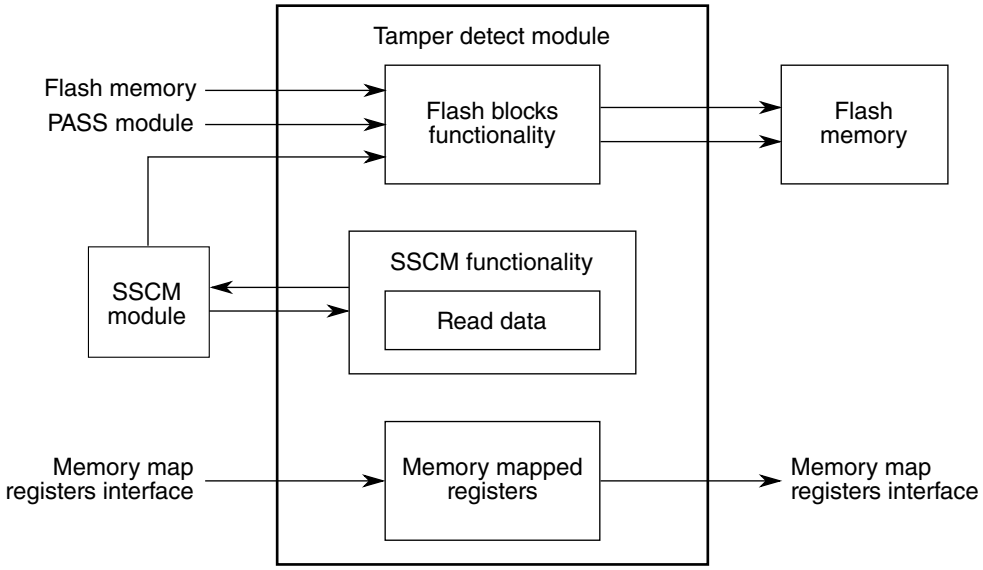

Figure 81-1. Tamper Detection Module block diagram

Security information is passed to the TDM by the SSCM module via the DCF bus. Among the data are:

- OTP (One Time Programmable) settings for each of the flash blocks
- Base address for the diary in the flash
- Block assignments for the TDRs
- Tamper region override information
- Software tamper region disable

The TDM module controls the flash blocks for erase operations and sets them as OTP.

The two flash buses are used to control the flash blocks for erase operation and set them as OTP. OTP means that flash erase of the entire block is disabled and the only words that are already erased can be programmed. Over-programming is not possible.

NOTE

The pass module provides the control for erase operation for each flash block as well as for each region of flash memory, and the PASS settings have priority over the settings of TDM.

The flash block indicates to the TDM the address of the programmed word. This address is internally decoded and provides a means to verify whether the block is part of any TDRs. The memory map registers interface provides a means to the user to read information of the TDM registers.

81.3 Features

The Tamper Detection Module supports these distinctive features:

- Erase counter (diary) for each TDR to record up to 256 write attempts on the flash blocks
  - The diary is divided into 4 parts (TDRs), each consisting of 256 64-bit records.
  - The diary block should be assigned as OTP region in flash.
  - The diary area can store any type of relevant information.
- Tamper Detection Region Block Assignment
  - Any flash block can be assigned to any TDR and be controlled.
- 32-bit Erase Lock DCF clients for each flash memory TDR defined.
- 32-bit OTP Enable DCF clients to disable the erase operation for an entire flash block
- Override TDR via DCF records[1]
  - Allows block assigned to a TDR to be unlocked for erase even if the TDR is locked for this operation.
- Memory mapped registers interface for reading via software of specific registers.

81.4 External signal description

There are no external signals driving or being driven by the TDM.

81.5 DCF clients

TDM-related DCF records perform the following functions:

- Establish a permanent diary base address
- Define Tamper Detect Regions (TDRs) to monitor on-chip flash memory program/ erase activity
- Permanently disable one or more Tamper Regions
- Configure flash memory as One Time Programmable (OTP) on a per-block basis

The following table gives an overview on the TDM DCF clients implemented.

1. The Tamper Region Override DCF record is a "write one only" DCF record. If an override is applied to a TDR it is permanent and cannot be reversed.

Table 81-1. DCF clients

DCF Client Name	Description	Strategy
Diary Base Address	Stores the base address of the tamper detection diary	write once, write 1 to 0 only
Tamper Region Override	Stores information of which TDR is to be overridden	write 0 to 1 only
Software Tamper Region Override Disable	Stores information to disable the software mechanism to override the TDR	write once, write 0 to 1 only
OTPEN[nb] (OTP Enable)	Stores information of which flash blocks is to be assigned as OTP (One Time Programmable) - nb means one register for each Lock register of the flash memory	write 0 to 1 only
TDR[n]_LOCK[m] Region Assignment	Stores information of which flash block is assigned to a TDR. • n specifies a TDR • m specifies the flash blocks as per the LOCK registers of the flash memory.	write 0 to 1 only

81.5.1 Diary Base Address (DBA) DCF client

This DCF client holds base address information of the diary. The following diagram depicts this client.

CAUTION

This write-once DCF client can be written only one time. After one DCF record has written to this client, all subsequent writes are ignored.

DCF Client Address: 0x0000 Access: DCF write

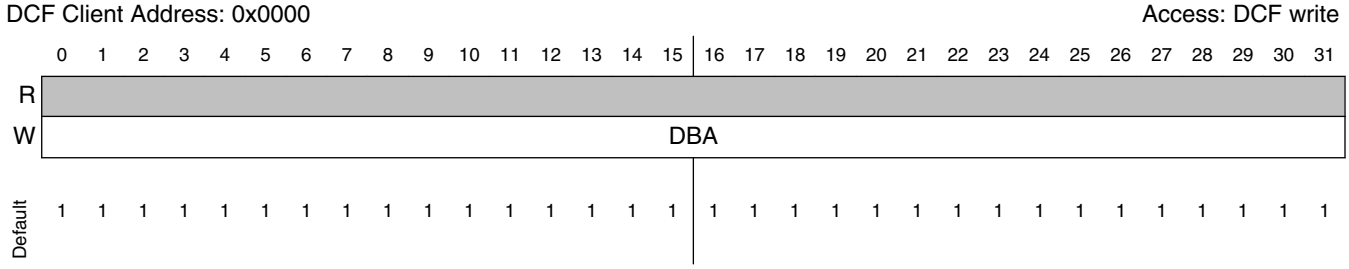

Table 81-2. Diary Base Address (DBA) DCF client field description

Field	Description
0–31 DBA	Diary Base Address. This field holds the base address of the diary. This information is then used to verify if the diary being programmed matches any TDR region. **NOTE:** Diary Base Address must be on a 16 KB boundary.

81.5.2 Tamper Region Override (TO) DCF client

This DCF client holds override information for each TDR. The following figure shows the diagram for this register.

CAUTION

This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the override of a TDR permanent.

DCF Client Address: 0x0001 Access: DCF write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Table 81-3. Tamper Region Override (TO) DCF client field descriptions

Field	Description
0–27 Reserved	This field is reserved and should be written with all zeroes when programming the TOE fields.
28–31 TOE3 to TOE0	TDR Override Enable. Each TOE*n* field, where *n* represents the TDRs, holds information of the Override Enable status for each TDR. 0 Normal operation. Blocks assigned to this TDR can NOT be erased until the diary is written. 1 Diary override. The blocks assigned to this TDR can be erased WITHOUT writing to the diary.

81.5.3 Software Tamper Region Override Disable (STO_DIS) DCF client

This DCF client holds information to disable the software mechanism to override the tamper detect regions.

CAUTION

This write-once DCF client can be written only one time. After one DCF record has written to this client, all subsequent writes are ignored.

DCF Client Address: 0x0002 Access: DCF write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Table 81-4. Software Tamper Region Override Disable (STO_DIS) DCF client field descriptions

Field	Description
0–27 Reserved	This field is reserved and should be written with all zeroes when programming the STO_DIS fields.
28–31 STO_DIS3 to STO_DIS0	Software TDR Override Disable TDR*n*. Each STO_DIS*n* field, where *n* represents the TDR number, holds information to disable the software mechanism to override TDR*n*. 0 Software tamper detect override mechanism supported 1 Software tamper detect override mechanism disabled. Any attempt to override TDR*n* by loading a service key value in STO_KEY*n* register is ignored.

81.5.4 One Time Programmable Enable (OTPEN0) DCF client

This DCF client holds OTP information for particular blocks of flash memory. This DCF client mirrors the LOCK0 register of the flash memory. The following diagram depicts this client.

CAUTION

This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the OTP assignment of a flash memory block irreversible.

DCF Client Address: 0x0008 Access: DCF write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Table 81-5. One Time Programmable Enable (OTPEN0) DCF client

Field	Description
0–3 Reserved	This field is reserved and should be written with all zeroes when writing to this client.
4–15 LOWOTPEN	Low Block OTP Enable. This field affects flash memory blocks in Low address space. See the chip-specific information for the mapping between field bits and flash blocks. The same mapping also applies to control similar functions in the flash memory module. 0 Corresponding flash blocks are not assigned as OTP 1 Corresponding flash blocks are assigned as OTP
16–31 MIDOTPEN	Mid Block OTP Enable. This field affects flash memory blocks in Mid address space. See the chip-specific information for the mapping between field bits and flash blocks. The same mapping also applies to control similar functions in the flash memory module. 0 Corresponding flash blocks are not assigned as OTP 1 Corresponding flash blocks are assigned as OTP

81.5.5 One Time Programmable Enable (OTPEN1) DCF client

This DCF client holds OTP information for particular blocks of flash memory. This DCF client mirrors the LOCK1 register of the flash memory. The following diagram depicts the client.

CAUTION

This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the OTP assignment of a flash memory block irreversible.

DCF Client Address: 0x0009 Access: DCF write

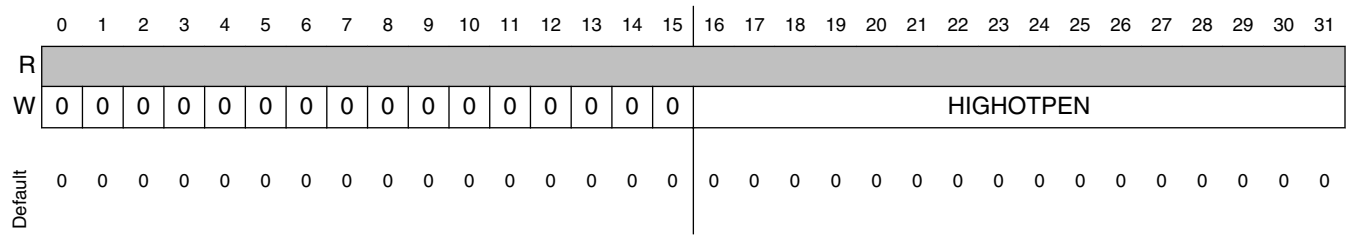

Table 81-6. One Time Programmable Enable (OTPEN1) DCF client field descriptions

Field	Description
0–15 Reserved	This field is reserved and should be written with zeroes when writing to this client.
16–31 HIGHOTPEN	High Block OTP Enable. This field affects flash memory blocks in High address space. See the chip-specific information for the mapping between field bits and flash blocks. The same mapping also applies to control similar functions in the flash memory module. 0 Corresponding flash blocks are not assigned as OTP 1 Corresponding flash blocks are assigned as OTP

81.5.6 One Time Programmable Enable (OTPEN2) DCF client

This DCF client holds OTP information for particular blocks of flash memory. This DCF client mirrors the LOCK2 register of the flash memory. The following diagram depicts the client.

CAUTION

This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the OTP assignment of a flash memory block irreversible.

DCF Client Address: 0x000A Access: DCF write

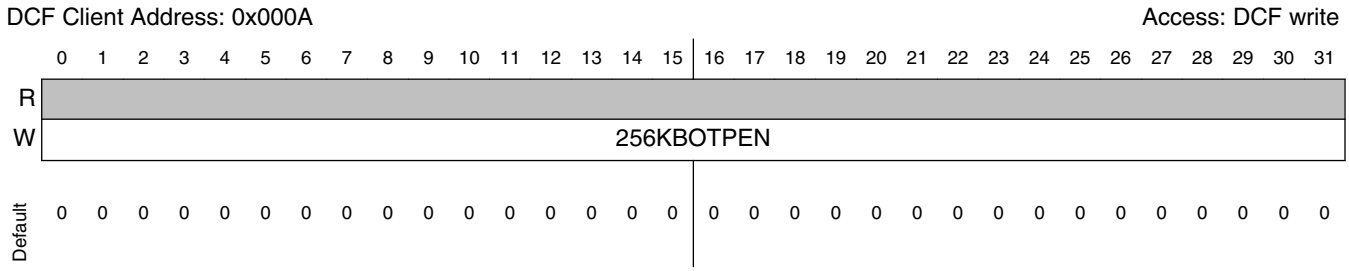

Table 81-7. One Time Programmable Enable (OTPEN2) DCF client field descriptions

Field	Description
0–31 256KBOTPEN	256 KB Block OTP Enable. This field affects flash memory blocks in 256KB address space. See the chip-specific information for the mapping between field bits and flash blocks. The same mapping also applies to control similar functions in the flash memory module. 0 Corresponding flash blocks are not assigned as OTP 1 Corresponding flash blocks are assigned as OTP

81.5.7 One Time Programmable Enable (OTPEN3) DCF client

This DCF client holds OTP information for particular blocks of flash memory. This DCF client mirrors the LOCK3 register of the flash memory. The following diagram depicts the client.

CAUTION

This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the OTP assignment of a flash memory block irreversible.

DCF Client Address: 0x000B — Access: DCF write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Table 81-8. One Time Programmable Enable (OTPEN3) DCF client field descriptions

Field	Description
0–15 Reserved	This field is reserved and should be written with zeroes when writing to this client.
16–31 256KBOTPEN	256 KB Block OTP Enable. This field affects flash memory blocks in the upper range of 256KB address space. See the chip-specific information for the mapping between field bits and flash blocks. The same mapping also applies to control similar functions in the flash memory module. 0 Corresponding flash blocks are not assigned as OTP 1 Corresponding flash blocks are assigned as OTP

81.5.8 Tamper Region Assignment DCF client (TDRn_LOCK0)

This DCF client holds the assignment information of flash memory blocks to a specific TDR. Each flash memory block can be assigned to any TDR (*n* varies from 0 to 4). This DCF client holds the assignment information for only those blocks specified in the LOCK0 register in the flash memory. For that reason, the layout of this DCF client mirrors the LOCK0 register in the flash memory. The following diagram depicts the TDRn_LOCK0 DCF client.

CAUTION

This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the assignment of a flash memory block to a TDR irreversible unless the entire TDR is overridden.

DCF Client Address: 0x0014 + ((n x 4) + 0) Access: DCF write

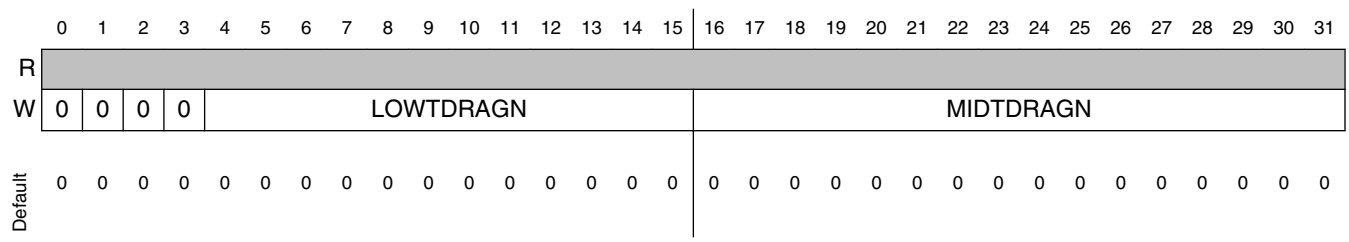

Table 81-9. Tamper Region Assignment DCF client (TDRn_LOCK0)

Field	Description
0–3 Reserved	This field is reserved and should be written with zeroes when writing to this client.
4–15 LOWTDRAGN	Low Block Tamper Region Assignment. This field affects flash memory blocks in Low address space. See the chip-specific information for the mapping between field bits and flash blocks. The same mapping also applies to control similar functions in the flash memory module. 0 Corresponding flash blocks are not assigned to the TDRn 1 Corresponding flash blocks are assigned to the TDRn
16–31 MIDTDRAGN	Mid Block Tamper Region Assignment. This field affects flash memory blocks in Mid address space. See the chip-specific information for the mapping between field bits and flash blocks. The same mapping also applies to control similar functions in the flash memory module. 0 Corresponding flash blocks are not assigned to the TDRn 1 Corresponding flash blocks are assigned to the TDRn

81.5.9 Tamper Region Assignment DCF client (TDRn_LOCK1)

This DCF client holds the assignment information of flash memory blocks to a specific TDR. Each flash memory block can be assigned to any TDR (*n* varies from 0 to 4). This DCF client holds the assignment information for only those blocks specified in the LOCK1 register in the flash memory. For that reason, the layout of this DCF client mirrors the LOCK1 register in the flash memory. The following diagram depicts the TDRn_LOCK1 DCF client.

CAUTION

This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the assignment of a flash memory block to a TDR irreversible unless the entire TDR is overridden.

DCF Client Address: 0x0014 + ((n x 4) + 1) Access: DCF write

81.6.1 TDR Status Register (TDM_TDRSR)

This register contains the current status, i.e., locked or unlocked, of each tamper region, i.e., TDR.

- If a tamper region is locked, the blocks assigned to that tamper region cannot be erased.
- If a region is unlocked, the blocks within the tamper region can be erased.

The register contains a status bit for each TDR. Status is determined as follows:

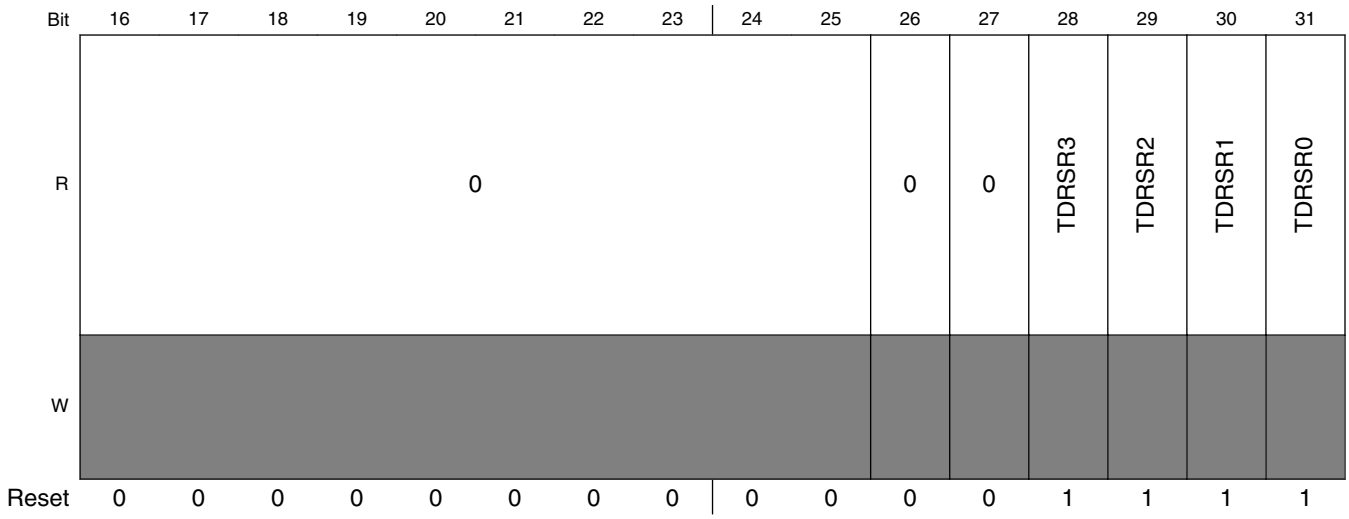
1. The default status for each TDR is ‘1’, which indicates that the erase operation is disabled for all flash blocks associated with the TDR.
2. The status bit for a TDR is set to ‘0’ (indicating that the erase operation for all flash blocks associated with the TDR is enabled) if either a successful programming operation to the TDR diary region has been performed or the TDR Override bit for that TDR is set.

NOTE

- TDRSR is a read-only register and writes have no effect on it. Write operations result in a transfer error.
- If the reset value for this register is determined by a DCF record, it will be noted in the chip-specific information at the beginning of this chapter. Otherwise, the reset value is as shown.

Address: 0h base + 0h offset = 0h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0



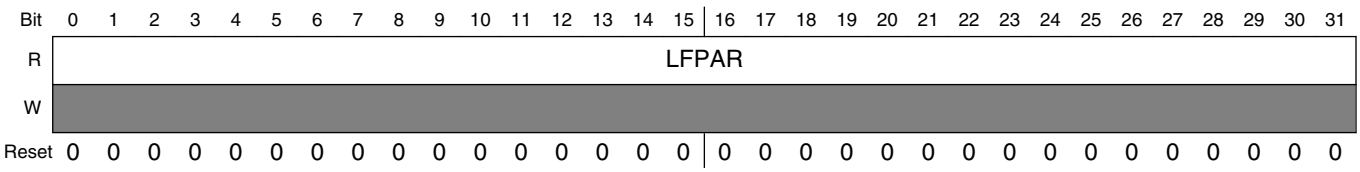
TDM_TDRSR field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 TDRSR3	Represents the status of TDR 3 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.
29 TDRSR2	Represents the status of TDR 2 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.
30 TDRSR1	Represents the status of TDR 1 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.
31 TDRSR0	Represents the status of TDR 0 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.

81.6.2 Last Flash Programmed Address Register (TDM_LFPAR)

This register holds information of the address of the last successful programming operation provided from the flash memory to the TDM. Writes to this register are ignored and will generate a transfer error.

Address: 0h base + 4h offset = 4h



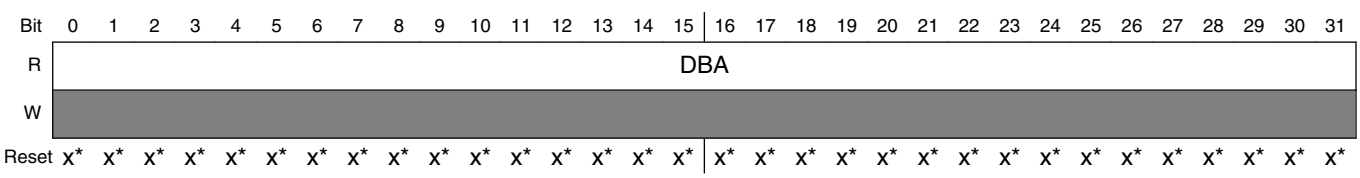
TDM_LFPAR field descriptions

Field	Description
0–31 LFPAR	Last Flash Programmed Address. These bits represent the address of the last successful programming operation.

81.6.3 Diary Base Address (TDM_DBA)

This register holds base address information of the diary. Any write to this register is ignored and generates a transfer error.

Address: 0h base + 8h offset = 8h



* Notes:
- The reset value of this register is set via DCF record.x = Undefined at reset.

TDM_DBA field descriptions

Field	Description
0–31 DBA	Diary Base Address. These bits represent the address of the diary location in the flash. **NOTE:** The diary base address is established via the DBA DCF record. The reset value of this register is determined by that record.

81.6.4 Software Tamper Override Key Region (TDM_STO_KEY*n*)

The STO_KEYn register holds the service key for overriding the Tamper Detect Region n, where n denotes the Tamper Detect Region number.

Caution

1. The STO_KEYn registers can only be written once.
2. The associated DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored.

Address: 0h base + 10h offset + (4d × i), where i=0d to 3d

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

TDM_STO_KEY*n* field descriptions

Field	Description
0–31 STO_KEY	Software Tamper Override Key Diary n. This field holds the service key value for overriding Tamper Detect Region n. By loading STO_KEYn with the correct signature of 0x55AA5A5A, Tamper Detect Region n is overridden, and the flash blocks assigned to Tamper Detect Region n are open for erase. This field has no effect when STO_DISn field of STO_DIS DCF client is set. **Caution:** The STO_KEYn registers can only be written once.

81.7 Functional description

The primary purpose of the TDM is to provide a Tamper Detection mechanism by enabling an Erase Counter (or diary) for regions within the flash. These regions are called Tamper Detection Regions. The following sections cover the entire functionality of this module.

81.7.1 Flash erase counter and tamper detection

A flash region block or part of it is assigned for implementing the diary. The base address for the diary is defined by a DCF Record.

The diary is divided into 4 parts where each part consists of 256 × 64-bit records, to record up to 256 write attempts on the flash blocks assigned to each Tamper Detection Region. For correct operation, the diary should reside in a flash block that is assigned as OTP.

Each flash block can be assigned to any of the TDRs. Related to each TDR is a group of 4 × 32-bit internal hardware registers that are initialized by DCF records that define the tamper region. These registers mirror exactly the LOCK registers bits from the flash module.

Each TDR*n*_LOCK*m* register is loaded at boot time by the SSCM, which defines if the associated flash block is Locked for Erase in a particular TDR:

- ’1’ means the flash block is locked for erase
- ’0’ means the flash block is not locked for erase

Before performing an erase in one of the blocks locked for erase and associated to a TDR, a program operation has to be performed on the diary part for that TDR. As the diary should be OTP, successive writes are allowed on unprogrammed double words only. This ensures that diary records can only increase and that data recorded in the diary is not modifiable by software.

At the end of a successful double-word program operation, the flash module indicates to the TDM the address of the programmed double word. The TDM determines whether the programmed data was written to the correct TDR diary location and then unlocks the blocks for erase operation for the corresponding TDR. The TDM ensures that this erase operation on unlocked blocks is allowed until the completion of the erase sequence or until next desctructive reset.

When attempting to update the TDM diary and erase flash blocks, set MCR[PECIE] in the Embedded Flash Memory registers to enable interrupt notification for program and erase operations. Then clear MCR[PECIE] to service the interrupt after each program or erase operation. This sequence must be executed before attempting to update the TDM diary, and then again before attempting to erase the unlocked flash blocks.

NOTE

All blocks associated to a TDR where an erase operation is allowed can be erased all together.

The data programmed in the diary location is flexible, and may include count information or other important customer information.

NOTE

There is no restriction on the type or format of data that can be programmed in the diary, so software must verify whether the diary is full. If a TDR's diary area is full, the tamper detect mechanism can be disabled for that TDR by creating a Tamper Region Override (TO) DCF record with the TDR's corresponding TDR Override Enable (TOE) bit set to '1'. This

allows erase operations to be performed to the TDR without any diary entry.

The setting from “override tamper region lock” DCF record (Diary) has priority over the settings in the TDRn_LOCK0 – 3 registers. In other words, if a TDR is unlocked for erase by the override tamper region lock, the TDR*n*_LOCK*m* bits have no effect on the TDR that has been overridden, but the tamper detection remains active for all TDRs not having the override bit set.

Moreover, if a block is locked by the PASS_LOCK*x*_PG*n* registers or by TDR*n*_LOCK*m*, the block is locked for erase.

NOTE

The settings in the Tamper Region Override Register have priority over the TDR*n*_LOCK*m* registers. The PASS module also has priority over the settings done in the TDM. For instance, if blocks in a TDR are unlocked for erase operation via the TDM, but the same blocks are programmed to be locked for erase operation in PASS, the blocks end up being locked for erase operation.

Attempts to erase the flash without first writing the diary will be ignored by the flash. The contents in the flash block will remain unchanged and MCR[PEG] will be asserted, indicating the operation was successful and the contents of the block are properly protected from the erase operation.

81.7.2 Assigning blocks to Tamper Detect Regions (TDR)

Each TDR is defined by a group of 4 x 32-bit DCF records and clients, with each containing bits that map to specific blocks in a flash region. These mappings mirror exactly the LOCK registers bits from the flash module. Hence, the block assignment registers are named as TDR*n*_LOCK*m* where *n* is the number of a tamper region, that is, 0- 4 and *m* varies from 0-3 as flash contains four Lock registers.

In these DCF records:

- ’1’ means that the corresponding flash block is assigned to this TDR
- ’0’ means that the corresponding flash block is not assigned to this TDR (Default)

DCF clients are not visible to software. They can not be read nor written. They can only be initialized by DCF record within the UTest flash block during reset. The value of these registers can be evaluated by reading all the UTest DCF records and searching for records that correspond to these clients.

NOTE

No flash block should be assigned to more than one TDR. Each block should correspond to a single TDR. For example, if a single block is assigned to TDR0 and TDR1, then even if the Diary is programmed for both TDR0 and TDR1, this flash block will never be unlocked for erase operation.

81.7.3 Diary

The diary is a region of the flash memory where records of block erases for each TDR are stored. The format and size of the records are not fixed. The only requirements are that each diary has a maximum size of 2 KB, and the minimum size of any programming operation is 8 bytes to honor OTP restrictions. Therefore, each diary can hold a maximum of 256 64-bit entries.

A flash region block or part of it must be assigned for implementing the diary. The base address for the diary is determined by a value written in a DCF record. The diary can be placed within any flash block in flash array, and history records in it can be read by any core.

NOTE

To maintain the security of the TDR, the block where the diary is placed must be assigned as OTP within the OTP registers.

The base address of the diary is implemented using a DCF Client. The DCF client is only writable once and the default bit state is 1.

The DCF clients can not be read nor written by software. They can only be initialized by DCF record from within UTEST block during reset. The value of these registers can be evaluated by reading all the UTEST DCF records and searching for records that write these DCF clients.

81.7.4 Specifying the diary base address

The diary is a region of flash memory where records of block erases for each TDR are stored. The format and size of these records is defined by the customer. The only hardware constraints are that each diary has a maximum size of 2 KB and the minimum size of any programming operation is 8 bytes. Therefore, each diary region limits the erases of the assigned blocks to 256 erases.

The diary can be placed within any flash block in the flash array. To maintain the security of the TDR, the block where the diary is placed, must be assigned as OTP within the OTP registers, while in customer delivery or OEM production life cycle states.

The base address of the diary is implemented with a 20-bit DCF client that can be initialized by the SSCM during reset. The DCF client is writable once and the default bit state is ‘1’.

The base address register is not visible to software. It cannot be read nor written. It can only be initialized by DCF record within UTest flash during reset. The value of this register can be evaluated by reading all the UTest flash DCF Records and searching for record that writes this register.

Each TDR is assigned a 2 KB section of the diary. With 4 TDRs, 8 KB of diary space is required.

The diary base address must be at a 16 KB boundary. Therefore the least significant 14 bits of the base address must all be ‘0’.

The Base address of the diary is represented by:

Diary_Base_Address = 0bxxxx_xxxx_xxxx_xxxx_xx00_0000_0000_0000

The base address of each TDR is shown below:

- TDR0 = Diary_Base_Address + 0b00_0000_0000_0000
- TDR1 = Diary_Base_Address + 0b00_1000_0000_0000
- TDR2 = Diary_Base_Address + 0b01_0000_0000_0000
- TDR3 = Diary_Base_Address + 0b01_1000_0000_0000
- End of the diary = Diary_Base_Address + 0b11_0000_0000_0000

81.7.5 TDR lock status

The status of whether a TDR is locked for erase is maintained by the TDM. This is accomplished by implementing a register with as many bits as the number of TDRs. The default state of these bits is 1, which is defined as "TDR Erase Blocked". See TDR Status Register (TDM_TDRSR) for further details about this register.

When the flash memory module has completed a programming operation, the address of the location programmed is output from the flash module. The TDM in turn compares that address to determine if it falls within the range of any TDR diary regions. If it is within any TDR, the corresponding status bit is set to 0 meaning "TDR Erase Enabled".

These status bits are all reset to 1 when the flash module signals an erase complete by asserting the PEC (Program Erase Complete) signal.

The state of the 4 status bits can be read through the TDRSR. See TDR Status Register (TDM_TDRSR). The address of the last successful programming operation provided from the flash memory to the TDM can be read through the LFPAR. See Last Flash Programmed Address Register (TDM_LFPAR).

81.7.6 TDR override

Before a block protected by a tamper detect region can be erased, a record must be written to the associated diary. Software must search through the diary to find the end of the records, where the next available diary location that can be written. After a maximum of 256 records are programmed to the diary, a TDR diary is full. Full means that at least 1 bit has been programmed to ‘0’ in each 64 bit double word within the 2 KB diary.

If software determines that a particular TDR diary is full it may override the diary to allow erasing to continue or it may choose to stop further erases and to flag an error.

Diary Override bits are implemented with a DCF client consisting of 6 bits, one for each TDR. See the device configuration information at the beginning of this chapter for TDM DCF client details.

The Diary Override bits are by default set to ‘0’; which means the diary must be written before an erase can occur. The DCF client can be written many times but the bits can only be written to ‘1’. Writes to ‘0’ are ignored. In this way, by default, all Tamper Detect Regions are active. The Tamper detect region diaries can be individually overridden by writing a DCF record that sets that corresponding bit to ‘1’. In this mode, the TDR status bit is permanently set to 0 to allow flash erase.

The application can also override the diary by loading a service key to the STO_KEY*n* program-visible register, where n denotes the tamper detect region. By loading the value 0x55AA5A5A into STO_KEYn register, the corresponding tamper detect region is overridden. This software override mechanism is disabled if the STO_DISn field of the STO_DIS DCF Client is set.

81.7.7 One time programmable (OTP)

81.7.7.1 Overview

Any flash block within the flash array can be assigned, at any time, to be OTP. Once a flash block is assigned OTP, it cannot be changed back.

OTP means that flash erase of the entire block is disabled and only 64-bit double words that are already erased (that is, flash content is 0xFFFF_FFFF_FFFF_FFFF) can be programmed. Over-programming is not possible.

Flash blocks are assigned as OTP by writing a DCF record. The block will become OTP after the next functional reset.

Chapter 82
Cryptographic Services Engine (CSE)

82.1 Chip-specific CSE information

82.1.1 Overview

This chip has one instance of the CSE module. When enabled, the CSE module:

- Can execute the chip's secure boot process.
- Has exclusive access to the flash memory blocks mapped to the 16 Kb HIGH blocks of the C55FMC_LOCK1 register, PASS_LOCK1_PGn registers, and TDRn_LOCK1 DCF client. The system MPU is automatically configured to prevent other bus masters from interfering with CSE's access to the flash memory. For details, refer "Flash Block Assignment" spreadsheet attached with the document.

82.1.1.1 CSE SECURE_BOOT execution, and other configuration

The DCF client configures various aspects of CSE operation. For details about Secure boot configurations, refer DCF_CSE_SECURE_BOOT and DCF_CSE_SECURE_BOOT_SIZE in 'UTEST DCF clients' and 'DCF Client Register Bits' tabs of the DCF sheet spreadsheet attached with this document. The settings in the DCF client load during reset.

For details about how and when the SECURE_BOOT command is issued in this chip, refer SECURE BOOT details.

82.1.1.2 Making secure flash blocks accessible for the Failure Analysis life cycle

Before advancing the chip's life cycle to Failure Analysis, make its secure flash blocks accessible. To do so, issue the DEBUG_CHAL and DEBUG_AUTH commands described in Debug Challenge and Debug Authorization.

82.1.1.3 CSE operation while JTAGM is in use

In order to use CSE memory slots for decryption/encryption which have the DEBUG_PROT flag set, the user must disable the JTAGM module by writing JTAGM_MCR[DTM] = 0b0 and give short functional reset to clear CSE_SR[EDB].

The JTAGM module is disabled by default, so if it is not used in the application then no action is necessary.

82.1.1.4 CSE command-processing completion before Stop mode entry

To ensure proper CSE operation: Before the chip enters Stop mode, CSE_SR[BSY] must be 0.

82.2 Introduction

82.2.1 Overview

The Cryptographic Services Engine (CSE) is a peripheral module that implements the security functions described in the *Secure Hardware Extension (SHE) Functional Specification Version 1.1*.

The CSE design includes a host interface with a set of memory mapped registers that are used by the CPU to issue commands and a system bus interface that allows the CSE to directly access system memory. Two dedicated blocks of system flash memory are used by the CSE for secure key storage.

82.2.2 Features

The CSE has the following features:

- Secure storage for cryptographic keys
- AES-128 encryption and decryption
- AES-128 CMAC authentication
- True random number generation
- Secure boot mode
- System bus master interface

82.2.3 Modes of operation

The CSE supports operation in Normal and Debug modes of operation. The use of the cryptographic keys stored by the CSE is controlled based on the activation of the CPU debug port and the successful completion of the secure boot process.

The CSE has a low-power mode that disables the clock to all logic except the host interface. Register accesses are supported in this mode, but commands are not processed.

82.2.4 Block diagram

The CSE design includes a command processor, host interface, system bus interface, local memory, AES logic, and True Random Number Generator (TRNG) as shown below.

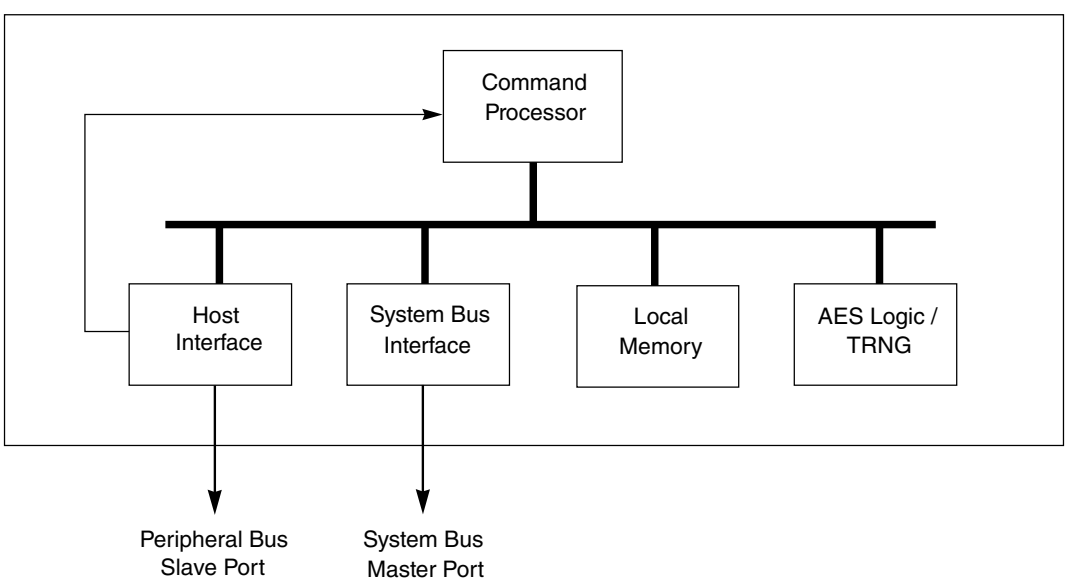

Figure 82-1. CSE block diagram

82.3 External signal description

The CSE has no external interface signals.

82.4 Memory Map and Register Definition

The CSE programming model has ten 32-bit registers. The programming model can only be accessed using 32-bit (word) accesses. References using a different size are invalid. The CSE memory map is shown in the table below.

CSE memory map

Address offset (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

CSE_CR field descriptions

Field	Description
0–15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16–23 DIV	TRNG Clock Divider Select. Sets the clock divide ratio for the TRNG clock. The TRNG clock is the module clock divided by a programmable ratio: TRNG Clk Freq = CSE Clk Freq / (2*(DIV+1)) The divide ratio must be set such that the TRNG clock frequency is between 500 kHz and 2MHz. 0x00 divide by 2 0x01 divide by 4 0x02 divide by 6 ... 0xFE divide by 510 0xFF divide by 512
24–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 KBS	Key Bank Select. Selects which set of application keys are visible for commands. See Table 82-1. 0 Select KEY_1-KEY_10 1 Select KEY_11-KEY_20
27 SFE	Security Flag Extension. When the SFE bit is set, the CSE recognizes the VERIFY_ONLY security flag during LOAD_KEY processing; otherwise, it is ignored. The SFE bit has no effect on the enforcement of the VERIFY_ONLY security flag once a key is loaded. 0 Security Flag Extension disabled. 1 Security Flag Extension enabled.
28 MDIS	Module Disable. When the MDIS bit is set, the CSE is put into a low-power mode that disables the clock to all of the CSE logic except for the host interface. The MDIS bit should not be set during command processing (CSE_SR[BSY] = 1). The current command should be canceled and processing stopped (CSE_SR[BSY] = 0) before setting the MDIS bit. 0 Normal mode 1 Low-power mode
29 SUS	Suspend Command Processing. When the SUS bit is set, the CSE suspends processing of the current command until the SUS bit is cleared. The current execution status of the command processor is reflected by the CSE_SR[EX] flag. 0 Enable processing of commands. 1 Suspend command processing.
30 DRE	DMA Request Enable. When the DRE bit is set, the DMA request is asserted when command processing is completed. 0 DMA request not enabled. 1 DMA request enabled.
31 CIE	Command Complete Interrupt Enable. When the CIE bit is set, an interrupt request is generated when command processing is completed. 0 Command Complete Interrupt disabled. 1 Command Complete Interrupt enabled.

82.4.2 CSE Status Register (CSE_SR)

The CSE_SR contains flags indicating the status of the CSE. Reading CSE_SR[24:31] is the same as the SHE GET_STATUS command.

Address: 0h base + 4h offset = 4h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0							EX	IDB	EDB	RIN	BOK	BFN	BIN	SB	BSY
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CSE_SR field descriptions

Field	Description
0–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 EX	Execute. **NOTE:** Ignore the status of CSE_SR[EX] when CSE_SR[BSY] flag is '0'. 0 Command processor is idle or suspended. 1 Command processor is executing a command.
24 IDB	Internal Debug. The IDB bit is set by the SECURE_BOOT, INIT_CSE, and DEBUG_AUTH commands when no user keys (i.e. all keys except SECRET_KEY and UID) are stored. It is cleared on reset and by the LOAD_KEY command. 0 Internal Debug functions disabled. 1 Internal Debug functions enabled.
25 EDB	External Debug. The EDB bit is set when the CPU debug port is activated and is cleared on reset. 0 External debugger not attached. 1 External debugger attached.
26 RIN	Random Number Generator Initialized. The RIN bit is set by the INIT_RNG command and is cleared on reset and by the DEBUG_AUTH command. 0 Random number generator not initialized. 1 Random number generator initialized.
27 BOK	Secure Boot OK. The BOK bit is set by the successful completion of the SECURE_BOOT command. It is cleared by reset and by the BOOT_FAILURE command.

Table continues on the next page...

CSE_SR field descriptions (continued)

Field	Description
	0 Secure boot not completed or secure boot failure. 1 Secure boot successful.
28 BFN	Secure Boot Finished. The BFN bit is set by the SECURE_BOOT command when the BIN bit is set, when an error is encountered, or when the BOOT_MAC value does not match. It is also set by the BOOT_OK or BOOT_FAILURE commands. It is cleared on reset. The BFN bit is not set in the event the CSE flash blocks are accessible, but contain an invalid firmware image as detected by a checksum mismatch (CSR_ECR=0x13). 0 Secure boot not finished. 1 Secure boot finished.
29 BIN	Secure Boot Initialization. The BIN bit is set by the SECURE_BOOT command if the BOOT_MAC memory slot is empty and is cleared on reset. 0 Secure boot personalization not completed. 1 Secure boot personalization completed.
30 SB	Secure Boot. The SB bit is set by the SECURE _BOOT command if the BOOT_MAC_KEY slot is not empty, and is cleared on reset. 0 Secure boot not activated. 1 Secure boot activated.
31 BSY	Busy. The BSY bit is set when a command is issued and cleared when command processing is completed. 0 Command processing completed. 1 Command processing not completed.

82.4.3 CSE Interrupt Register (CSE_IR)

The CSE_IR contains the command completion interrupt flag bit.

Address: 0h base + 8h offset = 8h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0

Table continues on the next page...

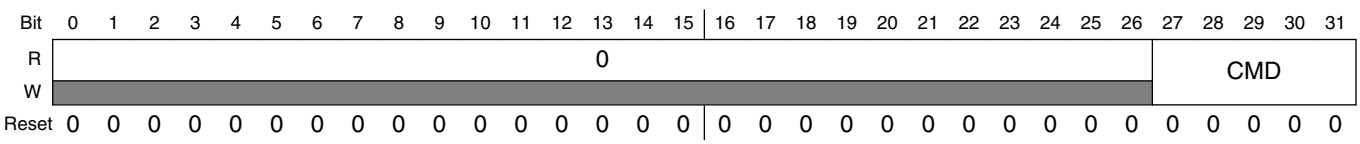
CSE_ECR field descriptions (continued)

Field	Description
	0x12 TRNG error 0x13 CSE flash block error 0x14 Internal command processor error 0x15 Length error

82.4.5 CSE Command Register (CSE_CMD)

Commands are issued by first loading the appropriate parameter registers (CSE_Px) and then writing a command code to the command register (CSE_CMD). Reads of the CSE_CMD register have no effect on the operation of the CSE. See Command processing for a description of command processing and CSE commands for a description of each command.

Address: 0h base + 20h offset = 20h



CSE_CMD field descriptions

Field	Description
0–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–31 CMD	Command. See CSE commands for details of each command. 0x01 = ENC_ECB 0x02 = ENC_CBC 0x03 = DEC_ECB 0x04 = DEC_CBC 0x05 = GENERATE_MAC 0x06 = VERIFY_MAC 0x07 = LOAD_KEY 0x08 = LOAD_PLAIN_KEY 0x09 = EXPORT_RAM_KEY 0x0A = INIT_RNG 0x0B = EXTEND_SEED 0x0C = RND

CSE_P*n* field descriptions

Field	Description
0–31 PARM	Command parameter (data value or address of data value).

82.5 CSE functional description

The CSE implements a comprehensive set of cryptographic functions as described in the *SHE Functional Specification*, including secure key storage, AES encryption, secure boot, AES CMAC authentication, and random number generation.

82.5.1 Host interface

The host interface includes all of the CSE memory mapped registers (see the memory map and register section).

The Control Register (CSE_CR) is used to set configuration options and control operation of the CSE. If the CSE_CR[CIE] bit is set, an interrupt request is generated after the CSE finishes processing each command. The interrupt is cleared by writing a 1 to the CSE_IR[CIF] bit. If present, the CSE also supports servicing by the system DMA module. The DMA request is asserted after the CSE finishes processing each command if the CSE_CR[DRE] bit is set. When the CSE_CR[SUS] bit is set, the CSE suspends processing of the current command and does not respond to new commands including the CANCEL command.

Command processing is resumed by clearing the CSE_CR[SUS] bit. The CSE cannot respond immediately to changes in the CSE_CR[SUS] bit, so the CSE_SR[EX] flag indicates the current status of the CSE command processor. The CSE_SR[EX] flag is set when the CSE command processor is running and is cleared when the CSE is idle or has suspended processing. The CSE_CR[MDIS] bit puts the CSE into a low-power mode. In low-power mode, registers can be accessed but commands are not processed. Before setting the CSE_CR[MDIS] bit or entering any device low-power modes, application software should cancel any pending command and wait for the CSE_SR[BSY] bit to be cleared. The CSE_CR[SFE] bit enables loading of the VERIFY_ONLY flag during the LOAD_KEY command. The CSE_CR[KBS] bit selects which key bank (KEY_1–KEY10 or KEY_11–KEY_20) is active.

The Status Register (CSE_SR) contains a set of nine status flags. Reading CSE_SR[24:31] is equivalent to the SHE GET_STATUS command. The CSE_SR[BSY] bit indicates when the CSE is processing a command. The flag is cleared when processing is completed. Polling the CSE_SR[BSY] bit is an alternative to interrupt-driven operation. The CSE_SR[SB], CSE_SR[BIN], CSE_SR[BFN] and CSE_SR[BOK] bits reflect the secure boot status (see Secure boot). The CSE_SR[RIN] bit is set when the PRNG is initialized with a seed value generated by the TRNG. The CSE_SR[EDB] is set if an external debugger is connected. The CSE_SR[IDB] flag is set when internal debugging has been enabled with the DEBUG_CHAL and DEBUG_AUTH commands. The CSE_SR is a read-only register and can be read at any time.

The Error Code Register (CSE_ECR) contains the error code from the last completed command. The CSE_ECR is set to 0 if no error occurred while processing the command. The CSE_ECR is a read-only register.

82.5.2 Command processing

CSE functions are accessed through a set of commands that are listed in CSE commands. Commands are issued by first loading the appropriate parameter registers (CSE_Px) and then writing a command code to the command register (CSE_CMD). CSE_CMD register reads have no effect on the operation of the CSE.

Command inputs and outputs that are 32 bits or less in size are stored directly into a parameter register. Inputs and outputs that are larger than 32 bits are kept in system memory and the address of the data (pointer) is loaded into the parameter register. All data must be aligned on a 32-bit (word) boundary. The two least significant bits of an address are ignored. All data is stored in big-endian format with the most significant byte of the data block stored in the lowest address.

The first command issued to the CSE after reset must be either SECURE_BOOT or INIT_CSE. In some device boot modes, system boot logic or BAM code will issue the SECURE_BOOT command, which initializes the CSE and starts the SHE secure boot protocol (see Secure boot). For details about how and when the SECURE_BOOT command is issued on this chip, see the chip-specific CSE information. For the other boot modes, application software must issue the INIT_CSE command before issuing other CSE commands. The INIT_CSE command can only be issued one time after reset and only in boot modes that do not issue the SECURE_BOOT command. Application software cannot issue the SECURE_BOOT command.

The CSE can only process one command at a time. Commands take a number of clock cycles to complete, so one of the following must to be used to determine when the output data is valid and the next command can be issued:

- The CSE_SR[BSY] flag
- The interrupt request
- The DMA request

Parameter registers cannot be modified while the CSE is processing a command. Command processing can be suspended and resumed using the CSE_CR[SUS] bit (see Host interface). If the CSE_CMD register is written while a command is being processed, processing is aborted and an error is generated with CSE_ECR[EC] = 0x0B. The CANCEL command can be used to abort processing of a command without generating an error. The CSE_ECR is updated and the CSE_SR[BSY] bit is cleared upon completion of command processing (see Error handling).

82.5.3 Secure storage

The CSE provides secure, nonvolatile storage for cryptographic keys as described in the *SHE Functional Specification*. The keys are stored in 25 memory slots, with one ROM slot, 23 nonvolatile slots, and one RAM slot as shown in Table 82-1. The first four slots have a dedicated use; the other slots are available for application specific keys. The CSE extends the SHE specification by providing 10 extra application key slots (KEY_11–KEY_20) which are enabled by setting the CSE_CR[KBS] bit. The BOOT_MAC slot is loaded with a MAC value used by the secure boot process. All other slots are used for encryption or message authentication keys. The SECRET_KEY slot is programmed with a random value during device fabrication. All CSE encryption and message authentication commands specify a key by its Key ID.

Table 82-1. Memory slots

Slot name	KBS	Key ID	Type
SECRET_KEY	x	0x0	ROM
MASTER_ECU_KEY	x	0x1	nonvolatile
BOOT_MAC_KEY	x	0x2	nonvolatile
BOOT_MAC	x	0x3	nonvolatile
KEY_1–KEY_10	0	0x4–0xD	nonvolatile
KEY_11–KEY_20	1	0x4–0xD	nonvolatile
RAM_KEY	x	0xE	RAM

In addition to the 25 memory slots, the CSE holds a 120-bit read-only unique identification number (UID) that is programmed during device fabrication. The UID is used in the memory update procedure and is available for application-specific uses.

Each memory slot holds a 128-bit value, 6 security flags, and a 28-bit counter. See the *SHE Functional Specification* for the required structure needed for the LOAD_KEY command. The security flags are defined in Table 82-2. The 28-bit counter must be advanced each time a new key is loaded. The counter value is zero for an empty memory slot.

Table 82-2. Memory slot security flags

Flag name	Description
VERIFY_ONLY	If set, the memory slot key cannot be used by the GENERATE_MAC command, only by the VERIFY_MAC command. This bit has no effect if KEY_USAGE = 0.
WRITE_PROT	If set, the memory slot cannot be updated.
BOOT_PROT	If set, the memory slot is disabled if CSE_SR[BOK] = 0 or CSE_SR[BFN] = 0.
DEBUG_PROT	If set, the memory slot is disabled if CSE_SR[EDB] = 1.
KEY_USAGE	If set, the memory slot holds a MAC key; otherwise, it holds an encryption key.
WILDCARD	If set, the memory slot cannot be updated with the wildcard UID.

The memory slot security flags for a specified key are checked against the associated bits in the CSE_SR during command processing as described in the SHE specification. If the memory slot is disabled due to security flag settings, a key not available error (EC = 0x03) is returned by the command. The VERIFY_ONLY security flag is a CSE-specific feature that is not defined in the SHE specification. If the CSE_CR[SFE] bit is set when the LOAD_KEY command is executed, the security flag field (FID) in the M2 message is extended by one bit with the VERIFY_ONLY flag and the adjacent zero fill field is reduced to 94 bits. The CSE_CR[SFE] bit has no effect on the enforcement of the VERIFY_ONLY flag for commands issued after the LOAD_KEY.

A key is loaded into a memory slot using the LOAD_KEY command which implements the SHE memory update protocol. An empty key slot can only be used as the authorization key to update itself (KeyID = AuthID). In this case, the authorization key has a value of 0. The BOOT_PROT and DEBUG_PROT security flags are not enforced for the LOAD_KEY command except when the RAM_KEY slot is loaded. In that case, the BOOT_PROT and DEBUG_PROT flags of the AuthID slot are applied. Additionally, when loading the RAM_KEY slot, the counter and security flag fields in the M2 message must be zero.

The LOAD_PLAIN_KEY command can be used to load a key into the RAM_KEY slot. The EXPORT_RAM_KEY command can then be used to export the key in an encrypted form compatible with the LOAD_KEY command for storage outside the CSE. The BOOT_PROT and DEBUG_PROT security flags of the MASTER_ECU_KEY are enforced for the EXPORT_RAM_KEY command.

Two dedicated blocks in the system flash memory are used to implement the secure storage feature. These blocks are not program visible and only the CSE can read, erase, and program these blocks. The CSE reads and writes to the system flash memory via the system bus master interface during the SECURE_BOOT, INIT_CSE, DEBUG_AUTH, and LOAD_KEY commands. During execution of these commands, the system MPU (if present) must be configured to allow the CSE access to the system flash memory and other bus masters must be programmed properly to avoid interfering with the CSE.

82.5.4 Encryption and decryption

The CSE supports AES-128 encryption and decryption in ECB and CBC modes of operation. The key is selected from one of the memory slots, which must be enabled for the operation. A plaintext key can be loaded into the RAM_KEY slot using the LOAD_PLAIN_KEY command for keys that are not stored in a nonvolatile memory slot.

82.5.5 Message authentication

The CSE uses the AES-128 CMAC algorithm for message authentication. The key for the CMAC operation is selected from one of the memory slots which must be enabled for the operation. A plaintext key can be loaded into the RAM_KEY slot using the LOAD_PLAIN_KEY command for keys that are not stored in a nonvolatile memory slot. The VERIFY_MAC command supports comparison of a calculated MAC with an input MAC value.

82.5.6 Secure boot

The CSE implements the SHE secure boot protocol. In some device boot modes, the BAM or system boot logic issues the SECURE_BOOT command to the CSE, which starts the secure boot process. For details about how and when the SECURE_BOOT command is issued on this chip, see the chip-specific CSE information.

The first step in the process is for the CSE to download the command processor firmware and memory slot data from the CSE flash memory blocks into local memory. If the BOOT_MAC_KEY slot is empty, the CSE_SR[SB] flag is cleared and the process is finished. Otherwise, the CSE_SR[SB] flag is set and CSE calculates the MAC over the specified bootloader code. If the BOOT_MAC slot is empty, the calculated MAC is loaded into the BOOT_MAC slot, the CSE_SR[BIN] and CSE_SR[BFN] flags are set, and the process is finished. Otherwise, the calculated MAC value is compared to the value in the BOOT_MAC slot. If the values match, the CSE_SR[BOK] bit is set; otherwise, the CSE_SR[BFN] bit is set. If the CSE_SR[BOK] flag is set, the user boot code can issue the BOOK_OK command which sets the CSE_SR[BFN] bit. The memory slots that have the BOOT_PROT flag set are enabled when both the CSE_SR[BFN] and CSE_SR[BOK] flags are set.

The SECURE_BOOT command can run either before the user boot code is executed or in parallel with the user boot code. If the parallel mode is used, the user boot code must suspend command processing (set CSE_CR[SUS] to 1) while performing any operations —such as configuring the flash controller—that may interfere with the CSE accessing flash memory. A device-specific bit selects whether to run the SECURE_BOOT command before or in parallel with the user boot code. For details about this bit, see the chip-specific CSE information.

The CSE implements an internal timer that is started when the SECURE_BOOT command is issued. The initial value of the timer is set to 0x00F4_2400 (16,000,000 CSE system clocks). If the timer expires before the SECURE_BOOT command completes, any application code intended to be blocked by the SECURE_BOOT process will instead see the non-completed SECURE_BOOT status of CSE_SR[BSY]=1 and

CSE_SR[BOK]=0. In the event of a SECURE_BOOT timeout, the CSE will continue executing the SECURE_BOOT command until completion, until suspended, or until receiving the CANCEL command from the application code. There is no error code associated with a SECURE_BOOT timeout.

82.5.7 Random number generation

The CSE has both a Pseudo Random Number Generator (PRNG) and a True Random Number Generator (TRNG).

The PRNG has a 128-bit state variable and uses AES in output feedback mode to generate pseudo random values. A key derived from the SECRET_KEY is used for the PRNG. The RND command updates the state of the PRNG and returns the 128-bit random value. The EXTEND_SEED command can be used to add entropy to the PRNG state. The PRNG state is initialized after each reset with the INIT_RNG command, which uses the TRNG to generate a 128-bit seed value for the PRNG. The CSE_SR[RIN] flag is set when the PRNG is initialized.

The INIT_RNG and TRNG_RND commands use the TRNG to generate truly random values. The TRNG hardware runs off of a slower clock derived from the system clock. The CSE_CR[DIV] field needs to be configured for these commands such that the TRNG clock is between 500 kHz and 2 MHz. Random values generated by the TRNG are checked with a statistical test to verify proper operation of the TRNG. If the test fails, a TRNG error (EC = 0x12) is returned. Due to the statistical nature of this test, there is a very small probability ($< 10^{-9}$) that a properly operating TRNG will return an error. If an TRNG error is returned, the command can be issued again.

82.5.8 Error handling

When the CSE command processor encounters an error condition, it stops processing and returns an error code as described in Table 82-3. The CSE_SR[BSY] and CSE_SR[EX] bits are cleared with interrupt and/or DMA requests generated the same as if the command had completed successfully. In most cases, error conditions are detected before data processing begins and no output values are written. Intermediate or invalid output data is never written to the parameter registers or system memory. However, it is possible for outputs to system memory to be partially written when an error occurs. The CSE does not zero out this partially written data.

Table 82-3. Error code summary

Error code	Error description	Error conditions
0x00	No error	1. Command successfully executed with no errors encountered.
0x02	Command sequence error	1. Command issued (except for CANCEL) before the SECURE_BOOT or INIT_CSE command. 2. The DEBUG_AUTH command issued before the DEBUG_CHAL command. 3. SECURE_BOOT or INIT_CSE command issued after an initial SECURE_BOOT or INIT_CSE is issued.
0x03	Key not available	1. A required key is not available due to a BOOT_PROT or DEBUG_PROT security flag restriction (see Secure storage).
0x04	Invalid key	1. The specified key slot is not valid for the command. (See the SHE specification.) 2. The specified key slot is not available due to a KEY_USAGE security flag restriction (see Secure storage).
0x05	Empty key	1. The specified key slot is empty.
0x06	No secure boot	1. SECURE_BOOT issued when secure boot is disabled or the BOOT_MAC_KEY slot is empty. 2. BOOT_FAIL or BOOT_OK issued with incorrect settings for either the CSE_SR[SB], CSE_SR[BFN] or CSE_SR[BOK] flags.
0x07	Key write protected	1. Attempt to load a key slot with the WRITE_PROT security flag set. 2. Attempt to enter internal debug mode (DEBUG_CHAL, DEBUG_AUTH) with a WRITE_PROT security flag set in one or more key slots.
0x08	Key update error	The LOAD_KEY command failed due to one of the following conditions: 1. The M3 MAC value is invalid. 2. The wildcard UID is specified with the WILDCARD flag set. 3. The specified UID does not match the device UID. 4. The update counter or security flag values are not zero when loading the RAM_KEY slot. 5. The specified update counter value is not greater than the current counter value for the slot. (Counter value is zero for an empty slot.)
0x09	Random number seed not initialized	1. RND, EXTEND_SEED, or DEBUG_CHAL command issued before the INIT_RNG command.
0x0A	Internal debug not allowed	1. DEBUG_AUTH command issued with invalid MAC value.
0x0B	Command issued while busy	1. Command issued when the CSE_SR[BSY] bit is set.
0x0C	System memory error	1. A system memory error was encountered while executing the command. (The CSE flash memory block error code is generated for bus errors encountered when accessing the CSE flash memory blocks.)
0x10	Internal memory error	1. An internal memory error was encountered while executing the command.

Table continues on the next page...

Table 82-3. Error code summary (continued)

Error code	Error description	Error conditions
0x11	Invalid command	1. Value written to CSE_CMD register is out of range.
0x12	TRNG error	1. One or more statistical tests run on the TRNG output failed (see Generate Random Number).
0x13	CSE flash memory block error	1. Error reading, programming, or erasing one of the CSE flash memory blocks. 2. UID or SECRET_KEY required but not available.
0x14	Internal command processor error	1. An internal error condition was encountered while executing the command.
0x15	Length error	1. MAC length for VERIFY_MAC command is greater than 128. 2. Message length for GENERATE_MAC, VERIFY_MAC, or MP_COMPRESS command is greater than 0x7FFFFFFF (4 GB).

82.6 CSE commands

This section describes the set of CSE commands. Commands are issued by first loading the appropriate parameter registers (CSE_Px) and then writing a command code to the command register (CSE_CMD) as described in Command processing. The first command issued to the CSE after reset must be INIT_CSE for device boot modes that do not support secure boot. Command inputs and outputs that are 32 bits or less in size are stored directly in a parameter register. Inputs and outputs that are larger than 32 bits are kept in system memory and the address of the data (pointer) is loaded into the parameter register. The data direction indication in the tables below refers to the command parameter value which may be stored in memory.

82.6.1 Encrypt ECB

The ENC_ECB command performs AES-128 encryption in ECB mode on n 128-bit blocks of data with the parameters specified in the table below.

Table 82-4. ENC_ECB command

Register	Value	Data direction
CSE_CMD	0x01	—
CSE_P1	Key ID	Input
CSE_P2	Number of blocks (*n*)	Input

Table continues on the next page...

Table 82-4. ENC_ECB command (continued)

Register	Value	Data direction
CSE_P3	First plaintext block address	Input
CSE_P4	First ciphertext block address	Output

82.6.2 Encrypt CBC

The ENC_CBC command performs AES-128 encryption on n 128-bit blocks of data in CBC mode with the parameters specified in the table below. The number of blocks parameter is a 32-bit value.

Table 82-5. ENC_CBC command

Register	Value	Data direction
CSE_CMD	0x02	—
CSE_P1	Key ID	Input
CSE_P2	IV address	Input
CSE_P3	Number of blocks (*n*)	Input
CSE_P4	First plaintext block address	Input
CSE_P5	First ciphertext block address	Output

82.6.3 Decrypt ECB

The DEC_ECB command performs AES-128 ECB decryption on *n* 128-bit blocks of data with the parameters specified in the table below.

Table 82-6. DEC_ECB command

Register	Value	Data direction
CSE_CMD	0x03	—
CSE_P1	Key ID	Input
CSE_P2	Number of blocks (*n*)	Input
CSE_P3	First ciphertext block address	Input
CSE_P4	First plaintext block address	Output

82.6.4 Decrypt CBC

The DEC_CBC command performs AES-128 decryption in CBC mode on *n* 128-bit blocks of data with the parameters specified in the table below. The number of blocks parameter is a 32-bit value.

Table 82-7. DEC_CBC command

Register	Value	Data direction
CSE_CMD	0x04	—
CSE_P1	Key ID	Input
CSE_P2	IV address	Input
CSE_P3	Number of blocks (*n*)	Input
CSE_P4	First ciphertext block address	Input
CSE_P5	First plaintext block address	Output

82.6.5 Generate MAC

The GENERATE_MAC command calculates the MAC of a given message with the parameters specified in the table below. The AES CMAC algorithm is used to calculate a 128-bit MAC output. The message length input is a 64-bit value that specifies the length of the message in bits. A length error (EC = 0x15) is returned if the message length is greater than 0x7fffffff (4 GB).

Table 82-8. GENERATE_MAC command

Register	Value	Data direction
CSE_CMD	0x05	—
CSE_P1	Key ID	Input
CSE_P2	Message length (bits) address	Input
CSE_P3	Message start address	Input
CSE_P4	MAC address	Output

82.6.6 Verify MAC

The VERIFY_MAC command verifies the MAC of a given message with the parameters specified in Table 82-9. The AES CMAC algorithm is used to calculate a 128-bit MAC that is truncated according to the MAC length parameter, which specifies the number of most significant bits in the MAC to compare. A MAC length value of 0 indicates that all 128 bits are compared; a value greater than 128 returns a length error (EC = 0x15). The

message length input is a 64-bit value that specifies the length of the message in bits. A length error (EC = 0x15) is returned if the message length is greater than 0x7fffffff (4 GB). If the input MAC matches the MAC calculated over the message, the CSE_P5 register is set to 0; otherwise, it is set to 1.

Table 82-9. VERIFY_MAC command

Register	Value	Data direction
CSE_CMD	0x06	—
CSE_P1	Key ID	Input
CSE_P2	Message length (bits) address	Input
CSE_P3	Message start address	Input
CSE_P4	MAC address	Input
CSE_P5	MAC length (bits)/ Verification status	Input / Output

82.6.7 Load Key

The LOAD_KEY command updates a memory slot using parameters specified in Table 82-10 according to the SHE memory slot update protocol (see Secure storage). The 128-bit M1 message contains the UID, Key ID, and Authentication Key ID. The 256-bit M2 message contains the new security flags, the counter, and the key value all encrypted using a derived key generated from the Authentication Key. The 128-bit M3 message is a MAC generated over messages M1 and M2. The 256-bit M4 message is the concatenation of the UID, Key ID, Authorization Key ID, and the encrypted counter value. The 128-bit M5 message is the MAC calculated over message M4.

The derived keys used to generate messages M2, M3, M4, and M5 deviate from the SHE memory slot update protocol when updating the second bank of user keys (KEY_11–KEY_20). During the generation of M2 and M4, K1 and K3 shall be derived using a constant equal to KEY_UPDATE_ENC_C + 0x00800000_00000000_00000000_00000000. Similarly, during generation of M3 and M5, K2 and K4 shall be derived using a constant equal to KEY_UPDATE_MAC_C + 0x00800000_00000000_00000000_00000000. This is intended to prevent aliasing between the two banks of user keys.

Table 82-10. LOAD_KEY command

Register	Value	Data direction
CSE_CMD	0x07	—
CSE_P1	M1 address	Input

Table continues on the next page...

Table 82-10. LOAD_KEY command (continued)

Register	Value	Data direction
CSE_P2	M2 address	Input
CSE_P3	M3 address	Input
CSE_P4	M4 address	Output
CSE_P5	M5 address	Output

82.6.8 Load Plain Key

The LOAD_PLAIN_KEY command updates the RAM key memory slot with a 128-bit plaintext key with the parameter shown in the table below.

Table 82-11. LOAD_PLAIN_KEY command

Register	Value	Data direction
CSE_CMD	0x08	—
CSE_P1	Key address	Input

82.6.9 Export RAM Key

The EXPORT_RAM_KEY command exports the RAM key data with the parameters in the table below. Only keys loaded with the LOAD_PLAIN_KEY command may be exported. The output messages are compatible with the messages used for LOAD_KEY (see Load Key for details).

Table 82-12. EXPORT_RAM_KEY command

Register	Value	Data direction
CSE_CMD	0x09	—
CSE_P1	M1 address	Output
CSE_P2	M2 address	Output
CSE_P3	M3 address	Output
CSE_P4	M4 address	Output
CSE_P5	M5 address	Output

82.6.10 Initialize RNG

The INIT_RNG command initializes the internal PRNG state with a seed value generated by the TRNG and sets the CSE_SR[RIN] flag. It takes 2048 TRNG clock cycles to generate a seed value. The CSE_CR[DIV] field must be properly configured before this command is executed (see register descriptions for further information). There is a very small probability that this command may return a TRNG error (EC = 0x12) even when the TRNG is operating properly (see Random number generation). The INIT_RNG command must be called after each reset before the RND command is issued. The command has no parameters as shown the table below.

Table 82-13. INIT_RNG command

Register	Value	Data direction
CSE_CMD	0x0A	—

82.6.11 Extend PRNG Seed

The EXTEND_SEED command extends the state of the PRNG using a 128-bit entropy input value. The current PRNG state and the input data are compressed into a new PRNG state value. This command is issued with the parameter shown in the table below.

Table 82-14. EXTEND_SEED command

Register	Value	Data direction
CSE_CMD	0x0B	—
CSE_P1	Entropy value address	Input

82.6.12 Generate Random Number

The RND command generates a 128-bit random value and updates the state of the internal PRNG. The PRNG state must be initialized after reset using the INIT_RNG command before this command can be issued. This command is issued with the parameter shown in the table below

Table 82-15. RND command

Register	Value	Data direction
CSE_CMD	0x0C	—
CSE_P1	Random value address	Output

82.6.13 Secure Boot

The SECURE_BOOT command loads the command processor firmware and memory slot data from the CSE flash memory blocks, and then it executes the SHE secure boot protocol using the parameters shown in Table 82-16 (see Secure boot for details). The bootloader size is a 32-bit value. The CSE firmware version is loaded into CSE_P3 register.

The SECURE_BOOT command is issued during the boot processes by the system boot logic. For details about how and when the SECURE_BOOT command is issued on this chip, see the chip-specific CSE information.

Table 82-16. SECURE_BOOT command

Register	Value	Data direction
CSE_CMD	0x0D	—
CSE_P1	Bootloader size (bytes)	Input
CSE_P2	Bootloader start address	Input
CSE_P3	Firmware version	Output

82.6.14 Boot Failure

The BOOT_FAILURE command sets the CSE_SR[BFN] flag and clears the CSE_SR[BOK] flag to disable use of memory slots that have the BOOT_PROT flag set. This command is issued with no parameters as shown in the table below.

Table 82-17. BOOT_FAILURE command

Register	Value	Data direction
CSE_CMD	0x0E	—

82.6.15 Boot OK

The BOOT_OK command sets the CSE_SR[BFN] flag and leaves the CSE_SR[BOK] flag set to confirm successful completion of the secure boot processes. This enables the use of memory slots that have the BOOT_PROT flag set if they are not disabled for some other reason. This command is issued with no parameters as shown in the table below.

Table 82-18. BOOT_OK command

Register	Value	Data direction
CSE_CMD	0x0F	—

82.6.16 Get ID

The GET_ID command returns the UID, CSE_SR[24:31], and a 128-bit MAC calculated over the concatenation of a 128-bit input challenge value, UID, and CSE_SR[24:31]. The MASTER_ECU_KEY is used for the MAC calculation. A value of 0 is returned for the MAC if the MASTER_ECU_KEY slot is empty. The UID output is a 128-bit value with the 8 least significant bits set to 0. This command is issued with the parameters shown in the table below.

Table 82-19. GET_ID command

Register	Value	Data direction
CSE_CMD	0x10	—
CSE_P1	Challenge address	Input
CSE_P2	UID output address	Output
CSE_P3	CSE_SR[24:31] value	Output
CSE_P4	MAC address	Output

82.6.17 Cancel

The CANCEL command aborts processing of the current command and clears the CSE_SR[BSY] flag. This command is issued with no parameters as shown in the table below.

Table 82-20. CANCEL command

Register	Value	Data direction
CSE_CMD	0x11	—

82.6.18 Debug Challenge

The DEBUG_CHAL command generates a 128-bit random challenge output value that is used in conjunction with the DEBUG_AUTH command. The PRNG state must be initialized after reset using the INIT_RNG command before this command can be issued. This command is issued with the parameter shown in the table below.

Table 82-21. DEBUG_CHAL command

Register	Value	Data direction
CSE_CMD	0x12	—
CSE_P1	Challenge address	Output

82.6.19 Debug Authorization

The DEBUG_AUTH command erases all user keys and sets the CSE_SR[IDB] flag which enables internal debugging if the 128-bit authorization input value is valid and no memory slots are write protected. The authorization input is generated using the DEBUG_CHAL command output and the UID as described in the *SHE Functional Specification*. If the DEBUG_CHAL command is not issued before the DEBUG_AUTH command, a command sequence error (EC = 0x02) is returned. However, other commands may be issued between the DEBUG_CHAL and DEBUG_AUTH commands. This command is issued with the parameter shown in the table below.

Table 82-22. DEBUG_AUTH command

Register	Value	Data direction
CSE_CMD	0x13	—
CSE_P1	Authorization address	Input

82.6.20 Generate TRNG Random Number

The TRNG_RND command generates a 128-bit random output value using the TRNG. It takes 2048 TRNG clock cycles to generate a random value. The CSE_CR[DIV] field must be properly configured before this command is executed (see the register descriptions section for further information). This command takes much longer to execute than the RND command that should normally be used to generate random values. There is a very small probability that this command may return a TRNG error (EC = 0x12) even when the TRNG is operating properly (see Random number generation). This command is issued with the parameter shown in the table below.

Table 82-23. TRNG_RND Command

Register	Value	Data direction
CSE_CMD	0x14	—
CSE_P1	Random value address	Output

82.6.21 Initialize CSE

The INIT_CSE command loads the command processor firmware and memory slot data from the CSE flash memory blocks into local memory. It does not execute the secure boot protocol. The CSE firmware version is loaded into the CSE_P1 register as shown in the table below. This command must be issued before any other command when secure boot is not enabled.

Table 82-24. INIT_CSE Command

Register	Value	Data direction
CSE_CMD	0x15	—
CSE_P1	Firmware version	Output

82.6.22 Miyaguchi-Preneel (MP) Compression

The MP_COMPRESS command is a one-way compression function used to derive a 128-bit output from a given message with the parameters specified in Table 82-25. The AES ECB algorithm is used to derive the 128-bit output as described in the SHE specification. The message length input is a 64-bit value which specifies the length of the message in bits. A length error (EC=0x15) is returned if the message length is greater than 0x7fffffff (4GB).

Table 82-25. MP_COMPRESS Command

Register	Value	Data direction
CSE_CMD	0x016	
CSE_P1	Message length (bits) address	Input
CSE_P2	Message start address	Input
CSE_P3	Output address	Output

Appendix A
Release Notes

A.1 General changes

- See the changes for each individual chapter.

A.2 Introduction changes

- No substantial content changes

A.3 Memory Map changes

- Please see attached Memory map spreadsheet. Check "Revision" tab for list of changes in the memory map.

A.4 Signal Description changes

- Please see attached 'IO Signal Description and Input multiplexing tables' spreadsheet. Check "Revision History" tab for list of changes.

A.5 Clocking changes

- No substantial content changes

A.6 Reset changes

- No substantial content changes

A.7 System Boot changes

- No substantial content changes

A.8 Interrupt and DMA Overview changes

- No substantial content changes

A.9 Functional Safety changes

- No substantial content changes

A.10 Embedded memories changes

- No substantial content changes

A.11 Device Configuration Format Records changes

- No substantial content changes

A.12 SIUL2 changes

- In Table 12-1
  - Changed part from FS32R274KBK2MMM to FS32R274KSK2MMM and changed configuration from "B" to "S".
  - Changed part from FS32R274KBK2VMM to FS32R274KSK2VMM and changed configuration from "B" to "S".
  - Added "B or S" to Table 12-2.

A.13 Core Complex Overview changes

- No substantial content changes

A.14 Core description module changes

- No substantial content changes

A.15 z7 Core description changes

- No substantial content changes

A.16 Nexus changes

- No substantial content changes
